# Introduction

This document describes installation of third-party trusted SSL digital certificate on the ASA for Clientless SSLVPN and AnyConnect connections.

## Prerequisites

### Requirements

This document requires access to a trusted third-party Certificate Authority (CA) for certificate enrollment. Examples of third-party CA vendors include, but are not limited to, Baltimore, Cisco, Entrust, Geotrust, G, Microsoft, RSA, Thawte, and VeriSign.

Before you start, verify that the ASA has the correct clock time, date, and time zone. With certificate authentication, it is recommended to use a Network Time Protocol (NTP) server to synchronize the time on the ASA. The [Cisco ASA Series General Operations CLI Configuration Guide, 9.1](#) details the steps to take in order to set up the time and date correctly on the ASA.

### Components Used

This document uses an ASA 5500-X that runs software version 9.4.1 and ASDM version 7.4(1).

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, ensure that you understand the potential impact of any command.

## Background Information

A GoDaddy Certificate is used in this example. Each step contains the Adaptive Security Device Manager (ASDM) procedure and the CLI equivalent.

## Configure

The SSL protocol mandates that the SSL Server provide the client with a server certificate for the client to perform server authentication. Cisco does not recommend use of a self-signed certificate because of the possibility that a user could inadvertently configure a browser to trust a certificate from a rogue server. There is also the inconvenience to users to have to respond to a security warning when it connects to the secure gateway. It is recommended to use trusted third-party CAs to issue SSL certificates to the ASA for this purpose.

The lifecycle of a third-party certificate on the ASA essentially takes place with these steps:

## CSR Generation

CSR generation is the first step in the lifecycle of any X.509 digital certificate.

Once the private/public Rivest-Shamir-Adleman (RSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) keypair is generated ([Appendix A](#) details the difference between the use of RSA or ECDSA), a Certificate Signing Request (CSR) is created.

A CSR is a PKCS10 formatted message that contains the public key and identity information of the host which sends the request. [PKI Data Formats](#) explains the different certificate formats applicable to the ASA and Cisco IOS®.

---

### Notes:

1. Check with the CA on the required keypair size. The CA/Browser Forum has mandated that all certificates generated by their member CAs have a minimum size of 2048 bits.
2. ASA currently does not support 4096 bit keys (Cisco bug ID [CSCut53512](#)) for SSL server authentication. However, IKEv2 does support the use of 4096 bit server certificates on the ASA 5580, 5585, and 5500-X platforms alone.
3. Use the DNS Name of the ASA in the FQDN field of the CSR in order to prevent Untrusted Certificate warnings and pass Strict Certificate check.

---

There are three methods to generate CSR.

- Configure with ASDM.
- Configure with the ASA CLI.

- Use OpenSSL to Generate the CSR.

## 1. Configure with the ASDM

1. Navigate to **Configuration > Remote Access VPN > Certificate Management**, and choose **Identity Certificates**.
2. Click **Add**.

**Add Identity Certificate**

Trustpoint Name:

Import the identity certificate from a file (PKCS12 format with Certificate(s) +Private Key):

Decryption Passphrase:

File to Import From:

**Add a new identity certificate:**

Key Pair:

Certificate Subject DN:

Generate self-signed certificate

Act as local certificate authority and issue dynamic certificates to TLS-Proxy

Enable CA flag in basic constraints extension

3. Define a trustpoint name in the Trustpoint Name input field.
4. Click the **Add a new identity certificate** radio button.
5. For the Key Pair, click **New**.

**Add Key Pair**

Key Type:  RSA  ECDSA

---

Name:  Use default key pair name  
 Enter new key pair name:

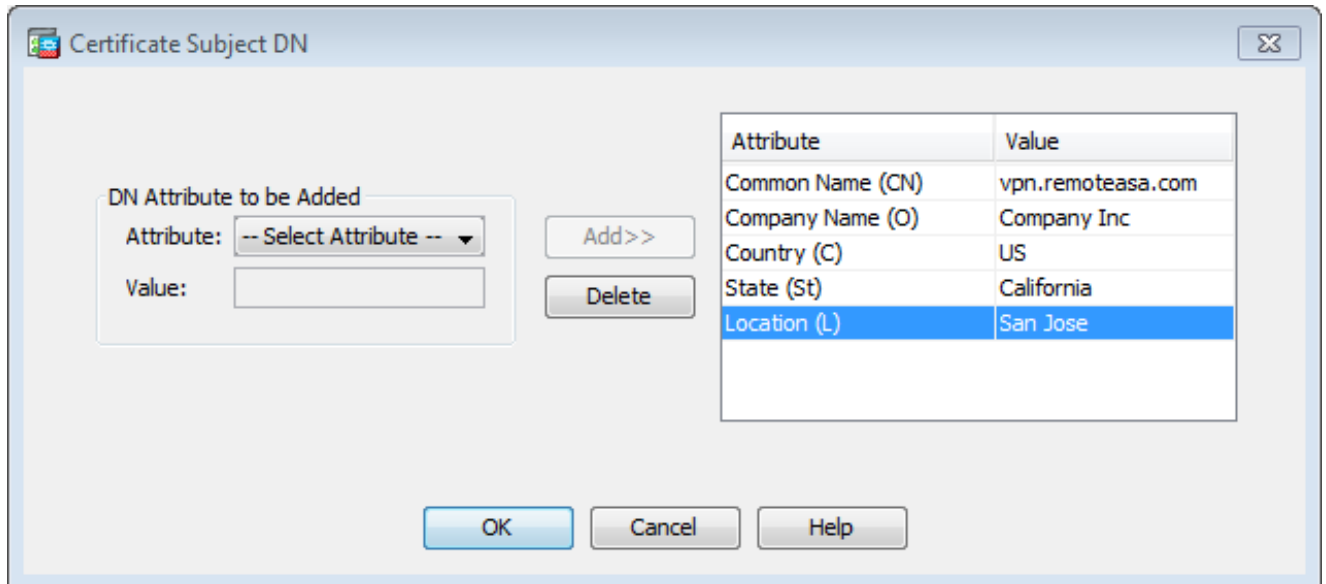

Size:  ▼

Usage:  General purpose  Special

6. Choose the **Key Type - RSA** or **ECDSA**. (Refer to [Appendix A](#) to understand the differences.)
7. Click the **Enter new key pair name** radio button. Identify the key pair name for recognition purposes.
8. Choose the **Key Size**. Choose **General Purpose** for **Usage** with **RSA**.
9. Click **Generate Now**. The key pair are created.
10. To define the Certificate Subject DN, click **Select**, and configure the attributes listed in this table:

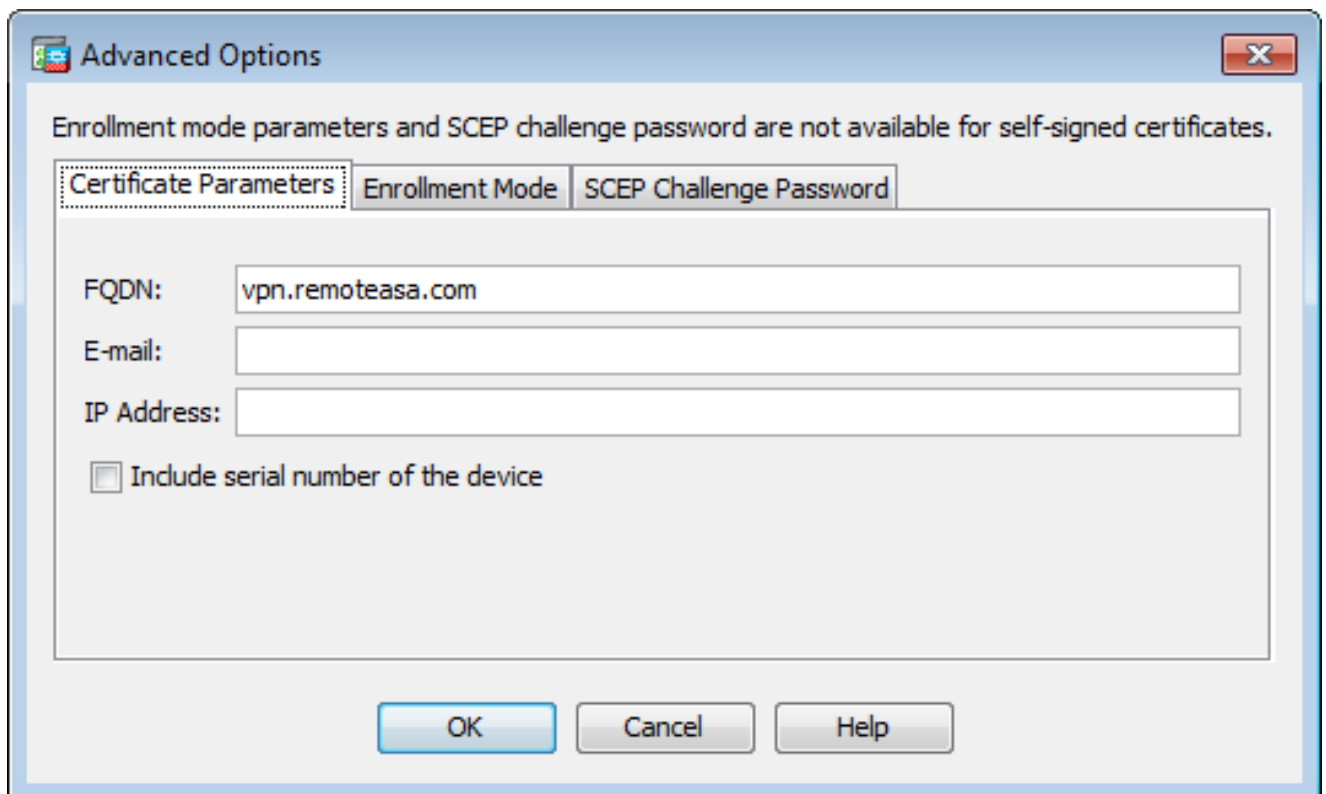

| Attribute | Description   |
|-----------|---|
| CN        | FQDN (Full Qualified Domain Name) that will be used for connections to your firewall. For example, webvpn.cisco.com |
| OU        | Department Name   |
| O         | Company Name (Avoid using Special Characters)   |
| C         | Country Code (2 Letter Code without Punctuation)  |
| St        | State (Must be spelled out completely. For example, North Carolina)   |
| L         | City  |
| EA        | Email Address   |

To configure these values, choose a **value** from the **Attribute** drop-down list, **enter** the value, and click **Add**.

 **Note:** Some third-party vendors require particular attributes to be included before an identity certificate is issued. If unsure of the required attributes, check with the vendor for details.

11. After the appropriate values are added, click **OK**. The Add Identity Certificate dialog box appears with the Certificate Subject DN field populated.
12. Click **Advanced**.

13. In the **FQDN** field, enter the **FQDN** that is used to access the device from the Internet. Click **OK**.
14. Leave the Enable CA flag in basic constraints extension option checked. Certificates without the CA flag now cannot be installed on the ASA as CA certificates by default. The basic constraints extension identifies whether the subject of the certificate is a CA and the maximum depth of valid certification paths that include this certificate. Un-check the option to bypass this requirement.
15. Click **OK**, and then click **Add Certificate**. A prompt displays in order to save the CSR to a file on the local

machine.

16. Click **Browse**, choose a **location** in which to save the CSR, and save the **file** with the .txt extension.

---

 **Note:** When the file is saved with a .txt extension, the PKCS#10 request can be opened and viewed with a text editor (such as Notepad).

---

## 2. Configure with the ASA CLI

In the ASDM, the trustpoint is automatically created when a CSR is generated or when the CA certificate is installed. In the CLI, the trustpoint must be created manually.

```
<#root>
```

```
! Generates 2048 bit RSA key pair with label SSL-Keypair.
```

```
MainASA(config)#
```

```
crypto key generate rsa label SSL-Keypair modulus 2048
```

```
INFO: The name for the keys are: SSL-Keypair  
Keypair generation process begin. Please wait...
```

```
! Define trustpoint with attributes to be used on the SSL certificate
```

```
MainASA(config)#
```

```
crypto ca trustpoint SSL-Trustpoint
```

```
MainASA(config-ca-trustpoint)#
```

```
enrollment terminal
```

```
MainASA(config-ca-trustpoint)#
```

```
fqdn (remoteasavpn.url)
```

```
MainASA(config-ca-trustpoint)#
```

```
subject-name CN=(asa.remotevpn.url),O=Company Inc,C=US,
St=California,L=San Jose
```

```
MainASA(config-ca-trustpoint)#
```

```
keypair SSL-Keypair
```

```
MainASA(config-ca-trustpoint)#
```

```
exit
```

! Initiates certificate signing request. This is the request to be submitted via Web or Email to the third party vendor.

```
MainASA(config)#
```

```
crypto ca enroll SSL-Trustpoint
```

WARNING: The certificate enrollment is configured with an fqdn that differs from the system fqdn. If this certificate is used for VPN authentication this may cause connection problems.

Would you like to continue with this enrollment? [yes/no]:

```
yes
```

```
% Start certificate enrollment ..
```

```
% The subject name in the certificate is: subject-name CN=
```

```
(remoteasavpn.url)
```

```
,
O=Company Inc,C=US,St=California,L=San Jose
```

```
% The fully-qualified domain name in the certificate will be:
```

```
(remoteasavpn.url)
```

```
,
% Include the device serial number in the subject name? [yes/no]:
```

```
no
```

Display Certificate Request to terminal? [yes/no]:

```
yes
```

```
Certificate Request:
```

```
-----BEGIN CERTIFICATE REQUEST-----
```

```

DuHN12EYNpYkjVk1wI53/5w3
-----END CERTIFICATE REQUEST-----
```

Redisplay enrollment request? [yes/no]:

no

! Displays the PKCS#10 enrollment request to the terminal. Copy this from the terminal to a text file to submit to the third party CA.

### 3. Use OpenSSL to Generate the CSR

OpenSSL makes use of the OpenSSL configfile to pull the attributes to be used in the CSR generation. This process results in the generation of a CSR and a Private Key.

---

 **Caution:** Verify that the **Private key** that is generated is not shared with anyone else as it compromises the integrity of the certificate.

---

1. Ensure that OpenSSL is installed on the system that this process is run on. For Mac OSX and GNU/Linux users, this is installed by default.
2. Switch to a functional directory.

On Windows: By default, the utilities are installed in C:\OpenSSL\bin. Open a command prompt in this location.

On Mac OSX/Linux: Open the Terminal window in the directory needed to create the CSR.

3. Create an OpenSSL config file with a text editor with the attributes given . Once done, save the **file** as openssl.cnf in the location mentioned in the previous step (If you use version 0.9.8h and later, the file isopenssl.cfg).

```
<#root>
```

```
[req]
```

```
default_bits = 2048
default_keyfile = privatekey.key
distinguished_name = req_distinguished_name
req_extensions = req_ext
```

```
[req_distinguished_name]
```

```
commonName = Common Name (eg, YOUR name)
commonName_default = (asa.remotevpn.url)
```

```
countryName = Country Name (2 letter code)
countryName_default = US
```

```
stateOrProvinceName = State or Province Name (full name)
stateOrProvinceName_default = California
```

```
localityName = Locality Name (eg, city)
localityName_default = San Jose
```

```
0.organizationName = Organization Name (eg, company)
0.organizationName_default = Company Inc
```

```
[req_ext]
```

```
subjectAltName = @alt_names
```

```
[alt_names]
```

```
DNS.1 = *.remotearsa.com
```

#### 4. Generate the CSR and Private Key with this command:

```
openssl req -new -nodes -out CSR.csr -config openssl.cnf
```

```
<#root>
```

```
# Sample CSR Generation:
```

```
openssl req -new -nodes -out CSR.csr -config openssl.cnf
```

```
Generate a 2048 bit RSA private key
```

```
.....+++
.....+++
writing new private key to 'privatekey.key'
-----
```

```
You are about to be asked to enter information that will be incorporated
into your certificate request.
What you are about to enter is what is called a Distinguished Name or a DN.
There are quite a few fields but you can leave some blank
For some fields there will be a default value,
If you enter '.', the field will be left blank.
-----
```

```
Common Name (eg, YOUR name) [(asa.remotevpn.url)]:
Country Name (2 letter code) [US]:
State or Province Name (full name) [California]:
Locality Name (eg, city) [San Jose]:
Organization Name (eg, company) [Company Inc]:
```

Submit the saved CSR to the third-party CA vendor. Once the certificate is issued, the CA provides the identity certificate and the CA certificate to be installed on the ASA.

## SSL Certificate Generation on the CA

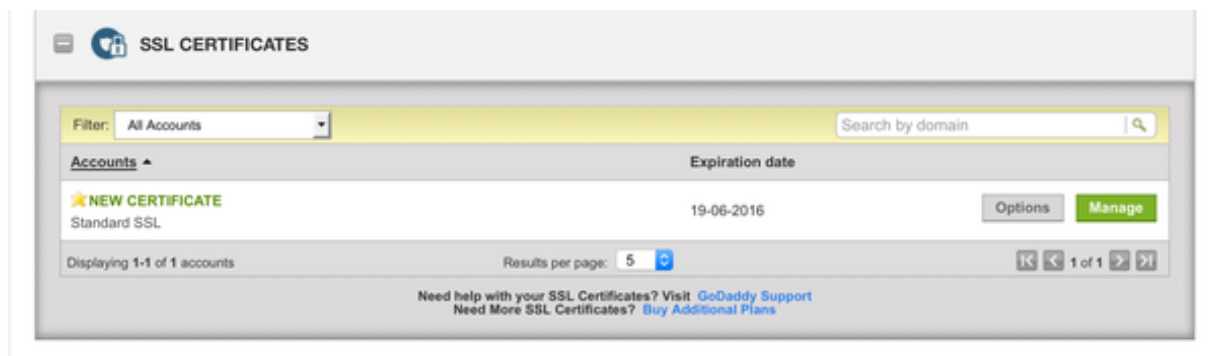

The next step is to get the CSR signed from the CA. The CA provides either a newly generated PEM encoded Identity Certificate or with a PKCS12 certificate along with the CA certificate bundle.

If the CSR is generated outside the ASA (either via OpenSSL or on the CA itself), the PEM encoded Identity Certificate with the Private Key and CA certificate are available as separate files. [Appendix B](#) provides the steps to bundle these elements together into a single PKCS12 file (.p12 or .pfx format).

In this document, the GoDaddy CA is used as an example to issue identity certificates to the ASA. This process differs in other CA vendors. Read through the CA documentation carefully before proceeding.

## Example of SSL Certificate Generation on GoDaddy CA

After purchase, and the initial setup phase of the SSL certificate, navigate to the **GoDaddy Account** and view the SSL Certificates. There must be a new certificate. Click **Manage** to proceed.

This then brings up a page to provide the CSR as seen in this image.

Based on the CSR entered, the CA determines the Domain Name to which the certificate is to be issued.

Verify that this matches the FQDN of the ASA.

## Choose website

Select a domain hosted with us

Provide a certificate signing request (CSR)

Certificate Signing Request (CSR) [Learn more](#)

```
/ypj9KO49fP5ap8al0qvLtYYcCcfwrCt+OojOrZ1YyJb3dFuMNRRedAX37t
DuHNI2EYNpYkjVklwI53/5w3
-----END CERTIFICATE REQUEST-----
```

Domain Name (based on CSR):

**vpn.remoteasa.com**

## Domain ownership

We'll send an email with a unique code to your address on file. Follow its instructions to verify you have website or DNS control over the selected domain. [More info](#)

### AND

We can send domain ownership instructional emails to one or both of the following:

- Contacts listed in the domain's public WHOIS database record
- Email addresses: admin@[domain], administrator@[domain], hostmaster@[domain], postmaster@[domain], and webmaster@[domain]

[Hide advanced options](#)

Signature Algorithm [Learn more](#)

GoDaddy SHA-2

I agree to the terms and conditions of the [Subscriber Agreement](#).

 **Note:** GoDaddy and most other CAs use SHA-2 or SHA256 as the default Certificate Signature Algorithm. ASA supports the SHA-2 signature algorithm which starts from 8.2(5) [pre-8.3 releases] and 8.4(1) [post-8.3 releases] onwards (Cisco bug ID [CSCti30937](#) ). Choose SHA-1 signature algorithm if a version older than 8.2(5) or 8.4(1) is used.

Once the request is submitted, GoDaddy verifies the request before it issues the certificate. After the

certificate request is validated, GoDaddy issues the certificate to the account. The certificate can be then downloaded for installation on the ASA. Click **Download** on the page in order to proceed further.

The screenshot shows the GoDaddy SSL Certificate Management interface. At the top, there is a navigation bar with 'Certificates', 'Repository', 'Help', and 'Report EV Abuse'. Below this, the domain 'vpn.remoteasa.com' is displayed as a 'Standard SSL Certificate'. Under 'Certificate Management Options', there are three buttons: 'Download', 'Revoke', and 'Manage'. The 'Download' button is highlighted. To the right, there is a section for 'Display your SSL Certificate security seal', which includes a 'Color' dropdown set to 'Light' and a 'Language' dropdown set to 'English'. Below these is a 'Preview' of the security seal and a 'Code' section with a JavaScript snippet for embedding the seal. The 'Certificate Details' table is as follows:

| Certificate Details |                         |
|---------------------|-------------------------|
| Status              | Certificate issued      |
| Domain name         | vpn.remoteasa.com       |
| Encryption Strength | GoDaddy SHA-2           |
| Validity Period     | 7/22/2015 - 7/22/2016   |
| Serial Number       | 25.cd:73:a9:84:07:06:05 |

Choose **Other** as the Server Type and download the certificate zip bundle.

The screenshot shows the 'Download Certificate' page for 'vpn.remoteasa.com'. It includes instructions on how to secure the site by downloading a zip file and installing certificates on the hosting server. A 'Server type' dropdown menu is open, showing options: 'Select ...', 'Apache', 'Exchange', 'IIS', 'Mac OS X', 'Tomcat', and 'Other'. The 'Other' option is selected. There are 'File' and 'Cancel' buttons next to the dropdown.

The .zip file contains the identity certificate and GoDaddy CA certificate chain bundles as two separate .crt files. Proceed to SSL certificate installation to install these certificates on the ASA.

## SSL Certificate Installation on the ASA

The SSL certificate can be installed on the ASA with either ASDM or CLI in two ways:

1. Import the CA and identity certificate separately in PEM formats.
2. Or import the PKCS12 file (base64 encoded for CLI) wherein Identity certificate, CA certificate, and private key are bundled in the PKCS12 file.

**Note:** If the CA provides a CA certificate chain, only install the immediate intermediate CA certificate in the hierarchy on the trustpoint used to generate the CSR. The Root CA certificate and any other intermediate CA certificates can be installed in new trustpoints.

---

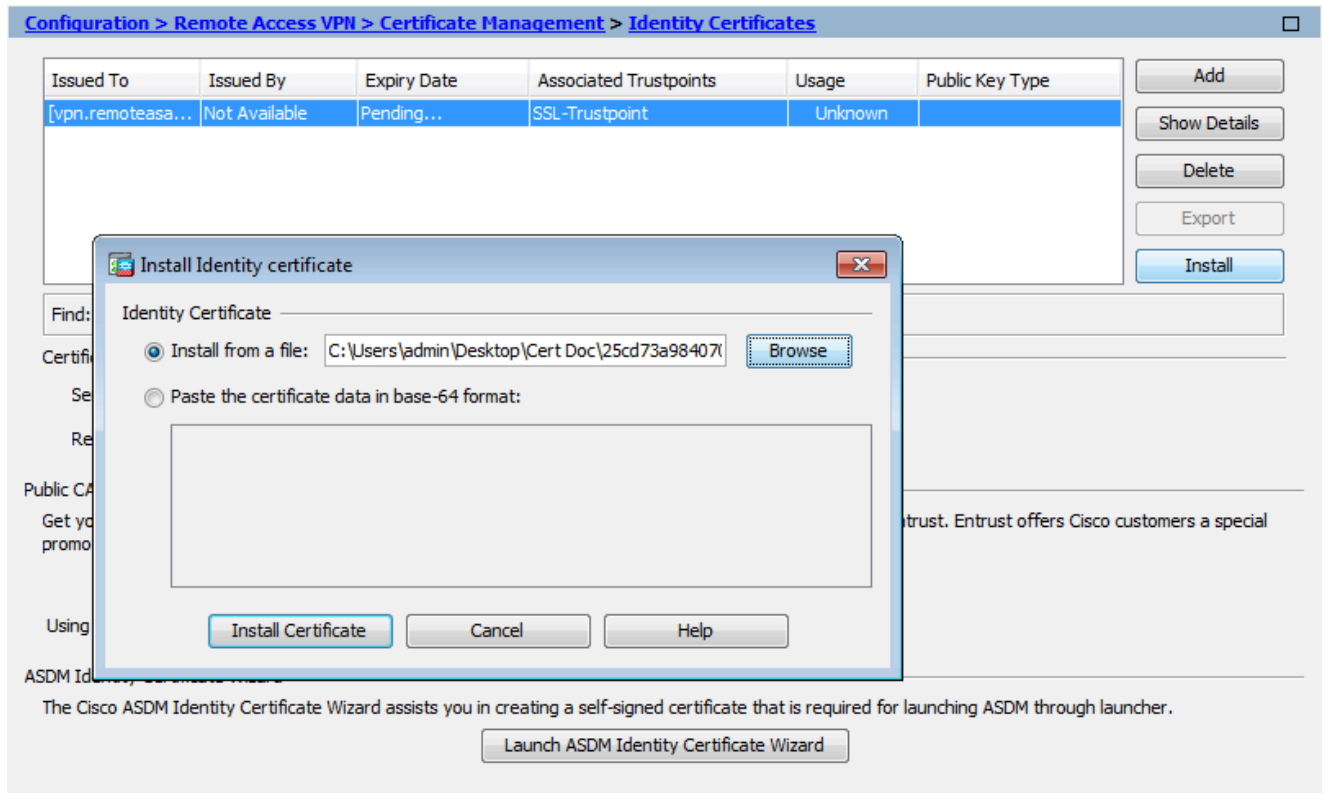

### 1.1 Installation of the Identity Certificate in PEM Format with ASDM

The installation steps given assume that the CA provides a PEM encoded (.pem, .cer, .crt) identity certificate and CA certificate bundle.

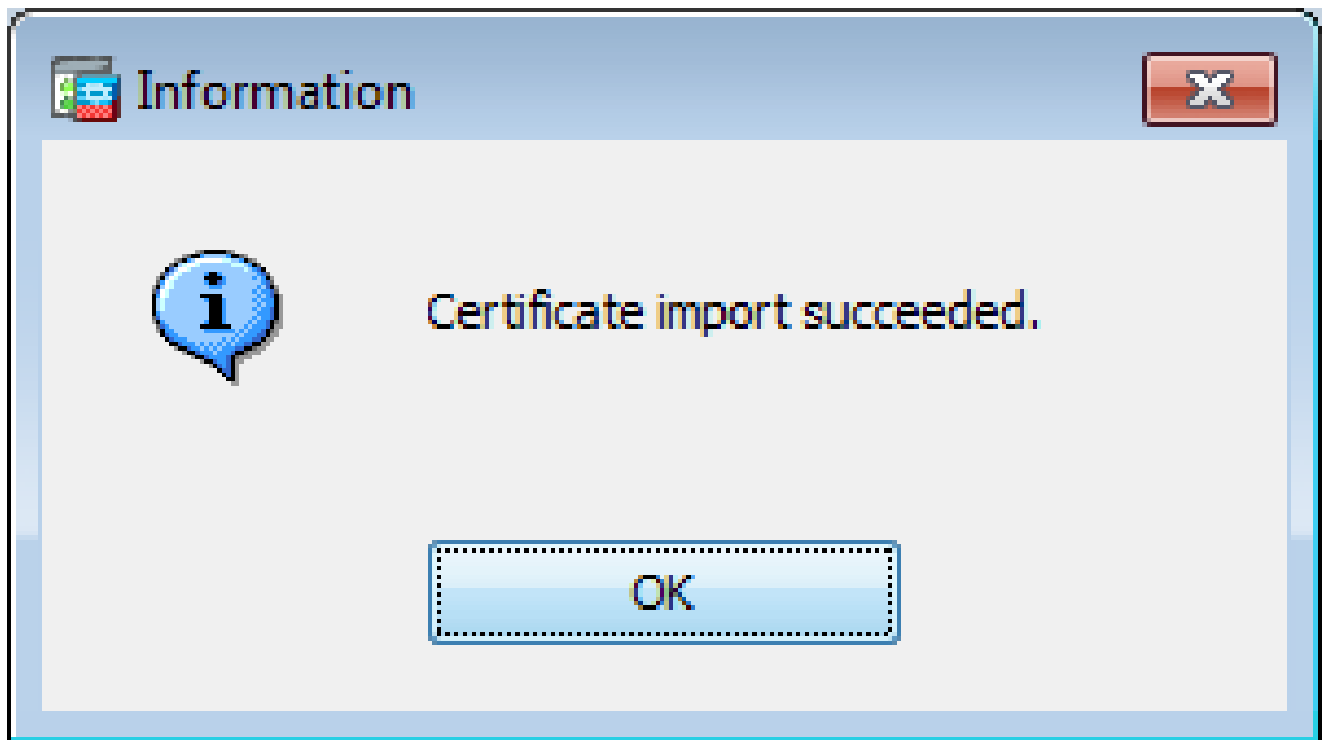

1. Navigate to **Configuration > Remote Access VPN > Certificate Management**, and choose **CA Certificates**.
2. The PEM encoded certificate in a text editor and copy and paste the base64 CA certificate provided by the third-party vendor into the text field.

3. Click **Install certificate**.
4. Navigate to **Configuration > Remote Access VPN > Certificate Management**, and choose **Identity Certificates**.
5. Select the Identity Certificate created previously. Click **Install**.
6. Either click the option **Install from a file** radio button and choose the **PEM encoded Identity certificate** or, open the **PEM encoded certificate** in a text editor and copy and paste the **base64 Identity certificate** provided by the third-party vendor into the text field.

7. Click **Add Certificate**.

8. Navigate to **Configuration > Remote Access VPN > Advanced > SSL Settings**.

9. Under **Certificates**, select the **interface** that is used to terminate WebVPN sessions. In this example, the outside interface is used.

10. Click **Edit**.

11. In the **Certificate** drop-down list, choose the **newly installed certificate**.

12. Click **OK**.

13. Click **Apply**. The new certificate is now utilized for all WebVPN sessions that terminate on the interface specified.

## 1.2. Installation of a PEM Certificate with the CLI

```
<#root>
```

```
MainASA(config)#
```

```
crypto ca authenticate SSL-Trustpoint
```

Enter the base 64 encoded CA certificate.  
End with the word "quit" on a line by itself

```
-----BEGIN CERTIFICATE----- MIIADCCAuigAwIBAgIBADANBgkqhkiG9w0BAQUFADBjMQswCQYDVQQGEwJVuzEh MB8GA1UECh
```

```
!!! - Installing Next-level SubCA in the PKI hierarchy
```

```
.
```

```
!!! - Create a separate trustpoint to install the next subCA certificate (if present)  
in the hierarchy leading up to the Root CA (including the Root CA certificate)
```

```
MainASA(config)#crypto ca trustpoint SSL-Trustpoint-1
```

```
MainASA(config-ca-trustpoint)#enrollment terminal
MainASA(config-ca-trustpoint)#exit
MainASA(config)#
MainASA(config)# crypto ca authenticate SSL-Trustpoint-1
Enter the base 64 encoded CA certificate.
End with the word "quit" on a line by itself
```

```
-----BEGIN CERTIFICATE-----

INFO: Certificate successfully imported

! Apply the newly installed SSL certificate to the interface accepting SSL connections

MainASA(config)#

```
ssl trust-point SSL-Trustpoint outside
```

## 2.1 Installation of a PKCS12 Certificate with ASDM

In cases where the CSR is not generated on the ASA, such as in the case of a wildcard certificate or when a UC certificate is generated, an Identity certificate along with the private key are received as separate files or a single bundled PKCS12 file (.p12 or pfx format). In order to install this type of certificate, complete these steps.

1. In the Identity certificate, bundle the CA certificate and private key into a single PKCS12 file. [Appendix B](#) provides the steps to do this with OpenSSL. If already bundled by the CA, proceed to the next step.
2. Navigate to **Configuration > Remote Access VPN > Certificate Management**, and choose **Identity Certificates**.

3. Click **Add**.
4. Specify a Trustpoint name.
5. Click the **Import the identity certificate from a file** radio button.
6. Enter the **passphrase** used to create the PKCS12 file. Browse and select the **PKCS12 file**. Enter the **certificate passphrase**.

**Add Identity Certificate**

Trustpoint Name:

Import the identity certificate from a file (PKCS12 format with Certificate(s) +Private Key):

Decryption Passphrase:

File to Import From:

Add a new identity certificate:

Key Pair:

Certificate Subject DN:

Generate self-signed certificate

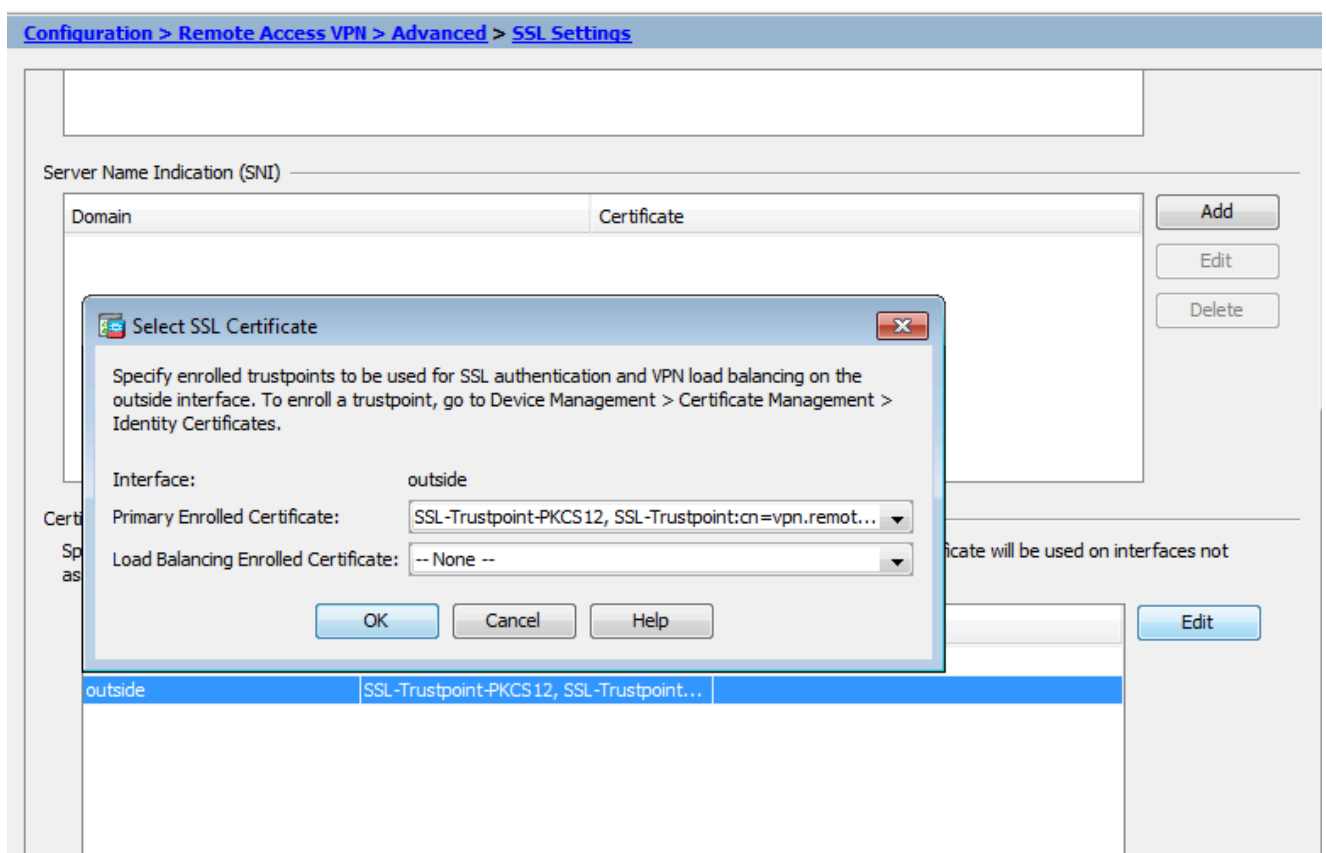

Act as local certificate authority and issue dynamic certificates to TLS-Proxy

Enable CA flag in basic constraints extension

7. Click **Add Certificate**.

8. Navigate to **Configuration > Remote Access VPN > Advanced**, and choose **SSL Settings**.
9. Under **Certificates**, choose the **interface** that is used to terminate WebVPN sessions. In this example, the outside interface is used.
10. Click **Edit**.
11. In the **Certificate drop-down list**, choose the **newly installed certificate**.

12. Click **OK**.
13. Click **Apply**. The new certificate are now utilized for all WebVPN sessions that terminate on the

interface specified.

## 2.2 Installation of a PKCS12 Certificate with the CLI

```
<#root>
```

```
MainASA(config)#
```

```
crypto ca trustpoint SSL-Trustpoint-PKCS12
```

```
MainASA(config-ca-trustpoint)#
```

```
enrollment terminal
```

```
MainASA(config-ca-trustpoint)#
```

```
exit
```

```
MainASA(config)#
```

```
crypto ca import SSL-Trustpoint-PKCS12 pkcs12 cisco123
```

Enter the base 64 encoded pkcs12.

End with the word "quit" on a line by itself:

```
-----BEGIN PKCS12-----
```

```

!!! Link the SSL trustpoint to the appropriate interface  
MainASA(config)#

```
ssl trust-point SSL-Trustpoint-PKCS12 outside
```

## Verify

Use these steps in order to verify successful installation of the third-party Vendor Certificate and use for SSLVPN connections.

## View Installed Certificates via ASDM

1. Navigate to **Configuration > Remote Access VPN > Certificate Management**, and choose **Identity Certificates**.
2. The identity certificate issued by the third-party vendor appears.

The screenshot shows the ASDM interface for Identity Certificates. The breadcrumb path is Configuration > Remote Access VPN > Certificate Management > Identity Certificates. A table lists the installed certificates with the following columns: Issued To, Issued By, Expiry Date, Associated Trustpoints, Usage, and Public Key Type. One certificate is listed with the following details:

| Issued To        | Issued By        | Expiry Date          | Associated Trustpoints | Usage           | Public Key Type |
|------------------|------------------|----------------------|------------------------|-----------------|-----------------|
| cn=vpn.remote... | cn=Go Daddy S... | 12:04:38 UTC Jul ... | SSL-Trustpoint         | General Purp... | RSA (2048 bits) |

On the right side of the table, there are buttons for Add, Show Details, Delete, Export, and Install.

## View Installed Certificates via the CLI

...(and the rest of the Sub CA certificates till the Root CA)

## Verify Installed Certificate for WebVPN with a Web Browser

Verify that WebVPN uses the new certificate.

1. Connect to the WebVPN interface through a web browser. Use https:// along with the FQDN used in order to request the certificate (for example, [WebVPN Interface](#))
2. Double-click the **lock** icon that appears in the lower-right corner of the WebVPN log in page. The installed certificate information must appear.
3. Review the contents in order to verify that it matches the third-party vendor issued certificate.

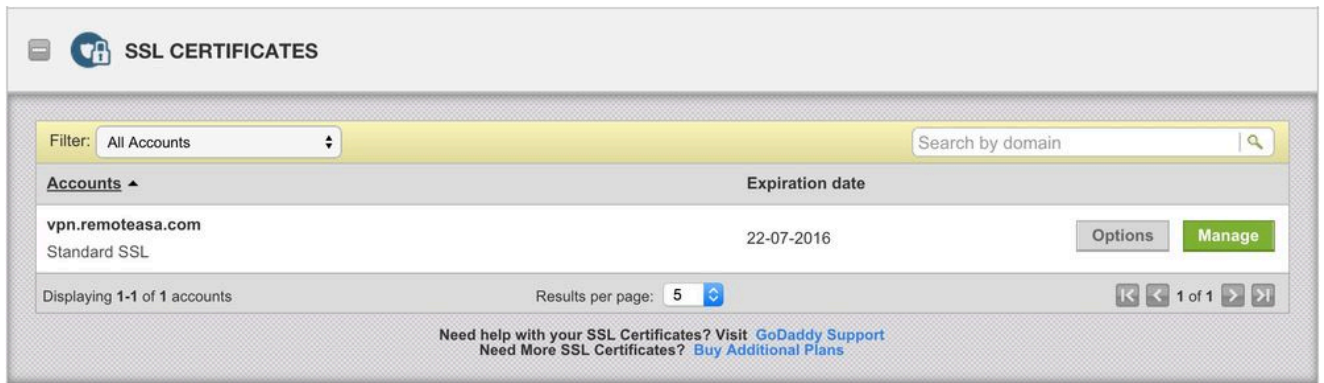

## Renew SSL Certificate on the ASA

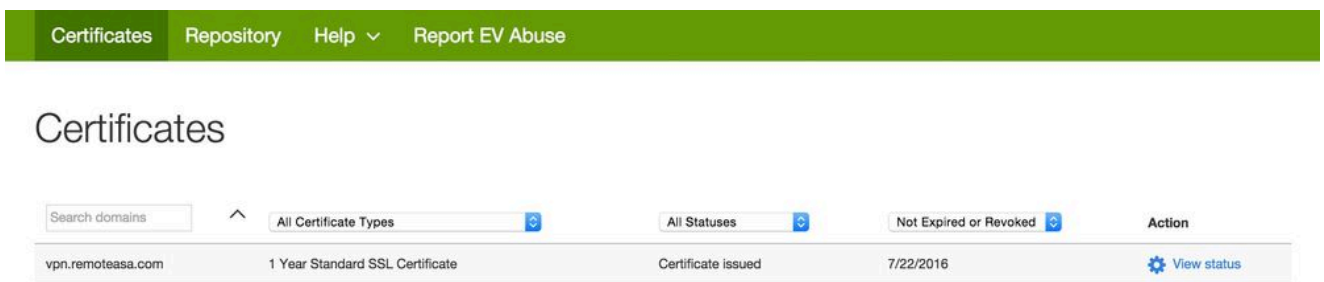

1. Regenerate the CSR either on the ASA, or with OpenSSL or on the CA with the same attributes as the old certificate. Complete the steps given in [CSR Generation](#).
2. Submit the CSR on the CA and generate a new Identity certificate in PEM format (.pem, .cer, .crt) along with the CA certificate. In the case of a PKCS12 certificate there is also a new Private key.

In the case of GoDaddy CA, the certificate can be rekeyed with a new CSR generated.

Navigate to the **GoDaddy** account and click **Manage** under SSL Certificates.

Click **View Status** for the required domain name.

Click **Manage** in order to give options to re-key the certificate.

# All > vpn.remoteasa.com

Standard SSL Certificate

Standard SSL Certificate

Use this page to submit your certificate changes for review all at once, not individually. We'll review them together so your changes happen faster.

Submitting any changes on this form will issue a new certificate and your current certificate will be revoked. You will have 72 hours to install the new certificate on your website.

**Re-Key certificate** *Private key lost, compromised, or stolen? Time to re-key.*

Certificate Signing Request (CSR)

```
13gHfepjRd3QX0kDh4P/wKl12bz/zb1v/SI  
N80GsenQVuZaYzIHn3R9EU/3Rz9  
PcctuZ18yZLZTr6NSxki9im111aCuxlH9FmW
```

Domain Name (based on CSR):  
**vpn.remoteasa.com**

**New Keys, please...**  
You can generate a Certificate Signing Request (CSR) by using a certificate signing tool specific to your operating system. Your CSR contains a public key that matches the private key generated at the same time.

**Change the site that your certificate protects** *If you want to switch your certificate from one site to another, do it here.*

**Change encryption algorithm and/or certificate issuer** *Upgrade your protection or change the company behind your cert.*

Save and proceed to the next step. GoDaddy issues a new certificate based on the CSR provided.

3. Install the **new certificate** on a new trustpoint as shown in the SSL Certificate Installation on the ASA section.

## Frequently Asked Questions

### 1. What is the best way to transfer identity certificates out of one ASA onto a different ASA?

Export the certificate along with the keys to a PKCS12 file.

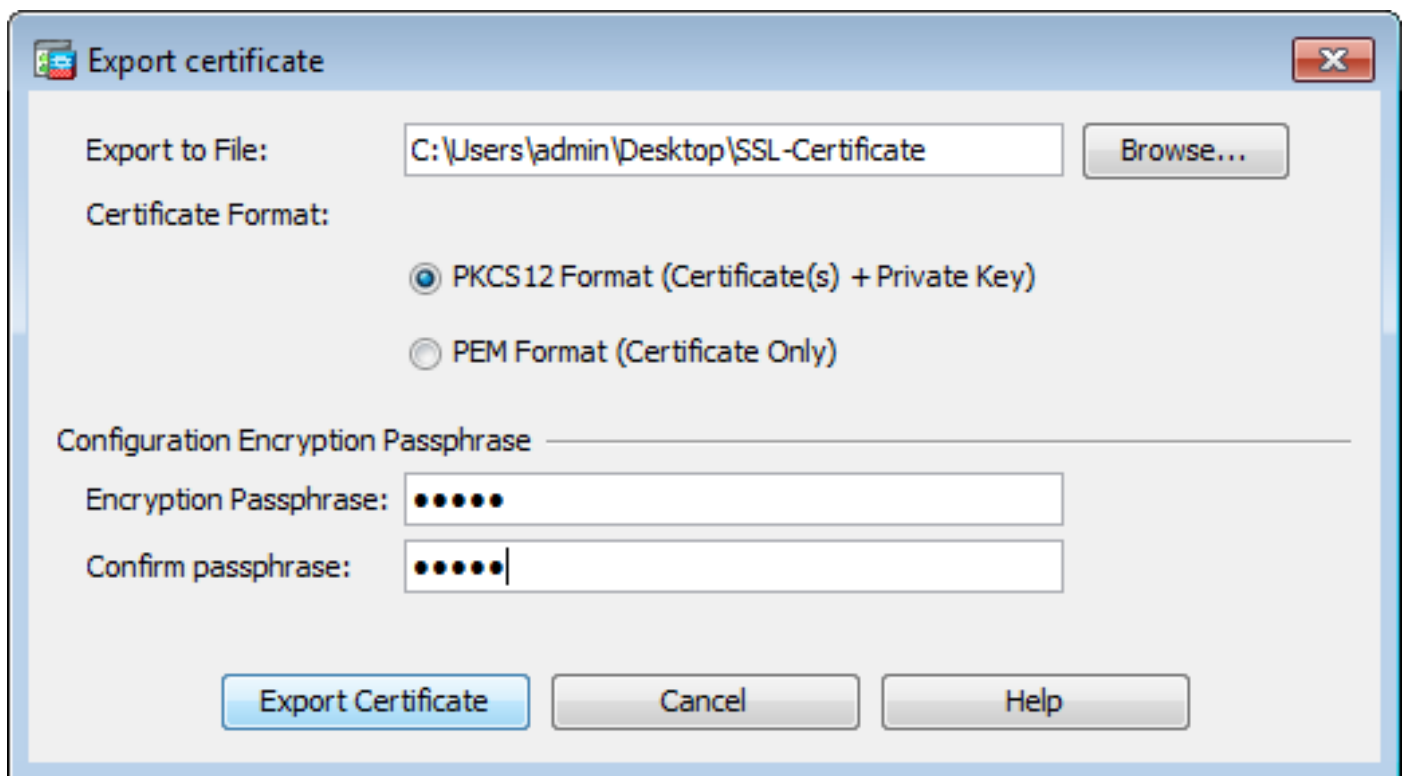

Use this command in order to export the certificate via the CLI from the original ASA:

```
<#root>
```

```
ASA(config)#
```

```
crypto ca export <trust-point-name> pkcs12 <passphrase>
```

ASDM configuration:

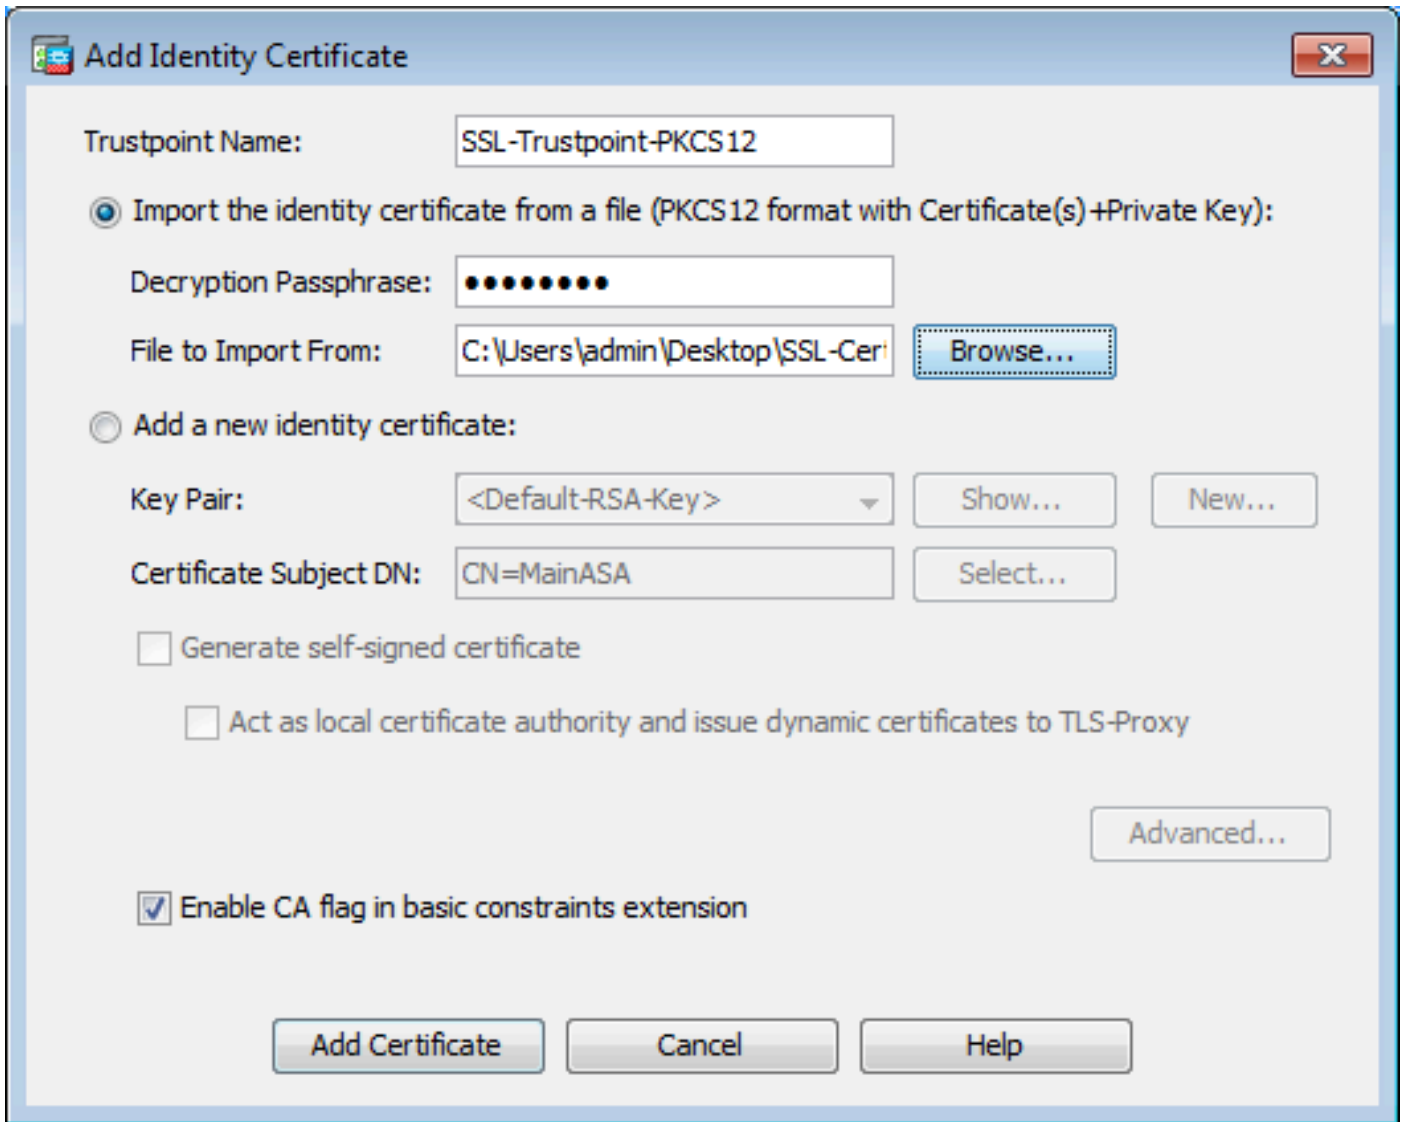

Use this command in order to import the certificate via CLI to the target ASA:

```
<#root>
```

```
ASA(config)#
```

```
crypto ca import <trust-point-name> pkcs12 <passphrase>
```

ASDM configuration:

This can also be done via the Backup/Restore feature on the ASDM with these steps:

1. Log in to the ASA via ASDM and choose **Tools > Backup Configuration**.
2. Backup All Configuration or just the Identity certificates.
3. On the target ASA, open the ASDM and choose **Tools > Restore Configuration**.

## 2. How to generate SSL certificates for use with VPN Load Balancing ASAs?

There are multiple methods that can be used to set up ASAs with SSL certificates for a VPN Load Balancing environment.

1. Use a single Unified Communications/Multiple Domains Certificate (UCC) which has the load-balancing FQDN as the DN and each of the ASA FQDNs as a separate Subject Alternative Name (SAN). There are several well known CAs like GoDaddy, Entrust, Comodo and others that support such certificates. When you choose this method, it is important to remember that the ASA currently does not support the creation of a CSR with multiple SAN fields. This has been documented in the enhancement Cisco bug ID [CSCso70867](#). In this case, there are two options to generate the CSR
  - a. Via the CLI or ASDM. When the CSR is submitted to the CA, add in the multiple SANs on the CA portal itself.
  - b. Use OpenSSL to generate the CSR and include the multiple SANs in the openssl.cnf file.

Once the CSR has been submitted to the CA and the certificate generated, import this PEM certificate to the ASA that generated the CSR. Once done, export and import this certificate in the PKCS12 format onto the other member ASAs.

2. Use a Wildcard certificate. This is a less secure and flexible method when compared to a UC certificate. In the case that the CA does not support UC certificates, a CSR is generated either on the CA or with OpenSSL where the FQDN is on the form of \*.domain.com. Once the CSR has been submitted to the CA and the certificate generated, import the PKCS12 certificate to all the ASAs in the cluster.
3. Use a separate certificate for each of the member ASAs and the for the load-balancing FQDN. This is the least effective solution. The certificates for each of the individual ASAs can be created as shown in this document. The certificate for the VPN Loadbalancing FQDN is created on one ASA and exported and imported as a PKCS12 certificate onto the other ASAs.

### **3. Do the certificates need to be copied from the Primary ASA to the Secondary ASA in an ASA failover pair?**

There is no need to manually copy the certificates from the Primary to Secondary ASA as the certificates are synced between the ASAs as long as Stateful Failover is configured. If on initial setup of failover, the certificates are not seen on the Standby device, issue the command **write standby** in order to force a sync.

### **4. If ECDSA keys are used, is the SSL certificate generation process different?**

The only difference in configuration is the keypair generation step, where an ECDSA keypair is generated instead of an RSA keypair. The rest of the steps remain the same.

The CLI command to generate ECDSA keys are shown here:

```
<#root>
```

```
MainASA(config)#
```

```
cry key generate ecdsa label SSL-Keypair elliptic-curve 256
```

```
INFO: The name for the keys will be: SSL-Keypair  
Keypair generation process begin. Please wait...
```

## **Troubleshoot**

### **Troubleshoot Commands**

These debug commands are to be collected on the CLI in the case of an SSL Certificate Installation failure:

```
debug crypto ca 255
```

```
debug crypto ca messages 255
```

```
debug crypto ca transactions 255
```

### **Common Issues**

Untrusted certificate warning with a valid third-party SSL certificate on the external interface on ASA

with 9.4(1) and later.

Solution:

This issue presents itself when an RSA keypair is used with the certificate. On ASA versions from 9.4(1) onwards, all the ECDSA and RSA ciphers are enabled by default and the strongest cipher (usually an ECDSA cipher) is used for negotiation. If this happens, the ASA presents a Self-Signed certificate instead of the currently configured RSA-based certificate. There is an enhancement in place to change the behavior when an RSA-based certificate is installed on an interface and is tracked by Cisco bug ID [CSCuu02848](#)

Recommended Action: Disable ECDSA ciphers with these CLI commands:

```
ssl cipher tls1.2 custom "AES256-SHA:AES128-SHA:DHE-RSA-AES256-SHA:DHE-RSA-AES128-SHA:DES-CBC3-SHA:DES-CBC-SHA:RC4-SHA:RC4-MD5"
```

Or, with the ASDM, navigate to **Configuration > Remote Access VPN > Advanced**, and choose **SSL Settings**. Under the Encryption section, select **tls1.2 Cipher version** and edit it with the custom string **AES256-SHA:AES128-SHA:DHE-RSA-AES256-SHA:DHE-RSA-AES128-SHA:DES-CBC3-SHA:DES-CBC-SHA:RC4-SHA:RC4-MD5**

## Appendix

### Appendix A: ECDSA or RSA

The ECDSA algorithm is a part of the Elliptic curve cryptography (ECC) and uses an equation of an elliptic curve to generate a Public Key whereas the RSA algorithm uses the product of two primes plus a smaller number to generate the Public Key. This means that with ECDSA the same level of security as RSA can be achieved, but with smaller keys. This reduces computation time and increases the connection times for sites that use ECDSA certificates.

The document on [Next Generation Cryptography and the ASA](#) provides more in-depth information.

### Appendix B: Use OpenSSL to Generate a PKCS12 Certificate from an Identity Certificate, CA Certificate, and Private Key

1. Verify that the OpenSSL is installed on the system that this process is run on. For Mac OSX and GNU/Linux users, this is installed by default.
2. Switch to a valid directory.

On Windows: By default, the utilities are installed in C:\Openssl\bin. Open a command prompt in this location.

On Mac OSX/Linux: Open the Terminal window in the directory needed to create the PKCS12 certificate.

3. In the directory mentioned in the previous step, save the private key (privateKey.key), identity certificate (certificate.crt) and root CA certificate chain (CACert.crt) files.

Combine the private key, identity certificate and the root CA certificate chain into a PKCS12 file. Enter a passphrase to protect your PKCS12 certificate.

```
strong> openssl pkcs12 -export -out certificate.pfx -inkey privateKey.key -in certificate.crt -cer
```

4. Convert the PKCS12 certificate generated to a Base64 encoded certificate:

```
<#root>
```

```
openssl base64 -in certificate.pfx -out certificate.p12
```

Next, import the certificate that was generated in the last step for use with SSL.

## Appendix C: Trusted CA Certificate Security Considerations

### Certificate Authentication Risks and Recommendations

#### Default Trustpoint Validation-Usage Behavior

When a trusted CA certificate is installed, with `crypto ca trustpoint authenticate`, it can be used to authenticate different types of VPN connections using certificate authentication. It is controlled with `validation-usage` trustpoint command. The validation-usage types are:

- `ipsec-client`: Validates IPsec client connections.
- `ssl-client`: Validates SSL client connections.
- `ssl-server`: Validates SSL server certificates.

By default, the command allows validation for `ipsec-client` and `ssl-client`.

#### Default Configuration Risks

- Any CA certificate installed as trusted can be used by default to authenticate incoming client identity certificates for any tunnel group using certificate authentication.
- This default setting can be a security risk if you are not aware of it.

#### Recommended Action

Disable `validation-usage` for unintended trustpoints. If a CA certificate is not meant to authenticate VPN peers or users, disable `validation-usage` for that trustpoint.

#### Example Configuration:

```
trustpoint public-root-ca  
no validation-usage
```

### Authorization Risks and Recommendations

By default, a trusted CA certificate can be used to authenticate VPN peer or user connecting to any tunnel-group. Proper authorization needs to be designed.

#### Recommended Action

Use certificate maps and tunnel-group maps to ensure only authorized certificates are used for specific tunnel groups. Set a default tunnel group map rule, that points to a no-access tunnel group to restrict unauthorized access.

## Example Configuration

Certificate authentication is only allowed for:

- Machines with certificate issued by cn=example.com and having OU=machines in certificate subject.
- Users with certificate issued by cn=example.com and having OU=users in certificate subject.

Users with other certificates are assigned to no\_access tunnel-group by default, because of **tunnel-group-map default-group no\_access** command. The Certificate Map Rules have priority over group-url thanks to **tunnel-group-map enable rules** command. Knowing group-url does not help to bypass the Certificate Map Rules.

```
tunnel-group mgmt-tunnel type remote-access
tunnel-group mgmt-tunnel general-attributes
address-pool vpn_pool
default-group-policy mgmt-tunnel
tunnel-group mgmt-tunnel webvpn-attributes
authentication certificate
group-url https://ftd.example.com/mgmt enable
