Introduction

This document provides a sample configuration for PPP callback between two Cisco routers.

Prerequisites

Requirements

There are no specific requirements for this document.

Components Used

The information in this document is based on these software and hardware versions:

- Cisco IOS® Software Release 12.0(3)T or later.

Note: To configure PPP callback with the help of an AAA server assigned callback string, you need to use the **dialer aaa** command, which is available in Cisco IOS Software Release 12.0(3)T or later. However in Cisco IOS versions 12.1(4)T, 12.2(1)T, and later, this command is not required for PPP callback with an AAA server assigned callback string.

Note: The **dialer aaa** command is only supported with Legacy DDR (as shown in figure1).

The information in this document was created from the devices in a specific lab environment. All of the devices used in this document started with a cleared (default) configuration. If your network is live, make sure that you understand the potential impact of any command.

Conventions

For more information on document conventions, refer to Cisco Technical Tips Conventions.

Background Information

The TACACS+ (AAA server) is used to supply the callback dialstring to the callback server. However, you can also use RADIUS to supply the callback string. To configure PPP callback with local authentication, authorization, and accounting (AAA), see Configuring PPP Callback Over ISDN.

In this sample configuration, callback uses PPP and the facilities specified in RFC 1570. The PPP callback across the ISDN circuit is completed in this order:

1. The callback client initiates and brings up an ISDN connection to the callback server router.
2. The callback client and callback server negotiate PPP link control protocol (LCP). In LCP negotiation, callback is requested, negotiated, and agreed upon.
3. The callback client and callback server authenticate each other with PPP Password Authentication Protocol (PAP) or Challenge Handshake Authentication Protocol (CHAP). However, you can configure the callback client not to authenticate the callback server, through the **ppp authentication chap callin** command.
4. The Callback server obtains the necessary callback attributes, such as the callback dialstring (the phone number of the client) from the AAA server.
5. Both routers drop the ISDN connection.
6. The callback server initiates the callback to the client. When the call connects, the routers authenticate each other, and the link is established.

Configure

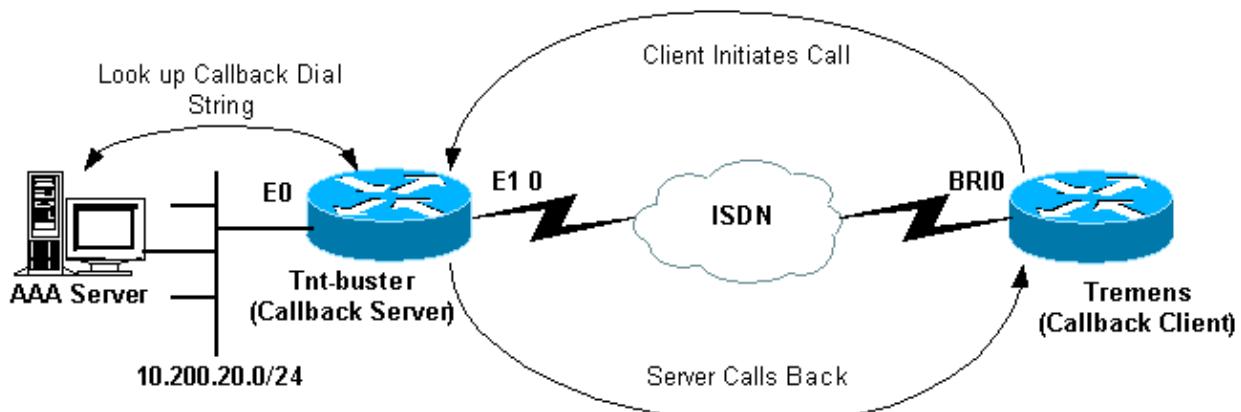

In this section, you are presented with the information to configure the features described in this document.

Note: To find additional information on the commands used in this document, use the Command Lookup Tool (registered customers only) .

Network Diagram

This document uses this network setup:

Figure 1 Network Diagram

Configurations

This document uses these configurations:

- Freeware TACACS+ Configuration
- RADIUS Configuration
- Alternate RADIUS Configuration
- Tnt–buster (Callback Server) Configuration
- Tremens (Callback Client) Configuration

Freeware TACACS+ Configuration

```
user = tremens {
    default service = permit
    login = cleartext "cisco"
    chap = cleartext "cisco"

!--- CHAP password.

service = ppp protocol = lcp {
    callback-dialstring = "6083"

!--- Number to callback.

send-secret = "cisco"
}
}
```

You can also use RADIUS as your AAA server to supply the callback attributes instead of TACACS+. An example of the RADIUS configuration is provided here:

RADIUS Configuration

```
tremens      Auth-Type = Local, Password = "cisco"
              Service-Type = Framed-User,
              !--- Service-Type(6) is Framed User(4).

              Cisco-AVPair = "lcp:callback-dialstring=6083",
              Cisco-AVPair = "lcp:send-secret=cisco"
```

Note: In the RADIUS configuration shown above, the Cisco AVPair **lcp:send-secret=cisco** is needed at the time of authentication of the callback. If you do not include this AVPair, you must configure the CHAP username and password of the remote router locally on the callback server.

Note: This document deals primarily with TACACS+. The debugs provided in this document do not show a RADIUS–initiated callback.

Note: From Cisco IOS version 12.1(7), it is possible to use the Internet Engineering Task Force (IETF) RADIUS attribute 19 for ISDN and Analog Microsoft callback. In such a case, it is unnecessary to use the Cisco AVPairs, shown in the previous configuration. Refer to the alternate RADIUS configuration example shown here:

Alternate RADIUS Configuration

```
tremens      Auth-Type = Local, Password = "cisco"
              Service-Type = callback framed
              !--- Service-Type (6) is callback framed (4).
```

```

!--- Callback framed is also known as
      !--- Dialback-Framed-User.

      Callback =6083

!--- IETF RADIUS Callback attribute (19) with the phone
      !--- number for the callback.

```

Note: The RADIUS debugs will show the IETF RADIUS attribute 19 returned to the callback server.

The configurations for the two routers used in this example are shown here:

Tnt-buster (Callback Server)

```

Verify

This section provides information you can use to confirm your configuration is working properly.

Certain **show** commands are supported by the Output Interpreter Tool (registered customers only) , which allows you to view an analysis of **show** command output.

- **show dialer interface type number** displays general diagnostic information for interfaces configured for dial-on-demand routing (DDR). The source and destination addresses of the packet that initiated the dialing are shown in the **dial reason** line. This command also displays the connection timers.
- **show isdn status** enables you to ensure that the router communicates properly with the ISDN switch. In the output, verify that **Layer 1 Status** is **ACTIVE**, and that the **Layer 2 Status state = MULTIPLE_FRAME_ESTABLISHED** appears. This command also displays the number of active calls.

Troubleshoot

This section provides information you can use to troubleshoot your configuration.

Refer to Cisco IOS Release 12.0 Debug Command Reference for more information on debug commands.

Troubleshooting Commands (Optional)

Certain **show** commands are supported by the Output Interpreter Tool (registered customers only) , which allows you to view an analysis of **show** command output.

Note: Before issuing **debug** commands, refer to Important Information on Debug Commands.

- **debug isdn q931** shows call setup and tear down of the ISDN network connection (Layer 3).
- **debug dialer [events / packets]** displays DDR debugging information about the packets received on a dialer interface.
- **debug aaa authentication** displays information on AAA authentication.
- **debug aaa authorization** displays information on AAA authorization.
- **debug tacacs** displays detailed debugging information associated with TACACS+.
- **debug ppp negotiation** displays information on PPP traffic and exchanges while negotiation of the PPP components is in progress, including Link Control Protocol (LCP), Authentication, and NCP. A successful PPP negotiation will first open the LCP state, then Authenticate, and finally negotiate NCP.
- **debug ppp authentication** displays the PPP authentication protocol messages, including Challenge Authentication Protocol (CHAP) packet exchanges and Password Authentication Protocol (PAP) exchanges. If you observe a failure verify whether the CHAP username and password are configured correctly.
- **debug callback** displays callback events when the router uses a modem and a chat script to call back on a terminal line. As this command is for modems and chat scripts, it is not used in this configuration.
