Medianet Metadata

This module provides an overview of medianet metadata. It also describes how metadata is used by different components of a network to make policy decisions.

- Finding Feature Information, page 1
- Restrictions for Medianet Metadata, page 1
- Information About Medianet Metadata, page 2
- How to Configure and Verify Medianet Metadata, page 7

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for Medianet Metadata

- The metadata transport mechanism (Resource Reservation Protocol [RSVP]) carries metadata only in the downstream direction, that is, toward the destination IP address.
- Metadata does not support high availability (HA). Therefore, after switchover, the RSVP path refresh messages are generated every 30 seconds to update the RSVP and metadata database.

- A path tear can happen in RSVP because of reservation preemption for higher priority reservation, but the flow could still be active. Metadata deletes entries in the database on path tear and reprograms the data forwarding path. The flow continues to be active without any metadata features applied on it.
- RSVP does not support Network Address Translation (NAT). Hence, metadata needs to track flow key and attribute information before and after NAT.

Information About Medianet Metadata

Metadata Overview

The metadata infrastructure provides a framework that allows data from one component to be available to another component on the same network element and across network elements.

Flow metadata is the data that describes a flow in the network. This metadata describes the five-tuple flow along with its attributes. Network elements can take action based on the metadata generated by the endpoints.

The metadata infrastructure consists of two major components—producers and consumers.

- Producers—Metadata producer is any source of metadata. The producer propagates all the attributes of a given flow. Producers can be anywhere in the network—endpoint, proxy agents or intermediate nodes. Metadata generated by the endpoints is supported. Producers use a specific transport protocol such as Resource Reservation Protocol (RSVP) for signaling metadata attributes to store the information in a database, referred to as the control plane database, which can then be used by the consumers.
- Consumers—Metadata consumer is any network element that uses the flow tuple and metadata provided by producers. The flow tuple and metadata can also be propagated along the media path to consumers in different network elements via a transport infrastructure.

Only the initiator of metadata is source aware. The initiator stores the source with its list of attributes along with the flow. But the downstream devices get only one list of attributes. The list is a consolidation of attributes from all sources with the attribute from a higher priority source, overriding the attribute from a lower priority source. Media Services Interface (MSI) has the highest priority followed by Media Services Proxy (MSP) and Network Based Application Recognition (NBAR).

Metadata Properties

Metadata is represented as a list of <Attribute, Value> pairs. Actions such as configuring the metadata values and updating and deleting the existing metadata are driven by the producers. Consumers read these metadata values and take appropriate action based on the control plane classification.

Metadata Control Plane Classification

Classifying network traffic allows you to organize traffic (that is, packets) into traffic classes or categories on the basis of whether the traffic matches specific criteria. You can classify network traffic to enable many quality of service (QoS) features on your network.

The metadata control plane classification is activated only when a consumer is registered with the metadata infrastructure. The metadata framework supports Cisco Common Classification Policy Language-based control plane classification.

Cisco Common Classification Policy Language is a replacement for feature-specific configuration commands. Cisco Common Classification Policy Language allows you to create traffic policies based on events, conditions, and actions. If Cisco Common Classification Policy Language classification succeeds, then the <Attribute, Value> pair is distributed to all the registered consumers.

In a scenario where QoS is a metadata consumer, the following steps briefly describe the control plane classification process:

- The required classification **match** commands are provisioned for a class map attached to the relevant target interface.
- Every incoming flow from the producer is matched against the provisioned class.
- If an appropriate match is found, relevant actions specified in the policy are performed.

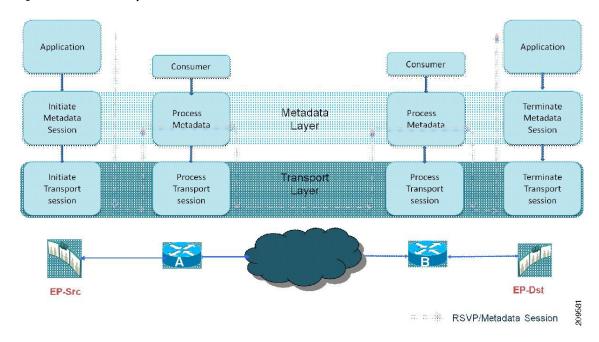

If the control plane classification is successful, then the <Attribute, Value> pair is distributed to all the consumers registered for metadata infrastructure. When packets related to the flow reach the network element, appropriate actions provisioned in the class are applied. For instance, if the action was set dscp 0xef, then this particular QoS action is applied on all packets matching this flow.

Metadata Transport

Metadata generated by the producers must be available at every network element in the media path. The metadata transport mechanism ensures that the metadata is propagated across the network and is delivered to all the network elements in the media path.

The figure below illustrates the metadata transport architecture.

Figure 1: Metadata Transport Architecture

The application at the source endpoint triggers the metadata layer to initiate a metadata session with the appropriate <Attribute, Value> pairs. The information with the <Attribute, Value> pairs is then carried along the media path and terminated at the destination endpoint.

The metadata with the <Attribute, Value> pairs is provided to the consumers at every network element, if the consumers are registered. Additional metadata elements that are generated at every network element can be sent along with the existing metadata. The metadata flows in the down stream of the media path.

Metadata applications have several subapplications. Each subapplication has an identifier. Metadata supports the following sub-applications:

- Traffic-type
- Transport-type
- Signaling-type
- Multiplex-type

Each subapplication is dependent on a specific application. The table below lists subapplications associated with eat application.

Table 1: Application to Subapplications Mapping

Application Name	Traffic Type	Transport Type	Signaling Type	Multiplex Type
cisco-phone	10 (control)	2 (rtp)	1 (sip)	
		3 (rtcp))	2 (bfcp)

			5 (xccp)	
			6 (mscp)	
			7 (clue)	

Metadata Flow Entries

Any producer can add flow metadata into the database and any consumer can access this information.

Metadata can be updated during the flow. When metadata attributes change during the flow, the network elements are notified through Resource Reservation Protocol (RSVP) PATH TEAR messages.

When the RSVP session terminates via a PATH TEAR message, the metadata framework listens to these messages and deletes the relevant flow entry in the database.

Medianet Metadata Implementation

The figure below illustrates a sample deployment scenario for the medianet metadata implementation.

MPLS-WPN

Callin III

CE DMVPN

Figure 2: Medianet Metadata Implementation

As illustrated in the figure above, two users from different locations can be in a WebEx, Telepresence, or a Cisco IP phone session.

This example assumes the users to be in a WebEx session. WebEx sessions typically require low latency guarantee from the network. QoS configurations can be used to obtain the required behavior. To achieve the required behavior, the required types of policy maps must be configured on the given interface to match the

application ID of WebEx. Once this classification provisioning is done, metadata will also have a copy of this information in its classification database. One end of Webex session (endpoint A) signals the application as the metadata, using explicit signaling from the endpoints. The metadata information can be the application name, application ID, application version, and so on. This metadata information flows through the network along the media path.

Resource Reservation Protocol (RSVP) notifies the metadata framework about any incoming flow and provides the metadata information associated with the flow. A match action is performed between the decoded <Attribute, Value> pair and the WebEx metadata properties. If the match is successful, then the same information is propagated to the data plane. The data plane checks the appropriate classification requirements and takes the required QoS actions.

The following example shows how to configure QoS properties to work with the metadata framework. In the following sample configuration, a class map v1 is created.

```
! Creates a class-map with metadata-based filters class-map match-all v1 match application webex-video exit \frac{1}{2} \frac{1}{2}
```

Next, a policy map p1 is created and the class v1 is added to it. The packets belonging to class v1 are given priority by giving the entire class a guaranteed bandwidth of 1 Mbps. That is, the aggregate of all the flows that match the <Attribute, Value> pair defined in the class v1 are given a guaranteed bandwidth. Any other QoS solutions such as policing, marking, or queueing can also be applied as a classification criterion.

```
! Create policy map and apply the classification properties policy-map p1 class v1 priority 1000
```

Then, the policy map is attached to the target interface:

```
! Attach the policy map to the target interface interface Ethernet 1/0 \\ service-policy output p1
```

For more information about QoS network traffic classification and solutions such as policing, marking, or queuing, see the *Quality of Service Solutions Configuration Guide*.

How to Configure and Verify Medianet Metadata

Enabling Metadata Globally or on a Specific Interface

The first consumer registering for metadata triggers the enabling of metadata. The corresponding egress interface for a given flow enables metadata and Resource Reservation Protocol (RSVP) if they are not enabled already. Although you can disable metadata by using the **no metadata flow** command, we recommend that the metadata be enabled.

Perform this task to enable metadata on a specific interface.

SUMMARY STEPS

- 1. enable
- 2. configure terminal
- 3. metadata flow
- **4. interface** *type number*
- 5. metadata flow
- 6. end

DETAILED STEPS

	Command or Action	Purpose	
Step 1	enable	Enables privileged EXEC mode.	
	Example:	• Enter your password if prompted.	
	Device> enable		
Step 2	configure terminal	Enters global configuration mode.	
	Example:		
	Device# configure terminal		
Step 3	metadata flow	Enables metadata globally.	
	Example:		
	Device(config)# metadata flow		
Step 4	interface type number	Specifies the interface type and number and enters interface configuration mode.	
	Example:		
	Device(config) # interface fastethernet 0/1		
Step 5	metadata flow	Enables metadata on the specified interface.	
	Example:		
	Device(config-if) # metadata flow		
Step 6	end	Returns to privileged EXEC mode.	
	Example:		
	Device(config-if)# end		

Provisioning Control Plane Classification

Every flow that enters a network element needs to be classified for appropriate actions. Perform this task to provision control plane classification.

SUMMARY STEPS

- 1. enable
- 2. configure terminal
- 3. class-map class-map-name
- 4. match application application-name
- 5 evi
- **6. policy-map** *policy-map-name*
- 7. class class-map-name
- **8.** Enter QoS solution commands, as required.
- 9. exit
- **10. interface** *type number*
- **11. service-policy** *policy-map-name*
- **12**. end

DETAILED STEPS

Command or Action	Purpose
enable	Enables privileged EXEC mode.
Example:	• Enter your password if prompted.
Device> enable	
configure terminal	Enters global configuration mode.
Example:	
Device# configure terminal	
class-map class-map-name	Creates a class map to be used for matching packets to a specified class and enters QoS class-map configuration mode.
Example:	
Device(config)# class-map class1	
	enable Example: Device> enable configure terminal Example: Device# configure terminal class-map class-map-name Example:

	Command or Action	Purpose
Step 4	<pre>match application application-name Example: Device(config-cmap) # match application test-application</pre>	Classifies the class map based on the application name specified.
Step 5	exit	Exits QoS class-map configuration mode.
	Example:	
	Device(config-cmap)# exit	
Step 6	policy-map policy-map-name	Creates or modifies a policy map that can be attached to one
	Example:	or more interfaces to specify a service policy and enters QoS policy-map configuration mode.
	Device(config) # policy-map pt1	
Step 7	class class-map-name	Specifies the name of the class whose policy you want to create or change.
	Example:	
	Device(config-pmap)# class class1	
Step 8	Enter QoS solution commands, as required.	Configures any QoS solution commands such as controlling, policing, classification, or marking.
		• For example, the set dscp command marks a packet by setting the differentiated services code point (DSCP) value in the type of service (ToS) byte.
Step 9	exit	Exits QoS policy-map configuration mode and enters global configuration mode.
	<pre>Example: Device(config-pmap)# exit</pre>	
Step 10	interface type number	Specifies the interface type and number and enters interface configuration mode.
	<pre>Example: Device(config)# interface fastethernet 0/1</pre>	
Step 11	service-policy policy-map-name	Attaches a policy map to an input interface.
	<pre>Example: Device(config-if)# service-policy pt1</pre>	

	Command or Action	Purpose
Step 12	end	Returns to privileged EXEC mode.
	Example: Device(config-if)# end	

Troubleshooting Tips

Typically, for the metadata information to propagate from the source to the destination, all the network elements along the media path need not support the metadata framework. However, perform the following steps to troubleshoot any flow-metadata-related problems along the path between the source and the destination:

- Perform the **ping** operation to test for the basic connectivity and reachability of the destination network element from the source.
- Enter the **show metadata flow** command and check the output to determine if the egress interface is correctly populated.
- Enable RSVP, if it was disabled intentionally (RSVP is enabled by default).
- Enter the **show metadata flow** command on the network elements along the media path to verify if the content of the metadata flow table is the same as that in the source network element. However, for you to be able to verify the metadata flow table of any network element, you must first enable metadata flow by using the **metadata flow** command.

Verifying Medianet Metadata Configuration

Use the following commands to verify the metadata configuration.

SUMMARY STEPS

- 1. show metadata application table
- 2. show metadata flow classification-table
- 3. show metadata flow statistics
- 4. show metadata flow table
- 5. debug metadata flow

DETAILED STEPS

Step 1 show metadata application table

Example:

Device# show metadata application table

Displays a list of metadata applications defined on the network element.

Step 2 show metadata flow classification-table

Example:

Device# show metadata flow classification table

Displays metadata control plane classification information.

Step 3 show metadata flow statistics

Example:

Device# show metadata flow statistics

Displays metadata flow statistics. The output includes event and memory details.

Step 4 show metadata flow table

Example:

Device# show metadata flow table

Displays details of every flow.

Step 5 debug metadata flow

Example:

Device# debug metadata flow all

Debugs the metadata flow and checks if the control plane classification was completed successfully.

Troubleshooting Medianet Metadata Flow

In the absence of endpoints, you can simulate the creation of flow entries for troubleshooting metadata flow. Perform this task to troubleshoot metadata flow.

SUMMARY STEPS

- 1. enable
- 2. configure terminal
- 3. metadata flow entry entry-name
- 4. exit
- 5. metadata flow flow-specifier entry-name
- **6. source-ip** *ip-address* **source-port** *port-number*
- 7. dest-ip ip-address dest-port port-number
- 8. exi
- 9. metadata flow session-params session-name
- **10.** application name application-name
- **11.** exit
- 12. metadata flow entry entry-name
- **13. flow-specifier** *flow-specifier-name*
- **14. session-params** session-name
- **15**. end
- 16. debug metadata flow all

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example: Device> enable	• Enter your password if prompted.
Step 2	configure terminal	Enters global configuration mode.
	Example: Device# configure terminal	
Step 3	metadata flow entry entry-name	Creates a flow entry with the specified name with five-tuple information and enters metadata entry configuration mode.
	<pre>Example: Device(config) # metadata flow entry entry1</pre>	
Step 4	exit	Exits metadata entry configuration mode and enters global configuration mode.
	<pre>Example: Device(config-md-entry)# exit</pre>	

	Command or Action	Purpose
Step 5	metadata flow flow-specifier entry-name	Enters metadata flow specifier configuration mode.
	<pre>Example: Device(config) # metadata flow flow-specifier flow1</pre>	
Step 6	source-ip ip-address source-port port-number	Specifies the source IP address and source port number for the endpoint.
	Example: Device(config-md-flowspec)# source-ip 209.165.201.16 source-port 1000	
Step 7	dest-ip ip-address dest-port port-number	Specifies the destination IP address and destination port number for the endpoint.
	Example: Device(config-md-flowspec)# dest-ip 209.165.201.25 dest-port 1001	• Use the show metadata flow table command to check if the metadata flow table is created. Refer to the "Verifying Metadata Attributes" section for sample output from the show metadata flow table command. You can check for the ingress and the egress interfaces and the source and destination IP addresses of the flow.
Step 8	exit	Exits metadata flow specifier configuration mode and enters global configuration mode.
	<pre>Example: Device(config-md-flowspec)# exit</pre>	
Step 9	metadata flow session-params session-name	Configures a name for the session that is newly created and adds it to the metadata flow table.
	<pre>Example: Device(config) # metadata flow session-params session1</pre>	Enters metadata session parameters configuration mode.
Step 10	application name application-name	Associates the specified application name to the session.
	<pre>Example: Device(config-md-session-params)# application name appl</pre>	
Step 11	exit	Exits metadata session parameters configuration mode and enters global configuration mode.
	<pre>Example: Device(config-md-session-params)# exit</pre>	
Step 12	metadata flow entry entry-name	Enters metadata entry configuration mode.
	Example: Device(config)# metadata flow entry entry1	

	Command or Action	Purpose	
Step 13	flow-specifier flow-specifier-name	Associates the flow specifier with the specified flow entry.	
	<pre>Example: Device(config-md-entry)# flow-specifier flow1</pre>		
Step 14	session-params session-name	Associates the session parameters with the specified flow entry.	
	<pre>Example: Device(config-md-entry)# session-params session1</pre>		
Step 15	end	Returns to privileged EXEC mode.	
	<pre>Example: Device(config-md-entry)# end</pre>		
Step 16	debug metadata flow all	Debugs all metadata flow information.	
	Example: Device# debug metadata flow all	 Refer to the "Verifying Metadata Attributes" section for sample output from the debug metadata flow all command. 	
		• To check the control plane classification details, use the show metadata flow classification-table command.	

Configuration Examples for Medianet Metadata

Example: Enabling Metadata Globally or on a Specific Interface

The following example shows how to enable metadata globally:

Device> enable
Device# configure terminal
Device(config)# metadata flow
Device(config)# exit

The following example shows how to enable metadata on a specific interface:

Device> enable
Device# configure terminal
Device(config)# interface fastethernet 0/1
Device(config-if)# metadata flow
Device(config-if)# exit

Example: Provisioning Control Plane Classification

```
Device> enable
Device# configure terminal
Device(config)# class-map class1
Device(config-cmap)# match application test-application
Device(config-cmap)# exit
Device(config-pmap)# class class1
Device(config-pmap-c)# exit
Device(config-pmap)# exit
Device(config-pmap)# exit
Device(config-pmap)# exit
Device(config)# interface fastethernet 0/1
Device(config-if)# service-policy pt1
Device(config-if)# end
```

Example: Verifying Metadata

The following is sample output from the **show metadata application table** command:

Device# show metadata application table

ID	Name	Vendor	Vendor id
113	telepresence-media		_
114	telepresence-contr\$	_	_
478	telepresence-data	-	-

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	

Feature Information for Medianet Metadata

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 2: Feature Information for Medianet Metadata

Feature Name	Releases	Feature Information
Medianet Metadata	15.1(1)SY 15.3(1)T 15.1(2)SY 15.4(1)T	The following commands were introduced or modified: debug metadata, match application (class-map), metadata application-params, metadata flow, metadata flow
	15.4(1)S	(troubleshooting), show metadata application table, show metadata flow, metadata flow transmit and metadata flow reverse transmit.

Feature Information for Medianet Metadata

Metadata NBAR Integration

The Metadata NBAR Integration feature integrates Network-Based Application Recognition (NBAR) with metadata so that NBAR is enabled as the source for metadata. The flow information gathered from NBAR is stored and propagated using metadata.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see Bug Search Tool and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table at the end of this module.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Reverse Flow Metadata Support

Benefits of Metadata NBAR Integration

The flow information from NBAR is generated only on the node on which NBAR is configured and is not available to the downstream devices. To gather flow information, NBAR must be enabled on all downstream devices. Enabling NBAR on all downstream devices may not be possible always because some nodes may be incapable of performing deep packet inspection (DPI). When NBAR is integrated with metadata, metadata

information can be propagated to downstream nodes using Resource Reservation Protocol (RSVP), thereby substituting NBAR for DPI whenever DPI is not possible.

Metadata NBAR Integration

NBAR as a source for metadata is enabled by default when you create a class map with metadata-based filters, create a policy map that uses the class, and attach the policy map to the target.

You can disable NBAR as a source for metadata by using the **no metadata nbar** command.

NBAR does not support the telepresence-data, vmware-view, webex-video, webex-voice, and wyze-zero-client application types.

How to Configure Reverse Flow Metadata Support

Integrating NBAR with Metadata

SUMMARY STEPS

- 1. enable
- 2. configure terminal
- 3. metadata flow
- 4. metadata flow transmit
- 5. class-map class-map-name
- 6. match application application-name
- 7. exit
- 8. policy-map policy-map-name
- 9. class class-map-name
- 10. exit
- **11.** exit
- **12**. **interface** *type number*
- **13.** service-policy {input | output} policy-map-name
- **14**. exit

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
		Enter your password if prompted.
	Example:	
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	metadata flow	Enables metadata on a device.
	Example: Device(config) # metadata flow	
Step 4	metadata flow transmit	Enables RSVP transmission of information flows to downstream devices.
	Example: Device(config) # metadata flow transmit	
Step 5	class-map class-map-name	Creates a class map that is to be used for matching packets to a specified class, and enters QoS class-map configuration mode.
	Example: Device(config) # class-map c1	
Step 6	match application application-name	Classifies an application based on the specified application name.
	Example: Device(config-cmap)# match application webex-meeting	
Step 7	exit	Exits QoS class-map configuration mode.
	<pre>Example: Device(config-cmap)# exit</pre>	
Step 8	policy-map policy-map-name	Creates or modifies a policy map that can be attached to one or more interfaces to specify a service policy, and enters QoS
	Example: Device(config) # policy-map p1	policy-map configuration mode.
Step 9	class class-map-name	Specifies the name of the class whose policy you want to create or change, and enters QoS policy-map class configuration mode.
	Example: Device(config-pmap)# class c1	

	Command or Action	Purpose
Step 10	exit	Exits QoS policy-map class configuration mode and enters QoS policy-map configuration mode.
	<pre>Example: Device(config-pmap-c)# exit</pre>	
Step 11	exit	Exits QoS policy-map configuration mode and enters global configuration mode.
	<pre>Example: Device(config-pmap)# exit</pre>	
Step 12	interface type number	Specifies the interface type and number and enters interface configuration mode.
	Example: Device(config)# interface gigabitethernet 0/0	
Step 13	service-policy {input output} policy-map-name	Attaches a policy map to an input interface, a virtual circuit (VC), an output interface, or a VC that will be used as the
	Example: Device(config-if)# service-policy output p1	service policy for the interface or VC.
Step 14	exit	Exits interface configuration mode and returns to global configuration mode.
	<pre>Example: Device(config-if)# exit</pre>	

Configuration Examples for Metadata NBAR Integration

Example: Integrating NBAR with Metadata

The following example shows how to create a class map with metadata-based filters, create a policy map that uses the class, and attach the policy map to a target, thereby enabling NBAR as a source for metadata:

```
Device> enable

Device# configure terminal

Device(config)# metadata flow

Device(config)# metadata flow transmit

Device(config)# metadata flow reverse transmit

Device(config)# class-map cl

Device(config-cmap)# match application webex-meeting

Device(config-cmap)# exit

Device(config-pmap)# class cl

Device(config-pmap-c)# exit

Device(config-pmap)# class cl

Device(config-pmap)# class cl

Device(config-pmap)# exit

Device(config-pmap)# exit
```

```
Device(config-if)# service-policy output p1
Device(config-if)# exit
```

Feature Information for Metadata NBAR Integration

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 3: Feature Information for Metadata NBAR Integration

Feature Name	Releases	Feature Information
Metadata NBAR Integration	15.2(4)M	The Metadata NBAR Integration feature provides integration of NBAR with metadata so that NBAR acts as the source for metadata, and the flow information gathered from NBAR is stored and propagated using metadata. The following commands were
		introduced or modified: debug metadata nbar, metadata flow transmit, metadata source nbar.

Reverse Flow Metadata Support

The Reverse Flow Metadata Support feature creates reverse metadata flow sessions to act as proxy and signal metadata, and support QoS for the reverse session. The reverse sessions are created using the attributes of the forward session.

Information About Reverse Flow Metadata Support

Metadata Reverse Flows

End devices provisioned with metadata producers such as Media Services Interface (MSI), Media Services Proxy (MSP), and Network Based Application Recognition (NBAR) add flows to metadata database. When an end device cannot signal metadata, a reverse metadata flow session is created to act as a proxy and signal metadata, and support QoS for the reverse session. The reverse sessions are created using the attributes of a

forward session. The reverse flow session is enabled only on the device, which is connected to the endpoint and cannot signal metadata. That is when the device is not provisioned with a metadata producer such as MSP, MSI or NBAR.

How to Configure Reverse Flow Metadata Support

Configuring Reverse Flow Metadata Support

SUMMARY STEPS

- 1. enable
- 2. configure terminal
- 3. metadata flow
- 4. metadata flow reverse transmit
- 5. exit

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.
	Example:	• Enter your password if prompted.
	Device> enable	
Step 2	configure terminal	Enters global configuration mode.
	Example:	
	Device# configure terminal	
Step 3	metadata flow	Enables metadata on a device.
	<pre>Example: Device(config) # metadata flow</pre>	
Step 4	metadata flow reverse transmit	Enables reverse metadata information flows for the forward sessions.
	<pre>Example: Device(config) # metadata flow reverse transmit</pre>	
Step 5	exit	Returns to privileged EXEC mode.
	<pre>Example: Device(config) # end</pre>	

How to Configure Reverse Flow Metadata Support

Example: Configuring Reverse Flow Metadata Support

The following example shows how to enable reverse flow of metadata information in Global configuration mode:

```
Device> enable
Device# configure terminal
Device(config)# metadata flow
Device(config)# metadata flow reverse transmit
Device(config)# exit
```

The following example shows how to enable reverse flow of metadata information in Interface configuration mode:

```
Device> enable
Device# configure terminal
Device(config)# metadata flow
Device(config)# interface Ethernet 0/1
Device(config-if)# metadata flow reverse transmit
Device(config)# exit
```
