About This Guide

This guide helps you to perform tasks such as lifecycle management operations, monitoring, healing and scaling of the VNFs using the ETSI APIs.

• Audience, on page vii

Audience

This guide is designed for network administrators responsible for provisioning, configuring, and monitoring VNFs. Cisco Elastic Services Controller (ESC) and its VNFs are deployed in a Virtual Infrastructure Manager (VIM). Currently OpenStack, VMware vCenter, VMware vCloud Director, CSP 2100 / 5000, and Amazon Web Services (AWS) are the supported VIMs. The administrator must be familiar with the VIM layer, vCenter, OpenStack and AWS resources, and the commands used.

Cisco ESC is targeted for Service Providers (SPs) and Large Enterprises. ESC helps SPs reduce cost of operating the networks by providing effective and optimal resource usage. For Large Enterprises, ESC automates provisioning, configuring and monitoring of network functions.

Terms and Definitions

The below table defines the terms used in this guide.

Table 1: Terms and Definitions

Terms	Definitions
AWS	Amazon Web Services (AWS) is a secure cloud services platform, offering compute, database storage, content delivery and other functionalities.
ESC	Elastic Services Controller (ESC) is a Virtual Network Function Manager (VNFM), performing lifecycle management of Virtual Network Functions.
ETSI	European Telecommunications Standards Institute (ETSI) is an independent standardization organization that has been instrumental in developing standards for information and communications technologies (ICT) within Europe.

Terms	Definitions	
ETSI Deployment Flavour	A deployment flavour definition contains information about affinity relationships, scaling, min/max VDU instances, and other policies and constraints to be applied to the VNF instance. The deployment flavour defined in the VNF Descriptor (VNFD) must be selected by passing the <i>flavour_id</i> attribute in the InstantiateVNFRequest payload during the instantiate VNF LCM operation.	
НА	ESC High Availability (HA) is a solution for preventing single points of ESC failure and achieving minimum ESC downtime.	
KPI	Key Performance Indicator (KPI) measures performance management. KPIs specify what, how and when parameters are measured. KPI incorporates information about source, definitions, measures, calculations for specific parameters.	
MSX	Cisco Managed Services Accelerator (MSX) is a service creation and delivery platform that enables fast deployment of cloud-based networking services for both Enterprises and Service Providers customers.	
NFV	Network Function Virtualization (NFV) is the principle of separating network functions from the hardware they run on by using virtual hardware abstraction.	
NFVO	NFV Orchestrator (NFVO) is a functional block that manages the Network Service (NS) lifecycle and coordinates the management of NS lifecycle, VNF lifecycle (supported by the VNFM) and NFVI resources (supported by the VIM) to ensure an optimized allocation of the necessary resources and connectivity.	
NSO	Cisco Network Services Orchestrator (NSO) is an orchestrator for service activation which supports pure physical networks, hybrid networks (physical and virtual) and NFV use cases.	
OpenStack Compute Flavor	Flavors define the compute, memory, and storage capacity of nova computing instances. A flavor is an available hardware configuration for a server. It defines the <i>size</i> of a virtual server that can be launched.	
Service	A service consists of a single or multiple VNFs.	
VDU	The Virtualisation Deployment Unit (VDU) is a construct that can be used in an information model, supporting the description of the deployment and operational behaviour of a subset of a VNF, or the entire VNF if it was not componentized in subsets.	
VIM	The Virtualized Infrastructure Manager (VIM) adds a management layer for the data center hardware. Its northbound APIs are consumed by other layers to manage the physical and virtual resources for instantiation, termination, scale in and out procedures, and fault & performance alarms.	
VM	A Virtual Machine (VM) is an operating system OS or an application installed on a software, which imitates a dedicated hardware. The end user has the same experience on a virtual machine as they would have on dedicated hardware.	
VNF	A Virtual Network Function (VNF) consists of a single or a group of VMs with different software and processes that can be deployed on a Network Function Virtualization (NFV) Infrastructure.	

Terms	Definitions
VNFC	A Virtual Network Function Component is (VNFC) a composite part of the VNF, synonymous with a VDU, which could be implemented as a VM or a container.
VNFM	Virtual Network Function Manager (VNFM) manages the life cycle of a VNF.

Related Documentation

The Cisco ESC doc set comprises of the following guides to help you perform installation, configuration; the lifecycle management operations, healing, scaling, monitoring and maintenance of the VNFs using different APIs.

Guide	Information Provided in This Guide	
Cisco Elastic Services Controller Release Notes	Includes new features and bugs, known issues.	
Cisco Elastic Services Controller Install and Upgrade Guide	Includes procedure for new installation and upgrade scenarios, pre and post installation tasks, and procedure for ESC High Availability (HA) deployment.	
Cisco Elastic Services Controller User Guide	Includes lifecycle management operations, monitoring, healing and scaling of the VNFs.	
Cisco Elastic Services Controller ETSI NFV MANO User Guide	Includes lifecycle management operations, monitoring, healing and scaling of the VNFs using the ETSI APIs.	
Cisco Elastic Services Controller Administration Guide	Includes maintenance, monitoring the health of ESC, and information on system logs generated by ESC.	
Cisco Elastic Services Controller NETCONF API Guide	Information on the Cisco Elastic Services Controller NETCONF northbound API, and how to use them.	
Cisco Elastic Services Controller REST API Guide	Information on the Cisco Elastic Services Controller RESTful northbound API, and how to use them.	
Cisco Elastic Services Controller ETSI REST API Guide	Includes information on the Cisco Elastic Services Controller ETSI APIs, and how to use them.	
Cisco Elastic Services Controller Deployment Attributes	Includes information about deployment attributes used in a deployment datamodel.	
Cisco Elastic Services Controller Open Source	Includes information on licenses and notices for open source software used in Cisco Elastic Services Controller.	

Obtaining Documentation Request

For information on obtaining documentation, using the Cisco Bug Search Tool (BST), submitting a service request, and gathering additional information, see *What's New in Cisco Product Documentation*, at: http://www.cisco.com/c/en/us/td/docs/general/whatsnew/whatsnew.html.

Subscribe to *What's New in Cisco Product Documentation*, which lists all new and revised Cisco technical documentation, as an RSS feed and deliver content directly to your desktop using a reader application. The RSS feeds are a free service.

ETSI NFV MANO Northbound API Overview

• ETSI NFV MANO Northbound API Overview, on page 1

ETSI NFV MANO Northbound API Overview

The ETSI NFV MANO API (ETSI API) is another programmatic interface to ESC that uses the REST architecture. The ETSI MANO adheres to the standards defined by the European Telecommunications Standards Institute (ETSI), specifically around Management and Orchestration (MANO). The API accepts and returns HTTP messages that contain JavaScript Object Notation (JSON) payloads. The API contains its own datamodel designed around the ETSI MANO specifications that abstract away from the ESC core datamodel.

For information on VNF lifecycle management operations using the REST/NETCONF APIs, see the Cisco Elastic Services Controller User Guide.

Table 2: ETSI MANO Specifications

Specification	Version Support	Description
SOL001	v0.10.0	Format and structure for the VNF Descriptor
SOL002	v2.5.1	Defines all interactions over the Ve-Vnfm reference point
SOL003	v2.4.1	Defines all interactions over the Or-Vnfm reference point

Note

The terminology used in the ETSI-specific sections of the user guide align to the ETSI MANO standards defined in the ETSI documentation. For more information, see the ETSI website.

The current implementation of the ETSI NFV MANO standards consists of the Or-Vnfm and Ve-Vnfm reference points, which are the interfaces between the NFVO and VNFM, and the EM and the VNFM respectively. Both of these allow for the onboarding of ETSI-compliant CSAR packages, management of virtualized resources, and VNF lifecycle management (LCM) operations.

For more information on Or-Vnfm and Ve-Vnfm reference points, see the *ETSI Group Specification document* on the ETSI website. The figure below represents the NFV MANO architecture for all reference points.

OSS/BSS SOL005: Os-Nfvo (IFA013)

NFV Orchestrator (NFVO)

SOL003: Or-Vnfm (IFA007)

VNF Manager (VNFM)

VNF SOL002: VeNI-Vnfm (IFA008)

IFA006: Vnfm-Vi

IFA004: Nf-Vi

Figure 1: NFV MANO Architecture with Reference Points

For information on managing resources, see Resource Definitions for ETSI API, on page 3.

Managing Resources

- Managing Resources, on page 3
- Resource Definitions for ETSI API, on page 3
- OAuth (Open Authorization) 2.0 Authentication, on page 8

Managing Resources

Resource Definitions for ETSI API

Cisco Elastic Services Controller (ESC) resources comprises of images, flavours, tenants, volumes, networks, and subnetworks. These resources are the ones that ESC requests to provision a Virtual Network Function.

For ETSI MANO, these resource definitions are created by NFVO either at the time of onboarding the VNF package or onboarding the tenant, and represented by the VIM identifiers in the request to ESC.

For information on managing resources using NETCONF or REST APIs, see Managing Resources Overview in the Cisco Elastic Services Controller User Guide.

ETSI API Documentation

You can access the ETSI API documentation directly from the ESC VM:

http:[ESC VM IP]:8250/API

The ETSI API documentation provides details about all the various operations supported through the ESTI MANO interface. You can also see the Cisco ETSI API Guide for more information.

The following table lists the resource definitions on the VIM that must be made available before VNF instantiation.

Table 3: Resource Definitions on VIM

Resource Definitions	OpenStack		
Tenants	Out of band tenants		
	You can create a tenant using NETCONF API, REST API, or the ESC portal. You can also create a tenant directly on the VIM. The tenant is then referred to within the vimConnectionInfo data structure. For more information, see VIM Connectors Overview, on page 11.		
Images	Out of band images		
	The NFVO onboards a VNF package, extracts and then onboards the image contained within the VNF package on to the VIM. Though the VNFD refers to the image file, because of the size of the image file, instead of onboarding the image at the time of deployment, the vimAssets in the Grant stipulates the image to be used.		
Flavors	Out of band flavors		
	During onboarding of the VNF package, the NFVO looks at each cisco.nodes.nfv.Vdu.Compute node's capabilities in the VNFD to determine the flavor to be created. This is available later at the time of instantiation, or optionally overriden by a VIM flavor supplied at instantiation time as an additional parameter.		
	Note ETSI deployment flavour is a different concept than OpenStack compute flavor. For more information, see <i>Terms and Definitions</i> in About This Guide.		
Volumes	ESC supports out-of-band volumes as Cisco extension.		
External Networks (Virtual Link)	External networks specified in the instantiation payload to which external connection points will connect.		
Externally Managed Internal Virtual Links	External networks specified in the instantiation payload to which internal virtual links will be bound instead of creating ephemeral networks.		
Subnetworks	Out-of-band subnets		

For information on onboarding VNF packages and lifecycle operations using the ETSI API, see Managing the VNF Lifecycle, on page 21.

Updating Resource Definitions

This section provides details about updating ETSI API resource definitions.

Updating the VNF Flavour

A VNF flavour can be updated by updating the TOSCA parameters in the VNFD template. You can define the alternate VNF nodes and deployment flavours for a single VNFD using the following TOSCA parameters:

- **Import statements**—The import statement allows a single, parent VNFD yaml file to conditionally include other files based on an input value which can be specified dynamically, at run time.
- **Substitution mappings**—The substitution mapping applies only to the node types derived from the *tosca.nodes.nfv.VNF*. You cannot substitute values of other node types that is, Connection Points, Virtual Links and so on.

Example1:

In this example, the yaml file contains three import files.

All three files must exist in the VNFD ZIP archive file in the same location as the parent file importing them.

The *requirements* and *capabilities* are not defined in the derived *tosca.nodes.nfv.VNF* node. These are mandatory for defining characteristics of VNFs instantiated using this VNFD. They are defined within the imported files.

```
tosca definitions version: tosca simple yaml 1 2
description: Substitution Mapping Example
imports:
- df default.yaml
- df silver.yaml
- df gold.yaml
node_types:
mv-vnf:
derived from: tosca.nodes.nfv.VNF
topology template:
########################
# Substitution Mapping #
#########################
substitution mappings:
node type: my-vnf
requirements:
# None
node templates:
vnf:
type: my-vnf
properties:
descriptor id: 8717E6CC-3D62-486D-8613-F933DE1FB3A0
```

```
flavour_id: default
flavour_description: Default VNF Deployment Flavour
```

Example 2:

When the VNF is instantiated, the required flavour is sent in the Instantiate request to the VNFM. The TOSCA parser tries to match the flavour and the VNF node name with the defined substitution mappings. These may be imported or defined within the VNFD itself. For example, the *df silver.yaml* contains the following:

tosca_definitions_version: tosca_simple_yaml_1_2

description: Silver Deployment Flavour

imports:

```
topology_template:
substitution_mappings:
node_type: my-vnf
properties:
flavour_id: silver
flavour_description: Silver VNF Deployment Flavour
requirements:
    - virtual link: [ vml nicl, virtual link ]
```

silver is the flavourId passed in the Instantiate Request payload. The parent yaml shown above has its empty requirements section updated with the requirements from the silver profile, and the existing flavour_id and flavour description properties are updated as well.

```
tosca definitions version: tosca simple profile for nfv 1\ 0\ 0
description: Deployment Flavour SILVER
topology template:
  substitution mappings:
   node type: tosca.nodes.nfv.VNF.CiscoESC
   requirements:
      virtual link: [ anECP, external virtual link ]
    capabilities:
        deployment flavour:
          properties:
            flavour id: silver
            description: 'SILVER Deployment Flavour'
            vdu profile:
              vdu node 1:
                min number of instances: 2
                max number of instances: 2
            instantiation levels:
              default:
                description: 'Default Instantiation Level'
                vdu levels:
                  vdu node 1:
                   number of instances: 1
                scale info:
                  default_scaling_aspect:
                   scale_level: 2
              silver level:
                description: 'SILVER Instantiation Level'
                vdu levels:
                  vdu node 1:
                    number of instances: 2
                scale info:
                  default scaling aspect:
                    scale level: 2
            default instantiation level id: default
            vnf_lcm_operations_configuration: {}
```

ESC sends a POST request to update the VNF flavour:

Method Type:

POST

VNFM Endpoint:

/vnflcm/v1/vnfinstances/{vnfInstanceId}/change flavour

Updating the External VNF Connectivity

You can update the external VNF connectivity in an existing deployment. The API supports the following changes:

- Disconnect the existing connection points (CPs) to the existing external virtual link and connect to a different virtual link.
- Change the connectivity parameters of the existing external CPs, including changing the addresses.

ESC sends a POST request to update the VNF external connectivity:

Method Type

POST

VNFM Endpoint

/vnflcm/v1/vnfinstances/{vnfInstanceId}/change_ext_conn

Request Payload (Data structure = ChangeExtVnfConnectivityRequest)

```
"extVirtualLinks": [
    "id": "extVL-98345443-7797-4c6d-a0ed-e18771dacf1c",
    "resourceId": "node 1 ecp",
    "extCps": [
        "cpdId": "node 1 ecp",
        "cpConfig": [
            "cpProtocolData": [
                "layerProtocol": "IP OVER ETHERNET",
                "ipOverEthernet": {
                  "ipAddresses": [
                      "type": "IPV4",
                      "numDynamicAddresses": 2,
                      "subnetId": "esc-subnet"
                 ]
                }
              }
            ]
```

```
} ;
```

Note

The id in the extVirtualLinks, extVL-98345443-7797-4c6d-a0ed-e18771dacf1c in the above example, must also exist in the instantiatedVnfInof in the vnfInstance.

Merging Policy

The substitution merges the new values into the VNFD.

- 1. For regular scalar properties such as name=joe, the value is replaced in the VNFD.
- 2. Arrays such as [list, of, strings] are merged. The new values are added into the array, if they do not exist.
- **3.** Objects such as where a key is indented under another key, are replaced. The configurable_properties object in the matched substitution will overwrite that defined in the VNFD.

Parser Behaviour

- If the VNF is instantiated by the Test Harness, the flavour is persisted and used in the subsequent LCM operations so that the VNFD always uses the same mappings.
- If the instantiate operation is called from elsewhere (such as cURL or Postman) then the flavour contained in the grant is persisted and used in the subsequent LCM operations.
- If the Test Harness receives a grant request for a VNF not instantiated through it, then the grant is most likely to fail if no substitution mapping occurs.
- After the substitution mappings are made, the parser tries to populate any *additionalParams* provided. Note that the command fails if the input parameters do not match those in the template.

For more information on VNF lifecycle operations, see Managing the VNF Lifecycle, on page 21.

OAuth (Open Authorization) 2.0 Authentication

The ETSI NFV MANO supports OAuth 2.0 authentication for SOL003 Or-Vnfm reference point. The NFVO makes a token request to ESC providing the client credentials such as client id and client secret for authentication. In turn, ESC verifies the request and returns the access token.

The NFVO makes a POST request providing the clientId and secret as primary authentication.

Method Type

POST

URL

{apiRoot}/oauth2/token

Header

```
Authorization: Basic {base 64 encoded CLIENT_ID:CLIENT_SECRET} Accept: application/json Content-Type: application/x-www-form-urlencoded Body
```

grant type=client credentials

ESC returns the access token in response.

Example:

```
{
    "access_token":
"eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJjaHJpcyIsImlzcyI6IkVUU0ktVk5GTSIsImlhdCI6MTU10DYwMzk2NiwiZXhwIjoxNTU4NjA0NTY2f

Q.lAtre7vdCKJjgzNs7p9P3NS2qMcXegC-oWXmy5Kakn0AL95gLWF6liOqPViMZNnWZLOsG5r1kPnGoBWnN0tgIw",
    "token_type": "bearer",
    "expires_in": 600
}
```

The access token is then used to access the or_vnfm endpoints.

Example:

Method

GET

URL

{apiRoot}/vnflcm/v1/subscriptions

Headers

Authorization: Bearer eyJhbGciOiJIUzUxMiJ9.eyJzdWIiOiJjaHJpcyIsImlzcyI6IkVUU0k
tW5GISIsImlhdCIMUUDWWkNiwiZWwIjaNIUAYjANIY2fQ.lArreNdKJjgANs79FNS2qWxegC-dWmyKkn/AL95gIWF6liOgPviMNWWIOs5rlkhAcHwnNtgIw

Note

The existing tokens become invalid if the ETSI service is restarted.

Accessing and Updating the OAuth Properties File

ESC stores the client id and secret in the new *etsi-production.yaml* properties file in the same location as the *etsi-production.properties* file. The new escadm etsi commands are available to maintain the client id and secret values. The client secret is encrypted the same way as the existing rest username.

To add or update a client id

```
sudo escadm etsi oauth2_clients --set <CLIENT_ID>:<CLIENT_SECRET>
```

To remove a client id

sudo escadm etsi oauth2 clients --remove <CLIENT ID>

Note

Restart the ETSI services after updating the OAuth 2.0 values.

For information on other properties, see ETSI Production Properties, on page 87.

OAuth Calls from ETSI to the NFVO

ESC supports OAUTH 2.0 calls from ETSI to the NFVO.

The following properties are added to the etsi-production.properties file:

```
nfvo.clientID=<YourClientID>
nfvo.clientSecret=<YourClientSecret>
nfvo.tokenEndpoint=<Your NFVO Token Endpoint>
nfvo.authenticationType=OAUTH2
```

The Client id, ClientSecret and TokenEndpoint must match that of the OAUTH 2.0 Server. The authentication type determines authentication of the outgoing calls from ESC to the NFVO. The authentication type must be either BASIC, or OAUTH2.

The tokens from the NFVO are stored against the token endpoint in the properties file.

When the NFVO sends a call request, ETSI checks for the tokens stored against the token endpoint. If the token has not expired, then ETSI adds the old token to the header of the request and executes the call. A new token is required if the token fails to execute.

If there are no tokens against the token endpoint, then new tokens are required to execute the call.

OAuth 2.0 Notification and Subscription

The subscription payloads must add the following to enable OAuth 2.0 authentication with the notifications:

```
{
  "authentication": {
    "authType": [
        "OAUTH2_CLIENT_CREDENTIALS"
    ],
    "paramsOauth2ClientCredentials": {
        "clientId": <client_id>,
        "clientPassword": <client_secret>,
        "tokenEndpoint": <token_endpoint>
    }
}
```

Managing VIM Connectors

- VIM Connectors Overview, on page 11
- Creating New VIM Connectors, on page 12
- Using an Existing VIM Connector, on page 12
- Updating the VIM Connector, on page 13

VIM Connectors Overview

The ETSI API creates VIM connectors during the processing of an LCM operation or uses an existing connector.

The Grant response or the LCM operation request from the NFVO supplies new VimConnectionInfo to the VnfInstance. During the processing of the LCM operation, ETSI synchronizes the new *VimConnectionInfo* with the VIM connectors in ESC.

A *VimConnectionInfo* is new if the VnfInstance does not have an existing VimConnectionInfo with the same id. Any *VimConnectionInfo* supplied that matches an existing *VimConnectionInfo* id stored against any VnfInstance as part of a LCM request uses the existing connector and ignore any changes submitted in the new request.

ESC creates a new VIM connector only if a matching VIM connector is not available.

The ETSI API allows only the existing *VimConnectionInfo*, and the associated VIM connector, to be updated via the Modify VNF information operation.

The Grant from the NFVO specifies the vimConnectionId for each resource. This value identifies the VimConnectionInfo and the associated VIM connector for creating the locator for each resource. The VIM specific *VimConnectionInfo.accessInfo* properties are set as additional properties in the locator.

VimConnectionInfo in OpenStack:

```
"id": "435456",
"vimType": "OPENSTACK_V3",
"interfaceInfo": {
    "endpoint": "https://10.18.54.42:13001/v3/"
},
"accessInfo": {
    "username": "admin",
    "password": "bmkQJtyDrbPFnJT8ENdZw2Maw",
    "project": "cbamnso",
    "projectDomain": "Default",
    "userDomain": "Default",
```

```
"vim_project": "cbamnso"
}
```

VimConnectionInfo in vCloud Director:

```
{
  "id": "435456",
  "vimType": "VMWARE_VCD",
  "interfaceInfo": {
      "endpoint": "https://10.85.103.150"
  },
  "accessInfo": {
      "username": "admin@cisco",
      "password": "bmkQJtyDrbPFnJT8ENdZw2Maw",
      "vim_project": "cbamnso",
      "vim_vdc": "vdc1"
  }
}
```

Creating New VIM Connectors

During the ETSI LCM operation, ESC checks each VimConnectionInfo against the VnfInstance to see if an existing VIM connector is available. If an existing VIM connector is not available, ESC creates a new VIM connector.

If the *VimConnectionInfo.vimId* is supplied, then this value is used as the id of the new VIM connector. If the *VimConnectionInfo.vimId* is not supplied, then an id is generated for the new VIM connector and this value is also set as the *VimConnectionInfo.vimId*.

To use an existing VIM connector, see Using an Existing VIM Connector, on page 12.

Using an Existing VIM Connector

During an ETSI LCM operation, ESC checks for an existing vimConnectionInfo with a matching identifier stored against any VnfInstance.

Existing VIM connectors are found by:

- Matching the VimConnectionInfo.vimId, if supplied, to the id of a VIM connector.
- Matching the VIM specific properties of the *VimConnectionInfo* to a VIM connector.
 - OpenStack
 - vimType
 - interfaceInfo.endpoint
 - accessInfo.project
 - · vCloud Director
 - vimType
 - interfaceInfo.endpoint

If a matching VIM connector is found, and the *VimConnectionInfo.vimId* is not set, then the *VimConnectionInfo.vimId* is set to the id of the VIM connector.

If an NFVO provides a VimConnectionInfo with accessInfo to stipulate some of the connection properties, we use the following keys to configure the VIM connectors:

OpenStack

- username
- · password
- project
- projectDomain
- userDomain
- · vim project

vCloud Director

- username
- password
- · vim_project
- vim vdc

The ETSI specifications does not specify the keys to be used as part of the accessInfo attribute. In order to ease integration, in the event that an NFVO uses different keys, the properties file allows the user to specify a mapping from the third party keys to the ones that ESC understands.

- mapping.vimConnectionInfo.accessInfo.username
- mapping.vimConnectionInfo.accessInfo.password
- mapping.vimConnectionInfo.accessInfo.project
- mapping.vimConnectionInfo.accessInfo.projectDomain
- mapping.vimConnectionInfo.accessInfo.userDomain
- mapping.vimConnectionInfo.accessInfo.vim project
- mapping.vimConnectionInfo.accessInfo.vim_vdc

To create a new VIM connector, see Creating New VIM Connectors, on page 12.

Updating the VIM Connector

The ETSI API updates the existing VimConnectionInfo, and the associated VIM connector via the Modifying Virtual Network Functions, on page 33 operation. The *VimConnectionInfo* in the modify request payload is compared to the existing *VimConnectionInfo* stored against the VnfInstance.

If an existing VimConnectionInfo stored against any VnfInstance with a matching id is not found, then then VimConnectionInfo is added to the VnfInstance.

If an existing *VimConnectionInfo* stored against ang VnfInstance with a matching id is found, then the VimConnectionInfo is updated. If the VimConnectionInfo has been modified and it has an associated VIM connector, then the VIM connector is also updated.

To create new VIM connectors, see Creating New VIM Connectors, on page 12.

Understanding Virtual Network Function Descriptors

- Virtual Network Function Descriptor Overview, on page 15
- Defining Extensions to the Virtual Network Function Descriptor, on page 15

Virtual Network Function Descriptor Overview

ESC supports a TOSCA-based Virtual Network Function Descriptor (VNFD) to describe the VNF properties. The VNFD conforms to the *GS NFV-SOL 001* specifications and standards specified by ETSI.

The VNFD file describes the instantiation parameters and operational behaviors of the VNFs. It contains KPIs, and other key requirements that can be used in the process of onboarding and managing the lifecycle of a VNF.

For VNF Lifecycle operations, see VNF Lifecycle Operations, on page 22.

Defining Extensions to the Virtual Network Function Descriptor

ESC implements extensions to the VNFD defined by Cisco to expose the more advanced concepts supported by ESC, but missing in the ETSI standards. These extensions are strongly typed in the Cisco types definition to describe the overridden data, node, and interface types.

VNF Configurable Properties

The VNF node type is always customized for each VNF. The Cisco extensions provide the ability to specify the recovery policy and time to wait for the VNF to recover before ESC considers any mitigating action.

For example:

```
configurable_properties:
    is_autoscale_enabled: false
    is_autoheal_enabled: false
lcm_operations_configuration:
    heal:
        recovery_action: REBOOT_THEN_REDEPLOY
        recovery_wait_time: 0
flavour_id: default
flavour_description: 'Default VNF Deployment Flavour'
```

Compute

The Cisco Compute node allows for many of the ESC features to be exposed via the extended ETSI data model. This includes the following:

- Overriding the automatically generated name for a VNFC on the VIM.
- VIM flavor (overriding the ETSI capabilities specified for a VNFC).
- Supplying ESC with an expected bootup time to prevent further actions being taken until this timer has
 expired.
- Providing Day-0 configuration blocks to execute/store on the VNFC once deployed.
- Specifying KPI parameters and associated rules to configure the monitoring agent.
- Intra-VM Group placement rules.

For example:

```
vdu1:
  type: cisco.nodes.nfv.Vdu.Compute
 properties:
   name: Example VDU1
   description: Example VDU
   boot order:
      - boot1-volume
    configurable properties:
     additional vnfc configurable properties:
       vim flavor: Automation-Cirros-Flavor
       bootup time: 1800
    name_override: my-vdu-1
    vdu profile:
     min_number_of_instances: 1
     max number_of_instances: 1
      static ip address pool:
       network: esc-net
        ip address range:
          start: { get input: VDU1 NETWORK START }
          end: { get input: VDU1 NETWORK END }
       ip addresses: { get input: VDU1 SCALE IP LIST }
    kpi data:
      VM ALIVE-1:
       event name: 'VM ALIVE-1'
       metric value: 1
       metric cond: 'GT'
       metric type: 'UINT32'
       metric occurrences true: 1
       metric occurrences false: 30
       metric collector:
          type: 'ICMPPing'
          nicid: 1
          poll frequency: 10
          polling_unit: 'seconds'
```

```
continuous alarm: false
  admin rules:
    VM ALIVE-1:
     event_name: 'VM ALIVE-1'
     action:
        - 'ALWAYS log'
        - 'FALSE recover autohealing'
        - 'TRUE esc vm_alive_notification'
  placement type: zone
  placement_target: nova
  placement enforcement: strict
  vendor section:
    cisco esc:
     config data:
        example.txt:
          file: ../Files/Scripts/example.txt
          variables:
            DOMAIN NAME: { get input: DOMAIN NAME }
            NAME SERVER: { get input: NAME SERVER }
            VIP ADDR: { get input: VIP ADDR }
            VIP_PREFIX: { get_input: VIP PREFIX }
capabilities:
 virtual compute:
   properties:
      virtual cpu:
        num virtual cpu: 8
     virtual memory:
       virtual mem size: 16
requirements:
  - virtual storage: cdrl-volume
  - virtual storage: boot1-volume
```

Note

You can supply a high number of input parameters, allowing the use of a single template for multiple deployments.

Connection Point

The Cisco extensions to the VduCp node type mainly allows for improved IP addressing capabilities and accessibility to the interface. The features added the connection point are as follows:

- Overriding the automatically generated name for a port on the VIM
- Static IP Addresses (and pools for scaling)
- Identification of whether the port is a management port (i.e. used for monitoring)
- · Allowed Address Pairs
- Support for specific network card types and interface types, e.g. SR-IOV
- Whether port security is enabled

For example:

```
vdul_nic0:
    type: cisco.nodes.nfv.VduCp
    properties:
        layer_protocols: [ ipv6 ]
        protocol:
        - associated_layer_protocol: ipv6
```

```
trunk_mode: false
  order: 0
  nw_card_model: virtio
  iface_type: direct
  management: true
  name_override: my-vdu1-nic0
  ip_subnet:
    - ip_address: { get_input: VDU1_NIC0_IP }
  allowed_address_pairs:
    - ip_address: { get_input: VDU1_NIC0_AADR_PAIRS }
  port_security_enabled: false
requirements:
    - virtual binding: vdu1
```

Volume

ESC supports out-of-band volume as a Cisco extension. This allows the specification of the persistent volume UUID as the resourceId property against the cisco.nodes.nfv.Vdu.VirtualBlockStorage node to be used in place of the ephemeral volume defined in the VNFD. Instead of adding extra properties, ESC allows to override the volume specified in the VNFD and supplies its own persistent (deployed out-of-band) storage by identifying it with a UUID from the VIM.

For example:

```
boot1-volume:
  type: cisco.nodes.nfv.Vdu.VirtualBlockStorage
  properties:
    resource id: { get input: VDU1 BOOT VOL UUID }
   virtual block storage data:
      size of storage: 4GB
      vdu storage requirements:
       vol id: 1
       bus: ide
       type: LUKS
    sw image data:
      name: 'Automation Cirros'
      version: '1.0'
      checksum: 9af30fce37a4c5c831e095745744d6d2
      container format: bare
      disk format: qcow2
      min disk: 2 GB
      size: 2 GB
  artifacts:
    sw image:
      type: tosca.artifacts.nfv.SwImage
      file: ../Files/Images/Automation-Cirros.qcow2
```

To specify the out-of-band resource in place of ephemeral resource, ESC allows you to use the incoming request to match tags in the VNFD during instantiation. A new data structure is appended to the existing InstantiateVnfRequest.

For example,

```
{
         "virtualStorageDescId": "cf-boot1-volume",
         "resourceId": "vol456"
}
],
...
}
```

Security Group Rule

As per the handling of the volume above, ESC provides the ability to specify an out-of-band security group instead of configuring one in the VNFD. This is because the verbs used to describe the security group in the standards documentation are too simplistic for a very complicated configuration.

For example:

```
- NETWORK_ORCH_SEC_GRP_1:
    type: cisco.policies.nfv.SecurityGroupRule
    group_name: { get_input: VIM_NETWORK_ORCH_SEC_GRP_1 }
    targets: [ vdul nic0 ]
```

Custom VM Name

The Cisco extension allows you to customize the VNFC (VM) name in a deployment using additional parameters. The ESC ETSI includes the additional parameters to customize VM names.

To configure the VM name on the VIM, you must first define the data type and then extend the Cisco node type for the compute node:

```
tosca_definitions_version: tosca_simple_yaml_1_2
data_types:
  cisco.datatypes.nfv.VnfcAdditionalConfigurableProperties:
    derived_from: tosca.datatypes.nfv.VnfcAdditionalConfigurableProperties
    properties:
       vim_flavor:
            type: string
            required: true
       bootup_time:
            type: integer
            required: true
    vm_name_override:
            type: string
            required: false
```

These definitions allow the VNFD node templates to use the inputs to map to the Compute node:

```
configurable_properties:
   additional_vnfc_configurable_properties:
    vim_flavor: { get_input: CF_FLAVOR }
   bootup_time: { get_input: BOOTUP_TIME_CF }
    vm_name_override: { get_input: VIM_C1_VM_NAME ] }
...
capabilities:
   virtual_compute:
    properties:
     virtual_cpu:
        num_virtual_cpu: 8
     virtual_memory:
        virtual_mem_size: 16 GiB
requirements:
   - virtual_storage: cf-cdr1-volume
   - virtual_storage: cf-boot1-volume
```

Specify *vm_name_override* under configurable properties of the compute node. If *vm_name_override* is not specified, ESC will auto generate the VM names.

ESC stores the VNFC specific value in

VnfInstance.instantiatedVnfInfo.vnfcResourceInfo.metadata.vim_vm_name for the VNFC identified by the vduId, which matches the label given to the Compute node representing the VNFC.

For information on lifecycle management operations, see Managing the VNF Lifecycle, on page 21.

SR-IOV

ESC ETSI NFV MANO supports SR-IOV properties using the Cisco data types. You can configure the interface to associate the VNFC with an SR-IOV pass through adapter.

Cisco data type:

```
cisco.datatypes.nfv.L2ProtocolData:
    derived_from: tosca.datatypes.nfv.L2ProtocolData
    properties:
        segmentation_id:
        type: integer
        required: false

Example VNFD:

virtual_link_protocol_data:
    - associated_layer_protocol: ethernet
    12_protocol_data:
        network_type: vlan
        physical_network: vlan_network
        segmentation_id: { get_input: VL1_SEG_ID }
```

Managing VNF Lifecycle Operations

- Managing the VNF Lifecycle, on page 21
- VNF Lifecycle Operations, on page 22

Managing the VNF Lifecycle

The NFVO communicates with ESC using the ETSI MANO API for lifecycle management of a VNF. A configuration template, the Virtual Network Function Descriptor (VNFD) file describes the deployment parameters and operational behaviors of a VNF type. The VNFD is used in the process of deploying a VNF and managing the lifecycle of a VNF instance.

The lifecycle operations of a VNF instance is as follows:

- 1. Create a VNF Identifier—ESC generates a new VNF Instance Id (a universally unique identifier) that is subsequently used as a handle to reference the instance upon which to execute further operations.
- 2. Instantiate / Deploy VNF—As part of VNF instantiation, ESC instantiates a new VNF instance in the VIM. ESC receives a request to instantiate a VNF instance from NFVO. The instantiate request contains resource requirements, networking and other service operational behaviors. All these requirements along with the VNFD and the grant information provides all the necessary information to instantiate the VNF.
- 3. Operate VNF—ESC allows you to start and stop a VNF instance. The resources are not released or changed, but the VNF instance in the VIM is toggled between these two states.
- **4. Query VNF**—To query one or more VNF instances known to ESC. To query one or more VNF instances known to ESC. This is a specific REST end point that can be filtered to find specific instances. The instances can be filtered using the VNF Instance Id.
 - Also, a separate REST end point allows the NFVO to query the status of one or more lifecycle operation occurrences associated with a VNF. The lifecycle operations can be filtered using a specific occurrence identifier.
- **5. Modify VNF**—ESC allows you to modify the properties of a single VNF instance. The instantiated VNF is updated, and the lifecycle management operation occurrence sends notification to the NFVO about the status of the VNF.
- **6. Scale and Scale to Level VNF**—ESC allows you to scale VNFs in two ways. You can scale a VNF incrementally, or to a specific level.
- 7. Heal VNF—ESC heals the VNF when there is a failure.

- **8. Terminate / Undeploy VNF**—To terminate the VNF instance in the VIM. The resources themselves remain reserved for the VNF instance, however the VNF itself is undeployed.
- **9. Delete VNF Identifier**—The resources are fully released in the VIM and in ESC and the associated VNF instance identifier is also released.

For VNF lifecycle operations using REST and NETCONF APIs, see Configuring Deployment Parameters in the Cisco Elastic Services Controller User Guide.

VNF Lifecycle Operations

VNFM Prerequisites

The following prerequisites must be met for VNF lifecycle operations:

- The resource definitions must be created out of band and must be available before VNF instantiation.
- There are two options with regards to connecting to the VIM. The VIM Connector specifies how ESC connects to the VIM and may be created and validated in advance of deploying a VNF (and identified by name) or created as part of the request if new vimConnectionInfo is supplied. See VIM Connectors Overview, on page 11.

NFVO Prerequisites

- The VNF to be instantiated has to be onboarded to the NFVO within an ETSI compliant VNF package.
 - The NFVO must provide ETSI compliant VNF Packages to ESC.
 - The VNF package must contain a VNF Descriptor (VNFD) file.

The NFVO must support the /vnf_packages API to allow access to the package artifacts. See chapter 10 in the ETSI GS NFV-SOL 003 specification on the ETSI website for details.

• Update the properties file, *etsi-production.properties* under: /opt/cisco/esc/esc_database/. The properties file provides details about the NFVO to ESC.

The single property *nfvo.apiRoot* allows specification of the NFVO host and port. For example, nfvo.apiRoot=localhost:8280.

Note

The initial implementation of the ETSI MANO API supports only a single VIM. The tenant/project is currently specified using the resourceGroupId.

For notes on ESC in HA mode, enabled with ETSI service, see the Cisco Elastic Services Controller Install and Upgrade Guide.

Deployment Request

The deployment request includes the following tasks:

The VNFD provides a description of the following constructs (see ETSI GS NFV-SOL 001 specification on the ETSI website for details)

• The deployment level configuration such as deployment flavours and external connections

- The VDU configuration, including any applicable images (Compute)
- The internal connection points (VduCp)
- Any volumes to be created, including any applicable images (VirtualBlockStorage)
- The internal virtual links (VnfVirtualLink)
- Policies and groups for placement, scaling and security

The InstantiateVnfRequest:

- The chosen deployment flavour
- The VIM connection details (vimConnectionInfo Or-Vnfm only)
- Any external networks to which to connect the external connection points (extVirtualLinks)
- Any external networks that may be bound to for internal virtual links (extManagedVirtualLinks)
- A list of key-value pairs to provide deployment specific variables for the deployment (additional Params)

The Grant from the NFVO (see ETSI GS NFV-SOL 003 specification on the ETSI website for details):

- Approved and/or updated resources to be added, updated or removed (UUIDs)
- Confirmed placement information

Creating the VNF Identifier

Creating the VNF Identifier is the first request for any VNF instance. This identifier is used for all further LCM operations executed by the ETSI API. Resources are neither created nor reserved at this stage.

ESC sends a POST request to create VNF instances:

```
Method Type:
```

```
POST
```

VNFM Endpoint:

```
/vnf instances/
```

HTTP Request Headers:

```
Content-Type:application/json
```

Request Payload (ETSI data structure: CreateVnfRequest):

```
{
    "vnfInstanceName": "Test-VNf-Instance",
    "vnfdId": "vnfd-88c6a03e-019f-4525-ae63-de58ee89db74"
}
```

Response Headers:

```

        },
        "self": {
            "href":
"http://localhost:8250/vnflcm/v1/vnf instances/14924fca-fb10-45da-bcf5-59c581d675d8"
```

For instantiating VNFs, see Instantiating Virtual Network Functions, on page 24.

Instantiating Virtual Network Functions

The instantiation request triggers a number of message exchanges, which allows the call flow to be completed in order to instantiate a VNF instance. The resources are allocated when the VNF instance is instantiated. It requires the VNF instance identifier, returned by the create VNF request, encoded into the URL to which the request is posted.

The instantiation request sub-tasks within the flow include:

- 1. Retrieving the VNF Descriptor template from the NFVO.
- 2. Requesting permission from the NFVO (bi-directional Grant flow). For more information see, Requesting Permission via Grant.

Method type:

POST

VNFM Endpoint:

/vnf instances/{vnfInstanceId}/instantiate

HTTP Request Header:

Content-Type:application/json

Request Payload (ETSI data structure: InstantiateVnfRequest)

```
"flavourId": "default",
"extManagedVirtualLinks":
    {
        "id": "my-network",
        "resourceId": "93fb90ae-0ec1-4a6e-8700-bf109a0f4fba",
        "virtualLinkDescId": "VLD1"
],
"vimConnectionInfo": [
    {
        "accessInfo": {
            "password": "P@55w0rd!",
            "username": "admin",
            "vim project": "tenantName"
        "extra": {
            "name": "esc"
        "id": "default_openstack_vim",
        "interfaceInfo": {
            "baseUrl": "http://localhost:8080"
        "vimId": "default openstack vim",
        "vimType": "OPENSTACK"
"additionalParams": {
    "CPUS": 2,
    "MEM SIZE": "512 MB",
    "VIM FLAVOR": "Automation-Cirros-Flavor",
    "BOOTUP TIME": "1800"
```

The flavourId value must be same as a single flavour_id specified in the VNFD.

Note

The Grant response from the NFVO provides the vimConnectionInfo. It is not provided in the SOL002 payload.

You can customize the VNF before instantiation by adding variables to the VNFD template. Specify the variables in the *additionalParams* field of the LCM request. The variables are name-value pairs, where the value can be either string, numeric or boolean. In the example below, the *cpus*, and *mem_size additionalParams* are defined in the VNFD template using the get_input: <TOSCA method>.

Note

If there are multiple vm groups within the VNFD in a single ETSI deployment, they must all use the same VIM.

When this template is submitted to the VNFM, the variables are merged into the same VNF instance. The *additionalParams* variables are merged with the VNF variables, and actual values for the variables are provided only during instantiation.

The list of parameters supplied are driven by the contents of the VNFD; the additionalParams specified in the request are used by the VNFD using the get_input TOSCA method within the VNFD. For example, the cpus, and mem_size variables are merged with the placeholders within the VNFD:

```
tosca definitions version: tosca simple yaml 1 2
imports:
  - cisco nfv sol001 types.yaml
  - etsi_nfv_sol001_vnfd_0_10_0_types.yaml
metadata:
 template name: Example
  template author: Cisco Systems
  template_version: '1.0'
topology_template:
  inputs:
    CPUS:
      description: Number of CPUs
      type: string
      default: "2"
    MEM SIZE:
      description: Memory size
      type: string
      default: "512 MB"
    VIM FLAVOR:
      description: VIM Flavor
      type: string
      default: "Automation-Cirros-Flavour"
    BOOTUP TIME:
      description: Time taken to boot the VNF
      type: string
      default: "1800"
node_templates:
    vdu1:
      type: cisco.nodes.nfv.Vdu.Compute
      properties:
       name: vdu1
        description: Example
        configurable properties:
          additional vnfc configurable properties:
            vim_flavor: { get_input: VIM_FLAVOR }
            bootup time: { get input: BOOTUP TIME }
        vdu profile:
          min_number_of_instances: 1
          max_number_of_instances: 1
      capabilities:
        virtual_compute:
          properties:
            virtual cpu:
              num virtual cpu: { get input: CPUS }
            virtual memory:
              virtual_mem_size: { get_input: MEM_SIZE }
```

If further LCM requests with *additionalParams* variables are submitted for the same VNF, then the new variables overwrite the existing variables. The VNFM uses the new variables for instantiation.

Although internal links are designed to be ephemeral, in some deployment scenarios they can be bound to external links that outlive the VNF. Consider the following example VNFD fragment:

```
automation_net:
  type: tosca.nodes.nfv.VnfVirtualLink
properties:
   connectivity_type:
    layer protocols: [ ipv4 ]
```

```
description: Internal Network VL
vl_profile:

    root: 10000
   min_bitrate_requirements:
    root: 0
```

To specify an external virtual link to be used in place of automation_net in the VNF deployment, the following data structure must be used as part of the instantiation request:

Although the ETSI specifications only support the concept of ephemeral volumes, many vendors require the specification of a persistent volume and so Cisco have implemented an extension to support this. The resource Id of the persistent volume can be supplied as an additional Param and tied to a volume in the VNFD using an optional property, as per the following example:

```
example-volume:
type: cisco.nodes.nfv.Vdu.VirtualBlockStorage
properties:
   resource_id: { get_input: EX_VOL_UUID }
   virtual_block_storage_data:
       size_of_storage: 200 GB
      vdu_storage_requirements:
      vol_id: 1
      bus: ide
      type: LUKS
```

Requesting Permission via Grant

The ETSI API requests for permission from the NFVO to complete lifecycle management operations for the VNF instance resources and gets resource Ids for any resources pre-provisioned. An example GrantRequest looks like:

```
"resourceTemplateI d": "node 1 nic0",
      "type": "LINKPORT",
      "vduId": "vdu1"
    },
      "id": "res-e88d8461-5f5a-4dba-af14-def82ce894e5",
      "resourceTemplateId": "automation_net",
      "type": "VL"
  ],
   links":
    "vnfInstance":
     "href": "https://172.16
.255.8:8251/vnflcm/v1/vnf instances/14924fca-fb10-45da-bcf5-59c581d675d8"
    "vnfLcmOpOcc":
    {
     "href":

        "vnfInstance": {
            "href": "https://172.16
.255.8:8251/vnflcm/v1/vnf instances/14924fca-fb10-45da-bcf5-59c581d675d8"
        "vnfLcmOpOcc": {
            "href":
"https://172.16.255.8:8251/vnflcm/v1/vnf lcm op occs/457736f0-c877-4e07-8055-39dd406c616b"
       }
```

The grant request is accepted only if all the requested resources have been granted, else the grant is rejected.

Retrieving the Deployment Descriptor from ESC

The NFVO can retrieve the ESC datamodel instance in the form of a deployment descriptor. The NFVO can view all the inputs provided at the time of instantiation and changes made later to the deployment descriptor.

To retrieve the deployment descriptor, you must:

- Create the VNF
- Provide the vnfinstanceId

Method Type

GET

VNFM Endpoint

/vnflcm/v1/ext/vnfinstances/{vnfInstanceId}/deployment

HTTP Request Header

content-Type:application/xml

Request Payload

not applicable.

Querying Virtual Network Functions

Querying VNFs does not affect the state of any VNF instance. This operation simply queries ESC for all the VNF instances it knows about, or a specific VNF isntance.

```
Method Type:
```

```
GET
```

VNFM Endpoint:

/vnf instances/vnf instances/{vnfInstanceId}

HTTP Request Header:

Content-Type: application/json

Request Payload:

```
not applicable.
```

Response Headers:

```
< HTTP/1.1 200
HTTP/1.1 200
< X-Content-Type-Options: nosniff
X-Content-Type-Options: nosniff

< Content-Type: application/json; charset=UTF-8
Content-Type: application/json; charset=UTF-8
< Transfer-Encoding: chunked
Transfer-Encoding: chunked
< Date: Thu, 04 Jan 2018 12:25:32 GMT
Date: Thu, 04 Jan 2018 12:25:32 GMT
```

Response Body for a single VNF Instance (ETSI Data structure:VnfInstance)

Note

The ETag response header is only returned for a single VNF query (that is, one with the VNF Instance ID specified). The ETag value is conditionally used during any subsequent VNF modify operations.

```
{
   "_links": {
     "instantiate": {
```

The query VNF operation output shows the instantiated state of the VNF. The *InstantiatedVnfInfo* element shows the VIM resource information for all the VNFs.

For example:

```
"instantiatedVnfInfo": {

```

Modifying Virtual Network Functions

You can modify or update the properties of a VNF instance, which is in the NOT_INSTANTIATED state, using the modify VNF lifecycle operation. ESC receives a PATCH request from NFVO to modify a single VNF instance.

A JSON merge algorithm is applied from the input payload against the stored data to modify the VNF instance.

Note

Modifying VNF operation updates only the properties, but not the functionality of the VNF. The modify operation is only valid on a VNF instance resource that is NOT_INSTANTIATED.

The following properties of an existing VNF instance can be modified:

- vnfInstanceName
- vnfInstanceDescription
- onboardedVnfPkgInfoId (null value is not allowed)
- vnfConfigurableProperties
- metadata
- extensions
- vimConnectionInfo

Method Type

PATCH

VNFM Endpoint

/vnf instances/{vnfInstanceId}

HTTP Request Header

Content-Type: application/merge-patch+json
If-Match: ETag value

Note

The ETag, if specified, is validated against the ETag value stored against the VNF instance resource. If the values do not match, the modify request will be rejected.

Request Payload (ETSI data structure: VnfInfoModifications)

```
"vnfInstanceName": "My NEW VNF Instance Name",
    "vnfInstanceDescription": "My NEW VNF Instance Description",
    "vnfPkgId": "pkg-xyzzy-123",
    "vnfConfigurableProperties": {
        "isAutoscaleEnabled": "true"
    "metadata": {
        "serialRange": "ab123-cc331",
        "manufacturer": "Cisco"
    "extensions": {
        "testAccess": "false",
        "ipv6Interface": "false"
    },
    "vimConnectionInfo": [
        {
            "id": "vci1",
            "vimType": "openstack",
            "interfaceInfo": {
                "uri": "http://172.16.14.27:35357/v3"
            "accessInfo": {
                "domainName": "default",
                "projectName": "admin",
                "userName": "default"
        }
    ]
}
```

Note

The Grant response from the NFVO provides the vimConnectionInfo instead of the *SOL002* payload. The *SOL002* request contains some attributes that affect the VNF resource at a finer VNFC-level such as vnfcInfoModifications. See *SOL002* on the *ETSI website* for more details.

Response Header:

not applicable.

Response Body:

not applicable.

When the PATCH operation is complete, the VNF instance is modified, and the details are sent to the NFVO through the notification.

Operating Virtual Network Functions

You can start or stop a VNF instance using the operate lifecycle management operation. The VNF instance can be stopped gracefully or forcefully.

Note

The OpenStack API supports only forceful stop.

The *changeStateTo* field must have the value STARTED or STOPPED in the request payload, to start or stop a VNF instance.

Permission is also required from the NFVO (bi-directional Grant flow) for this operation. See Requesting Grant Permission for more information.

Method Type:

POST

VNFM Endpoint:

/vnf instances/{vnfInstanceId}/operate

HTTP Request Headers:

Content-Type:application/json

Response Headers:

```
HTTP/1.1 202
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block
Cache-Control: no-cache, no-store, max-age=0, must-revalidate
Pragma: no-cache
Expires: 0
X-Frame-Options: TEST
Strict-Transport-Security: max-age=31536000 ; includeSubDomains
X-Application-Context: application:8250
Accept-Ranges: none
Location: http://localhost:8250/vnflcm/v1/vnf_lcm_op_occs/e775aad5-8683-4450-b260-43656b6b13e9
Content-Length: 0
Date: Thu, 04 Jan 2018 12:40:27 GMT
```

Response Body:

not applicable.

Terminating Virtual Network Functions

The terminating VNF request terminates a VNF instance. The resources are deallocated but remain reserved for this instance until it is deleted. Permission is required from the NFVO (bi-directional Grant flow) for this operation. The VNF instance can be decommissioned gracefully or forcefully.

Note

The OpenStack API supports only forceful termination.

As per the Instantiate VNF Request, the terminate VNF request requires the VNF instance identifier encoded into the URL to which the request is posted.

```
Method Type:
 POST
VNFM Endpoint:
/vnf instances/{vnfInstanceId}/terminate
HTTP Request Headers:
Content-Type:application/json
Request Payload (ETSI data structure: TerminateVnfRequest)
  "terminationType": "FORCEFUL",
Response Headers:
HTTP/1.1 202
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block
Cache-Control: no-cache, no-store, max-age=0, must-revalidate
Pragma: no-cache
Expires: 0
X-Frame-Options: TEST
Strict-Transport-Security: max-age=31536000; includeSubDomains
X-Application-Context: application:8250
Accept-Ranges: none
Location: http://localhost:8250/vnflcm/v1/vnf lcm op occs/dae25dbc-fcde-4ff9-8fd6-31797d19dbc1
Content-Length: 0
Date: Thu, 04 Jan 2018 12:45:59 GMT
Response Body:
not applicable.
```

Deleting Virtual Network Function Resource Identifier

Deleting VNF operation releases the VIM resources reserved for the VNF instance as well as deletes the VNF instance identifier. Upon deletion, the VNF instance identifier is no longer available. So, no further lifecycle management operations are possible using this identifier.

```
Method Type:

DELETE

VNFM Endpoint:

/vnf_instances/{vnfInstanceId}

HTTP Request Headers:

Content-Type:application/json

Request Payload:

not applicable.

Response Headers:

HTTP/1.1 204
```

```
X-Content-Type-Options: nosniff
X-XSS-Protection: 1; mode=block
Cache-Control: no-cache, no-store, max-age=0, must-revalidate
Pragma: no-cache
Expires: 0
X-Frame-Options: TEST
Strict-Transport-Security: max-age=31536000 ; includeSubDomains
X-Application-Context: application:8250
Accept-Ranges: none
Date: Thu, 04 Jan 2018 12:48:59 GMT
```

Response Body:

not applicable.

Deleting Virtual Network Function Resource Identifier

Monitoring Virtual Network Functions

• Monitoring Virtual Network Functions Using ETSI API, on page 39

Monitoring Virtual Network Functions Using ETSI API

During the deployment of a VNF, metrics must be defined to instruct the ESC monitoring agent component (MONA) how to determine if the VNF is healthy. The definition of metrics is within the Key Performance Indicator (KPI) section of the VNFD and allow MONA to periodically monitor the VNF to check its health and workload, defined on a per-VNFC basis. Actions are then associated with these KPIs and executed when the appropriate conditions are met.

There are several built-in monitoring methods such as ICMP Ping and SNMP. Some of the metrics to monitor on the constituent VNFCs include:

- · reachability
- resource usage (such as CPU, memory, disk and network throughput)

The following pre-requisites must be met for the deployed VNFCs to be monitored:

- The deployed VNFCs must be alive
- · Monitoring is enabled
- KPIs must be configured

Example:

```
nicid: 1
      poll_frequency: 10
      polling unit: 'seconds'
      continuous alarm: false
      property_list:
         - name: vmname
           value: vdu2
         - name: status
         value: ERROR
admin_rules:
 VM ALIVE-1:
   event name: 'VM ALIVE-1'
   action:
      - 'ALWAYS log'
      - 'FALSE recover autohealing'
      - 'TRUE esc_vm_alive_notification'
     property_list:
         - name: vmname
           value: vdu2
         - name: status
         value: SUCCESS
```

The kpi_data shown above is the default KPI required that is required in all deployments at a minimum so that the VM_ALIVE message is generated to tell ESC Manager that the VNFC has been deployed successfully; it consists of the KPI, how it is collected and the actions to be executed when the KPI is met.

Monitoring Virtual Network Functions Using ETSI API

Monitoring VNF Using D-MONA

- Onboarding D-MONA, on page 43
- Deploying D-MONA, on page 43
- Configuring D-MONA, on page 44
- Deploying VNF Using D-MONA, on page 44
- Monitoring Using D-MONA, on page 45

Onboarding D-MONA

ETSI NFV MANO supports Distributed Monitoring and Actions (D-MONA) for effective monitoring of the VNFs. D-MONA is a standalone monitoring application. For more information, see Monitoring VNFs Using D-MONA in the Cisco Elastic Services Controller User Guide.

To onboard D-MONA, you must fulfill the prerequisites and prepare the deployment data model:

Prerequisites

- Ensure connectivity between ESC and D-MONA.
- Ensure connectivity between D-MONA and the deployed VNFs.
- Only ESC Active/Active deployment is supported by D-MONA.

For information on deploying D-MONA, see Deploying D-MONA, on page 43.

Deploying D-MONA

ESC supports 1:1 D-MONA deployment for a VIM. A single D-MONA instance monitors VNF on a single VIM.

For using D-MONA in your infrastructure, you must:

- 1. Deploy the D-MONA with the monitoring infrastructure.
- 2. Deploy the VNFs using the D-MONA for monitoring their respective liveness.

After deployment, D-MONA is monitored by the local MONA running on the ESC VM.

For information on deploying VNFs using D-MONA, see Deploying VNF Using D-MONA, on page 44.

Configuring D-MONA

D-MONA reuses the ESC 5.0 image. You can view two types of runtime behavior; one from a typical ESC deployment, and the other one with capabilities provided by D-MONA.

D-MONA Day Zero Configuration

The D-MONA runtime behavior is controlled by the day 0 configuration provided to the VM at the time of deployment.

The following example shows D-MONA SSH access configuration:

```
<configuration>
  <dst>--user-data</dst>
  <file>file:///opt/cisco/esc/esc-config/dmona/iser-data.template</file>
  <variable>
    <name>vm_credentials</name>
    <val>REPLACED_WITH_GENERATED_PWD</val>
  </variable>
</configuration>
```

The vm_credentials passes the encrypted password to admin for SSH access to D-MONA.

The following example shows the D-MONA ESC certificate configuration:

```
<configuration>
  <dst>/opt/cisco/esc/moan/dmona.crt</dst>
  <data>$DMONA_CERT</data>
  </configuration>
```

For monitoring using D-MONA, see Monitoring Using D-MONA, on page 45.

Deploying VNF Using D-MONA

For deploying the VNFs using D-MONA for monitoring, you must have the D-MONA with the monitoring.agent.vim.mapping day-0 variable set to true within the same vim_connector. When ESC detects D-MONA, monitoring of the VNF is assigned to that D-MONA, otherwise the local MONA handles the monitoring.

The following example shows the D-MONA VNFD:

```
tosca_definitions_version: tosca_simple_yaml_1_2
description: D-MONA VNFD (SOL001 v0.10.0)

imports:
    - cisco_nfv_sol001_types.yaml
    - etsi_nfv_sol001_vnfd_0_10_0_types.yaml

metadata:
    template_name: D-MONA
    template_author: Cisco Systems
    template_version: '1.0'

dsl_definitions:
    descriptor_id: &descriptor_id f5b37b47-d9bd-4605-afb0-30c0d659a3c2
    provider: &provider cisco
    product_name: &product_name D-MONA
```

```
software_version: &software_version '1.0'
descriptor_version: &descriptor_version '1.0'
flavour_id: &flavour_id default
flavour_description: &flavour_description 'Default VNF Deployment Flavour'
vnfm: &vnfm '9:Cisco Elastic Services Controller:v04.04.01'
```

Monitoring Using D-MONA

To monitor the VNFs using D-MONA, you must deploy the ESTI VNFD D-MONA and then deploy the ESTI VNFD monitored by D-MONA. For information on deploying D-MONA, see Deploying VNF Using D-MONA, on page 44.

The D-MONA parameters are defined within the VNFD, or provided as additional params in the instantiate D-MONA VNF payload.

An ETSI compliant VNFD is used for the deployment of D-MONA.

The input parameters, KPI data, and config parameters are required for instantiation of D-MONA deployment.

The input parameters are either defined within the VNFD or provided as additional Params section of instantiate D-MONA VNF payload.

Table 4: Input Parameters for D-MONA Deployment

Parameter	Description
SW_IMAGE_NAME	The name of ESC image
DMONA_CERT	The HTTPS certificate
DMONA_AGENT_ID	The URL or ID of the monitoring agent that will monitor the VM
ADMIN_PASSWORD	The admin user password
SECURITY_BASIC_ENABLED	A flag that indicates whether basic security is enabled or not
SECURITY_USER_NAME	A security user to communicate with ESCManager
SECURITY_USER_PASSWORD	A security user's password used to communicate with ESCManager

KPI data:

- monitoring_agent—value defined for DMONA_AGENT_ID in the input parameter.
- property_list
 - name—protocol
 - value—https
 - name—port
 - value—8443

- name—path
- value—mona/v1/health/status

Config data parameters:

- user-data.txt
 admin_password—value defined for ADMIN_PASSWORD in input parameter
- application—dmona.template
 - · monitoring.agent—true
 - security_basic_enabled—value defined for SECURITY_BASIC_ENABLED in input parameter
 - security_user_name—value defined for SECURITY_USER_NAME in input parameter
 - security_user_password—value defined for SECURITY_USER_PASSWORD in input parameter
 - monitoring.agent.vim.mapping—true

Example payload:

```
config_data:
    '--user-data':
        file: ../Files/Scripts/user-data.txt
        variables:
            admin_password: { get_input: ADMIN_PASSWORD }
    '/opt/cisco/esc/mona/dmona.crt':
        data: { get_input: DMONA_CERT }
    '/opt/cisco/esc/mona/config/application-dmona.properties':
        file: ../Files/Scripts/application-dmona.template
        variables:
            monitoring.agent: true
            security_basic_enabled: { get_input: SECURITY_BASIC_ENABLED }
            security_user_name: { get_input: SECURITY_USER_NAME }
            security_user_password: { get_input: SECURITY_USER_PASSWORD }
            monitoring.agent.vim.mapping: true
```

Healing Virtual Network Functions

• Healing Virtual Network Functions Using ETSI API, on page 47

Healing Virtual Network Functions Using ETSI API

As part of life cycle management, ESC heals the VNFs when there is a failure. The recovery policy specified during deployment controls the recovery. ESC supports recovery using the policy-driven framework, see Configuring a Recovery Policy Using the Policy-driven Framework in the Cisco Elastic Services Controller User Guide.

The healing parameters define the behavior that is monitored to trigger a notification to heal a VNF. These parameters are configured in the KPI section of each compute node in the VNFD along with rules. The rules define the action to be taken (including events that are triggered) as a result of these KPI conditions to heal a VNF.

ESC ETSI configures monitoring using the following two sections:

- kpi data—defines the type of monitoring, events, polling interval and other parameters
- admin rules—defines the actions when the KPI monitoring events are triggered

Example:

```
vdu1:
 type: cisco.nodes.nfv.Vdu.Compute
 properties:
   name: Example VDU1
    description: Example VDU
    kpi data:
     VM ALIVE-1:
       event_name: 'VM ALIVE-1'
       metric value: 1
       metric_cond: 'GT'
       metric_type: 'UINT32'
       metric occurrences true: 1
       metric occurrences false: 30
        metric collector:
          type: 'ICMPPing'
         nicid: 1
         poll frequency: 10
         polling unit: 'seconds'
          continuous_alarm: false
```

```
admin_rules:
   VM_ALIVE-1:
     event_name: 'VM_ALIVE-1'
     action:
        - 'ALWAYS log'
        - 'FALSE recover autohealing'
        - 'TRUE esc_vm_alive_notification'
```

This example shows the default KPI and rule to support the service alive notification required to complete the deployment in ESC. For more information on KPI, rules, and the underlying data model that is exposed in the VNFD, see KPIs, Rules and Metrics in the Cisco Elastic Services Controller User Guide.

There are three types of actions for recovery when an event denoting that an instance requires attention is received, a timer expires or a manual recovery request is received; the healing workflow will:

- REBOOT_THEN_REDEPLOY—first attempt to reboot the affected VNFCs; if this fails, then it attempts to redeploy the affected VNFCs (on the same host)
- REBOOT_ONLY—only attempt to reboot the VM
- REDEPLOY ONLY—only attempt to redeploy the VM

The recovery policy is configured at a VNF-level, and applies to each VNFC contained within. The monitoring agent monitors each VNFC and when a recovery situation arises, the message is converted to an alarm and sent to any subscribed consumers (e.g. an NFVO or Element Manager).

If autoheal is *enabled* on the VNF instance, then ESC automatically attempts to recover the VNF based on the recovery policy configured on deployment. This may be configured in the VNFD or alternatively modified against the VNF instance prior to instantiation.

The recovery of the VNF is to request action against the affected VNFCs. If the service fails to deploy, then the lifecycle management operation fails, if ESC cannot manage to recover the service using the defined policy after the initial deployment operation times out.

To modify the autoheal flag (*isAutohealEnabled*) VNF instance resource, see Modifying Virtual Network Functions, on page 33.

If autoheal is *not enabled*, only the alarm is dispatched to all the subscribers. The subscriber can initiate a manual HealVnfRequest. The data structures are available for any VNF specific actions. There are no mandatory parameters.

Example for SOL003:

```
Request Payload (ETSI data structure: HealVNFRequest)
POST /vnf_instances/{vnfInstanceId}/heal
{
    "cause": "b9909dde-e21e-45ec-9cc0-9e9ae413eee0",
}
Example for SOL002:

POST /vnf_instance/{vnfInstanceId}/heal
{
    "vnfcInstanceId": ["b9909dde-e21e-45ec-9cc0-9e9ae413eee0"],
    "cause": "b9909dde-e21e-45ec-9cc0-9e9ae413eee0",
    "healScript": "REBOOT_ONLY"
}
```

The healScript is implemented as an enumeration of the valid recovery policy names which allow the policy configured in the deployment data model to be overriden. The list of vnfcInstanceIds allow the required VNFCs to be affected, however the absence of this list means the request applies to the entire VNF.

Additional parameters can be used to specify an overriding recovery policy, regardless of the policy configured at the time of deployment.

The recovery policy can be specified at VNFC level using additional parameters. This will override the values set at the VNF level. If the recovery policy is not specified at VNFC level, then ESC will inherit the properties from the VNF level recovery policy.

An optional additional parameter is added to the cisco.datatypes.nfv.VnfcAdditionalConfigurableProperties data type to support VNFC level recovery.

For information on monitoring, see Monitoring Virtual Network Functions Using ETSI API, on page 39.

Healing Virtual Network Functions Using ETSI API

Scaling Virtual Network Functions

• Scaling Virtual Network Functions Using ETSI API, on page 51

Scaling Virtual Network Functions Using ETSI API

One of the main benefits of ESC is its capability to elastically scale a service. This allows a VNFC that performs a particular role or aspect within the VNF to be able to service requests and scale out to meet high demand or scale in when being under utilized. This aspect may span across multiple VNFCs.

The scaling requests may be manual or automatic. The different approaches to accomplishing scaling are detailed below.

For more details on these concepts and specification, please see Annex B of ETSI GS NFV-SOL 003.

For information on Scaling VNFs using REST and NETCONF APIs, see the *Cisco Elastic Services Controller User Guide*.

Scale

The Scale VNF request uses the *scaleStatus*, an attribute found as part of the instantiatedVnfInfo when querying a VnfInstance resource. This attribute describes the current scale level of each aspect in the VNF, for example:

This forms the starting point for a Scale VNF request, which allows a single aspect to be scaled horizontally (i.e. adding or removing VNFCs) relative to the current *scaleLevel* for that dimension of the VNF. Any scaling operation on an aspect will be applied to each VNFC that supports that aspect.

Note

The current specification does not support vertical scaling (adding/removing resources to/from existing VNFC instances) at this time.

Request Payload (ETSI data structure: ScaleVNFRequest)

```
{
    "type": "SCALE_OUT",
    "aspectId": "processing",
    "numberOfSteps": 1,
    "additionalParams": {}
}
```

The above payload results in the *scaleStatus* example above being updated to and the addition of the number of VNFCs for this step required to scale out to scaleLevel 3:

To understand the scaling steps and other related policies configured to support scaling, see the VNFD Policies for Scaling.

Scale To Level

The Scale VNF To Level request, rather than the relative scaling that Scale VNF offers, specifies the absolute scale result desired and so some aspects may be scaled out and others scaled in. This option uses one of the two approaches to define the scaling required:

- · instantiation level
- scale level

These are mutually exclusive and allow for more than one aspect to be scaled in a single request.

Instantiation Level

An Instantiation level is a predefined size for each aspect, where each level has a scale level associated with each aspect. There is no further granularity offered and so the entire VNF (that is, all aspects) is scaled according to the instantiation level requested.

Example:

Request Payload (ETSI data structure: ScaleVNFToLevelRequest)

```
{
    "instantiationLevelId": "premium"
}
```

See the VNFD Policies for the definition of instantiation levels.

Scale Level

The Scale Level is also a pre-defined size for each aspect where each aspect has target VNFCs, defined step_deltas (since each scaling step may not be uniform) and a maximum scale level. The policies that define this option allow the different targets to have different scaling outcomes.

Note

The scale level does not represent the number of VMs; for example scaleLevel=0 means the initial number of instances (initial delta) for that aspect on the target VNFC and scaleLevel=1 is the initial delta plus the first scaling step defined for that aspect and VNFC tuple.

Request Payload (ETSI data structure: ScaleVNFToLevelRequest)

For information on definition of scale levels, See the VNFD Policies for Scaling.

VNFD Policies for Scaling

There are a number of policies that make up the overall scaling behavior of a VNF. These policies will support the various scaling approaches described above. The first policy defines the aspects that may be scaled (or not):

```
policies:
    - scaling aspects:
        type: tosca.policies.nfv.ScalingAspects
        properties:
          aspects:
            webserver:
              name: 'webserver'
              description: 'The webserver cluster.'
              max scale level: 5
              step_deltas:
                - delta 1
            processing:
              name: 'processing'
              description: 'An example processing function'
              max_scale_level: 3
              step deltas:
                - delta 1
                - delta 2
                - delta 1
            database:
              name: 'database'
              description: 'A test database'
              max scale level: 0
```

You can see in this example that the database aspect has a max_scale_level of 0, which denotes that it cannot be scaled out - this does not mean 0 instances of that aspect - see the algorithm below to see why. The webserver aspect only has a single step_delta, meaning that all scaling steps are uniform whereas the processing aspect has different step_deltas specified for each scaling step. This is called non-uniform scaling. This is only the

declaration of the aspects of this VNF, and this is one of the policies used to perform the validation when a scaling request is received.

Next, they must be applied to VNFCs to control their behavior:

```
- db initial delta:
       type: tosca.policies.nfv.VduInitialDelta
       properties:
         initial delta:
           number_of_instances: 1
       targets: [ vdu1 ]
   - ws initial delta:
       type: tosca.policies.nfv.VduInitialDelta
       properties:
         initial delta:
           number of instances: 1
       targets: [ vdu2, vdu4 ]
    - pc initial delta:
       type: tosca.policies.nfv.VduInitialDelta
       properties:
         initial delta:
           number of instances: 1
       targets: [ vdu3 ]
   - ws scaling aspect_deltas:
       type: tosca.policies.nfv.VduScalingAspectDeltas
       properties:
         aspect: webserver
         deltas:
           delta 1:
             number of instances: 1
       targets: [ vdu2, vdu4 ]
   - pc scaling aspect deltas:
       type: tosca.policies.nfv.VduScalingAspectDeltas
       properties:
         aspect: processing
         deltas:
           delta 1:
             number of instances: 1
           delta 2:
             number of instances: 2
       targets: [ vdu2, vdu4 ]
```

In the examples above, the VNFCs are identified as targets; the aspects could have different behaviours on different VNFCS, but this is not shown here. The definition of the step_deltas are also shown here which are used in the validation and generation of scaling requests (these steps are inferred by the scale level requested). The minimum number of instances of a VNFC is always assumed to be 0 and the maximum number is calculated by the following algorithm:

initial_delta plus the number of instances for each step up to the max_scale_level.

These policies are considered for the scale-level based scaling. There are similar constructs used for instantiation-level based scaling.

```
- instantiation_levels:
        type: tosca.policies.nfv.InstantiationLevels
        properties:
        levels:
        default:
        description: 'Default instantiation level'
        scale info:
```

```
database:
       scale level: 0
      webserver:
       scale level: 0
     processing:
       scale level: 0
 premium:
   description: 'Premium instantiation level'
   scale info:
     database:
       scale level: 0
      webserver:
       scale level: 2
     processing:
       scale level: 3
default level: default
```

Similar to the scaling aspects, the first part of the definition of instantiation levels is just their declaration. Here each aspect must already be declared and then each aspect's scale_level is declared for the instantiation level; a default instantiation level is also stipulated in the event that no other is specified. What each scale_level means for each VNFC is further elaborated upon in the VduInstantiationLevels policies, for example:

```
- ws_instantiation_levels:
          type: tosca.policies.nfv.VduInstantiationLevels
          properties:
          levels:
          default:
          number_of_instances: 1
          targets: [ vdu2, vdu4 ]
```

So these policies together state that the default instantiation level is 'default' which will result in the webserver aspect being instantiated at scale_level 0 which is 1 VNFC instance.

Dependencies on Multiple IP Addresses

Static IP Addresses

If the VNFC has connection points configured with a static IP address, the VNFC cannot be scaled as there are no further IP addresses to assign to the connection points on the newly spun up VNFC instances. Instead, a pool of further static IP addresses can be specified. This is an extension to the ETSI specification.

The following example explains how to create a static IP pool using a list of IP addresses, IP ranges or a gateway with netmask (one or a combination of more than one can be specified):

```
vd112:
 type: cisco.nodes.nfv.Vdu.Compute
 properties:
   name: 'Webserver1'
    description: 'Webserver VNFC'
    vdu profile:
     min_number of instances: 1
     max number of instances: 6
      static ip address pool:
       network: network1
        ip addresses:
          - ip address: 192.168.100.0
          - ip address: 192.168.100.1
          - ip address: 192.168.100.2
          - ip address: 192.168.100.3
        ip address range:
           start: 172.16.233.10
```

```
end: 172.16.233.15
- start: 172.16.233.20
end: 172.16.233.25
gateway: 172.10.11.0
netmask: 255.255.255.0
```

The scaled out VNFC instance that has connection points with static IP addresses is assigned to a network. This is the key to identify which IP address pool to use when the scaled out instance is deployed. The static IPs are specified at deployment as part of the inputs in the InstantiateVnfRequest. For information on instantiating VNFs, see Instantiating VNFs.

The inputs are provided as part of the additional Params through the VNFD.

Day Zero Configuration

After deploying the VNFs, day 0 variables are configured in the VNFC instance for the deployment service. In most cases, the values for the day 0 configuration is constant. In other cases, there is a resource pool of values supplied to the day 0 parameter to allow new values to be assigned to the new VNFC instances.

Day 0 configuration within the vendor_section of the VNFD:

```
vdu3:
      type: cisco.nodes.nfv.Vdu.Compute
     properties:
        name: 'Processing1'
        description: 'Processing VNFC'
        vdu profile:
         min number_of_instances: 1
         max number of instances: 5
        vendor section:
          cisco esc:
            config data:
              '/tmp/OSRESTTestETSIDay0 Inline data.cfg':
                data: I
                  NODE NAME $NODE NAME
                  NUM OF CPU $NUM OF CPU
                  MEM SIZE $MEM SIZE
                  PROXY ADDRS $PROXY ADDRS
                  SPECIAL CHARS $SPECIAL CHARS
                variables:
                  NODE NAME: vdu node 1
                  NUM OF CPU: 1
                  MEM SIZE: 1GB
                  PROXY ADDRS: ["1.1.1.1", "1.1.2.1", "1.1.3.1", "1.1.4.1", "1.1.5.1",
"1.1.6.1", "1.1.7.1"]
                  SPECIAL CHARS: '`~!@#$%^&*()- =+[{]}|;:<.>/?'
```

In the above example the day 0 configuration is specified inline, with velocity variables defined in the target configuration. Each of these variables are supported by a variable with one or more values. In order to support multiple values for the \$PROXY_ADDRS variable, a list of values are provided. These values are used to populate subsequent uses of the variable on new instances of the VNFC.

For information on day 0 configuration in the deployment data model, see Day Zero Configuration in the *Cisco Elastic Services Controller User Guide*.

Autoscaling of VNFs

KPIs, rules and actions defined in the VNFD determine the conditions under which scaling must be considered. The details are provided in Monitoring Virtual Network Functions. The scaling policies are also defined in

the VNFD using several policy types that control the allowed scaling boundaries. These policy items are described below.

After deployment, ESC configures a monitoring agent (this may be the centralised or distributed instance) with the KPIs to monitor each VNFC. The scaling workflow begins if a KPI reaches its threshold; based on the action defined, ESC performs scale in or scale out and generates appropriate notifications and event logs. This is subject to some built-in functions that can be specified such as log or an onboarded script.

ESC sends appropriate notifications to the subscribed consumers. At this time, ESC interrogates the VNF instance resource for the <code>isAutoscaleEnabled</code> flag (this is set initially by the value in the VNFD but can be modified after creation). If this flag is set to true, ESC invokes the scaling workflow (instigated using a <code>ScaleVnfToLevelRequest</code> to request the scaling of multiple aspects in a single request). If the <code>isAutoscaleEnabled</code> is set to false, then the control is with an external system such as an NFVO or EM to trigger the desired action using the requests described above.

Autoscaling of VNFs

Error Handling Procedures

• VNF Lifecycle Management Error Handling Procedures, on page 59

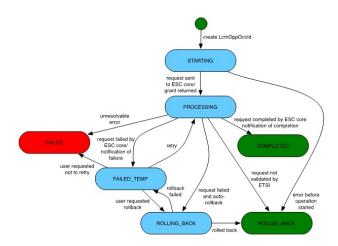

VNF Lifecycle Management Error Handling Procedures

ETSI invokes the following error handling procedures for all its ETSI VNF lifecycle management (LCM) operations:

- Retry
- · Rollback
- Fail
- Cancel

The image below represents the transitional states of the VNF lifecycle management operational occurrence.

Figure 2: VNF Lifecycle Management Transitional States

Note

The *vnfLcmOpOccId* is encoded into the URI, which is the primary key to retrieve the request details.

The retry, rollback and fail requests are rejected if the LCM operation is in any other state other than the FAILED_TEMP state. This error returns HTTP code 409.

The retry, rollback, fail and cancel requests are not supported for the particular VNF LCM operation for the particular VNF. This error returns HTTP code 404.

An error occurs if the *vnfLcmOpOccId* does not exist in the ETSI database. This error returns HTTP code 404.

Retry

A retry request is applicable if there is a possibility of the LCM operation to succeed. The operation should be (pre-condition) in the FAILED_TEMP state for a retry request. You can send several retry requests, as long as the operation is in the FAILED_TEMP state.

Precondition	FAILED_TEMP state
Request	POST {api_root}/vnf_lcm_op_occs/{vnfLcmOpOccId}/retry()
Postcondition	PROCESSING state

Upon successful retry, ESC sends a START or PROCESSING notification. If the retry request fails, then ESC sends a notification to the NFVO with the details.

Rollback

A rollback request is made if it is not possible for the operation to succeed even after a retry request.

Set the *rollback required* flag to true. If this is not set to true, then rollback is not performed.

Precondition	FAILED_TEMP state
Request	POST {api_root}/vnf_lcm_op_occs/{vnfLcmOpOccId}/rollback()
Postcondition	ROLLED_BACK

Upon successful rollback, the LCM operation is rolled back. If the rollback request fails, then the LCM operation is back to the failed temp sate.

Fail

When an LCM operation does not require a retry request, or a clean up, a fail request allows you to free up resources for a subsequent request.

If the *rollback_required* flag is set to true, a fail request cannot be made.

Precondition	FAILED_TEMP state
Request	POST {api_root}/vnf_lcm_op_occs/{vnfLcmOpOccId}/fail()
Postcondition	FAILED state

Upon successful execution of this request, the LCM operation is in FAILED state.

Cancel

A cancel request is possible if the operation is in STARTING state.

Note

A cancel request is currently possible in the STARTING or PROCESSING state for Instantiate, but only STARTING for all other LCM operations.

Precondition	STARTING state
Request	POST {api_root}/vnf_lcm_op_occs/{vnfLcmOpOccId}/cancel(CancelMode)
Postcondition	ROLLED_BACK

The cancel request is Forceful.

Note

ETSI supports canceling an LCM operation in starting state only. The cancel request for LCM operations in processing or rolling back states are currently not supported.

Example JSON payload (CancelMode):

```
{
  "cancelMode": "FORCEFUL",
  "action": "cancel"
}
```

Set the *IsCancelPending* attribute of the *VnfLcmOpOcc* to true. This will stop the processing request, and move the LCM operation to ROLLED_BACK state.

Error Handling Procedures for ETSI VNF Lifecycle Operations

If the LCM operation for a VNF instance fails, the operation moves to the FAILED_TEMP state according to the state machine. To complete the intended operation, you must either run the retry or rollback request.

- If creating a VNF identifier fails, then no further action is required. The rollback request is not supported.
- If instantiating the VNF fails, then ESC terminates the request, and sends a new instantiation request.
- If operating the VNF fails, then no further action is required.
- If terminating the VNF fails, you must retry the operation, as rollback is not supported.
- If deleting the VNF operation fails, then no further action is required. The erollback request is not supported.

Note

The error handling requests do not impact the operating VNF lifecycle operation.

For information on VNF lifecycle operations, see VNF Lifecycle Operations, on page 22.

VNF Lifecycle Management Error Handling Procedures

Alarms and Notifications for ETSI LCM Operations

- ETSI Alarms, on page 63

- ETSI Failure and Load Notifications for VNFs, on page 68

ETSI Alarms

ESC provides alarms and notifications to the NFVO. The NFVO has to subscribe to these alarms and notifications and send requests to ESC.

The NFVO can receive information about the alarms in the following ways:

Query All Alarms

The NFVO can get a list of all the alarms from the alarms resource.

Method Type:

GET

VNFM Endpoint:

/vnffm/v1/alarms

HTTP Request Header:

Accept:application/json

For example, to query all alarms with the event type as ENVIRONMENTAL ALARM

Method Type:

GET

VNFM Endpoint:

http://localhost:8250/vnffm/v1/alarms?eventType="ENVIRONMENTAL_ALARM"

HTTP Request Headers:

Accept:application/json

While querying for multiple alarms, the NFVO can use the URI query parameters to filter the results. The following attribute names are supported for the URI query of the alarms:

- id
- · managedObjectId
- rootCauseFaultyResource.faultyResourceType
- eventType
- perceivedSeverity
- probableCause

The URI query parameters are for querying multiple alarms only.

Query an Individual Alarm

The NFVO can query a particular alarm from the *alarmId* resource.

Method Type:

GET

VNFM Endpoint

/vnffm/v1/alarms/{alarmId}

HTTP Request Header:

Accept:application/json

Modify an Individual Alarm

To modify an alarm, the NFVO must send a PATCH request to the *AlarmModifications* resource.

Method Type:

PATCH

VNFM Endpoint:

/vnffm/v1/alarms/{alarmId}

HTTP Request Header:

Content-Type: application/merge-patch+json
If-Match: ETag value

Note

If-Match: is optional. If specified, its value is validated against the ETag value stored against the VNF (and returned from a single VNF query).

The supported attribute is ackState, and the supported attribute value is ACKNOWLEDGE. All other modification payloads are rejected.

VNF Failure and Load Alarms

The following alarms are created for ETSI VNF failure and load notifications.

• Failure Alarm—ESC generates the failure alarms when one of the compute resources within the VNF becomes unreachable based upon the VM_ALIVE KPI configuration of the VFND. For more information, see ETSI Failure and Load Notifications for VNFs.

Example:

Method Type

POST

VNFM Endpoint

/vnffm/v1/extension/alarms

HTTP Request Header

Content-Type:application/json

Request Payload:

```
"externalAlarmId": "26bf1e3d-cefa-4f59-88ea-210a29358a5c", #generated value
  "alarmSource" : "MONA", #hard-coded
  "managedObjectId": "08733ef2-319b-46ce-9d8d-95730306bd1a", #external deployment id
 "rootCauseFaultyResource": "chrimann-dep g1 0 212da327-0573-421b-ae37-057f6b1a6aef",
  "alarmRaisedTime" : "$timestamp", #generated value
  "ackState" : "UNACKNOWLEDGED", #hard-coded
  "perceivedSeverity" : "CRITICAL", #hard-coded
  "eventTime": "2018-05-08T00:59:32.571+00:00", #do we have the eventTime?
  "eventType" : "EQUIPMENT ALARM", #hard-coded
  "faultType" : "COMPUTE", #hard-coded
  "probableCause" : "VM MANUAL RECOVERY NEEDED", #event name
  "isRootCause" : "TRUE", #hard-coded
  "links" : {
   "objectInstance" :
"{http scheme}://{api root}/vnflcm/v1/vnf_instances/08733ef2-319b-46ce-9d8d-95730306bd1a"
}
```

Load Alarm—ESC generates the load alarms when one of the compute resources within the VNF becomes
over or under loaded based upon the related KPI configurations of the VFND. ESC creates these alarms
after receiving notifications from the NFVO. For more information, see ETSI Failure and Load
Notifications for VNFs.

Example:

Method Type

POST

VNFM Endpoint

/vnffm/v1/extension/alarms

HTTP Request Header

Content-Type:application/json

Request Payload

Alarm Extensions

ETSI provides an extension for the alarms to interact with the third party tools. You must send a POST request to create the alarms.

```
Method Type
```

POST

VNFM Endpoint

/vnffm/v1/extension/alarms

HTTP Request Header

Content-Type:application/json

Request Payload

```
[admin@davwebst-esc-4-2-0-49-keep ETSI]$ cat CreateAlarm.json
   "id": "alm87032",
   "externalAlarmId": "ext-id-xx11214",
   "managedObjectId": "930fb087-c1b9-4660-bec8-2a8d97dc1df5",
   "rootCauseFaultyResource": {
       "id": "fres7629",
       "faultyResource": {
            "resourceId": "res7727"
       "faultyResourceType": "NETWORK"
   "alarmRaisedTime": "2018-05-30T13:55:15.645000+00",
   "ackState": "UNACKNOWLEDGED",
   "perceivedSeverity": "MAJOR",
   "eventTime": "2018-05-30T13:55:15.645000+00",
   "eventType": "ENVIRONMENTAL ALARM",
   "probableCause": "Server room overheading",
   "isRootCause": "false"
```

Subscribing to Notifications

The NFVO can subscribe to the ETSI notifications related to fault management from ESC.

Create a Subscription

The NFVO sends a POST request to subscribe to the notifications.

Method Type:

POST

VNFM Endpoint:

/vnffm/v1/subscriptions

```
"filter" : {
    "notificationTypes" : [
    "AlarmNotification",
    "AlarmClearedNotification",
```

```
"AlarmListRebuiltNotification"
],
   "perceivedSeverities" : [
        "CRITICAL",
        "MAJOR"
]
},
   "callbackUri" : "https://nfvo.endpoint.listener",
"authentication" : {
        "authType" : "BASIC",
        "paramsBasic" : {
            "userName" : "admin",
            "password" : "pass123"
}
}
```

This creates a new subscription resource and a new identifier. The callbackUri is the only mandatory parameter. The others are all optional. You can verify if the callbackuri is valid and reachable by sending a GET request.

Query all Subscriptions

The NFVO can query information about its subscriptions by sending a GET request to the *subscriptions* resource.

Method Type:

GET

VNFM Endpoint:

/vnffm/v1/subscriptions

HTTP Request Header:

Accept:application/json

For example, to query all alert subscriptions, when the callbackUri is

```
http://10.10.1.44:9202/alerts/subscriptions/callback GET
```

VNFM Endpoint

HTTP Request Header

Accept:application/json

The NFVO can use the URI query parameters to filter the results. The following attribute names are supported for the URI query of the subscriptions:

- id
- filter
- callbackUri

Note

The URI query parameters are for querying multiple subscriptions only.

Query an Individual Subscription

You must know the subscription ID to query an individual subscription.

Method Type:

GET

VNFM Endpoint:

/vnffm/v1/subscriptions/{subscriptionId}

HTTP Request Header:

Accept:application/json

Delete a Subscription

You can delete a subscription if the NFVO does not need it. Send a delete request to the individual subscription.

Method Type:

DELETE

VNFM Endpoint:

/vnffm/v1/subscriptions/{subscriptionId}

HTTP Request Header:

http://localhost:8250/vnffm/v1/subscriptions/682791f8-34ad-487e-811a-553036bf49b2

ETSI Failure and Load Notifications for VNFs

ESC generates notifications for the following:

• VM Failure

The NFVO receives failure notifications from ESC, when the VMs within the deployed VNFs fail. After receiving the notifications, alarms are generated. For more information on alarms, see ETSI Alarms, on page 63.

The NFVO must subscribe to the ESC for notifications.

Example:

```
<address id>0</address id>
          <gateway>172.16.0.1</gateway>
          <ip address>172.16.0.0</ip address>
          <dhcp enabled>true</dhcp enabled>
          <prefix>20</prefix>
          <subnet>365a0884-fdb3-424c-afe9-2deb3b39baae</subnet>
        </address>
      </addresses>
      <network uuid>c7fafeca-aa53-4349-9b60-1f4b92605420/network uuid>
      <mac_address>fa:16:3e:38:1d:6c</mac_address>
      <nic id>0</nic id>
      <port forwarding/>
      <port uuid>0aeb9585-5190-4f3b-b1aa-495e09c56b7d</port uuid>
      <security groups/>
      <subnet uuid>none</subnet uuid>
      <type>virtual</type>
<vim interface name>sample-dep vm1 0 fbc3da46-e0c6-40dc-91c8-70b1a88857de</vim interface name>
    </interfaces>
    <vim_id>default_openstack_vim</vim_id>
    <vim project>admin</vim project>
    <vim project id>c12f013306d849e5b1bbf257c54d5891/vim project id>
    <host_uuid>6b8cf361c5ff08a5a886e26f591b8087dadcf2d2b34fb3b5d2772a8d</host_uuid>
    <host name>my-server</host name>
    <vm uuid>9fea3fe7-9417-4734-b962-b24340941ef3/vm uuid>
    <vm_group_name>vm1</vm_group_name>
    <vm name>sample-dep vm1 0 fbc3da46-e0c6-40dc-91c8-70b1a88857de/vm name>
  </vm source>
</esc event>
```

VM Overload and Underload

Similarly, the NFVO receives an overload or underload notification for a VM.

If scaling is not enabled automatically, ESC generates a notification depending on the state of the VM.

Examples:

```
<?xml version="1.0" encoding="UTF-8"?>
<esc event xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <deployment name>sample-dep</deployment name>
  <event name>MY VM UNDERLOADED
  <event type>VM UNDERLOADED
 <external deployment id>e911eecf-5f3f-456c-9c80-d99aca2416da</external deployment id>
  <external_tenant_id>etsi_tenant/external_tenant_id>
 <internal deployment id>99f7629f-98d3-40f5-ad68-7addcfe07006</internal deployment id>
  <internal_tenant_id>etsi_tenant</internal_tenant_id>
  <vm source>
<generated vm name>sample-dep vm1 0 fbc3da46-e0c6-40dc-91c8-70b1a88857de/generated vm name>
    <interfaces>
      <addresses>
       <address>
         <address id>0</address id>
         <gateway>172.16.0.1</gateway>
          <ip address>172.16.0.0</ip address>
         <dhcp_enabled>true</dhcp_enabled>
         <prefix>20</prefix>
         <subnet>365a0884-fdb3-424c-afe9-2deb3b39baae/subnet>
        </address>
      </addresses>
```

```
<network uuid>c7fafeca-aa53-4349-9b60-1f4b92605420/network uuid>
      <mac address>fa:16:3e:38:1d:6c</mac address>
      <nic id>0</nic id>
      <port forwarding/>
      <port_uuid>0aeb9585-5190-4f3b-b1aa-495e09c56b7d</port uuid>
      <security groups/>
      <subnet uuid>none</subnet uuid>
      <type>virtual</type>

    <vim project>admin</vim project>
```

Auto-Scaling VNFs Using KPI Instructions

ESC can auto-scale VMs using the KPI instructions. The scaling workflow begins when the VNF instance is in the instantiated state. The NFVO enables and disables the auto-scaling while modifying *isAutoscaleEnabled* configurable property of the VNF.

Following are the events that trigger an ETSI-compliant auto-scale, which requires an instigation of a *ScaleVnfToLevelRequest:* functionality.

• Overload and Underload

If the state of a VM changes and it is under or overloaded, ESC gets a notification to determine if the scaling is automatically enabled. If it is not, ESC generates a notification towards the ETSI-VNFM component to check the VNF's state.

The following example shows underloaded notification from ESC:

```
Headers:
  esc-status-code = 200
  esc-status-message = VM [sample-dep vm1 0 fbc3da46-e0c6-40dc-91c8-70b1a88857de]
underloaded.
<?xml version="1.0" encoding="UTF-8"?>
<esc event xmlns="urn:ietf:params:xml:ns:netconf:base:1.0">
  <deployment name>sample-dep</deployment name>
  <event name>MY VM UNDERLOADED</event name>
  <event type>VM UNDERLOADED</event type>
 <external deployment id>e911eecf-5f3f-456c-9c80-d99aca2416da</external deployment id>
  <external tenant id>etsi tenant/external tenant id>
 <internal deployment id>99f7629f-98d3-40f5-ad68-7addcfe07006</internal deployment id>
  <internal tenant id>etsi tenant</internal tenant id>

```

VNFD

The VNFD notification contains the instructions for the scale action required for *isAutoscaleEnabled* configurable property of the VNF operation flow.

If the scaling is not enabled automatically, you can instigate the manual LCM operations using the KPI instructions. It is instigated by processing the ESC notification stream. You must validate the notification once you receive the KPI events.

You must take the following actions:

- Find the matching VNF instance
- Validate that the appropriate configuration property is set to enable the automated operation

If the validation passes then you can request to instigate the operation flow to generate the appropriate operation occurrence and associated notifications. For scaling, any specified KPI data determines the scaling parameters. The properties file includes the following new attributes:

```
external.scaling.decision = 1
  #external.scaling.window = 120
  external.healing.decision = 1
  #external.healing.window = 120
```

• VnfInstance resource

The VNFD determines the scale level using the current scaleStatus. The processing of the request determines the number of VMs to request from ESCManager. The request only supplies a relative number of increments (SCALE_IN or SCALE_OUT).

You can call the *ScaleVnfToLevel* endpoint with the following payload, using *vnfInstanceId* from the vnfInstance resource of the VNF to be scaled.

Ensure that the VnfLcmOpOcc.isAutomaticInvocation is set to true.

The following eexample shows JSON payload:

Healing VNFs Using KPI Instructions

ESC can auto-heal VMs using the KPI instructions. The NFVO enables and disables the auto-healing while modifying *isAutohealEnabled* configurable property of the VNF.

The isAutohealEnabled property permits to enable (TRUE)/disable (FALSE) the auto-healing functionality.

•

Administering ESC

- ETSI Performance Reports, on page 75
- Performance Management Jobs, on page 75
- Configuring Threshold for Performance Management Job, on page 78
- Subscribing to Performance Management Job, on page 81

ETSI Performance Reports

ESC allows you to collect the performance information of the VNFs such as metrics and notifications using the performance management job functionality. You must first create a performance management (PM) job. After creating the PM job, you can perform the following tasks:

- Query, delete, or notify performance management jobs
- Read an individual report, or obtain the performance reports
- Configure the threshold of the performance management jobs
- Query, delete or notify the threshold of the performance management jobs
- Manage subscriptions, query, subscribe or terminate subscriptions

Performance Management Jobs

This section describes the performance management jobs.

Create Performance Management Job

You must create a performance management job to further query and run reports.

Method Type:

POST

VNFM Endpoint:

{api_root}/vnfpm/v1/pm_jobs (Data structure=CreatePmJobRequest)

Request Payload:

"http://host:port/vnflcm/v1/vnf instances/cc6a34e5-0463-459a-b367-493ba997775f"
     }
  }
}
```

Query an Individual Performance Management Job

The NFVO queries for the individual performance management job.

Method Type:

GET

VNFM Endpoint:

```
\label{local_pm_v1/pm_jobs_pm_job} $$ {\rm api\_root}/vnfpm/v1/pm_jobs_{pm_jobld} $$ api\_root_vnfpm/v1/pm_jobs_{pm_jobld} $$ $$
```

Request Payload:

NA.

```
"id": "13963644-11b0-4302-a13b-26ca3d9eb8f8",
 "objectInstanceIds": [
   "cc6a34e5-0463-459a-b367-493ba997775f"
 "criteria": {
    "performanceMetric": [
     "default"
    "performanceMetricGroup": [
     "default"
    "collectionPeriod": 3600,
    "reportingPeriod": 14400,
    "reports": [
        "href": "uri_where_report_can_be_obtained",
       "readyTime": "2018-08-20T06:17:35.081+0000",
       "expiryTime": "2018-10-20T06:17:35.081+0000",
        "fileSize": "5000"
   ]
 " links": {
    "self": {
     "href": "http://host:port/vnfpm/v1/pm_jobs/13963644-11b0-4302-a13b-26ca3d9eb8f8"
    "objects": [
      {
        "href":
"http://host:port/vnflcm/v1/vnf_instances/cc6a34e5-0463-459a-b367-493ba997775f"
     }
    ]
}
```

A reports section is added to the response payload (as shown above) only if a report is available.

All the attribute names and the data types referenced from the attribute names in the response payload are supported in the attribute-based filtering.

Query All Performance Management Jobs

The NFVO gets the list of all the performance management jobs.

Method Type:

GET

VNFM Endpoint:

 $\label{lem:cot} $$ {\rm api_root}/{\rm vnfpm/v1/pm_jobs} \ {\rm or} \ {\rm GET} \ {\rm api_root}/{\rm vnfpm/v1/pm_jobs} $$$

Request Payload:

NA.

Response Payload:

{

```
"id": "13963644-11b0-4302-a13b-26ca3d9eb8f8",
 "objectInstanceIds": [
    "cc6a34e5-0463-459a-b367-493ba997775f"
 "criteria": {
   "performanceMetric": [
     "default"
   1,

    "reportingPeriod": 14400,
    "reports": [
        "href": "uri_where_report_can_be_obtained",
        "readyTime": "2018-08-20T06:17:35.081+0000",
        "expiryTime": "2018-10-20T06:17:35.081+0000",
        "fileSize": "5000"
   ]
   links": {
    "self": {
     "href": "http://host:port/vnfpm/v1/pm jobs/13963644-11b0-4302-a13b-26ca3d9eb8f8"
    "objects": [
     {
        "href":
"http://host:port/vnflcm/v1/vnf instances/cc6a34e5-0463-459a-b367-493ba997775f"
 }
```

A reports section is added to the response payload (as shown above) only if a report is available.

All the attribute names in the response payload and data types referenced from the attribute names are supported in the attribute-based filtering.

Delete a Performance Management Job

The NFVO sends a delete request to the existing performance management job.

```
DELETE {api_root}/vnfpm/v1/pm_jobs/{pmJobId}
```

The NFVO is notified using the PerformanceInformationAvailableNotification notification.

Configuring Threshold for Performance Management Job

This seciton describes how to set the threshold for the performance management jobs.

Create a Threshold

The NFVO sends a create request to create a threshold for the performance management job.

Method Type:

POST

```
VNFM Endpoint:
```

```
{\tt api\_root} / {\tt vnfpm/v1/thresholds} \ \ ({\tt Datastructure=CreateThresholdRequest})
```

Request Payload:

```
{
  "objectInstanceId": "cc6a34e5-0463-459a-b367-493ba997775f",
  "criteria": {
    "performanceMetric": "default",
    "thresholdType": "SIMPLE",
    "simpleThresholdDetails": {
        "thresholdValue": 0.8,
        "hysteresis": 0.9
    }
}
```

Response Payload:

```
"id": "23f52511-9f72-4797-881b-c0f72e60a052",
 "objectInstanceId": "cc6a34e5-0463-459a-b367-493ba997775f",
 "criteria": {
   "performanceMetric": "default",
    "thresholdType": "SIMPLE",
    "simpleThresholdDetails": {
     "thresholdValue": 0.8,
      "hysteresis": 0.9
  " links": {
    "self": {
     "href": "http://host:port/vnfpm/v1/thresholds/23f52511-9f72-4797-881b-c0f72e60a052"
    "object": [
        "href":
"http://host:port/vnflcm/v1/vnf instances/cc6a34e5-0463-459a-b367-493ba997775f"
     }
    1
}
```

Query an Individual Threshold

The NFVO can query the threshold of a performance management job.

GET

```
VNFM Endpoint:
```

```
{api_root}/vnfpm/v1/thresholds/{thresholdId}
```

Request Payload: NA

```
|
| "id": "23f52511-9f72-4797-881b-c0f72e60a052",
| "objectInstanceId": "cc6a34e5-0463-459a-b367-493ba997775f",
```

```
"criteria": {
    "performanceMetric": "default",
    "thresholdType": "SIMPLE",
    "simpleThresholdDetails": {
     "thresholdValue": 0.8,
     "hysteresis": 0.9
 },
 " links": {
    "self": {
     "href": "http://host:port/vnfpm/v1/thresholds/23f52511-9f72-4797-881b-c0f72e60a052"
    "object": [
       "href":
"http://host:port/vnflcm/v1/vnf instances/cc6a34e5-0463-459a-b367-493ba997775f"
     }
    ]
 }
```

Attribute-based filtering is not possible when specifying a threshold id.

Query All Thresholds

The NFVO can query the threshold of a performance management job.

Method Type:

GET

VNFM Endpoint:

{api_root}/vnfpm/v1/thresholds

Request Payload: NA

```
"id": "23f52511-9f72-4797-881b-c0f72e60a052",
 "objectInstanceId": "cc6a34e5-0463-459a-b367-493ba997775f",
 "criteria": {
   "performanceMetric": "default",
    "thresholdType": "SIMPLE",
   "simpleThresholdDetails": {
     "thresholdValue": 0.8,
     "hysteresis": 0.9
    }
 },
 " links": {
   "self": {
     "href": "http://host:port/vnfpm/v1/thresholds/23f52511-9f72-4797-881b-c0f72e60a052"
    },
    "object": [
       "href":
"http://host:port/vnflcm/v1/vnf instances/cc6a34e5-0463-459a-b367-493ba997775f"
     }
```

}

Note

All the attribute names in the response payload and data types referenced from the attribute names are supported in the attribute-based filtering.

Delete a Threshold

The NFVO sends a delete request to delete the threshold configuration of the existing performance management job.

```
DELETE {api root}/vnfpm/v1/thresholds/{thresholdId}
```

The NFVO receives the ThresholdCrossedNotification if ESC crosses a configured threshold.

Subscribing to Performance Management Job

This section describes subscribing to the performance management jobs.

Create a Performance Management Subscription

The NFVO can subscribe to the performance management jobs.

Method Type:

POST

VNFM Endpoint:

 ${\tt \{api_root\}/vnfpm/v1/subscriptions}\ ({\tt DataStructure=PmSubscriptionRequest})$

Example 1:

Request Payload:

```
"callbackUri": "http://host:port/notification",
           "filter": {
                      "notificationTypes": ["ThresholdCrossedNotification",
"PerformanceInformationAvailableNotification"],
                      "vnfInstanceSubscriptionFilter": {
                            "vnfdIds": ["25ec9e1c-ad9e-4613-9280-411920f3649a"],
                             "vnfInstanceIds": ["cc6a34e5-0463-459a-b367-493ba997775f"]
                          }
                   Response Payload:
                   {
                           "id": "4fba7dcb-e015-4674-9c50-8cee7059eb91"
                           "callbackUri": "http://host:port/notification",
                              "filter": {
                                             "notificationTypes": ["ThresholdCrossedNotification",
                   PerformanceInformationAvailableNotification"],
                                              "vnfInstanceSubscriptionFilter": {
```

```
"vnfdIds": ["25ec9e1c-ad9e-4613-9280-411920f3649a"],
                                        "vnfInstanceIds":
["cc6a34e5-0463-459a-b367-493ba997775f"]
         " links": {
                    "self": {
                                      "href":
"http://host:port/vnfpm/v1/subscriptions/4fba7dcb-e015-4674-9c50-8cee7059eb91"
           }
Example 2:
Request Payload:
{
      "callbackUri": "http://host:port/notification",
                 "notificationTypes": ["ThresholdCrossedNotification",
"PerformanceInformationAvailableNotification"],
                  "vnfInstanceSubscriptionFilter": {
                                   "vnfProductsFromProviders": [{
                                                       "vnfProvider": "Cisco",
                                                        "vnfProducts": [{
                                                              "vnfProductName": "vnfd-1VDU",
                                                                         "versions": [{
"vnfSoftwareVersion": "1.3.1",
                                                                             "vnfdVersions":
 ["1.0", "1.1", "1.2"]
                                                                     }]
                                                         } ]
                                       }],
                                  "vnfInstanceNames":
["kaswaczy-TestETSIPmSubscriptionGet-114113"]
Response Payload:
{
      "id": "4fba7dcb-e015-4674-9c50-8cee7059eb92"
       "callbackUri": "http://host:port/notification",
         "filter": {
                    "notificationTypes": ["ThresholdCrossedNotification",
"PerformanceInformationAvailableNotification"],
                      "vnfInstanceSubscriptionFilter": {
                      "vnfProductsFromProviders": [{
                                                        "vnfProvider": "Cisco",
                                                        "vnfProducts": [{
                                                                           "vnfProductName":
 "vnfd-1VDU",
                                                                           "versions": [{
"vnfSoftwareVersion": "1.3.1",
"vnfdVersions": ["1.0", 1.1", 1.2"]
                                                                        } ]
                                                          } ]
                                        }],
```

- The vnfdIds and vnfProductsFromProviders attributes are mutually exclusive. Only one of them can be provided in a single create request.
- The vnfInstanceIds and vnfInstanceNames attributes are mutually exclusive. Only one of them can be provided in a single create request.
- If the specified callbackUri and filter precisely matches an existing subscription, the create subscription operation will fail with an error message stating duplicate subscriptions are not allowed.

Query an Individual Performance Management Subscription

Method Type:

GET

VNFM Endpoint:

 $\{ \verb"api_root"\} / \verb"vnfpm/v1/subscriptions/ \{ \verb"subscriptionId"\} \}$

Request Payload: NA

Attribute-based filtering is not possible when specifying a subscription id.

Query all Performance Management Subscriptions

Method Type:

GET

{api root}/vnfpm/v1/subscriptions

Request Payload: NA

```
" embedded": {
                                "pmSubscriptions": [{
                                                "id":
"4fba7dcb-e015-4674-9c50-8cee7059eb91""callbackUri": "http://host:port/notification",
                                                "filter": {
                                                                "notificationTypes":
["ThresholdCrossedNotification", "PerformanceInformationAvailableNotification"],
"vnfInstanceSubscriptionFilter": {
                                                                               "vnfdIds":
 ["25ec9e1c-ad9e-4613-9280-411920f3649a"],
"vnfInstanceIds": ["cc6a34e5-0463-459a-b367-493ba997775f"]
                                                                                "href":
"http://host:port/vnfpm/v1/subscriptions/4fba7dcb-e015-4674-9c50-8cee7059eb91"
                               },
                                                "id":
"4fba7dcb-e015-4674-9c50-8cee7059eb92""callbackUri": "http://host:port/notification",
                                                "filter": {
                                                                "notificationTypes":
["ThresholdCrossedNotification", "PerformanceInformationAvailableNotification"],
"vnfInstanceSubscriptionFilter": {
"vnfProductsFromProviders": [{
       "vnfProvider": "Cisco",
       "vnfProducts": [{
                       "vnfProductName": "vnfd-1VDU",
                       "versions": [{
                                        "vnfSoftwareVersion": "1.3.1",
                                        "vnfdVersions": ["1.0", "1.1", "1.2"]
```

All attribute names and data types referenced in the response payload are supported in attribute-based filtering of the parameters.

Terminate a Performance Management Subscription

The NFVO can terminate a subscription.

DELETE {api_root}/vnfpm/v1/subscriptions/{subscriptionId}

Subscribing to Performance Management Job

ETSI Production Properties

• ETSI Production Properties, on page 87

ETSI Production Properties

There are many properties that can be set to determine the behaviour of ESC. These properties enable integration of ESC with the NFVO in the system architecture.

You can access the properties file in the following location:

/opt/cisco/esc/esc_database/etsi-production.properties

The following table describes the parameters that can be used to control the behaviour of ESC acting as a VNFM within the ETSI NFV MANO stack.

Table 5: ETSI Production Properties

Property Name	Description	Туре	Default Value
server.host	The host IP address on which the ETSI service is located. This is a mandatory property if the server has multiple IP addresses, or if the deployment is configured for High Availability (it should then be set to the VIP).	String	
server.host.preferInet6	Where there are multiple IP address types assigned to the server, use the IPv6 address over any IPv4 address.	Boolean	false
server.port	The port used to communicate over HTTP.	Integer	8250

Property Name	Description	Туре	Default Value
server.port.https	The port used to communicate over HTTPS.	Integer	8251
certificate.validation	Determine whether to validate a host in any certificate presented when using HTTPS. Allows for looser validation, especially useful in testing.	Boolean	true
notification.maxThreads	The maximum number of threads utilised for the notification service.	Integer	3
notification.subscription.test	Upon creating a new subscription, determine whether to test	Boolean	true
notification.links.httpScheme	The HTTP scheme used for communicating with the NFVO for notifications. Valid values: http, https.	Enum	https
notification.retry.maxAttempt	The number of retries for the notification retry mechanism.	Integer	5
notification.retry.backOff.delay	The interval for the notification retry mechanism.	Integer	1000
security.user.name	Mandatory. This is the REST API username. It is set by sudo escadm etsi set rest_user <username>:<password> and should be synchronized here.</password></username>	String	
nfvo.apiRoot	Mandatory. The apiRoot for the NFVO.	String	localhost:8280

Property Name	Description	Туре	Default Value
nfvo.httpScheme	The HTTP scheme used for communicating with the NFVO. Valid values: http, https.	Enum	http
nfvo.isPackageNotificationSupported	Determine if the VNFM will attempt to subscribe to package notifications.	Boolean	true
nfvo.callback.httpScheme	The HTTP scheme used for communicating with the NFVO when polling for responses. Valid values: http, https.	Enum	https
nfvo.username	The username for NFVO credentials.	String	
nfvo.password	The password for NFVO credentials, required in plain text.	String	
retryTemplate.expotential.retryPolicy.maxAttempt	The number of retries for the exponential retry mechanism.	Integer	1000
retryTemplate.expotential.backOffPolicy.interval.initial	The starting interval for the exponential retry mechanism.	Integer	1000
retry.simple.maxAttempt	The number of retries for the simple retry mechanism.	Integer	50
retry.simple.backOff.delay	The interval for the simple retry mechanism.	Integer	1000
nfvo.allPackagesFilter	The value to use to filter packages on the NFVO when querying for packages.	String	

Property Name	Description	Туре	Default Value
mapping.vim Connection Info. access Info. username	Provide an alternate attribute name when specifying the username in accessInfo.	String	username
mapping.vim Connection Info. access Info. password	Provide an alternate attribute name when specifying the password in accessInfo.	String	password
mapping.vimConnectionInfo.accessInfo.project	Provide an alternate attribute name when specifying the project in accessInfo.	String	project
mapping.vimConnectionInfo.accessInfo.projectDomain	Provide an alternate attribute name when specifying the projectDomain in accessInfo.	String	projectDomain
mapping.vim Connection Info. access Info. user Domain	Provide an alternate attribute name when specifying the userDomain in accessInfo.	String	userDomain
mapping.vimConnectionInfo.accessInfo.vim_project	Provide an alternate attribute name when specifying the vim_project in accessInfo.	String	vim_project
mapping.vimConnectionInfo.accessInfo.vim_vdc	Provide an alternate attribute name when specifying the vim_vdc in accessInfo.	String	vim_vdc
nfvo.grantRequest.retry.maxAttempt	The number of retries for failed GrantRequest attempts.	Integer	5
nfvo.grantRequest.retry.backOff.delay	The interval for the retries for failed GrantRequest attempts.	Integer	1000

Property Name	Description	Туре	Default Value
spring.jackson.date-format	A string to represent a date format to allow for varying NFVO implementations to read dates correctly.	String	yyyAMA dF Hnn s SSSXXX
nfvo.authenticationType	Setting the authentication type of the NFVO that is being used. Optional property. Valid options are "BASIC", "OAUTH2", "OFF". All other Strings will be treated the same as "OFF". Use this to enable Basic and OAuth2 authentication.	String	
nfvo.clientID	For NFVO OAuth2 Authentication. Client ID.	String	
nfvo.clientSecret	For NFVO OAuth2 Authentication. Client Secret.	String	
nfvo.tokenEndpoint	For NFVO OAuth2 Authentication. The endpoint for ETSI to retrieve a OAuth2 token from the NFVO.	String	
rate.limit.capacity.read	Set the bucket capacity for read (GET) requeusts to the ETSI REST API.	Integer	
	By default this is disabled.		
rate.limit.perSecond.read	Sets the rate (per second) at which the bucket empties for the read (GET) requests to the ETSI REST API.	Double	
	By default this is disabled.		

Property Name	Description	Туре	Default Value
