Domain filtering is applied to all the DNS traffic even if the DNS requests are made in the context of non-HTTP(S) requests such as FTP, telnet, and so on. The blocked listed non-HTTP(S) traffic (FTP, telnet, and so on.) will also be forwarded to the block server. It is block server's responsibility to serve a block page or deny the request. You can configure an internal or external block server. For configuration steps, see [Configure Domain-based Web Filtering with an External Block Server, on page 2120](#) and [Configure Domain-based Web Filtering with a Local Block Server , on page 2121](#).

If the traffic is not part of the allowed list or on the blocked list during domain filtering, it will be subjected to URL filtering and Snort IPS if they are configured.

A user may consider using a combination of domain filtering allowed and blocked pattern lists to design the filters. For example, if a user wants to create an allowed list `www\foo\com` but also wants other domains on a blocked list, such as `www\foo\abc` and `www\foo\xyz`, configure the `www\foo\com` in the allowed list pattern and `www\foo\` in the blocked list pattern.

Note If you are using the `www` prefix in the allowed or blocked regex pattern, it can create a problem if the Server Name Indicator (SNI) returned in the client message doesn't match. For example, if you want to allow `www.foo.com` and SNI returns as `foo.com` only. We recommend not to include the `www` in the regex match.

URL-based Filtering

URL-based filtering allows a user to control access to Internet websites by permitting or denying access to specific websites based on the allowed list/blocked list, category, or reputation configuration. For example, when a client sends a HTTP/HTTP(s) request through the Cisco CSR 1000V Cloud Services Router, the HTTP/HTTP(s) traffic is inspected based on the URL filtering policies (Allowed list, Blocked list, Category, and Reputation). If the HTTP/HTTP(s) request matches the blocked list, the HTTP(s) request is blocked either by inline block page response or redirects the URL to a block server. If the HTTP/HTTP(s) request matches the allowed list, the traffic is allowed without further URL filtering inspection.

For HTTPS traffic, the inline block page will not be displayed. URL-based filtering will not decode any encoded URL before performing a lookup.

When there is no allowed list/blocked list configuration on the device, based on the category and reputation of the URL, traffic is allowed or blocked either using a block page or redirect URL for HTTP. For HTTP(s), there is no block page or redirect URL, the flow will be dropped.

The URL database is downloaded from the cloud when the user configures the category/reputation-based URL filtering. The URL category/reputation database has only a few IP address based records and the category/reputation look up occurs only when the host portion of the URL has the domain name. After the full database is downloaded from the cloud, if there are any updates to the existing database, the incremental updates will be automatically downloaded in every 15 minutes. The complete database size is approximately 440 MB and the downloaded database should always synchronize with the cloud. The database will be invalid if the connection to the cloud is lost for more than 24 hours.

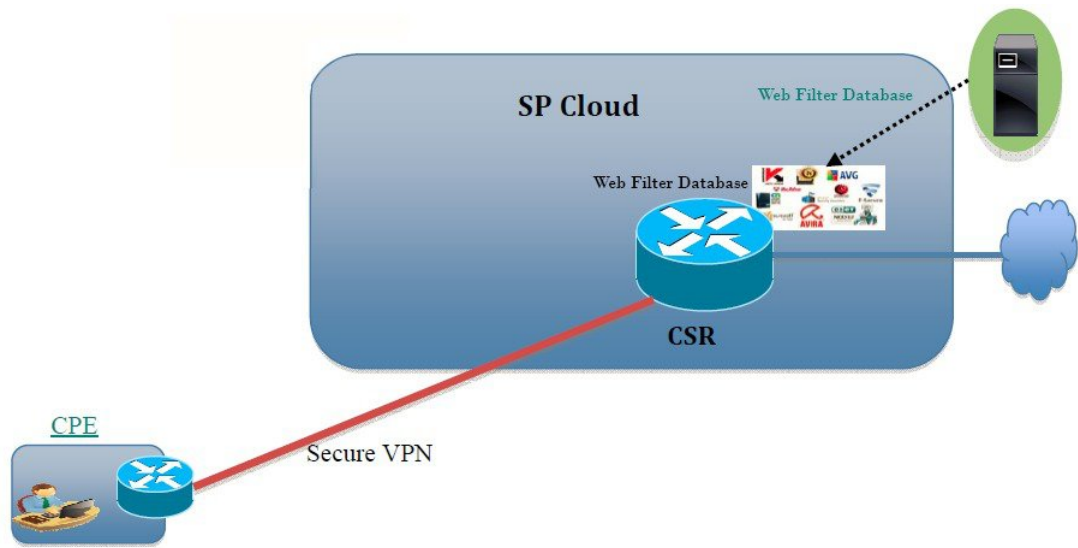

If the device does not get the database updates from the cloud, the fail-open option ensures that the traffic designated for URL filtering is not dropped. When you configure the fail-close option, all the traffic destined for URL filtering will be dropped when the cloud connectivity is lost.

Note The web filtering database is periodically updated from the cloud in every 15 minutes.

The figure illustrates the Web Filtering topology.

Figure 87: Web Filtering Network Topology

385194

Virtual Service Resource Profiles for URL Filtering

The Cisco ISR 4000 Series Integrated Services Routers support *urlf-medium* and *urlf-high* resource profiles along with *urlf-low* profile. These profiles indicate the CPU and memory resources required to run the virtual service.

Platform	Profile	Virtual Service Resource Requirements		Platform Requirements
		System CPU	SP Memory	
CSR1000v, ISRv	<i>urlf-low</i>	25%	3 GB	8 GB (RAM)
	<i>urlf-medium</i>	50%	4 GB	8 GB (RAM)
	<i>urlf-high</i>	75%	6 GB	12 GB (RAM)

Cloud-Lookup

The Cloud-Lookup feature operates in single-tenancy mode to retrieve the category and reputation score of URLs that are not available in the local database. The Cloud-Lookup feature is enabled by default.

The Cloud-Lookup feature is an enhancement over the on-box database lookup feature. Earlier, the on-box database lookup feature allowed URLs that are not present in the on-box database and have a reputation score of 0. When Cloud-Lookup is enabled, the URLs that were allowed earlier may be dropped based on the reputation score and the configured block-threshold. In order to allow such URLs, one must add them to an allowed list. Category and reputation scores for different URLs from Cloud-Lookup are explained below.

There are two kinds of URLs:

- Name based URLs
- IP based URLs

When the Cloud-Lookup feature is enabled, the category and reputation score of unknown URLs are returned as follows:

Name based URLs

- Valid URL — corresponding category and reputation score is received.
- Unknown URL (new URL or unknown to the cloud) — category is 'uncategorized' and reputation score is 40
- Internal URLs with proper domain name (for example, internal.abc.com) — category and reputation score is based on the base domain name (abc.com from the example above).
- Completely internal URLs (for example, abc.xyz) — category is 'uncategorized' and reputation score is 40

IP based URLs

- Public hosted IP — corresponding category and reputation score is received.
- Private IP like 10.\diamond, 192.168.\diamond — category is 'uncategorized' and reputation score is 100
- Non-hosted/Non-routable IP — category is 'uncategorized' and reputation score is 40

The Cloud-Lookup score is different from the on-box database for these URLs (Unknown/Non-hosted/Non-routable/Internal URLs).

Note The Cloud-Lookup feature is not available in multi-tenancy mode.

Benefits of Web Filtering

The Web Filtering feature allows a user to provide controlled access to the internet by configuring domain and URL based policies and filters. It helps to secure the network by blocking malicious or unwanted websites. Web Filtering comprises of URL-based filtering and the Domain-based filtering. Domain-based filtering helps control access to websites/servers at domain level and the URL-based filtering helps control access to websites at URLs level. A user can use web filtering to add an individual URL to a blocked list or domain names and configure allowed listing policies for the same. A user can also provision to allow or block a URL based on reputation or category.

Prerequisites for Web Filtering

Before you configure the web filtering feature on the Cisco CSR 1000V Cloud Services Router, ensure that you have the following:

- The Cisco CSR 1000V Cloud Services Router runs the Cisco IOS XE Denali 16.3 software image or later.
- The Cisco CSR 1000V Cloud Services Router requires 2 vCPU, 8GB memory, and 2GB extra disk space for deploying the container service.

- The Cisco CSR 1000V Cloud Service Router must have a security K9 license to enable the web filtering feature.

Restrictions for Web Filtering

The following restrictions apply to the web filtering feature:

- This feature is only supported on Cisco CSR 1000V Cloud Services Router and it is not supported on Cisco 4000 Series Integrated Services Routers.
- The allowed list/blocked list pattern supports only regex pattern, and currently 64 patterns are supported for allowed list/blocked list. For more information on regex pattern, see the [Regular Expressions](#) chapter.
- Domain filtering supports only the IPv4 domains resolved through DNS protocol using IPv4 UDP transport. Domain filtering alerts are sent only to IOS syslog.
- Domain filtering with OpenDNS is not supported.
- URL filtering with Virtual Routing and Forwarding (VRF) is not supported.
- Domain filtering with CWS is not supported.
- Domain filtering does not support category and reputation.
- Local block server does not support serving HTTPS block page. When the URL filter tries to inject block page or redirect message, it does not support HTTPS traffic.
- When there is a username and password in the URL, URL filter does not remove them from the URL before matching the allowed list/blocked list pattern. However, the category/reputation lookup does not have this limitation and removes the username and password from the URL before lookup.
- HTTPS inspection is limited. Web filtering uses server certificate to obtain the URL/domain information. It is not possible to inspect the full URL path.
- UTD does not inter-operate with WCCP, and NBAR under inter-VRF scenario.
- Web filter profile names for URL, domain, block and sourcedb can have only alpha-numeric characters, dashes and underscores.
- If a virtual-service profile is modified, the virtual-service must be re-installed for the profile change to take effect.

How to Deploy Web Filtering

To deploy web filtering on supported devices, perform the following tasks:

Before you begin

- **Provision the device:** Identify the device to install the Web Filtering feature. This feature is supported on Cisco CSR 1000V Cloud Services Router.
- **Obtain the license:** The web filtering functionality is available only in security packages which require a security license to enable the service. Contact Cisco Support to obtain the license.

-
- Step 1** Install and activate the virtual container service—[How to Install and Activate the Virtual Container Service](#) , on page 2119
 - Step 2** Configure the domain-based web filtering with an external block server—[Configure Domain-based Web Filtering with an External Block Server](#), on page 2120
 - Step 3** Configure the domain-based web filtering with local block server—[Configure Domain-based Web Filtering with a Local Block Server](#) , on page 2121
 - Step 4** Configure the URL-based web filtering with a local block server—[Configure URL-based Web Filtering with a Local Block Server](#), on page 2123
 - Step 5** Configure the URL-based web filtering with an Inline block server—[Configure URL-based Web Filtering with an Inline Block Page](#), on page 2125
 - Step 6** Configure the Snort IPS/IDS—[Configuring Domain/URL based Web Filtering and Snort IPS](#), on page 2126
-

How to Install and Activate the Virtual Container Service

To install and activate the virtual container service, perform the following task:

-
- Step 1** Install the UTD OVA file—[Installing the UTD OVA File](#), on page 2119.
 - Step 2** Configure the VirtualPortGroup interfaces and virtual-service—[Configuring VirtualPortGroup Interfaces and Virtual Service](#), on page 2119.
 - Step 3** Activate the Snort virtual container service.
-

Installing the UTD OVA File

An OVA file is an Open Virtualization Archive that contains a compressed, installable version of a virtual machine. You must download this OVA file on to the router and use the virtual-service install CLI to install the service. The service OVA file is not bundled with the Cisco IOS XE Release images that are installed on the router. However, the OVA files may be preinstalled in the flash of the router.

You must use a Cisco IOS XE image with security license. During the OVA file installation, the security license is checked and an error is reported if the license is not present.

This is the sample configuration:

```
Device> enable
Device# virtual-service install name UTDIPS package harddisk:utd-ips-v102.ova media harddisk:

Device# show virtual-service list
Virtual Service List:
Name Status Package Name
-----
snort Installed utdsnort.1_2_2_SV2982_XE_main.20160
```

Configuring VirtualPortGroup Interfaces and Virtual Service

You must configure two VirtualPortGroup interfaces and configure guest IP addresses for both interfaces.

Note The VirtualPortGroup interface for data traffic must use a private or nonroutable IP address. We recommend the use of 192.0.2.0/30 IP address range for this interface.

This is the sample configuration:

```
Device# configure terminal
Device(config)# interface VirtualPortGroup0
Device(config-if)# ip address 192.0.2.1 255.255.255.252
Device(config-if)# exit
Device(config)# interface VirtualPortGroup 1
Device(config-if)# ip address 192.0.2.5 255.255.255.252
Device(config-if)# exit
Device(config)# virtual-service UTDIPS

Device(config-virt-serv)# profile urlf-low (This is minimum requirement for web filtering
to work.)

Device(config-virt-serv)# vnic gateway VirtualPortGroup 0 (The IP-address configured in
VPG0 interface should have access to Internet over http(s).If the VPG0 interface does not
have access to Internet, the web filter database will not be updated.)
Device(config-virt-serv-vnic)# guest ip address 192.0.2.2
Device(config-virt-serv-vnic)# exit
Device(config-virt-serv)# vnic gateway VirtualPortGroup 1
Device(config-virt-serv-vnic)# guest ip address 192.0.2.6
Device(config-virt-serv-vnic)# exit
Device(config-virt-serv)# activate
Device(config-virt-serv)# end

Device# show virtual-service list
Virtual Service List:

Name                               Status           Package Name
-----
snort                               Activated       utdsnort.1_2_2_SV2982_XE_main.20160
```

Configure Domain-based Web Filtering with an External Block Server

To configure domain-based web filtering with an external block server, perform these steps:

- Step 1** Install and activate the virtual service. For more information, see [Configuring VirtualPortGroup Interfaces and Virtual Service, on page 2119](#).
- Step 2** Configure the blocked list parameter-map:

```
parameter-map type regex domainfilter_blacklist_pmap1
  pattern examplebook\.com
  pattern bitter\.com
```
- Step 3** Configure the allowed list parameter-map:

```
parameter-map type regex domainfilter_whitelist_pmap1
  pattern example\.com
  pattern exmaplegoogle\.com
```
- Step 4** Configure the domain profile and associate the blocked list and allowed list parameter-maps:

```

utd web-filter domain profile 1
  blacklist
  parameter-map regex domainfilter_blacklist_pmap1
  whitelist
  parameter-map regex domainfilter_whitelist_pmap1

```

Step 5 (Optional) By default the domain filtering alerts are not enabled. Configure the alerts for the blocked list or allowed list, or both under the domain profile:

```

alert {all | blacklist | whitelist}

```

Step 6 Configure the external redirect-server under the domain profile:

```

redirect-server external x.x.x.x (This is the IP address that is used for serving block page when a
page is on the blocked list)

```

Step 7 Configure the UTD engine standard with domain profile:

```

utd engine standard
  web-filter
  domain-profile 1

```

Step 8 Configure the UTD with engine standard and enable it globally or on a specific interface:

```

utd
  all-interfaces
  engine standard

```

This example shows how to configure domain-based web filtering with an external block server:

```

parameter-map type regex domainfilter_blacklist_pmap1
  pattern examplebook\.com
  pattern bitter\.com
parameter-map type regex domainfilter_whitelist_pmap1
  pattern exmaplegoogle\.com
  pattern exmaplegoogle\.com
utd engine standard
  web-filter
  domain-profile 1
!
utd web-filter domain profile 1
  alert all
  blacklist
  parameter-map regex domainfilter_blacklist_pmap1
  whitelist
  parameter-map regex domainfilter_whitelist_pmap1
  redirect-server external 192.168.1.1
!
utd
  all-interfaces
  engine standard

```

Configure Domain-based Web Filtering with a Local Block Server

To configure domain-based web filtering with a local block server, perform these steps:

Step 1 Install and activate the virtual service. For more information, see [Configuring VirtualPortGroup Interfaces and Virtual Service, on page 2119](#).

Step 2 Configure a loopback interface or use any existing interface that the client can access:

```
interface loopback 110
 ip address 10.1.1.1 255.255.255.255
exit
```

Step 3 Configure the UTD web filter with the local block server profile:

```
utd web-filter block local-server profile 1
 block-page-interface loopback 110
 http-ports 80
 content text "Blocked by Web-Filter"
```

Step 4 Configure the blocked list parameter-map:

```
parameter-map type regex domainfilter_blacklist_pmap1
 pattern bitter\.com
```

Step 5 Configure the allowed list parameter-map:

```
parameter-map type regex domainfilter_whitelist_pmap1
 pattern sweet\.com
```

Step 6 Configure the domain profile and associate the blocked list and allowed list parameter-maps:

```
utd web-filter domain profile1
 blacklist
 parameter-map regex domainfilter_blacklist_pmap1
 whitelist
 parameter-map regex domainfilter_whitelist_pmap1
```

Step 7 (Optional) By default the domain filtering alerts are not enabled. Configure the alerts for blocked list or allowed list, or both under the domain profile:

```
alert {all |blacklist | whitelist}
```

Step 8 Configure the redirect-server as local block server under the domain profile:

```
redirect-server local-block-server 1
```

Step 9 Configure the UTD engine standard with domain profile:

```
utd engine standard
 web-filter
 domain-profile 1
```

Step 10 Configure the UTD with engine standard and enable it globally or on a specific interface:

```
utd
 all-interfaces
 engine standard
```

This example shows how to configure a domain-based web filtering with a local block server:

```
interface loopback 110
 ip address 10.1.1.1 255.255.255.255
exit
parameter-map type regex domainfilter_blacklist_pmap1
 pattern bitter\.com
parameter-map type regex domainfilter_whitelist_pmap1
 pattern sweet\.com
utd engine standard
 web-filter
 domain-profile 1
!
```

```

utd web-filter block local-server profile 1
  block-page-interface Loopback110
  content text "Blocked by Web-Filter"
  http-ports 80
!
utd web-filter domain profile 1
  alert all
  blacklist
    parameter-map regex domainfilter_blacklist_pmap1
  whitelist
    parameter-map regex df_whitelist_pmap1
  redirect-server local-block-server 1
!
utd
  all-interfaces
  engine standard

```

Configure URL-based Web Filtering with a Local Block Server

To configure URL-based web filtering with a local block server, perform these steps:

Step 1 Install and activate the virtual service. For more information, see [Configuring VirtualPortGroup Interfaces and Virtual Service, on page 2119](#).

Step 2 Configure a loopback interface or use any existing interface that the client can access:

```

interface loopback 110
 ip address 10.1.1.1 255.255.255.255
exit

```

Step 3 Configure the UTD web filter with the local block server profile:

```

utd web-filter block local-server profile 1
  block-page-interface loopback 110
  http-ports 80
  content text "Blocked by Web-Filter"

```

Step 4 Configure the blocked list parameter-map:

```

parameter-map type regex urlf_blacklist_pmap1
 pattern exmplee.com/sports

```

Step 5 Configure the allowed list parameter-map:

```

parameter-map type regex urlf_whitelist_pmap1
 pattern examplehoo.com/finance

```

Step 6 Configure the URL profile and do the following:

```

utd web-filter url profile 1

```

a) Associate the blocked list and allowed list parameter-maps:

```

blacklist
  parameter-map regex urlf_blacklist_pmap1
whitelist
  parameter-map regex urlf_whitelist_pmap1

```

- b) Configure the alerts for blocked list, allowed list or both under the local block-server profile:

```
alert {all | blacklist | whitelist}
```

- c) Configure the categories to be allowed or blocked:

```
categories allow
sports
```

- d) Configure the reputation block threshold:

```
reputation
block-threshold high-risk
```

- e) Configure the URL source database with the fail option:

```
sourcedb fail close
```

- f) Configure the log level. The default option is error. When you set the option to **info** or **detail**, the performance may impact:

```
log level error
```

- g) Configure local block server:block

```
block local-server 1
```

- Step 7** Configure the UTD engine standard with URL profile:

```
utd engine standard
web-filter
url-profile 1
```

- Step 8** Configure the UTD engine standard and enable the UTD on a global or specific interface:

```
utd
all-interfaces
engine standard
```

This example shows how to configuration a URL-based web filtering with a local block server:

```
parameter-map type regex urlf_blacklist_pmap1
pattern examplee.com/sports
parameter-map type regex urlf_whitelist_pmap1
pattern exmaplehoo.com/finance
!
interface loopback 110
ip address 10.1.1.1 255.255.255.255
exit
utd web-filter block local-server profile 1
block-page-interface loopback 110
http-ports 80
content text "Blocked by Web-Filter"
utd web-filter url profile 1
blacklist
parameter-map regex urlf_blacklist_pmap1
whitelist
parameter-map regex urlf_whitelist_pmap1
alert all
categories allow
sports
reputation
block-threshold high-risk
```

```

sourcedb fail close
log level error
block local-server 1
!
utd engine standard
web-filter
  url-profile 1
!
utd
all-interfaces
engine standard

```

Configure URL-based Web Filtering with an Inline Block Page

To configure URL-based web filtering with an in-line block page, perform these steps:

Step 1 Install and activate the virtual service. For more information, see [Configuring VirtualPortGroup Interfaces and Virtual Service, on page 2119](#).

Step 2 Configure the blocked list parameter-map:

```

parameter-map type regex urlf_blacklist_pmap1
pattern exmaplegoogle.com/sports

```

Step 3 Configure the allowed list parameter-map:

```

parameter-map type regex urlf_whitelist_pmap1
pattern exmaplehoo.com/finance

```

Step 4 Configure the UTD block page profile:

```

utd web-filter block page profile 1
text "Blocked by Web-Filter URLF" (The other options are file and redirect-url)

```

Step 5 Configure the URL profile and do the following:

```

utd web-filter url profile 1

```

a) Associate the blocked list and allowed list parameter-maps:

```

blacklist
  parameter-map regex urlf_blacklist_pmap1
whitelist
  parameter-map regex urlf_whitelist_pmap1

```

b) Configure the alerts for blocked list, allowed list or both under the local block-server profile:

```

alert {all | blacklist | whitelist | categories-reputation}

```

c) Configure the categories to be allowed or blocked:

```

categories allow
sports

```

d) Configure the reputation block threshold:

```

reputation
  block-threshold high-risk

```

e) Configure the URL source database with the fail option:

```
sourcedb fail close
```

- f) Configure the log level. The default option is error. When you set the option to **info** or **detail**, the performance may impact:

```
log level error
```

- g) Configure local block server:block

```
block local-server 1
```

- Step 6** Configure the UTD engine standard with URL profile:

```
utd engine standard
web-filter
url-profile 1
```

- Step 7** Configure the UTD engine standard and enable the UTD on a global or specific interface:

```
utd
all-interfaces
engine standard
```

This example shows how to configuration an URL-based web filtering with an inline block server:

```
parameter-map type regex urlf_blacklist_pmap1
pattern exmaplegoogle.com/sports
parameter-map type regex urlf_whitelist_pmap1
pattern exmaplehoo.com/finance
!
utd web-filter block page profile 1
text "Blocked by Web-Filter URLF"
!
utd web-filter url profile 1
blacklist
parameter-map regex urlf_blacklist_pmap1
whitelist
parameter-map regex urlf_whitelist_pmap1
alert all
categories allow
sports
reputation
block-threshold high-risk
sourcedb fail close
log level error
!
utd engine standard
web-filter
url-profile 1
!
utd
all-interfaces
engine standard
```

Configuring Domain/URL based Web Filtering and Snort IPS

To configure Domain/URL based web filtering and Snort IPS, perform these steps:

Step 1 Configure the domain profile:

```
utd web-filter domain profile 1
```

Step 2 Configure the URL profile:

```
utd web-filter url profile 1
```

Step 3 Configure the threat-inspection under UTD engine standard:

```
utd engine standard
threat-inspection
```

Step 4 Configure the web-filter under UTD engine standard with the domain and URL profiles:

```
utd engine standard
logging syslog
threat-inspection
threat protection
policy security
signature update server cisco username xxx password QhLb]Z[ifMbFgLYgR]^KLDUZ
signature update occur-at daily 0 0
logging level error
web-filter
domain-profile 1
url-profile 1
```

Step 5 Configure the UTD engine standard and enable it globally or on a specific interface:

```
utd
all-interfaces
engine standard
```

Verifying the Web Filter Configuration

You can verify the Web Filtering configuration using the following commands:

```
Device# show utd engine standard config
```

```
UTD Engine Standard Configuration:
Operation Mode : Intrusion Detection
Policy        : Balanced

Signature Update: Not Configured

Logging:
Server       : IOS Syslog
Level        : err (Default)
Statistics    : Disabled

Whitelist    : Disabled
Whitelist Signature IDs:

Web-Filter   : Enabled

Whitelist :
www.cisco.com
```

```

Blacklist :
  www.hotstar.com

Categories Action : Block
Categories :
  Fashion and Beauty

Block Profile:
  No config present

Reputation Block Threshold : Moderate risk
Alerts Enabled : Blacklist
Cloud Lookup : Enabled
Debug level : Error
Conditional debug level : Error

```

Troubleshooting Web Filtering

To collect the logs, use the **virtual-service move name "CONTAINER_NAME" log to bootflash:** command. You can troubleshoot issues that are related to enabling Web Filtering feature using the following commands on the device:

- **debug utd engine standard all**
- **debug utd engine standard climgr**
- **debug utd engine standard daq**
- **debug utd engine standard internal**
- **debug utd engine standard onep**
- **show utd engine standard logging events**

Note This tool will only show output for the configured URL filtering alerts/events. Users can configure the type of events and alerts they want to see in this output by following the steps in the section "Configuration Examples". For example, If you have configured "alert all", you will see "whitelist", "blacklist" and category & reputation events. If you configure only "alert whitelist", you will only see "whitelist" events."

For release 16.8.1, configuration error recovery on container is enhanced in order to apply configuration and signature updates to the container. With the improved error recovery, you can have:

- Greater robustness during configuration download to detect and act upon errors.
- Efficient way of handling signature and configuration updates occurring together.
- Early detect and recover from the loss of the oneP connection between IOSd and CLIMGR. For example, when CLIMGR crashes.
- Improved visibility to the detailed results of the (current or recent) configuration download, without requiring you to enable debugs.

The following site <https://www.brightcloud.com/tools/url-ip-lookup.php> can be used to validate how a website will be classified by our URL-Filtering feature.

Configuration Examples

The following example shows how to enable domain filtering on CSR 1000V Cloud Services Router:

```
Device# configure terminal
Device(config)# parameter-map type regex wlist1
Device(config-profile)# pattern google.com
Device(config-profile)# pattern cisco.com
Device(config-profile)# exit
Device(config)# parameter-map type regex blist1
Device(config-profile)# pattern exmaplehoo.com
Device(config-profile)# pattern bing.com
Device(config-profile)# exit
Device(config)# utd web-filter block local-server profile 1
Device(config--utd-webf-blk-srvr)# content file bootflash:test.utd.file
Device(config--utd-webf-blk-srvr)# end
```

For the local block server to work, HTTP server should be running. Use the `ip http server` command to configure the block server. The `show ip http server status` command displays the server status as enabled.

```
Device# show ip http server status
HTTP server status: Enabled
HTTP server port: 80
```

Example: Configuring Web Filter Domain Profile

The following example shows how to configure web filter domain profile:

```
Device(config)# utd web-filter domain profile 1
Device(config-utd-webfltr-domain)# blacklist
Device(config-utd-webf-dmn-bl)# parameter-map regex blist1
Device(config-utd-webf-dmn-bl)# whitelist
Device(config-utd-webf-dmn-wl)# parameter-map regex wlist1
Device(config-utd-webf-dmn-wl)# exit
Device(config-utd-webfltr-domain)# alert all
Device(config-utd-webfltr-domain)# redirect-server external 1.2.3.4
Device(config-utd-webfltr-domain)# exit
```

Configuring Web Filter URL Profile

The following example shows how to configure web filter URL profile:

```
Device(config)# utd web-filter url profile 1
Device(config-utd-webfltr-url)# blacklist
Device(config-utd-webf-url-bl)# parameter-map regex blist1
Device(config-utd-webf-url-bl)# whitelist
Device(config-utd-webf-url-wl)# parameter-map regex wlist1
Device(config-utd-webf-url-wl)# exit
Device(config-utd-webfltr-url)# categories allow
Device(config-utd-webf-url-cat)# news-and-media

```

Configuring UTD Snort IPS/IDS Allowed List Signatures

The following example shows how to configure signature allowed lists:

```

Device(config)# utd threat-inspection whitelist
Device(config-utd-whitelist)# generator id 1 signature id 1
Device(config-utd-whitelist)# generator id 1 signature id 2
Device(config-utd-whitelist)# exit

```

Example: Configuring Web Filter Profile

The following example shows how to configure web filter profile:

```

Device(config)# utd engine standard
Device(config-utd-eng-std)# logging server 1.2.3.4
Device(config-utd-eng-std)# threat-inspection
Device(config-utd-engstd-insp)#threat protection
Device(config-utd-engstd-insp)# policy security
Device(config-utd-engstd-insp)# logging level emerg
Device(config-utd-engstd-insp)# whitelist
Device(config-utd-engstd-insp)# web-filter
Device(config-utd-engstd-webf)# domain-profile 1
Device(config-utd-engstd-webf)# url-profile 1
Device(config-utd-engstd-webf)# exit

```

Example: Alert Messages for Web Filtering Events

The following example shows alert messages for web filtering events:

```

016/06/02-14:44:41.061501 IST [**] [Instance_ID: 1] [**] Drop [**] UTD WebFilter Blacklist

Feature Information for Cisco Web Filtering

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 220: Feature Information for Cisco Web Filtering

Feature Name	Releases	Feature Information
Cisco Web Filtering	Cisco IOS XE Denali Release 16.3.1	The Web Filtering feature enables the user to provide controlled access to Internet websites by configuring the domain-based or URL-based policies and filters on the device. The user can configure the web filtering profiles to manage the web access. Web Filtering feature is implemented using the container service and it is similar to the Snort IPS solution.
UTD feature parity on ISRv UTD Serviceability Enhancements	Cisco IOS XE Fuji Release 16.8.1	<p>Domain and URL filtering in both single-tenant and multi-tenant mode are supported for CSR. For ISRv, only single-tenant is supported. This feature is available on all models of the ENCS platforms.</p> <p>Error recovery feature in UTD is enhanced to allow the container to recover from internal error by initiating a bulk configuration download from IOS.</p> <p>The command utd web-filter profile name is modified.</p>
Web Root URL Filtering Enhancements	Cisco IOS XE Fuji Release 16.9.1	<p>The URLF Virtual Resource Profiles in Web Filtering are supported only on platforms CSR1000v and ISRv.</p> <p>The URL Filtering supports cloud-lookup feature to search for the URLs in cloud that are not present in the database.</p>

CHAPTER 166

Configuring Multi-Tenancy for Unified Threat Defense

Multi-tenancy for Unified Threat Defense provides Snort IPS and Web Filtering for multiple users. You can define policies for one or more tenants in a single Cisco CSR 1000v instance. Each policy can have a threat inspection profile and a web filtering profile. The following sections describe how to configure multi-tenancy for Unified Threat Defense. Many of the commands used in these configuration steps are similar to those used in configuring single-tenancy—see: [Snort IPS, on page 2065](#) and [Web Filtering, on page 2113](#).

- [Information About Multi-Tenancy for Unified Threat Defense, on page 2133](#)
- [Overview of Snort Virtual Service Interfaces, on page 2135](#)
- [Restrictions for Configuring Multi-Tenancy for Unified Threat Defense, on page 2136](#)
- [How to Configure Multi-Tenancy for Unified Threat Defense, on page 2136](#)
- [Verifying Unified Threat Defense Engine Standard Configuration, on page 2151](#)
- [Troubleshooting Multi-Tenancy for Unified Threat Defense, on page 2163](#)

Information About Multi-Tenancy for Unified Threat Defense

Multi-tenancy for Snort IPS and Web Filtering allows you to define policies for one or more tenants, in one Cisco CSR 1000v instance. This feature was introduced in Cisco IOS XE Everest 16.6.1.

Each tenant is a VPN routing and forwarding instance with one or more VPN routing and forwarding tables (VRFs). A Unified Threat Defense (UTD) policy is associated with a threat inspection profile and web filtering profile. Multiple tenants can share a UTD policy.

The system logs include the name of the VRF which allows you to produce statistics per-tenant.

The CLI commands used in multi-tenancy mode are similar to those used in single-tenancy mode (see [Snort IPS, on page 2065](#) and [Web Filtering, on page 2113](#)). In multi-tenancy, you enter a sub-mode `utd engine standard multi-tenancy` and configure UTD policies, web filtering and threat-inspection profiles. After exiting the `utd engine standard multi-tenancy` sub-mode, the UTD policies are applied.

The benefits of web filtering and threat inspection (Snort IPS/IDS) are explained in the following sections:

- [Benefits of Web Filtering, on page 2117](#)
- [Overview of Snort Virtual Service Interfaces, on page 2135](#)

Web Filtering Overview

Web Filtering allows you to provide controlled access to the internet by configuring URL-based policies and filters. Web Filtering helps to control access to websites by blocking malicious or unwanted websites and therefore making the network more secure. You can blocked list individual URLs or domain names and configure allowed list policies for the same. You can also make provision to allow or block a URL based on reputation or category.

Snort IPS Overview

The Snort IPS feature enables Intrusion Prevention System (IPS) or Intrusion Detection System (IDS) for branch offices on Cisco 4000 Series Integrated Services Routers and Cisco Cloud Services Router 1000v Series. This feature uses the Snort engine to provide IPS and IDS functionalities.

Snort is an open source network IPS that performs real-time traffic analysis and generates alerts when threats are detected on IP networks. It can also perform protocol analysis, content searching or matching, and detect a variety of attacks and probes, such as buffer overflows, stealth port scans, and so on. The Snort engine runs as a virtual container service on Cisco 4000 Series Integrated Services Routers and Cisco Cloud Services Router 1000v Series.

The Snort IPS feature works in the network intrusion detection and prevention mode that provides IPS or IDS functionalities. In the network intrusion detection and prevention mode, Snort performs the following actions:

- Monitors network traffic and analyzes against a defined rule set.
- Performs attack classification.
- Invokes actions against matched rules.

Based on your requirements, you can enable Snort either in IPS or IDS mode. In IDS mode, Snort inspects the traffic and reports alerts, but does not take any action to prevent attacks. In IPS mode, in addition to intrusion detection, actions are taken to prevent attacks.

The Snort IPS monitors the traffic and reports events to an external log server or the IOS syslog. Enabling logging to the IOS syslog may impact performance due to the potential volume of log messages. External third-party monitoring tools, which supports Snort logs, can be used for log collection and analysis.

Snort IPS Solution

The Snort IPS solution consists of the following entities:

- Snort sensor—Monitors the traffic to detect anomalies based on the configured security policies (that includes signatures, statistics, protocol analysis, and so on) and sends alert messages to the Alert/Reporting server. The Snort sensor is deployed as a virtual container service on the router.
- Signature store—Hosts the Cisco Signature packages that are updated periodically. These signature packages are downloaded to Snort sensors either periodically or on demand. Validated signature packages are posted to Cisco.com. Based on the configuration, signature packages can be downloaded from Cisco.com or a local server.

The following domains are accessed by the router in the process of downloading the signature package from cisco.com:

- api.cisco.com

- apx.cisco.com
- cloudsso.cisco.com
- cloudsso-test.cisco.com
- cloudsso-test3.cisco.com
- cloudsso-test4.cisco.com
- cloudsso-test5.cisco.com
- cloudsso-test6.cisco.com
- cloudsso.cisco.com
- download-ssc.cisco.com
- dl.cisco.com
- resolver1.opendns.com
- resolver2.opendns.com

Note If you are downloading signature packages from a local server to hold the signature packages, only HTTP is supported.

Signature packages must be manually downloaded from Cisco.com to the local server by using Cisco.com credentials before the Snort sensor can retrieve them.

The Snort container performs a domain-name lookup (on the DNS server(s) configured on the router) to resolve the location for automatic signature updates from Cisco.com or on the local server, if the URL is not specified as the IP address.

- Alert/Reporting server—Receives alert events from the Snort sensor. Alert events generated by the Snort sensor can either be sent to the IOS syslog or an external syslog server or to both IOS syslog and external syslog server. No external log servers are bundled with the Snort IPS solution.
- Management—Manages the Snort IPS solution. Management is configured using the IOS CLI. Snort Sensor cannot be accessed directly, and all configuration can only be done using the IOS CLI.

Overview of Snort Virtual Service Interfaces

The Snort sensor runs as a service on routers. Service containers use virtualization technology to provide a hosting environment on Cisco devices for applications.

You can enable Snort traffic inspection either on a per interface basis or globally on all supported interfaces. The traffic to be inspected is diverted to the Snort sensor and injected back. In Intrusion Detection System (IDS), identified threats are reported as log events and allowed. However, in Intrusion Prevention System (IPS), action is taken to prevent attacks along with log events.

The Snort sensor requires two VirtualPortGroup interfaces. The first VirtualPortGroup interface is used for management traffic and the second for data traffic between the forwarding plane and the Snort virtual container

service. Guest IP addresses must be configured for these VirtualPortGroup interfaces. The IP subnet assigned to the management VirtualPortGroup interface should be able to communicate with the Signature server and Alert/Reporting server.

The IP subnet of the second VirtualPortGroup interface must not be routable on the customer network because the traffic on this interface is internal to the router. Exposing the internal subnet to the outside world is a security risk. We recommend the use of 192.0.2.0/30 IP address range for the second VirtualPortGroup subnet. The use of 192.0.2.0/24 subnet is defined in RFC 3330.

You can assign the Snort virtual container service IP address on the same management network as the router on which the virtual service is running. This configuration helps if the syslog or update server is on the management network and is not accessible by any other interfaces

Restrictions for Configuring Multi-Tenancy for Unified Threat Defense

-
- Domain-based filtering is not supported.
- Up to 25 tenants are supported on each Cisco CSR 1000v instance.
- A maximum of 25 policies are supported.
- A maximum of 50,000 concurrent sessions are supported on a Cisco CSR 1000v.
-
- The blocked list/allowed list rules support only a regular expression (regex) pattern. Currently, 64 patterns are supported for each blocked list/allowed list rule. However, each tenant can have multiple rules.
- Local block server does not support serving HTTPS block page. When the URL filter tries to inject block page or redirect message, it does not support HTTPS traffic.
- When there is a username and password in the URL, URL filter does not remove them from the URL before matching the blocked list/allowed list pattern. However, the category/reputation lookup does not have this limitation and removes the username and password from the URL before lookup.
- HTTPS inspection is limited. Web filtering uses server certificate to obtain the URL/domain information. It is not possible to inspect the full URL path.
- UTD does not inter-operate with WCCP, and NBAR under inter-VRF scenario.
- The Snort IPS command `threat inspection profile profile-name` uses an alphanumeric profile-name, not an ID (number).

How to Configure Multi-Tenancy for Unified Threat Defense

To deploy multi-tenancy for Unified Threat Defense on supported devices, perform the following tasks:

Before you begin

Provision the device upon which you wish to install web filtering and threat inspection for multi-tenancy. This feature is currently only supported on the Cisco CSR 1000v.

Obtain the license. UTD is available only for routers running security packages and you will require a security license to enable the service. Contact Cisco Support to obtain a security license.

SUMMARY STEPS

1. Install and activate the virtual-service: [Installing the UTD OVA File for Multi-Tenancy, on page 2137](#).
2. Configure the VirtualPortGroup interfaces and the virtual-service: [How to Configure VirtualPortGroup Interfaces and Virtual Service for Multi-Tenancy, on page 2138](#).
3. Configure the VRFs: [How to Configure VRFs for Multi-Tenancy, on page 2141](#).
4. Configure threat inspection and web filtering for multi-tenancy: [How to Configure Multi-Tenancy Web Filtering and Threat Inspection, on page 2142](#)

DETAILED STEPS

-
- Step 1** Install and activate the virtual-service: [Installing the UTD OVA File for Multi-Tenancy, on page 2137](#).
- Step 2** Configure the VirtualPortGroup interfaces and the virtual-service: [How to Configure VirtualPortGroup Interfaces and Virtual Service for Multi-Tenancy, on page 2138](#).
- Step 3** Configure the VRFs: [How to Configure VRFs for Multi-Tenancy, on page 2141](#).
- Step 4** Configure threat inspection and web filtering for multi-tenancy: [How to Configure Multi-Tenancy Web Filtering and Threat Inspection, on page 2142](#)
-

Installing the UTD OVA File for Multi-Tenancy

The virtual-service OVA file is an Open Virtualization Archive file that contains a compressed, installable version of a virtual machine. You must download this OVA file to the router and then install the virtual-service. The virtual-service OVA file is not bundled with Cisco IOS XE release images that are installed on the router. OVA files may be available pre-installed in the router's flash memory.

For installing the OVA file, you must use a Cisco IOS XE image with a security license. During installation, the security license is checked.

Example of installing the virtual service:

```
Device> enable
Device# virtual-service install name utd package
bootflash:utdsnort.1.0.4_SV2983_XE_16_6.20170623_174453_RELEASE.ova
Device# show virtual-service list
```

```
Name Status   Package Name
-----
utd Activated utdsnort.1.0.4_SV2983_XE_16_6.20170
```

Example of upgrading the virtual service:

```
Device> enable
Device# virtual-service upgrade name utd package
bootflash:utdsnort.1.0.4_SV2983_XE_16_6.20170623_174453_RELEASE.ova
Device# show virtual-service list
```

```
Name Status Package Name
-----
utd Activated utdsnort.1.0.4_SV2983_XE_16_6.20170
```

Example of uninstalling the virtual service:

```
Device> enable
Device# virtual-service uninstall name utd
Device# show virtual-service list
```

Virtual Service List:

How to Configure VirtualPortGroup Interfaces and Virtual Service for Multi-Tenancy

As shown in this procedure, for multi-tenancy you must configure two VirtualPortGroup interfaces and guest IP addresses for both interfaces.

Note The VirtualPortGroup interface for data traffic must use a private or nonroutable IP address. We recommend the use of 192.0.2.0/30 IP address range for this interface.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface VirtualPortGroup** *interface-number*
4. **ip address** *ip-address mask*
5. **exit**
6. **interface VirtualPortGroup** *interface-number*
7. **ip address** *ip-address mask*
8. **exit**
9. **virtual-service** *name*
10. **profile multi-tenancy**
11. **vnic gateway VirtualPortGroup** *interface-number*
12. **guest ip address** *ip-address*
13. **exit**
14. **vnic gateway VirtualPortGroup** *interface-number*
15. **guest ip address** *ip-address*
16. **exit**
17. **activate**
18. **end**
19. **show virtual-service list**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface VirtualPortGroup interface-number Example: Device(config)# interface VirtualPortGroup 0	Enters interface configuration mode and configures a VirtualPortGroup interface. This interface is used for management traffic when the management interface GigabitEthernet0 is not used.
Step 4	ip address ip-address mask Example: Device(config-if)# ip address 10.1.1.1 255.255.255.252	Sets a primary IP address for an interface. This interface needs to be routable to the signature update server and external log server.
Step 5	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.
Step 6	interface VirtualPortGroup interface-number Example: Device(config)# interface VirtualPortGroup 1	Configures an interface and enters interface configuration mode. Configure a VirtualPortGroup interface. This interface is used for data traffic.
Step 7	ip address ip-address mask Example: Device(config-if)# ip address 192.0.2.1 255.255.255.252	Sets a primary IP address for an interface. This IP address should not be routable to the outside network. The IP address is assigned from the recommended 192.0.2.0/30 subnet.
Step 8	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.
Step 9	virtual-service name Example: Device(config)# virtual-service utd	Configures a virtual container service and enters virtual service configuration mode. The <i>name</i> argument is the logical name that is used to identify the virtual container service.
Step 10	profile multi-tenancy Example: Device(config-virt-serv)#profile multi-tenancy	Configures a resource profile. For multi-tenancy mode (Cisco CSR 1000v only), this <code>profile multi-tenancy</code> command must be configured.

	Command or Action	Purpose
Step 11	vnics gateway VirtualPortGroup <i>interface-number</i> Example: <pre>Device(config-virt-serv)# vnics gateway VirtualPortGroup 0</pre>	Enters the virtual-service virtual network interface card (vNIC) configuration mode. Creates a vNIC gateway interface for the virtual container service and maps the vNIC gateway interface to the virtual port group interface. This is the interface that was configured in Step 3.
Step 12	guest ip address <i>ip-address</i> Example: <pre>Device(config-virt-serv-vnic)# guest ip address 10.1.1.2</pre>	Configures a guest vNIC address for the vNIC gateway interface.
Step 13	exit Example: <pre>Device(config-virt-serv-vnic)# exit</pre>	Exits virtual-service vNIC configuration mode and returns to virtual service configuration mode.
Step 14	vnics gateway VirtualPortGroup <i>interface-number</i> Example: <pre>Device(config-virt-serv)# vnics gateway VirtualPortGroup 1</pre>	Enters virtual-service vNIC configuration mode. Configures a vNIC gateway interface for the virtual container service and maps the interface to the virtual port group. The interface (<i>interface-number</i>) configured in Step 6) is used by the Snort engine for monitoring user traffic.
Step 15	guest ip address <i>ip-address</i> Example: <pre>Device(config-virt-serv-vnic)# guest ip address 192.0.2.2</pre>	Configures a guest vNIC address for the vNIC gateway interface.
Step 16	exit Example: <pre>Device(config-virt-serv-vnic)# exit</pre>	Exits virtual-service vNIC configuration mode and returns to virtual service configuration mode.
Step 17	activate Example: <pre>Device(config-virt-serv)# activate</pre>	Activates an application installed in a virtual container service.
Step 18	end Example: <pre>Device(config-virt-serv)# end</pre>	Exits virtual service configuration mode and returns to privileged EXEC mode.
Step 19	show virtual-service list Example: <pre>Device# show virtual-service list Virtual Service List: Name Status Package Name ----- utd Activated utdsnort.1.0.4_SV2983_XE_16_6.20170</pre>	

How to Configure VRFs for Multi-Tenancy

This procedure describes the typical steps required for configuring VRFs for the tenants, which are later used in: [How to Configure Multi-Tenancy Web Filtering and Threat Inspection, on page 2142](#).

Note For inter-VRF traffic, if the traffic flowing between two VRFs has ingress and egress interfaces configured for UTD, rules are applied to decide which VRF represents the session. The UTD policy for the selected VRF then applies to all packets in the inter-VRF traffic.

SUMMARY STEPS

1. **vrf definition** *vrf-name*
2. **rd** *route-distinguisher*
3. **address-family ipv4**
4. **exit address-family**
5. Repeat steps 1 to 4 for each VRF.

DETAILED STEPS

	Command or Action	Purpose
Step 1	vrf definition <i>vrf-name</i> Example: Device(config)# vrf definition 100	Defines the name of the VRF and enters VRF configuration mode.
Step 2	rd <i>route-distinguisher</i> Example: Device(config-vrf)# rd 100:1	Creates the routing and forwarding tables and associates the <i>route-distinguisher</i> with the VRF instance named <i>vrf-name</i> . The router uses the route-distinguisher to identify the VRF to which a packet belongs. The route-distinguisher is of one of the following two types: <ul style="list-style-type: none"> • Autonomous System-related. An AS number xxx and an arbitrary number y—xxx:y • IP address-related. An IP address A.B.C.D and an arbitrary number y—A.B.C.D:y
Step 3	address-family ipv4 Example: Device(config-vrf)# address-family ipv4	Enters address family configuration mode for configuring routing sessions using the IP Version 4 address.
Step 4	exit address-family Example: Device(config-vrf-af)# exit	Exits address family configuration mode.
Step 5	Repeat steps 1 to 4 for each VRF.	

How to Configure Multi-Tenancy Web Filtering and Threat Inspection

To configure threat inspection (IPS/IDS) and web filtering for multi-tenancy (multiple tenants/VRFs), perform the following steps.

In this procedure, the definition of blocked list and allowed lists are shown in the initial steps 1 to 5. The main configuration steps (in UTD standard engine configuration mode for multi-tenancy) are shown in step 6 onwards.

Note For details about threat inspection and web filtering for single-tenancy, see [Snort IPS, on page 2065](#) and [Web Filtering, on page 2113](#).

Before you begin

Remove any existing single-tenancy UTD configuration, using the `no utd engine standard` command.

You must have previously configured a VRF for each tenant—see [How to Configure VRFs for Multi-Tenancy, on page 2141](#).

Procedure

	Command or Action	Purpose
Step 1	<p>parameter-map type regex <i>blacklist-name</i></p> <p>Example:</p> <pre>Device(config)# parameter-map type regex urlf-blacklist1</pre>	Defines a blocked list parameter map, which is used later in step 17.
Step 2	<p>pattern <i>URL-name</i></p> <p>Example:</p> <pre>Device(config-profile)# pattern www\.cnn\.com Device(config-profile)# pattern www\.msnbc\.com</pre>	Defines the URL to be on the blocked list. Note that the periods within <i>URL-name</i> must be preceded by an escape "." character. Repeat this step to configure multiple URLs to be on the blocked list.
Step 3	<p>parameter-map type regex <i>whitelist-name</i></p> <p>Example:</p> <pre>Device(config-profile)# parameter-map type regex urlf-whitelist1</pre>	Defines an allowed list parameter map, which is used later in step 20.
Step 4	<p>pattern <i>URL-name</i></p> <p>Example:</p> <pre>Device(config-profile)# pattern www\.nfl\.com</pre>	Defines the URL(s) to be on the allowed list. Note that, for URLs on the blocked list, periods within <i>URL-name</i> must be preceded by an escape "." character. Repeat this step to configure multiple URLs to be on the allowed list.
Step 5	<p>exit</p> <p>Example:</p> <pre>Device(config-profile)# exit</pre>	

	Command or Action	Purpose																		
Step 6	<p>utd multi-tenancy</p> <p>Example:</p> <pre>Device(config)# utd multi-tenancy</pre>	<p>This command acts a switch, in preparation for the following <code>u</code>td engine standard multi-tenancy command.</p>																		
Step 7	<p>utd engine standard multi-tenancy</p> <p>Example:</p> <pre>Device(config)# utd engine standard multi-tenancy</pre>	<p>Enters UTD standard engine configuration mode for multi-tenancy.</p> <p>Note Later, after you exit the UTD standard engine configuration mode in step 50, the policy configurations are applied.</p>																		
Step 8	<p>web-filter sourcedb <i>sourcedb-number</i></p> <p>Example:</p> <pre>Device(config)# web-filter sourcedb 1</pre>	<p>Configures a web filtering sourcedb profile—<i>sourcedb-number</i>, which is numeric. This is used later in step 29.</p>																		
Step 9	<p>logging level {alerts critical debugging emergencies errors informational notifications warnings}</p> <p>Example:</p> <pre>Device(config)# logging level errors</pre>	<p>Sets the level of system messages that are reported upon for web filtering events. Messages of the specified level and lower are reported. (Each level has a numeric value as shown in the table below.)</p> <p>Table 221: System Message Severity Levels</p> <table border="1"> <thead> <tr> <th>Level</th> <th>Description</th> </tr> </thead> <tbody> <tr> <td>0 – emergencies</td> <td>System unusable</td> </tr> <tr> <td>1 – alerts</td> <td>Immediate action needed</td> </tr> <tr> <td>2 – critical</td> <td>Critical condition</td> </tr> <tr> <td>3 – errors</td> <td>Error condition</td> </tr> <tr> <td>4 – warnings</td> <td>Warning condition</td> </tr> <tr> <td>5 – notifications</td> <td>Normal but significant condition</td> </tr> <tr> <td>6 – informational</td> <td>Informational messages only</td> </tr> <tr> <td>7 – debugging</td> <td>Appears during debugging only</td> </tr> </tbody> </table>	Level	Description	0 – emergencies	System unusable	1 – alerts	Immediate action needed	2 – critical	Critical condition	3 – errors	Error condition	4 – warnings	Warning condition	5 – notifications	Normal but significant condition	6 – informational	Informational messages only	7 – debugging	Appears during debugging only
Level	Description																			
0 – emergencies	System unusable																			
1 – alerts	Immediate action needed																			
2 – critical	Critical condition																			
3 – errors	Error condition																			
4 – warnings	Warning condition																			
5 – notifications	Normal but significant condition																			
6 – informational	Informational messages only																			
7 – debugging	Appears during debugging only																			
Step 10	<p>web-filter block local-server profile <i>profile-id</i></p> <p>Example:</p> <pre>Device(config-utd-multi-tenancy)# web-filter block local-server profile 1</pre> <p>The content text is displayed by the local server.</p>	<p>Configures the a local block server profile for web filtering. The range of values for <i>profile-id</i> is 1–255.</p> <p>See Configure URL-based Web Filtering with a Local Block Server.</p> <p>Note When configuring commands for multi-tenancy, compared to single-tenancy, you do not use the initial <code>u</code>td keyword.</p>																		

	Command or Action	Purpose
Step 11	block-page-interface loopback <i>id</i> Example: <pre>Device(config-utd-mt-webf-blk-srvr)# block-page-interface loopback 110</pre>	Associates a loopback interface with this profile. The IP address of this loopback interface is then used as the IP address of the block local-server.
Step 12	content text <i>display-text</i> Example: <pre>Device(config-utd-mt-webf-blk-srvr)# content text "Blocked by Web-Filter"</pre>	Specifies the warning text that appears after a blocked page is accessed.
Step 13	http-ports <i>port-number</i> Example: <pre>Device(config-utd-mt-webf-blk-srvr)# http-ports 80</pre>	The http-ports value is a string of ports separated by commas. The nginx HTTP server listens to these ports.
Step 14	web-filter block page profile <i>profile-name</i> Example: <pre>Device(config-utd-multi-tenancy)# web-filter block page profile 1 Device(config-utd-mt-webf-block-urc)# text "this page is blocked"</pre>	See Configure URL-based Web Filtering with an Inline Block Page, on page 2125 , except that the command used here for multi-tenancy does not use the <code>utd</code> keyword which is used for single-tenancy.).
Step 15	web-filter url profile <i>web-filter-profile-id</i> Example: <pre>Device(config-utd-multi-tenancy)# web-filter url profile 1 Device(config-utd-mt-webfltr-url)#</pre>	<p>Specifies a URL profile for web filtering—<i>web-filter-profile-id</i>. Values: 1–255. After this command, you can configure alerts for blocked lists, allowed lists, and categories. For further information, see: Configure URL-based Web Filtering with an Inline Block Page.</p> <p>Note When configuring commands for multi-tenancy, compared to single-tenancy, you do not use an initial <code>utd</code> keyword.</p>
Step 16	blacklist Example: <pre>Device(config-utd-mt-webfltr-url)# blacklist</pre>	Enters web filtering blocked list configuration mode.
Step 17	parameter-map regex <i>blacklist-name</i> Example: <pre>Device(config-utd-mt-webf-url-bl)# parameter-map regex urlf-blacklist1</pre>	Specifies a parameter-map regular expression using the blocked list that was defined earlier in step 1.
Step 18	exit Example: <pre>Device(config-utd-mt-webf-url-bl)# exit Device(config-utd-mt-webfltr-url)#</pre>	Exits web filtering blocked list configuration mode.

	Command or Action	Purpose
Step 19	whitelist Example: Device(config-utd-mt-webfltr-url)# whitelist Device(config-utd-mt-webf-url-wl)#	Enters web filtering allowed list configuration mode.
Step 20	parameter-map regex <i>whitelist-name</i> Example: Device(config-utd-mt-webf-url-wl)# parameter-map regex urlf-list1	Specifies a parameter-map regular expression using the allowed list that was defined earlier in step 3.
Step 21	exit Example: Device(config-utd-mt-webf-url-wl)# exit Device(config-utd-mt-webfltr-url)#	Exits web filtering allowed list configuration mode.
Step 22	exit Example: Device(config-utd-mt-webfltr-url)# exit Device(config-utd-multi-tenancy)#	Exits web filtering URL profile mode.
Step 23	utd global Example: Device(config-utd-multi-tenancy)# utd global	The commands entered for <code>utd global</code> apply to all tenants or policies e.g the commands shown below: <code>logging host syslog</code> and <code>threat inspection</code> for this Cisco CSR 1000v instance.
Step 24	logging {host <i>hostname</i> syslog} Example: In this example, alerts are logged to a designated host log file. Device(config-utd-mt-utd-global)# logging host systemlog1 Example: In this example, alerts are logged to IOS syslogs. Device(config-utd-mt-utd-global)# logging syslog	The <code>logging</code> command specifies either a host name or IOS syslog, to which syslog messages are sent.
Step 25	threat inspection Example: Device(config-utd-mt-utd-global)# threat inspection	Enters global threat inspection mode.
Step 26	signature update server {cisco url <i>url</i> } [username <i>username</i> [password <i>password</i>]] Example: Device(config-utd-mt-utd-global-threat)# signature update server cisco username abcd password cisco123	Configures the signature update server parameters. You must specify the signature update parameters with the server details. If you use <code>www.cisco.com</code> for signature updates, you must provide the username and password. If you use a local server for signature updates, based on the server settings you can provide the username and password.

	Command or Action	Purpose
		The router must be able to resolve the domain name by being connected to the internet.
Step 27	signature update occur-at <i>{daily monthly day-of-month weekly day-of-week} hour minute</i> Example: Device(config-utd-mt-utd-global-threat)# signature update occur-at daily 0 0	Configures the signature update interval parameters. This configuration will trigger the signature update to occur at midnight.
Step 28	web-filter Example: Device(config-utd-mt-utd-global-threat)# web-filter	This command, used in combination with the following <code>sourcedb</code> command, specifies the URL source database for web filtering.
Step 29	sourcedb <i>sourcedb-number</i> Example: Device(config-utd-mt-utd-global-threat)# sourcedb 1	Assigns a web filtering source database. Only one source database can be active.
Step 30	exit Example: Device(config-utd-mt-utd-global-threat)# exit	Exits threat inspection configuration mode.
Step 31	exit Example: Device(config-utd-mt-global)# exit	Exits global update configuration mode.
Step 32	threat-inspection whitelist profile <i>policy-name</i> Example: Device(config-utd-multi-tenancy)# threat-inspection whitelist profile wh101	Associates an allowed list profile with the policy currently being configured. A similar command is used in single-tenancy, but with a <code>utd</code> keyword.
Step 33	signature id <i>id</i> Example: Device(config-utd-mt-list)# signature id 101	Specify the ID <i>id</i> that you have previously identified as a threat; for example, after observing the ID in an alert log file. Repeat this command for multiple signature IDs.
Step 34	exit Example: Device(config-utd-mt-whitelist)# exit	Exits an allowed list configuration mode.
Step 35	threat-inspection profile <i>profile-name</i> Example: Device(config-utd-multi-tenancy)# threat-inspection profile 101	Configures a threat inspection profile, which can be reused by multiple tenants. You can configure multiple threat-inspection profiles. Within a profile you can configure multiple allowed lists. <i>profile-name</i> is alphanumeric.

	Command or Action	Purpose
Step 36	threat {detection protection } Example: Device(config-utd-mt-threat)# threat protection	Specifies Intrusion Detection System (IDS) or Intrusion Prevention System (IPS) as the operating mode for the Snort engine. The default is threat detection
Step 37	policy {balanced connectivity security } Example: Device(config-utd-mt-threat)# policy security	Configures the security policy for the Snort engine. <ul style="list-style-type: none"> The default security policy type is balanced.
Step 38	logging level {alert crit debug emerg err info notice warning }	Provides logs in one of these categories: <ul style="list-style-type: none"> alert—provides alert level logs (severity=2) crit—critical level logs (severity=3) debug—all logs (severity=8) emerg—emergency level logs (severity=1) err—error level logs (severity=4) Default. info—info level logs (severity=7) notice—notice level logs (severity=6) warning—warning level logs (severity=5)
Step 39	whitelist profile profile-name Example: Device(config-utd-mt-threat)# whitelist profile wh101	You can also specify allowed list profiles in a profile only for allowed lists in another place—the <code>threat-inspection whitelist profile</code> command above. (Optional) Enables allowed lists under the UTD engine.
Step 40	exit Example: Device(config-utd-mt-threat)# exit	Exits threat inspection mode.
Step 41	Repeat steps 35 to 40 to add additional threat-inspection profiles.	
Step 42	policy policy-name Example: Device(config-utd-multi-tenancy)# policy pol101	Defines the policy that will be associated with multiple tenants. A threat detection (IPS) and web filtering profile are added to the policy.
Step 43	vrf [vrf-name global] Example: This example shows the configuration of two tenants (VRFs) and two policies. Device(config-utd-mt-policy)# vrf vrf101	Repeat the <code>vrf vrf-name</code> command for each of the VRFs (tenants) that will use the UTD policy. These VRFs previously defined, see: How to Configure VRFs for Multi-Tenancy, on page 2141 . Alternatively use <code>vrf global</code> to associate with the global (default) VRF and enables VRF under the interface.

	Command or Action	Purpose
Step 44	all-interfaces Example: Device(config-utd-mt-policy)# all-interfaces	(Optional) Associates all interfaces under the VRF with the policy.
Step 45	threat-inspection profile <i>profile-name</i> Example: Device(config-utd-mt-policy)# threat-inspection profile 101	(Optional) Associates the policy with a previously defined threat inspection profile, see Step 35.
Step 46	web-filter url profile <i>web-filter-profile-id</i> Example: Device(config-utd-mt-policy)# web-filter url profile 1	(Optional) Associates the policy with a previously defined web filtering profile, see step 15.
Step 47	fail close Example: Device(config-utd-mt-policy)# fail close	(Optional) Drops IPS/IDS packets on engine failure. Default is <code>fail open</code> .
Step 48	exit	Exits from policy configuration mode.
Step 49	Repeat steps 42 to 48 for each policy	
Step 50	exit Example: Device(config-utd-multi-tenancy)# exit	Exits the <code>utd engine standard multi-tenancy mode</code> . The policy configurations are applied, which may take a few minutes. During this time, further <code>utd engine standard multi-tenancy configuration mode</code> commands cannot be entered.
Step 51	exit Example: Device(config)# exit Device#	
Step 52	show logging Example: Device(config)# show logging ..UTD MT configuration download has started ..UTD MT configuration download has completed	
Step 53	interface <i>sub-interface</i> Example: Device(config)# interface GigabitEthernet4.101	Specify a sub-interface to be used for the tenant (VRF).
Step 54	encapsulation dot1Q <i>vlan-id</i> Example: Device(config-if)# encapsulation dot1Q 101	Applies a VLAN ID to the sub-interface.

	Command or Action	Purpose
Step 55	ip vrf forwarding <i>vrf-name</i> Example: Device(config-if)# ip vrf forwarding vrf101	Associates a VRF instance with the sub-interface.
Step 56	ip address <i>ip-address subnet-mask</i> Example: Device(config-if)# ip address 111.0.0.1 255.255.255.0	Specifies the sub-interface IP address of the VRF.
Step 57	ip route <i>ip-address subnet-mask sub-interface</i> Example: In this example, the VRF's subnet GigabitEthernet4.101 is linked to the global routing table using the static IP address 111.0.0.0 255.255.255.0. Device(config-if)# ip route 111.0.0.0 255.255.255.0 GigabitEthernet4.101	(Optional) This <code>ip route</code> command and the <code>ip route vrf</code> command in the following step are optional—you can use these steps if you want to configure route leaking using a static route between the VRF and the global routing table. This configures a static route to the VRF subnet from the VRF interface, so that the VRF subnet is accessible from the global routing table. For further information on configuring route leaking, see Route Leaking in MPLS/VPN Networks .
Step 58	ip route vrf <i>vrf-name ip-address subnet-mask global</i> Example: Device(config-if)# ip route vrf vrf101 0.0.0.0 0.0.0.0 5.2.1.1 global	(Optional) This step and the previous step are optional—you can use these steps if you want to configure route leaking using a static route between the VRF and the global routing table. For further information on configuring route leaking, see Route Leaking in MPLS/VPN Networks . Specifies the static VRF default route to the global routing table.
Step 59	utd enable	(Optional) Enables UTD on an interface. You can use this command if the <code>all-interfaces</code> command was not configured (in step 44).
Step 60	To configure a sub-interface for each tenant (VRF), repeat steps 53 to 59.	
Step 61	exit	Exits interface configuration mode.

The profiles for web filtering and threat inspection (IPS) have now been applied.

Example Configuration—Multi-Tenancy for Unified Threat Defense

This example shows a typical running configuration after configuring Multi-Tenancy for UTD for two tenants.

Note The following example mentions parameter maps `urlf-blacklist1` and `urlf-whitelist1`. The configuration of these parameter maps is not shown in the example. For further information on blocked list and approved list parameter-maps, see [Configure URL-based Web Filtering with an Inline Block Page](#).

```

utd multi-tenancy
utd engine standard multi-tenancy
  web-filter block page profile 1
    text "This page is blocked"
  web-filter block page profile 2
    text "This page is blocked"
  web-filter url profile 1
  alert all
  blacklist
    parameter-map regex urlf-blacklist1
  whitelist
    parameter-map regex urlf-whitelist1
  categories block
    social-network
    sports

fail close
```

Verifying Unified Threat Defense Engine Standard Configuration

Use the following commands to verify your configuration.

SUMMARY STEPS

1. **enable**
2. **show utd multi-tenancy**
3. **show utd engine standard global**
4. **show utd engine standard status**
5. **show utd engine standard statistics**
6. **show utd engine standard statistics daq [dp | cp]**
7. **show utd engine standard statistics url-filtering [engine | no]**
8. **show utd engine standard statistics url-filtering vrf name vrf-name**
9. **show utd engine standard statistics internal**
10. **show utd engine standard logging event**
11. **show logging | include CONFIG_DOWNLOAD**
12. **show utd threat-inspection whitelist [profile profile-name]**
13. **show utd threat-inspection profile profile-name**
14. **show utd [policy profile-name]**
15. **show utd web-filter url [profile profile-name]**
16. **show utd web-filter block local-server [profile profile-name]**
17. **show utd web-filter sourcedb [profile profile-name]**
18. **show utd engine standard statistics daq dp [engine engine-num] [vrf [name vrf-name | global]]**
19. **show utd engine standard config threat-inspection whitelist [profile profile-name]**
20. **show utd engine standard config web-filter url profile profile-name**
21. **show utd engine standard config [vrf name vrf-name]**
22. **show utd engine standard config threat-inspection profile profile-name**
23. **show utd engine standard threat-inspection signature update status**
24. **show platform software qfp active feature utd config [vrf {id vrf-id | name vrf-name | global}]**
25. **show platform software utd interfaces**
26. **show platform hardware qfp active feature utd config [vrf {id vrf-id | name vrf-name | global}]**
27. **show platform hardware qfp active feature utd stats [clear | divert | drop | general | summary] [vrf {id vrf-id | name vrf-name | global}] [all] [verbose]**
28. **show platform hardware qfp active feature utd stats summary [vrf name vrf-name | all]**
29. **show platform hardware qfp active feature utd stats drop all**

DETAILED STEPS

-
- Step 1** **enable**
Example:

```
Device# enable
```

Enables privileged EXEC mode. Enter your password if prompted.

Step 2 **show utd multi-tenancy**

Displays the current status of multi-tenancy.

Example:

```
Device# show utd multi-tenancy
Multitenancy is enabled
```

Step 3 **show utd engine standard global**

Displays the global settings for utd engine standard.

Example:

```
Device# show utd engine standard global
UTD Engine Standard Global: enabled
Threat-inspection: enabled
Web-filter: enabled
Logging:
```

Step 4 **show utd engine standard status**

Verify that the status of the UTD engine is Green.

Example:

```
Device# show utd eng standard status
Engine version      : 1.0.2_SV2983_XE_16_8

Profile             : Multi-tenancy
System memory       :
                    Usage  : 3.50 %
                    Status  : Green
Number of engines   : 1

Engine      Running   CFT flows  Health   Reason
=====
Engine(#1):  Yes      0           Green    None
=====

Overall system status: Green

Signature update status:
=====
Current signature package version: 29.0.c
Last update status: Failed
Last successful update time: None
Last failed update time: Thu Jan 11 13:34:36 2018 PST
Last failed update reason: [Errno 113] No route to host
Next update scheduled at: None
Current status: Idle
```

Step 5 **show utd engine standard statistics**

Example:

```
Device# show utd engine standard statistics
*****Engine #1*****
=====
Memory usage summary:
```

```

Total non-mmapped bytes (arena): 80125952
Bytes in mapped regions (hblkhd): 359546880
Total allocated space (uordblks): 68314032
Total free space (fordblks): 11811920
Topmost releasable block (keepcost): 112
=====
Packet I/O Totals:
Received: 49088
Analyzed: 49088 (100.000%)
Dropped: 0 ( 0.000%)
Filtered: 0 ( 0.000%)
Outstanding: 0 ( 0.000%)
Injected: 640
=====
Breakdown by protocol (includes rebuilt packets):
Eth: 49394 (100.000%)

<output removed for brevity>

Total: 49394
=====
Action Stats:
Alerts: 65 ( 0.132%)
Logged: 65 ( 0.132%)
Passed: 0 ( 0.000%)

```

Step 6 **show utd engine standard statistics daq [dp | cp]**

Show Snort DAQ statistics.

Example:

```

Device# show utd engine standard statistics daq dp
IOS-XE DAQ Counters(Engine #1):
-----
Frames received 654101
Bytes received 549106120
RX frames released 654101
Packets after vPath decap 654101
Bytes after vPath decap 516510928
Packets before vPath encaps 651686
Bytes before vPath encaps 514800669
Frames transmitted 651686
Bytes transmitted 544447557

<output removed for brevity>

```

Example:

```

Device# show utd engine standard statistics daq cp
IOS-XE DAQ CP Counters(Engine #1):
-----
Packets received :16353210
Bytes received :1112018252
Packets transmitted :16353210
Bytes transmitted :1700733776
Memory allocation :16353212
Memory free :16353210
CFT API error :0
VPL API error :0
Internal error :0
External error :0
Memory error :0
Timer error :0

```

```

RX ring full 0
CFT full 0
sPath lib flow handle exhausted 0
Memory status changed to yellow :1
Memory status changed to red :0
Process restart notifications :0

```

Step 7 **show utd engine standard statistics url-filtering [engine | no]**

Gives the URL statistics for all the tenants combined: the number of hits for sites on the blocked list, number of hits for sites on the allowed list, and the number of sites that are blocked by category block and reputation block.

Example:

```

Device# show utd engine standard statistics url-filtering
UTM Preprocessor Statistics
-----
URL Filter Requests Sent:           377226166      379846771      381117940
URL Filter Response Received:       377009606      379622845      380892658
Blacklist Hit Count:                0              0              0
Whitelist Hit Count:                0              0              0

Reputation Lookup Count:            376859139      379458008      380706804
Reputation Action Block:            0              0              0
Reputation Action Pass:             307           280           102

Reputation Score None:              376858832      379457728      380706702
Reputation Score Out of Range:      0              0              0

Category Lookup Count:              376859139      379458008      380706804
Category Action Block:              0              0              0
Category Action Pass:               307           280           102
Category Action Default Pass:       376858832      379457728      380706702
Category None:                      376858832      379457728      380706702

```

```

Device# show utd engine standard statistics url-filtering engine1
UTM Preprocessor Statistics
-----
URL Filter Requests Sent:           377226166
URL Filter Response Received:       377009606
Blacklist Hit Count:                0
Whitelist Hit Count:                0

Reputation Lookup Count:            376859139
Reputation Action Block:            0
Reputation Action Pass:             307
Reputation Action Default Pass:     376858832
Reputation Score None:              376858832
Reputation Score Out of Range:      0

Category Lookup Count:              376859139
Category Action Block:              0
Category Action Pass:               307
Category Action Default Pass:       376858832
Category None:                      376858832

```

Step 8 **show utd engine standard statistics url-filtering vrf name vrf-name**

Gives per-tenant URL statistics by using the additional parameters—**vrf name** *vrf-name* .

Example:

```

Device# show utd engine standard statistics url-filtering vrf name vrf101
UTM Preprocessor Statistics
-----
URL Filter Requests Sent: 764
URL Filter Response Received: 764
Blacklist Hit Count: 3
Whitelist Hit Count: 44

Reputation Lookup Count: 764
Reputation Action Block: 0
Reputation Action Pass: 58
Reputation Action Default Pass: 706
Reputation Score None: 706
Reputation Score Out of Range: 0

Category Lookup Count: 764

Category None: 706

```

Step 9 show utd engine standard statistics internal

Example:

```

Device# show utd engine standard statistics internal
*****Engine #1*****
=====
Memory usage summary:
Total non-mmapped bytes (arena): 80125952
Bytes in mapped regions (hblkhd): 359546880
Total allocated space (uordblks): 68314032
Total free space (fordblks): 11811920
Topmost releasable block (keepcost): 112
=====
Packet I/O Totals:
Received: 49088

IP4: 49394 (100.000%)
Frag: 0 ( 0.000%)
ICMP: 5 ( 0.010%)
UDP: 2195 ( 4.444%)
TCP: 47194 ( 95.546%)

<output removed for brevity>

```

Step 10 show utd engine standard logging event

Displays the logs which contains alerts and URLs that are either on the blocked or allowed list per VRF.

Example:

```

Device# show utd engine standard logging event

2017/08/04-16:01:49.205959 UTC [**] [Instance_ID: 1] [**] Drop [**]

```

```

UTD WebFilter Category/Reputation [**] [URL: www.cricinfo.com] ** [Category: Sports]
** [Reputation: 96] [VRF: vrf101] {TCP} 23.72.180.26:80 -> 111.0.0.254:53509
2017/08/04-16:02:12.253330 UTC [**] [Instance_ID: 1] [**] Pass [**]
  UTD WebFilter Whitelist [**] [URL: www.espn.go.com/m]
[VRF: vrf101] {TCP} 111.0.0.254:53511 -> 199.181.133.61:80

```

Step 11 **show logging** | include CONFIG_DOWNLOAD

Example:

```

show# logging | include CONFIG_DOWNLOAD
Aug 23 11:34:21.250 PDT: %IOSXE_UTD-4-MT_CONFIG_DOWNLOAD: UTD MT configuration download has started
Aug 23 11:54:18.496 PDT: %IOSXE_UTD-4-MT_CONFIG_DOWNLOAD: UTD MT configuration download has completed

```

Step 12 **show utd threat-inspection whitelist** [profile *profile-name*]

Displays all allowed list profiles or a specific allowed list profile.

Example:

```

Device# show utd threat-inspection whitelist
Whitelist Profile: wh101
Signature ID: 101

```

Example:

```

Device# show utd threat-inspection whitelist profile wh101
Whitelist Profile: wh101
Signature ID: 101

```

Step 13 **show utd threat-inspection profile** *profile-name*

Displays the details of a threat-inspection profile specified by the *profile-name*.

Example:

```

Device# show utd threat-inspection profile 101
Threat-inspection Profile: 101
Operational Mode: Intrusion Protection
Operational Policy: Security
Logging Level: debug
Whitelist Profile: wh101

```

Step 14 **show utd** [policy *profile-name*]

Displays all UTD policies or a specific UTD policy.

Example:

```

Device# show utd policy pol101
Policy name: pol101
VRF name: vrf101, VRF ID: 1
Global Inspection (across above VRFs): Enabled
Threat-inspection profile: 101
Web-filter URL profile: 1
Fail Policy: Fail-open

```

Step 15 **show utd web-filter url** [profile *profile-name*]

Displays all URL profiles or a specific profile.

Example:

```
Device# show utd web-filter url profile 1
URL Profile: 1
Alert: all
Blacklist Parameter Map Regex: urlf-blacklist1
Whitelist Parameter Map Regex: urlf-whitelist1
Block Categories:
dating
sports
Block Page Profile 1
Log level error
reputation block-threshold high-risk
```

Step 16 **show utd web-filter block local-server [profile *profile-name*]**

Displays all block page profiles or a specific block page profile.

Example:

```
Device# show utd web-filter block local-server profile 2
Block Local Server Profile: 2
Content text: "Blocked by Web-Filter"
HTTP ports: 80
```

Step 17 **show utd web-filter sourcedb [profile *profile-name*]**

Displays all sourcedb profiles or a specific sourcedb profile.

Example:

```
Device# show utd web-filter sourcedb
SourceDB Profile: 1
database update server interval hour 0 minute 0
Fail open
Log level: error
Proxy host port 0

SourceDB Profile: 2
database update server interval hour 0 minute 0
Fail open
Log level: error
Proxy host port 0
```

Example:

```
Device# show utd web-filter sourcedb profile 1
SourceDB Profile: 1
database update server interval hour 0 minute 0
Fail open
Log level: error
Proxy host port 0
```

Step 18 **show utd engine standard statistics daq dp [engine *engine-num*] [vrf [name *vrf-name* | global]]**

Displays serviceplane data acquisition (DAQ) statistics for all VRFs or a specific VRF.

Example:

The following example shows the serviceplane data acquisition statistics for VRF vrf101.

```

Device# show utd engine standard statistics daq dp vrf name vrf101
IOS-XE DAQ Counters(Engine #1):
-----
Frames received 374509
Bytes received 303136342

Kernel frames received 373590
Kernel frames dropped 0

FO cached via timer 0
Cached fo used 0
Cached fo freed 0
FO not found 0
CFT full packets 0

```

Step 19 `show utd engine standard config threat-inspection whitelist [profile profile-name]`

Displays the details of a threat-inspection allowed list profile stored in a container.

Example:

```

Device# show utd engine standard config threat-inspection whitelist
UTD Engine Standard Configuration:

UTD threat-inspection whitelist profile table entries:
Whitelist profile: wh101
Entries: 1

```

Step 20 `show utd engine standard config web-filter url profile profile-name`

Displays the details of the web-filter profile stored in the container.

Example:

```

Device# show utd engine standard config web-filter url profile 1
UTD Engine Standard Configuration:

```

```

UTD web-filter profile table entries
Web-filter URL profile: 1
Whitelist:
www.espn.com
www.nbcsports.com
www.nfl.com
Blacklist:
www.cnn.com
Categories Action: Block
Categories:
Social Network
Sports
Block Profile: 1
Redirect URL: http://172.27.56.97/vrf101.html
Reputation Block Threshold: High risk
Alerts Enabled: Whitelist, Blacklist, Categories, Reputation
Debug level: Error
Conditional debug level: Error

```

Step 21 **show utd engine standard config [vrf name *vrf-name*]**

Displays the details of the UTD policy, threat-inspection profile and web-filter profile associated with a particular VRF.

Example:

```

Device# show utd engine standard config vrf name vrf101
UTD Engine Standard Configuration:

UTD VRF table entries:
VRF: vrf101 (1)
Policy: pol101
Threat Profile: 101
Webfilter Profile: 1

```

Step 22 **show utd engine standard config threat-inspection profile *profile-name***

Displays the details of a specific threat-inspection profile.

Example:

```

Device# show utd engine standard config threat-inspection profile 101
UTD Engine Standard Configuration:

UTD threat-inspection profile table entries:
Threat profile: 101
Mode: Intrusion Prevention
Policy: Security
Logging level: Debug
Whitelist profile: wh101

Description:
Displays the details of a threat-inspection profile stored in the container.

```

Step 23 **show utd engine standard threat-inspection signature update status**

Shows the output of the current signature package version, previous signature package version, and last status update.

Example:

```

Device# show utd engine standard threat-inspection signature update status
Current signature package version: 29.0.c
Current signature package name: default
Previous signature package version: None

```

```

-----
Last update status: Failed
-----
Last successful update time: None
Last successful update method: None
Last successful update server: None
Last successful update speed: None

Last attempted update server: http://172.27.57.252/UTD-STD-SIGNATURE-2983-1-S.pkg
-----
Total num of updates successful: 0
Num of attempts successful: 0
Num of attempts failed: 1
Total num of attempts: 1
-----
Next update scheduled at: None
-----
Current status: Idle

```

Step 24 `show platform software qfp active feature utd config [vrf {id vrf-id | name vrf-name | global }]`

Shows the service node statistics. The VRF information can only be shown in the case of multi-tenancy. Displays the data plane UTD configuration. In the following example the security context information is highlighted.

Example:

```

Device# Global configuration
NAT64: disabled
SN threads: 12
CFT inst_id 0 feat id 0 fo id 0 chunk id 4
Context Id: 0, Name: Base Security Ctx
  Ctx Flags: (0xf0000)
    Engine: Standard
    SN Redirect Mode : Fail-close, Divert
    Threat-inspection: Enabled, Mode: IPS
    Domain Filtering : Not Enabled
    URL Filtering    : Not Enabled
SN Health: Green

```

Step 25 `show platform software utd interfaces`

Example:

```

Device# show platform software utd interfaces

UTD interfaces
All dataplane interfaces

```

Step 26 `show platform hardware qfp active feature utd config [vrf {id vrf-id | name vrf-name | global }]`

Show UTD datapath configuration and status.

Example:

```
Device# show platform hardware qfp active feature utd config vrf name vrf101
Global configuration
  NAT64: disabled
  Drop pkts: disabled
  Multi-tenancy: enabled
  Data plane initialized: yes
  SN threads: 12
  CFT inst_id 0 feat id 1 fo id 1 chunk id 8
  SN Health: Green
```

Step 27 `show platform hardware qfp active feature utd stats [clear | divert | drop | general | summary] [vrf {id vrf-id | name vrf-name | global }] [all] [verbose]`

Displays dataplane UTD statistics, including counts of zeros

clear—Clear Statistics

divert—Display AppNav Redirect Statistics

drop—Display Drop Statistics

general—Display General Statistics

summary—Display Summary Statistics

verbose—Display Verbose Statistics

vrf Display per VRF stats—The VRF information can only be entered if multi-tenancy is enabled.

id—display stats associated with the VRF id

name—display stats associated with the VRF with the provided name

global—display the stats associated with the global VRF (i.e vrf-id 0)

Example:

```
Device# show platform hardware qfp active feature utd stats

Summary Statistics:
TCP Connections Created 29893
UDP Connections Created 24402
ICMP Connections Created 796
Pkts dropped pkt 258
byt 66365
Pkts entered policy feature pkt 715602
byt 562095214
Pkts entered divert feature pkt 662014
byt 516226302
Pkts slow path pkt 55091
byt 4347864
Pkts Diverted pkt 662014
byt 516226302
Pkts Re-injected pkt 659094
byt 514305557

Would-Drop Statistics:

Service Node flagged flow for dropping 258

General Statistics:
Non Diverted Pkts to/from divert interface 1022186
Inspection skipped - UTD policy not applicable 1081563
```

<output removed for brevity>

Example:

Step 28 **show platform hardware qfp active feature utd stats summary [vrf name *vrf-name* | all]**

Displays information about all VRFs or a specific VRF, taken from the summary option of the **show platform hardware qfp active feature utd stats** command.

Example:

```
Device# show platform hardware qfp active feature utd stats vrf name vrf101
Security Context: Id:1 Name: 1 : vrf101
```

```
Summary Statistics:
TCP Connections Created 18428
UDP Connections Created 13737
ICMP Connections Created 503
Pkts dropped pkt 258
byt 66365
Pkts entered policy feature pkt 407148
byt 296496913
Pkts entered divert feature pkt 383176
byt 283158966
Pkts slow path pkt 32668
byt 2571632
Pkts Diverted pkt 383176
byt 283158966
Pkts Re-injected pkt 381016
byt 281761395
```

<output removed for brevity>

Step 29 **show platform hardware qfp active feature utd stats drop all**

Displays information from all the VRFs taken from the drop option of the **show platform** command.

Example:

```
Device# show platform hardware qfp active feature utd stats drop all
```

```
Would-Drop Statistics:

No diversion interface                                0
No egress interface                                  0
Inspection service down                              0
Could not find divert interface                      0
Could not find divert fib                            0
UTD FIB did not contain oce_chain                    0
Invalid IP version                                   0
IPS not supported                                    0
Re-inject Error                                      0
Service Node flagged flow for dropping               1225
Could not attach feature object                       0
Could not allocate feature object                    0
Error getting feature object                         0
Policy: could not create connection                  0
NAT64 Interface Look up Failed                       0
Decaps: VPATH connection establishment error         0
Decaps: VPATH could not find flow, no tuple          0
Decaps: VPATH notification event error               0
Decaps: Could not delete flow                        0
Decaps: VPATH connection classification error        0
```

```

Encaps: Error retrieving feature object          0
Encaps: Flow not classified                     0
Encaps: VPATH connection specification error    0
Encaps: VPATH First packet meta-data failed    0
Encaps: VPATH No memory for meta-data          0
Encaps: VPATH Could not add TLV                0
Encaps: VPATH Could not fit TLV into memory    0
Service Node Divert Failed                     0
No feature object                              0
Service Node not healthy                       123
Could not allocate VRF meta-data               0
Could not allocate debug meta-data             0
Packet was virtually fragmented (VFR)         0
IPv6 Fragment                                 0
IPv4 Fragment                                 0

```

Troubleshooting Multi-Tenancy for Unified Threat Defense

Traffic is not Diverted

Problem Traffic is not diverted.

Possible Cause Virtual-service may not be activated.

Solution Check whether the virtual-service is activated by using the **show virtual-service list** command. The following is sample output from the command:

```

Device# show virtual-service list

Virtual Service List:

Name Status Package Name
-----
snort Activated utdsnort.1_0_1_SV2982_XE_16_3.20160701_131509.ova

```

Possible Cause Unified threat defense (UTD) may not be enabled for specified interface or interfaces.

Solution Use the **show platform software utd global** command to verify if UTD is enabled for the interface:

```

Device# show platform software utd global

UTD Global state
Engine           : Standard
Global Inspection : Disabled
Operational Mode : Intrusion Prevention
Fail Policy      : Fail-open
Container techonlogy : LXC
Redirect interface : VirtualPortGroup1
UTD interfaces
GigabitEthernet0/0/0

```

Possible Cause The service node may not be working properly.

Solution Use the **show platform hardware qfp active feature utd config** command to verify if the health of the service node is green:

```
Device# show platform hardware qfp active feature utd config
```

```
Global configuration
NAT64: disabled
SN threads: 12
CFT inst_id 0 feat id 0 fo id 0 chunk id 4
Context Id: 0, Name: Base Security Ctx
Ctx Flags: (0x60000)
Engine: Standard
SN Redirect Mode : Fail-open, Divert
Threat-inspection: Enabled, Mode: IDS
Domain Filtering : Not Enabled
URL Filtering : Not Enabled
SN Health: Green
```

Solution Alternatively, in the case of multi-tenancy, you can use the **show platform hardware qfp active feature utd config vrf name vrf-name** command to verify if the health of the service node, for a specific VRF, is green:

```
Device# show platform hardware qfp active feature utd config vrf name vrf102
```

```
Global configuration
NAT64: disabled
Drop pkts: disabled
Multi-tenancy: enabled
Data plane initialized: yes
SN threads: 12
CFT inst_id 0 feat id 0 fo id 0 chunk id 4
SN Health: Green
```

Possible Cause The Snort process may not be activated.

Solution Use the **show virtual-service detail** command to verify if the Snort process is up and running:

```
Device# show virtual-service detail
```

```
Virtual service UTDIPS detail
State           : Activated
Owner           : IOSd
Package information
Name            : utdsnort.1_0_1_SV2982_XE_16_3.20160701_131509.ova

```

Possible Cause The AppNav tunnel may not be activated.

Solution Use the **show service-insertion type utd service-node-group** and **show service-insertion type utd service-context** commands to verify if the AppNav tunnel is activated.

Solution The following is sample output from the **show service-insertion type utd service-node-group** command:

```
Device# show service-insertion type utd service-node-group
```

```
Service Node Group name : utd_sng_1
Service Context : utd/1
Member Service Node count : 1
```

```
Service Node (SN) : 30.30.30.2
Auto discovered : No
SN belongs to SNG : utd_sng_1
Current status of SN : Alive
Time current status was reached : Tue Jul 26 11:57:48 2016
```

```
Cluster protocol VPATH version : 1
Cluster protocol incarnation number : 1
Cluster protocol last sent sequence number : 1469514497
Cluster protocol last received sequence number: 1464
Cluster protocol last received ack number : 1469514496
```

Solution The following is sample output from the `show service-insertion type utd service-context` command:

```
Device# show service-insertion type utd service-context
```

```
Service Context : utd/1
Cluster protocol VPATH version : 1
Time service context was enabled : Tue Jul 26 11:57:47 2016
Current FSM state : Operational
Time FSM entered current state : Tue Jul 26 11:57:58 2016
Last FSM state : Converging
Time FSM entered last state : Tue Jul 26 11:57:47 2016
Cluster operational state : Operational
```

```

```

```
Current SN View:
30.30.30.2
```

Possible Cause Check data plane UTD statistics for the status of the traffic. If the traffic is not diverted, the number of packets diverted and rejected will be zero. If the numbers are nonzero, then traffic diversion is happening, and the Snort sensor is resending packets back to the dataplane.

Solution Use the `show platform hardware qfp active feature utd stats` command to verify the status of the traffic.

```
Device# show platform hardware qfp active feature utd stats
```

```
Security Context:      Id:0      Name: Base Security Ctx
```

```
Summary Statistics:
Active Connections                29
TCP Connections Created           712910
UDP Connections Created            80
Pkts entered policy feature      pkt  3537977
                                   byt  273232057
```

```

Signature Update is not Working

Problem Signature update from Cisco Borderless Software Distribution (BSD) server is not working.

Possible Cause Signature update may have failed due to various reasons. Check for the reason for the last failure to update the signatures.

Solution Use the **show utd engine standard threat-inspection signature update status** command to display the reason for the last failure to update the signatures:

```

Device# show utd eng standard threat-inspection signature update status
Current signature package version: 29.0.c
Current signature package name: default
Previous signature package version: None
-----
Last update status: Failed
-----
Last successful update time: None
Last successful update method: None
Last successful update server: None
Last successful update speed: None

```

```

-----
Last failed update time: Thu Jan 11 13:34:36 2018 PST
Last failed update method: Manual
Last failed update server: http://172.27.57.252/UTD-STD-SIGNATURE-2983-1-S.pkg
Last failed update reason: [Errno 113] No route to host
-----
Last attempted update time: Thu Jan 11 13:34:36 2018 PST
Last attempted update method: Manual
Last attempted update server: http://172.27.57.252/UTD-STD-SIGNATURE-2983-1-S.pkg
-----
Total num of updates successful: 0
Num of attempts successful: 0
Num of attempts failed: 1
Total num of attempts: 1
-----
Next update scheduled at: None
-----
Current status: Idle

```

Possible Cause Domain Name System (DNS) is not configured correctly.

Solution Use the **show running-config | i name-server** command to display the name server details:

```

Device# show run | i name-server

ip name-server 10.104.49.223

```

Possible Cause System error—Failed to process the username and password combination.

Solution Ensure that you have provided the correct credentials for signature package download.

Signature Update from the Local Server is not Working

Problem Signature update from the local server not working.

Possible Cause Last failure Reason: Invalid scheme—only HTTP/HTTPS supported.

Solution Ensure that you have provided the HTTP or secure HTTP (HTTPS) as the local download method.

Possible Cause Last failure Reason: Name or service not known.

Solution Ensure that the hostname or IP address provided for the local server is correct.

Possible Cause Last failure Reason: Credentials not supplied.

Solution Ensure that you have provided the credentials for local HTTP/HTTPS server.

Possible Cause Last failure Reason: File not found.

Solution Ensure that the signature file name or URL that you have provided is correct.

Possible Cause Last failure Reason: Download corrupted.

Solution

- Verify whether the retry signature update is corrupted as the previous signature download.
- Ensure that the correct signature package is available.

Logging to IOSd Syslog is not Working

Problem Logging to IOSd syslog is not working.

Possible Cause Logging to syslog may not be configured in the unified threat defense (UTD) configuration.

Solution Use the `show utd engine standard config` command to display the UTD configuration and to ensure that logging to syslog is configured.

```
Device# show utd engine standard config

UTD Engine Standard Configuration:
  Operation Mode : Intrusion Prevention
  Policy         : Security

Signature Update:
  Server        : cisco
  User Name     : ccouser
  Password      : YEX^SH\fhdOeEGaOBIQAicOVLgaVGf
  Occurs-at     : weekly ; Days:0 ; Hour: 23; Minute: 50

Logging:
  Server        : IOS Syslog; 10.104.49.223
  Level         : debug

Whitelist Signature IDs:
  28878
```

Solution Use the following `show utd engine standard logging events` command to display the event logs for the UTD engine.

```
Device# show utd engine standard logging events

2016/06/13-14:32:09.524475 IST [**] [Instance_ID: 1] [**] Drop [**] [1:30561:1]
BLACKLIST DNS request for known malware domain domai.ddns2.biz -
Win.Trojan.Beebone [**] [Classification: A Network Trojan was Detected]
[Priority: 1] [VRF_ID: 2] {UDP} 11.1.1.10:58016 -> 21.1.1.10:53
2016/06/13-14:32:21.524988 IST [**] [Instance_ID: 1] [**] Drop [**] [1:30561:1]
BLACKLIST DNS request for known malware domain domai.ddns2.biz -
Win.Trojan.Beebone [**] [Classification: A Network Trojan was Detected] [Priority: 1]
[VRF_ID: 2] {UDP} a000:0:0:0:0:0:0:10:59964 -> b000:0:0:0:0:0:0:10:53
```

Logging to an External Server is not Working

Problem Logging to an external server is not working.

Possible Cause Syslog may not be running on the external server.

Solution Verify whether syslog server is running on the external server. Configure the following command on the external server to view its status:

```
ps -eaf | grep syslog

root 2073 1 0 Apr12 ? 00:00:02 syslogd -r -m
```

Possible Cause Connectivity between unified threat defense (UTD) Linux Container (LXC) and external server may be lost.

Solution Verify the connectivity from the management interface to the external syslog server.

UTD Conditional Debugging

Conditional debugging is supported by multi-tenancy for Unified Threat Defense. For further details about how to configure conditional debugging, see:

http://www.cisco.com/.../troubleshooting-guides/3-sas-1000-book.htm#ak_AC96BB06B414DCBBDEF7ADD29EF8131

PART **XV**

Umbrella

- [Cisco Umbrella Integration, on page 2173](#)

CHAPTER 167

Cisco Umbrella Integration

The Cisco Umbrella Integration feature enables cloud-based security service by inspecting the Domain Name System (DNS) query that is sent to the DNS server through the device. The security administrator configures policies on the Cisco Umbrella portal to either allow or deny traffic towards the fully qualified domain name (FQDN). Cisco device acts as a DNS forwarder on the network edge, transparently intercepts DNS traffic, and forwards the DNS queries to the Cisco Umbrella portal. This feature is available on Cisco IOS XE Denali 16.3 and later releases.

- [Feature Information for Cisco Umbrella Integration](#) , on page 2182

Restrictions for Cisco Umbrella Integration

- If an application or host uses IP address directly instead of DNS to query domain names, policy enforcement is not applied.
- When the client is connected to a web proxy, the DNS query does not pass through the Cisco device. In this case, the connector does not detect any DNS request and the connection to the web server bypasses any policy from the Cisco Umbrella portal.
- When the Cisco Umbrella Integration policy blocks a DNS query, the client is redirected to a Cisco Umbrella block page. HTTPS servers provide these block pages and the IP address range of these block pages is defined by the Cisco Umbrella portal.

- User authentication and identity is not supported in this release.
- The type A, AAAA, and TXT queries are the only records that are redirected. Other types of query bypasses the connector. Cisco Umbrella Connector maintains a list of IP address that is known for malicious traffic. When the Cisco Umbrella roaming client detects the destination of packets to those addresses, it forwards those addresses to Cisco Umbrella cloud for further inspection.
- Only the IPv4 address of the host is conveyed in the EDNS option.
- A maximum of 64 local domains can be configured, and the allowed domain name length is 100 characters.

Prerequisites for Cisco Umbrella Integration

Before you configure the Cisco Umbrella Integration feature, ensure that the following are met:

- The device has a security K9 license to enable Cisco Umbrella Integration.
- The device runs the Cisco IOS XE Denali 16.3 software image or later.
- Cisco Umbrella subscription license is available.
- The device is set as the default DNS server gateway and needs to ensure that the DNS traffic goes through the Cisco device.
- Communication for device registration to the Cisco Umbrella server is via HTTPS. This requires a root certificate to be installed on the router. To download the DigiCert root certificate, go to <https://www.digicert.com/kb/digicert-root-certificates.htm#roots>. To download the scope API certificate, go to: <https://letsencrypt.org/certs/isrgrootx1.pem>

Cloud-based Security Service Using Cisco Umbrella Integration

The Cisco Umbrella Integration feature provides cloud-based security service by inspecting the DNS query that is sent to the DNS server through the device. When a host initiates the traffic and sends a DNS query, the Cisco Umbrella Connector in the device intercepts and inspects the DNS query. If the DNS query is for a local domain, it forwards the query without changing the DNS packet to the DNS server in the enterprise network. If it is for an external domain, it adds an Extended DNS (EDNS) record to the query and sends it to Cisco Umbrella Resolver. An EDNS record includes the device identifier information, organization ID and client IP. Based on this information, Cisco Umbrella Cloud applies different policies to the DNS query.

Encrypting the DNS Packet

The DNS packet sent from the Cisco device to Cisco Umbrella Integration server must be encrypted if the EDNS information in the packet contains information such as user IDs, internal network IP addresses, and so on. When the DNS response is sent back from the DNS server, device decrypts the packet and forwards it to the host.

You can encrypt DNS packets only when the DNSCrypt feature is enabled on the Cisco device.

The Cisco device uses the following Anycast recursive Cisco Umbrella Integration servers:

- 208.67.222.222

- 208.67.220.220
- 2620:119:53::53
- 2620:119:35::35

The Figure 1 describes the Cisco Umbrella Integration topology.

Figure 88: Cisco Umbrella Integration Topology

Benefits of Cisco Umbrella Integration

Cisco Umbrella Integration provides security and policy enforcement at DNS level. It enables the administrator to split the DNS traffic and directly send some of the desired DNS traffic to a specific DNS server (DNS server located within the enterprise network). This helps the administrator to bypass the Cisco Umbrella Integration.

Configuring the Cisco Umbrella Connector

You can configure Cisco Umbrella Connector using either the API tokens, or scope API keys.

To configure Cisco Umbrella Connector using API token:

- Get the API token from the Cisco Umbrella registration server.

- Have the root certificate establish the HTTPS connection with the Cisco Umbrella registration server. Import the root certificate of DigiCert given below into the device using the **crypto pki trustpool import terminal** command.

```

MrY=
-----END CERTIFICATE-----
```

Note You can also download this certificate here: <https://www.digicert.com/kb/digicert-root-certificates.htm#roots>

- Verify that the PEM import is successful. A message is displayed after importing the certificate.

This is the sample configuration:

```
enable
configure terminal
parameter-map type umbrella global
  token AABBA59A0BDE1485C912AFE472952641001EEEEC
exit
```

From Cisco IOS XE 17.15.1a, you can use scope API keys to configure DNS security, using the **use-v2-api** command. To continue using legacy keys, use the **no use-v2-api** command.

For devices running with Cisco IOS XE 17.15.1a and higher releases, the **use-v2-api** command does not need to be explicitly configured. The **no use-v2-api** command must be configured on devices running with Cisco IOS XE 17.15.1a and higher releases, when legacy credentials are used.

To configure Cisco Umbrella Connector using scope API keys:

Import the root certificate of DigiCert given below into the device:

```

-----END CERTIFICATE-----
```

Note You can also download this certificate here: <https://letsencrypt.org/certs/isrgrootx1.pem>

Note It is recommended to use the scope API keys for Umbrella configuration. Support for legacy keys will be deprecated.

The following example provides the configurations for DNS security with API keys:

```
parameter-map type umbrella global
api-key <api-key>
orgid <org-id>
secret 0 <secret>
dnscrypt
vrf 1
dns-resolver umbrella
```

Registering the Cisco Umbrella Tag

To register the Cisco Umbrella tag, perform these steps:

1. Configure the umbrella parameter map as shown in the previous section.
2. Configure **umbrella out** on the WAN interface:

```
interface gigabitEthernet 0/0/1
 umbrella out
```

3. Configure **umbrella in** on the LAN interface:

```
interface gigabitEthernet 0/0/0.4
 umbrella in mydevice_tag
```

Note For the Cisco devices, the length of the hostname and umbrella tag should not exceed 49 characters.

4. After you configure **umbrella in** with a tag using the **umbrella in mydevice_tag** command, the device registers the tag to the Cisco Umbrella Integration portal.
5. The device initiates the registration process by resolving *api.opendns.com*. You need to have a name server (*ip name-server x.x.x.x*) and domain lookup (*ip domain-lookup*) configured on the device to successfully resolve the FQDN.

Note You should configure the **umbrella out** command before you configure **umbrella in** command. Registration is successful only when the port 443 is in *open* state and allows the traffic to pass through the existing firewall.

Configuring Cisco Device as a Pass-through Server

You can identify the traffic to be bypassed using domain names. In the Cisco device, you can define these domains in the form of regular expressions. If the DNS query that is intercepted by the device matches one of the configured regular expressions, then the query is bypassed to the specified DNS server without redirecting to the Cisco Umbrella cloud. This sample configuration shows how to define a regex parameter-map with a desired domain name and regular expressions:

```
Device# configure terminal
Device(config)# parameter-map type regex dns_bypass
Device(config)# pattern www.fisco.com
Device(config)# pattern .*engineering.fisco.*
```

Attach the regex param-map with the openDNS global configuration as shown below:

```
Device(config)# parameter-map type umbrella global
Device(config-profile)# token AADDD5FF6E510B28921A20C9B98EEFF
Device(config-profile)# local-domain dns_bypass
```

DNSCrypt, Resolver, and Public-key

- DNSCrypt
- Resolver IP
- Public-Key

We recommend that you change the above parameters only when you perform certain tests in the lab. These parameters are reserved for future use. If you modify these parameters, it can affect the normal functioning of the device.

Resolver

The following commands change the redirection of DNS packets from the Cisco device to Cisco Umbrella cloud:

- **resolver ipv4 1.1.1.1**
- **resolver ipv4 1.1.1.2**
- **resolver ipv6 1234::1**
- **resolver ipv6 2345::1**

In this example, all the IPv4 DNS packets are redirected to 1.1.1.1 or 1.1.1.2 and IPv6 DNS packets are redirected to 1234::1 or 2345::1. You should remove the IP address to restore to the default values of the resolver. When you modify a resolver IP address, the following message is displayed:

```
User configured would overwrite defaults
Defaults are restored when no more user configured are present
```

With the default values of **208 . 67 . 222 . 222** and **208 . 67 . 220 . 220**, all DNS packets are redirected to Cisco Umbrella Anycast resolvers. The device uses the first default resolver IP address for all its redirection. When the Cisco device does not receive a response for three consecutive DNS queries, the device automatically switches to a different resolver IP address. This behavior remains the same for IPv6 resolver addresses.

Note IPv6 redirection is deferred and all IPV6 DNS packets are not redirected to Cisco Umbrella Anycast servers.

Public-key

Public-key is used to download the DNSCrypt certificate from Cisco Umbrella Integration cloud. This value is preconfigured to

B735 : 1140 : 206F : 225D : 3E2B : D822 : D7FD : 691E : A1C3 : 3CC8 : D666 : 8D0C : BE04 : BFAB : CA43 : FB79 which is the public-key of Cisco Umbrella Integration Anycast servers. If there is a change in the public-key and if you modify this command, then you have to remove the modified command to restore the default value. If you modify the value, the DNSCrypt certificate download may fail.

DNSCrypt

To disable DNSCrypt, use the **no dnsencrypt** command and to re-enable DNSCrypt, use the **dnsencrypt** command.

When the DNSCrypt is used, the DNS request packets size is more than 512 bytes. Ensure that these packets are allowed through the intermediary devices; otherwise, the response may not reach the intended recipients.

Verifying the Cisco Umbrella Connector Configuration

Verify the Cisco Umbrella Connector configuration using the following commands:

```
Router# show umbrella config
Umbrella Configuration
=====
Token: AAC1A2555C11B2B798FFF3AF27C2FB8F001CB7B2
OrganizationID: 1882034
Local Domain Regex parameter-map name: NONE
```

```

DNSCrypt: Enabled

```

Troubleshooting Cisco Umbrella Integration

Troubleshoot issues that are related to enabling Cisco Umbrella Integration feature using these commands:

- **debug umbrella device-registration**
- **debug umbrella config**
- **debug umbrella dnscrypt**

Depending on the OS, run either of these two commands from the client device:

- The `nslookup -type=txt debug.umbrella.com` command from the command prompt of the Windows machine
- The `nslookup -type=txt debug.umbrella.com` command from the terminal window or shell of the Linux machine

```
nslookup -type=txt debug.opendns.com 8.8.8.8
Server: 8.8.8.8
Address: 8.8.8.8#53
Non-authoritative answer:
debug.opendns.com text = "server r6.mum1"
debug.opendns.com text = "device 010A826AAABB6C3D"
debug.opendns.com text = "organization id 1892929"
debug.opendns.com text = "remoteip 171.168.1.7"
debug.opendns.com text = "flags 436 0 6040 39FF0000000000000000"
debug.opendns.com text = "originid 119211936"
debug.opendns.com text = "orgid 1892929"
debug.opendns.com text = "orgflags 3"
debug.opendns.com text = "actype 0"
debug.opendns.com text = "bundle 365396"
debug.opendns.com text = "source 72.163.220.18:36914"
debug.opendns.com text = "dnscrypt enabled (713156774457306E)"
```

Configuration Examples

This example shows how to enable Cisco Umbrella Integration:

Deploying Cisco Umbrella Integration Using Cisco Prime CLI Templates

You can use the Cisco Prime CLI templates to provision the Cisco Umbrella Integration deployment. The Cisco Prime CLI templates make provisioning Cisco Umbrella Integration deployment simple.

Note The Cisco Prime CLI templates is supported only on Cisco Prime version 3.1 or later.

To use the Cisco Prime CLI templates to provision the Cisco Umbrella Integration deployment, perform these steps:

-
- Step 1** Download the Cisco Prime templates corresponding to the Cisco IOS XE version running on your system.
 - Step 2** Unzip the file, if it is a zipped version.
 - Step 3** From Cisco Prime Web UI, choose **Configuration > Templates > Features and Technologies**, and then select **CLI Templates (User Defined)**.
 - Step 4** Click **Import**.
 - Step 5** Select the folder where you want to import the templates and click **Select Templates** and choose the templates that you just downloaded.
 - Step 6** The following Cisco Umbrella Integration templates are available:

- Umbrella—Use this template to provision Umbrella Connector on the device.
- Umbrella Cleanup—Use this template to remove previously configured Umbrella Connector.

Feature Information for Cisco Umbrella Integration

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 222: Feature Information for Cisco Umbrella Integration

Feature Name	Releases	Feature Information
Cisco Umbrella Integration	Cisco IOS XE Everest Release 16.6.1	The Cisco Umbrella Integration feature enables cloud-based security service by inspecting the DNS query that is sent to any DNS server through Cisco devices. The security administrator configures policies on the Umbrella cloud to either allow or deny traffic towards the fully qualified domain name (FQDN). This feature is supported only on Cisco ISRs.

CHAPTER 168

Cisco IOS Login Enhancements-Login Block

The Cisco IOS Login Enhancements (Login Block) feature allows users to enhance the security of a router by configuring options to automatically block further login attempts when a possible denial-of-service (DoS) attack is detected.

The login block and login delay options introduced by this feature can be configured for Telnet or SSH virtual connections. By enabling this feature, you can slow down “dictionary attacks” by enforcing a “quiet period” if multiple failed connection attempts are detected, thereby protecting the routing device from a type of denial-of-service attack.

Note Whenever you want to use the AAA "quiet-mode" feature, you have to configure the `aaa new-model` using the `aaa new-model` command.

Finding Feature Information

Your software release may not support all the features documented in this module. For the latest caveats and feature information, see [Bug Search Tool](#) and the release notes for your platform and software release. To find information about the features documented in this module, and to see a list of the releases in which each feature is supported, see the feature information table.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Cisco IOS Login Enhancements

Protecting Against Denial of Service and Dictionary Login Attacks

Connecting to a routing device for the purposes of administering (managing) the device, at either the User or Executive level, is most frequently performed using Telnet or SSH (secure shell) from a remote console (such as a PC). SSH provides a more secure connection option because communication traffic between the user's device and the managed device are encrypted. The Login Block capability, when enabled, applies to both Telnet connections and SSH connections.

The automated activation and logging of the Login Block and Quiet Period capabilities introduced by this feature are designed to further enhance the security of your devices by specifically addressing two well known methods that individuals use to attempt to disrupt or compromise networked devices.

If the connection address of a device is discovered and is reachable, a malicious user may attempt to interfere with the normal operations of the device by flooding it with connection requests. This type of attack is referred to as an attempted Denial-of-Service, because it is possible that the device may become too busy trying to process the repeated login connection attempts to properly handle normal routing services or will not be able to provide the normal login service to legitimate system administrators.

The primary intention of a dictionary attack, unlike a typical DoS attack, is to actually gain administrative access to the device. A dictionary attack is an automated process to attempt to login by attempting thousands, or even millions, of username/password combinations. (This type of attack is called a "dictionary attack" because it typically uses, as a start, every word found in a typical dictionary as a possible password.) As scripts or programs are used to attempt this access, the profile for such attempts is typically the same as for DoS attempts; multiple login attempts in a short period of time.

By enabling a detection profile, the routing device can be configured to react to repeated failed login attempts by refusing further connection request (login blocking). This block can be configured for a period of time, called a "quiet period". Legitimate connection attempts can still be permitted during a quiet period by configuring an access-list (ACL) with the addresses that you know to be associated with system administrators.

Login Enhancements Functionality Overview

Delays Between Successive Login Attempts

A Cisco device can accept virtual connections as fast as they can be processed. Introducing a delay between login attempts helps to protect the Cisco device against malicious login connections such as dictionary attacks and DoS attacks. Delays can be enabled in one of the following ways:

- Via the **auto secure** command. If you enable the AutoSecure feature, the default login delay time of one second is automatically enforced.
- Via the **login block-for** command. You must enter this command before issuing the **login delay** command. If you enter only the **login block-for** command, the default login delay time of one second is automatically enforced.
- Via the new global configuration mode command, **login delay**, which allows you to specify a the login delay time to be enforced, in seconds.

Login Shutdown If DoS Attacks Are Suspected

If the configured number of connection attempts fail within a specified time period, the Cisco device will not accept any additional connections for a “quiet period.” (Hosts that are permitted by a predefined access-control list [ACL] are excluded from the quiet period.)

The number of failed connection attempts that trigger the quiet period can be specified via the new global configuration mode command **login block-for**. The predefined ACL that is excluded from the quiet period can be specified via the new global configuration mode command **login quiet-mode access-class**.

This functionality is disabled by default, and it is not enabled if autosecure is enabled.

How to Configure Cisco IOS Login Enhancements

Configuring Login Parameters

Use this task to configure your Cisco device for login parameters that help detect suspected DoS attacks and slow down dictionary attacks.

All login parameters are disabled by default. You must issue the **login block-for** command, which enables default login functionality, before using any other login commands. After the **login block-for** command is enabled, the following defaults are enforced:

- A default login delay of one second
- All login attempts made via Telnet or SSH are denied during the quiet period; that is, no ACLs are exempt from the login period until the **login quiet-mode access-class** command is issued.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **login block-for** *seconds* **attempts** *tries* **within** *seconds*
5. **login quiet-mode access-class** {*acl-name* | *acl-number*}
6. **login delay** *seconds*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	aaa new-model Example: <pre>Router(config)# aaa new-model</pre>	Enables the authentication, authorization, and accounting (AAA) access control model.
Step 4	login block-for <i>seconds</i> attempts <i>tries</i> within <i>seconds</i> Example: <pre>Router(config)# login block-for 100 attempts 2 within 100</pre>	Configures your Cisco IOS XE device for login parameters that help provide DoS detection. Note This command must be issued before any other login command can be used.
Step 5	login quiet-mode access-class {<i>acl-name</i> <i>acl-number</i>} Example: <pre>Router(config)# login quiet-mode access-class myacl</pre>	(Optional) Although this command is optional, it is recommended that it be configured to specify an ACL that is to be applied to the router when the router switches to quiet mode. When the router is in quiet mode, all login requests are denied and the only available connection is through the console. If this command is not configured, then the default ACL sl_def_acl is created on the router. This ACL is hidden in the running configuration. Use the show access-list sl_def_acl to view the parameters for the default ACL. For example: <pre>Router#show access-lists sl_def_acl</pre> <pre>Extended IP access list sl_def_acl</pre> <pre>10 deny tcp any any eq telnet</pre> <pre>20 deny tcp any any eq www</pre> <pre>30 deny tcp any any eq 22</pre> <pre>40 permit ip any any</pre>
Step 6	login delay <i>seconds</i> Example: <pre>Router(config)# login delay 10</pre>	(Optional) Configures a delay between successive login attempts.

What to Do Next

After you have configured login parameters on your router, you may wish to verify the settings. To complete this task, see the following section [“Verifying Login Parameters, on page 2191.”](#)

Verifying Login Parameters

Use this task to verify the applied login configuration and present login status on your router.

SUMMARY STEPS

1. **enable**
2. **show login failures**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show login failures Example: Router# show login	Displays login parameters. <ul style="list-style-type: none"> • failures --Displays information related only to failed login attempts.

Examples

The following sample output from the **show login** command verifies that no login parameters have been specified:

```
Router# show login
No login delay has been applied.
No Quiet-Mode access list has been configured.
All successful login is logged and generate SNMP traps.
All failed login is logged and generate SNMP traps
Router NOT enabled to watch for login Attacks
```

The following sample output from the **show login** command verifies that the **login block-for** command is issued. In this example, the command is configured to block login hosts for 100 seconds if 16 or more login requests fail within 100 seconds; five login requests have already failed.

```
Router# show login
A default login delay of 1 seconds is applied.
No Quiet-Mode access list has been configured.
All successful login is logged and generate SNMP traps.
All failed login is logged and generate SNMP traps.
Router enabled to watch for login Attacks.
If more than 15 login failures occur in 100 seconds or less, logins will be disabled for 100 seconds.
Router presently in Watch-Mode, will remain in Watch-Mode for 95 seconds.
Present login failure count 5.
```

The following sample output from the **show login** command verifies that the router is in quiet mode. In this example, the **login block-for** command was configured to block login hosts for 100 seconds if 3 or more login requests fail within 100 seconds.

```

Router# show login
A default login delay of 1 seconds is applied.
No Quiet-Mode access list has been configured.
All successful login is logged and generate SNMP traps.
All failed login is logged and generate SNMP traps.
Router enabled to watch for login Attacks.
If more than 2 login failures occur in 100 seconds or less, logins will be disabled for 100
seconds.
Router presently in Quiet-Mode, will remain in Quiet-Mode for 93 seconds.
Denying logins from all sources.

```

The following sample output from **show login failures** command shows all failed login attempts on the router:

```

Router# show login failures
Information about login failure's with the device
Username      Source IPAddr  lPort Count  TimeStamp
try1          10.1.1.1      23    1    21:52:49 UTC Sun Mar 9 2003
try2          10.1.1.2      23    1    21:52:52 UTC Sun Mar 9 2003

```

The following sample output from **show login failures** command verifies that no information is presently logged:

```

Router# show login failures
*** No logged failed login attempts with the device.***

```

Configuration Examples for Login Parameters

Setting Login Parameters Example

The following example shows how to configure your router to enter a 100 second quiet period if 15 failed login attempts is exceeded within 100 seconds; all login requests will be denied during the quiet period except hosts from the ACL "myacl."

```

Router(config)# aaa new-model
Router(config)# login block-for 100 attempts 15 within 100
Router(config)# login quiet-mode access-class myacl

```

Feature Name	Releases	Feature Configuration Information
Cisco IOS Login Enhancements	Cisco IOS XE Release 2.1	<p>The Cisco IOS Login Enhancements (Login Block) feature allows users to enhance the security of a router by configuring options to automatically block further login attempts when a possible denial-of-service (DoS) attack is detected.</p> <p>In Cisco IOS XE Release 2.1, this feature was introduced on Cisco ASR 1000 Series Service Aggregation Routers.</p> <p>The following commands were modified by this feature: login block-for, login delay, login quiet-mode access-class, show login.</p>

CHAPTER 169

Configuring Security with Passwords, Privileges, and Logins

Cisco IOS based networking devices provide several features that can be used to implement basic security for CLI sessions using only the operating system running on the device. These features include the following:

- Different levels of authorization for CLI sessions to control access to commands that can modify the status of the networking device versus commands that are used to monitor the device
- Assigning passwords to CLI sessions
- Requiring users log in to a networking device with a username
- Changing the privilege levels of commands to create new authorization levels for CLI sessions

This module is a guide to implementing a baseline level of security for your networking devices. It focuses on the least complex options available for implementing a baseline level of security. If you have networking devices installed in your network with no security options configured, or you are about to install a networking device and you need help understanding the how to implement a baseline of security, this document will help you.

- [Restrictions for Configuring Security with Passwords, Privileges, and Logins, on page 2195](#)
- [Information About Configuring Security with Passwords, Privileges, and Logins, on page 2196](#)
- [How To Configure Security with Passwords Privileges and Logins, on page 2208](#)
- [Configuration Examples for Configuring Security with Passwords Privileges and Logins, on page 2228](#)
- [Where to Go Next, on page 2232](#)
- [Additional References, on page 2232](#)
- [Feature Information for Configuring Security with Passwords Privileges and Logins, on page 2233](#)

Restrictions for Configuring Security with Passwords, Privileges, and Logins

Your networking device must not be configured to use any local or remote authentication, authorization, and accounting (AAA) security features. This document describes only the non-AAA security features that can be configured locally on the networking device.

For information how to configure AAA security features that can be run locally on a networking device, or for information on how to configure remote AAA security using TACACS+ or RADIUS servers, see the *Securing User Services Configuration Guide Library*.

Restrictions and Guidelines for Reversible Password Types

- Password type 0 and type 7 are deprecated. So password type 0 and type 7, used for administrator login to Console, Telnet, SSH, webUI, and NETCONF, must be migrated to password type 8 or type 9.
- No action is required if username and password are type 0 and type 7 for local authentication such as CHAP, EAP and so on for ISG and Dot1x.
- Enable password type 0 and type 7 must be migrated to password type 8 or type 9.

Restrictions and Guidelines for Irreversible Password Types

- Password type 5 is deprecated. Password type 5 must be migrated to stronger password type 8 or type 9.
- For username secret password type 5 and for enable secret password type 5, migrate to type 8 or type 9.
- Secret password type 4 is not supported.

Information About Configuring Security with Passwords, Privileges, and Logins

Benefits of Creating a Security Scheme

The foundation of a good security scheme in the network is the protection of the user interfaces of the networking devices from unauthorized access. Protecting access to the user interfaces on your networking devices prevents unauthorized users from making configuration changes that can disrupt the stability of your network or compromise your network security.

The Cisco IOS XE features described in this document can be combined in many different ways to create a unique security scheme for each of your networking devices. Here are some possible examples that you can configure:

- You can enable non administrative users to run a subset of the administrative commands available on the networking device by lowering the entitlement level for the commands to the non administrative privilege level. This can be useful for the following scenarios:
 - ISPs that want their first-line technical support staff to perform tasks such as enabling new interfaces for new customers or resetting the connection for a customer whose connection has stopped passing traffic. See the [Example: Configuring a Device to Allow Users to Shutdown and Enable Interfaces, on page 2231](#) section for an example of how to do this.
 - When you want your first-line technical support staff to have the ability to clear console port sessions that were disconnected improperly from a terminal server. See the [Example: Configuring a Device to Allow Users to Clear Remote Sessions, on page 2228](#) section for an example of how to do this.

- When you want your first-line technical support staff to have the ability to view, but not change, the configuration of a networking device to facilitate troubleshooting a networking problem. See the [Example: Configuring a Device to Allow Users to View the Running Configuration, on page 2229](#) section for an example of how to do this.

Cisco IOS XE CLI Modes

To aid in the configuration of Cisco devices, the Cisco IOS XE command-line interface is divided into different command modes. Each command mode has its own set of commands available for the configuration, maintenance, and monitoring of router and network operations. The commands available to you at any given time depend on the mode you are in. Entering a question mark(?) at the system prompt (device prompt) allows you to obtain a list of commands available for each command mode.

The use of specific commands allows you to navigate from one command mode to another. The standard order in which a user would access the modes is as follows: user EXEC mode; privileged EXEC mode; global configuration mode; specific configuration modes; configuration submodes; and configuration subsubmodes.

Note The default configuration of a Cisco IOS XE software based networking device only allows you to configure passwords to protect access to user EXEC mode (for local, and remote CLI sessions) and privileged EXEC mode. This document describes how you can provide additional levels of security by protecting access to other modes, and commands, using a combination of usernames, passwords and the **privilege** command.

Most EXEC mode commands are one-time commands, such as **show** or **more** commands, which show the current configuration status, and **clear** commands, which clear counters or interfaces. EXEC mode commands are not saved across reboots of the router.

From privileged EXEC mode, you can enter *global configuration mode*. In this mode, you can enter commands that configure general system characteristics. You also can use global configuration mode to enter specific configuration modes. Configuration modes, including global configuration mode, allow you to make changes to the running configuration. If you later save the configuration, these commands are stored across router reboots.

From global configuration mode you can enter a variety of protocol-specific or feature-specific configuration modes. The CLI hierarchy requires that you enter these specific configuration modes only through global configuration mode. For example, *interface configuration mode*, is a commonly used configuration mode.

From configuration modes, you can enter configuration submodes. Configuration submodes are used for the configuration of specific features within the scope of a given configuration mode. As an example, this chapter describes the *subinterface configuration mode*, a submode of the interface configuration mode.

ROM monitor mode is a separate mode used when the router cannot boot properly. If your system (router, switch, or access server) does not find a valid system image to load when it is booting, the system will enter ROM monitor mode. ROM monitor (ROMMON) mode can also be accessed by interrupting the boot sequence during startup. ROMMON is not covered in this document because it does not have any security features available in it.

User EXEC Mode

When you start a session on a router, you generally begin in *user EXEC mode*, which is one of two access levels of the EXEC mode. For security purposes, only a limited subset of EXEC commands are available in

user EXEC mode. This level of access is reserved for tasks that do not change the configuration of the router, such as determining the router status.

If your device is configured to require users to log-in the log-in process will require a username and a password. You may try three times to enter a password before the connection attempt is refused.

User EXEC mode is set by default to privilege level 1. Privileged EXEC mode is set by default to privilege level 15. When you are logged into a networking device in user EXEC mode your session is running at privilege level 1. By default the EXEC commands at privilege level 1 are a subset of those available at privilege level 15. When you are logged into a networking device in privileged EXEC mode your session is running at privilege level 15. You can move commands to any privilege level between 1 and 15 using the **privilege** command.

In general, the user EXEC commands allow you to connect to remote devices, change terminal line settings on a temporary basis, perform basic tests, and list system information.

To list the available user EXEC commands, use the following command:

Command	Purpose
Device (config) # ?	Lists the user EXEC mode commands

The user EXEC mode prompt consists of the host name of the device followed by an angle bracket (>), as shown in the following example:

```
Device>
```

The default host name is generally Router, unless it has been changed during initial configuration using the **setup** EXEC command. You also change the host name using the **hostname** global configuration command.

Note Examples in Cisco IOS XE documentation assume the use of the default name of “Device.” Different devices (for example, access servers) may use a different default name. If the device (router, access server, or switch) has been named with the **hostname** command, that name will appear as the prompt instead of the default name.

To list the commands available in user EXEC mode, enter a question mark (?) as shown in the following example:

```
Device> ?
```

```
Exec commands:
<1-99>          Session number to resume
connect         Open a terminal connection
disconnect      Disconnect an existing telnet session
enable         Turn on privileged commands
exit           Exit from Exec mode
help           Description of the interactive help system
lat            Open a lat connection
lock           Lock the terminal
login          Log in as a particular user
logout         Exit from Exec mode and log out
menu          Start a menu-based user interface
mbranch       Trace multicast route for branch of tree
mrbranch      Trace reverse multicast route to branch of tree
```

```

mtrace          Trace multicast route to group
name-connection Name an existing telnet connection
pad             Open a X.29 PAD connection
ping           Send echo messages
resume         Resume an active telnet connection
show           Show running system information
systat         Display information about terminal lines
telnet         Open a telnet connection
terminal       Set terminal line parameters
tn3270         Open a tn3270 connection
trace          Trace route to destination
where          List active telnet connections
x3             Set X.3 parameters on PAD

```

The list of commands will vary depending on the software feature set and platform you are using.

Note You can enter commands in uppercase, lowercase, or mixed case. Only passwords are case sensitive. However, Cisco IOS XE documentation convention is to always present commands in lowercase.

Privileged EXEC Mode

In order to have access to all commands, you must enter *privileged EXEC mode*, which is the second level of access for the EXEC mode. Normally, you must enter a password to enter privileged EXEC mode. In privileged EXEC mode, you can enter any EXEC command, because privileged EXEC mode is a superset of the user EXEC mode commands.

Because many privileged EXEC mode commands set operating parameters, privileged EXEC level access should be password protected to prevent unauthorized use. The privileged EXEC command set includes those commands contained in user EXEC mode. Privileged EXEC mode also provides access to configuration modes through the **configure** command, and includes advanced testing commands, such as **debug**.

Privileged EXEC mode is set by default to privilege level 15. User EXEC mode is set by default to privilege level 1. For more information see the [User EXEC Mode, on page 2197](#). When you are logged into a networking device in privileged EXEC mode your session is running at privilege level 15. When you are logged into a networking device in user EXEC mode your session is running at privilege level 1. By default the EXEC commands at privilege level 15 are a superset of those available at privilege level 1. You can move commands to any privilege level between 1 and 15 using the **privilege** command. See the [Cisco IOS XE Privilege Levels, on page 2206](#) for more information on privilege levels and the **privilege** command.

The privileged EXEC mode prompt consists of the host name of the device followed by a pound sign(#), as shown in the following example:

```
Device#
```

To access privileged EXEC mode, use the following command:

Command	Purpose
Device> enable Password Device# exit Device>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • If a privileged EXEC mode password has been configured the system will prompt you for a password after you issue the enable command. • Use the exit command to leave privileged EXEC mode.

Note Privileged EXEC mode is sometimes referred to as “enable mode,” because the **enable** command is used to enter the mode.

If a password has been configured on the system, you will be prompted to enter it before being allowed access to privileged EXEC mode. The password is not displayed on the screen and is case sensitive. If an enable password has not been set, privileged EXEC mode can be accessed only by a local CLI session (terminal connected to the console port).

If you attempt to access privileged EXEC mode on a router over a remote connection, such as a telnet connection, and you have not configured a password for privileged EXEC mode you will see the **% No password set** error message. For more information on remote connections see the [Remote CLI Sessions, on page 2203](#). The system administrator uses the **enable secret** or **enable password** global configuration commands to set the password that restricts access to privileged EXEC mode. For information on configuring a password for privileged EXEC mode, see the [Protecting Access to Privileged EXEC Mode, on page 2212](#).

To return to user EXEC mode, use the following command:

Command	Purpose
Device# disable	Exits from privileged EXEC mode to user EXEC mode.

The following example shows the process of accessing privileged EXEC mode:

```
Device> enable
Password:<letmein>
Device#
```

Note that the password will not be displayed as you type, but is shown here for illustrational purposes. To list the commands available in privileged EXEC mode, issue the **?** command at the prompt. From privileged EXEC mode you can access global configuration mode, which is described in the following section.

Note Because the privileged EXEC command set contains all of the commands available in user EXEC mode, some commands can be entered in either mode. In Cisco IOS XE documentation, commands that can be entered in either user EXEC mode or privileged EXEC mode are referred to as EXEC mode commands. If user or privileged is not specified in the documentation, assume that you can enter the referenced commands in either mode.

Global Configuration Mode

The term “global” is used to indicate characteristics or features that affect the system as a whole. Global configuration mode is used to configure your system globally, or to enter specific configuration modes to configure specific elements such as interfaces or protocols. Use the **configure terminal** privileged EXEC command to enter global configuration mode.

To access global configuration mode, use the following command in privileged EXEC mode:

Command	Purpose
Device# configure terminal	From privileged EXEC mode, enters global configuration mode.

The following example shows the process of entering global configuration mode from privileged EXEC mode:

```
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)#
```

Note that the system prompt changes to indicate that you are now in global configuration mode. The prompt for global configuration mode consists of the host-name of the device followed by (config) and the pound sign (#). To list the commands available in privileged EXEC mode, issue the ? command at the prompt.

Commands entered in global configuration mode update the running configuration file as soon as they are entered. In other words, changes to the configuration take effect each time you press the Enter or Return key at the end of a valid command. However, these changes are not saved into the startup configuration file until you issue the **copy running-config startup-config** EXEC mode command. This behavior is explained in more detail later in this document.

As shown in the example above, the system dialogue prompts you to end your configuration session (exit configuration mode) by pressing the Control (Ctrl) and “z” keys simultaneously; when you press these keys, ^Z is printed to the screen. You can actually end your configuration session by entering the Ctrl-Z key combination, using the **end** command, using the Ctrl-C key combination. The **end** command is the recommended way to indicate to the system that you are done with the current configuration session.

Caution If you use Ctrl-Z at the end of a command line in which a valid command has been typed, that command will be added to the running configuration file. In other words, using Ctrl-Z is equivalent to hitting the Enter (Carriage Return) key before exiting. For this reason, it is safer to end your configuration session using the **end** command. Alternatively, you can use the Ctrl-C key combination to end your configuration session without sending a Carriage Return signal.

You can also use the **exit** command to return from global configuration mode to EXEC mode, but this only works in global configuration mode. Pressing Ctrl-Z or entering the **end** command will always take you back to EXEC mode regardless of which configuration mode or configuration submode you are in.

To exit global configuration command mode and return to privileged EXEC mode, use one of the following commands:

Command	Purpose
Device (config) # end or Device (config) # ^Z	Ends the current configuration session and returns to privileged EXEC mode.
Device (config) # exit	Exits the current command mode and returns to the preceding mode. For example, exits from global configuration mode to privileged EXEC mode.

From global configuration mode, you can enter a number of protocol-specific, platform-specific, and feature-specific configuration modes.

Interface configuration mode, described in the following section, is an example of a configuration mode you can enter from global configuration mode.

Interface Configuration Mode

One example of a specific configuration mode you enter from global configuration mode is interface configuration mode.

Many features are enabled on a per-interface basis. Interface configuration commands modify the operation of an interface such as an Ethernet, FDDI, or serial port. Interface configuration commands always follow an **interface** global configuration command, which defines the interface type.

For details on interface configuration commands that affect general interface parameters, such as bandwidth or clock rate, refer to the Release 12.2 *Cisco IOS Interface Configuration Guide*. For protocol-specific commands, refer to the appropriate Cisco IOS XE software command reference.

To access and list the interface configuration commands, use the following command:

Command	Purpose
Device (config) # interface <i>type number</i>	Specifies the interface to be configured, and enters interface configuration mode.

In the following example, the user enters interface configuration mode for serial interface 0. The new prompt, *hostname (config-if)#*, indicates interface configuration mode.

```
Device (config) # interface serial 0
Device (config-if) #
```

To exit interface configuration mode and return to global configuration mode, enter the **exit** command.

Configuration submodes are configuration modes entered from other configuration modes (besides global configuration mode). Configuration submodes are for the configuration of specific elements within the configuration mode. One example of a configuration submode is subinterface configuration mode, described in the following section.

Subinterface Configuration Mode

From interface configuration mode, you can enter subinterface configuration mode. Subinterface configuration mode is a submode of interface configuration mode. In subinterface configuration mode you can configure

multiple virtual interfaces (called subinterfaces) on a single physical interface. Subinterfaces appear to be distinct physical interfaces to the various protocols.

For detailed information on how to configure subinterfaces, refer to the appropriate documentation module for a specific protocol in the Cisco IOS XE software documentation set.

To access subinterface configuration mode, use the following command in interface configuration mode:

Command	Purpose
Device (config-if) # interface <i>type</i> <i>number</i>	Specifies the virtual interface to be configured and enters subinterface configuration mode.

In the following example, a subinterface is configured for serial line 2, which is configured for Frame Relay encapsulation. The subinterface is identified as “2.1” to indicate that it is subinterface 1 of serial interface 2. The new prompt *hostname* (config-subif)# indicates subinterface configuration mode. The subinterface can be configured to support one or more Frame Relay PVCs.

```
Device (config) # interface serial 2
Device (config-if) # encapsulation frame-relay
Device (config-if) # interface serial 2.1
Device (config-subif) #
```

To exit subinterface configuration mode and return to interface configuration mode, use the **exit** command. To end your configuration session and return to privileged EXEC mode, press Ctrl-Z or enter the **end** command.

Cisco IOS XE CLI Sessions

Local CLI Sessions

Local CLI sessions require direct access to the console port of the networking device. Local CLI sessions start in user EXEC mode. All of the tasks required to configure and manage a networking device can be done using a local CLI session. The most common method for establishing a local CLI session is to connect the serial port on a PC to the console port of the networking device and then to launch a terminal emulation application on the PC. The type of cable and connectors required and the settings for the terminal emulation application on the PC are dependant on the type of networking device that you are configuring. See to the documentation for your networking device for more information on setting it up for a local CLI session.

Remote CLI Sessions

Remote CLI sessions are created between a host such as a PC and a networking device such as a router over a network using a remote terminal access application such as Telnet and Secure Shell (SSH). Local CLI sessions start in user EXEC mode. Most of the tasks required to configure and manage a networking device can be done using a remote CLI session. The exceptions are tasks that interact directly with the console port (such as recovering from a corrupted operating system (OS) by uploading a new OS image over the console port) and interacting with the networking device when it is in ROM Monitor Mode.

This document explains how to configure security for remote Telnet sessions. Telnet is the most common method for accessing a remote CLI session on a networking device.

Note SSH is a more secure alternative to Telnet. SSH provides encryption for the session traffic between your local management device such as a PC and the networking device that you are managing. Encrypting the session traffic with SSH prevents hackers that might intercept the traffic from being able to decode it. See Secure Shell Version 2 Support feature module for more information on using SSH.

Terminal Lines are Used for Local and Remote CLI Sessions

Cisco networking devices use the word lines to refer to the software components that manage local and remote CLI sessions. You use the **line console 0** global configuration command to enter line configuration mode to configure options, such as a password, for the console port.

```
Device# configure terminal
Device(config)# line console 0
Device(config-line)# password password-string
```

Remote CLI sessions use lines that are referred to virtual teletypewriter (VTY) lines. You use the **line vty line-number [ending-line-number]** global configuration command to enter line configuration mode to configure options, such as a password, for remote CLI sessions.

```
Device# configure terminal
Device(config)# line vty 0 4
Device(config-line)# password password-string
```

Protect Access to Cisco IOS XE EXEC Modes

Cisco IOS XE provides the ability to configure passwords that protect access to the following:

Protecting Access to User EXEC Mode

The first step in creating a secure environment for your networking device is protecting access to user EXEC mode by configuring passwords for local and remote CLI sessions.

You protect access to user EXEC mode for local CLI sessions by configuring a password on the console port. See the [Configuring and Verifying a Password for Local CLI Sessions, on page 2210](#).

You protect access to user EXEC mode for remote CLI sessions by configuring a password on the virtual terminal lines (VTYs). See the [Configuring and Verifying a Password for Remote CLI Sessions, on page 2208](#) for instructions on how to configure passwords for remote CLI sessions.

Protecting Access to Privileged EXEC mode

The second step in creating a secure environment for your networking device is protecting access to privileged EXEC mode with a password. The method for protecting access to privileged EXEC mode is the same for local and remote CLI sessions.

You protect access to privileged EXEC mode by configuring a password for it. This is sometimes referred to as the enable password because the command to enter privileged EXEC mode is **enable**.

Command	Purpose
<pre>enable Device> enable Password Device#</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted. The password will not be shown in the terminal window. • The “>” at the end of the prompt string is changed to a “#” to indicate that you are in privileged EXEC mode.

Cisco IOS XE Password Encryption Levels

Some of the passwords that you configure on your networking device are saved in the configuration in plain text. This means that if you store a copy of the configuration file on a disk, anybody with access to the disk can discover the passwords by reading the configuration file. The following password types are stored as plain text in the configuration by default:

- Console passwords for local CLI sessions
- Virtual terminal line passwords for remote CLI sessions
- Username passwords using the default method for configuring the password
- Privileged EXEC mode password when it is configured with the **enable password** *password* command
- Authentication key chain passwords used by RIPv2 and EIGRP
- BGP passwords for authenticating BGP neighbors
- OSPF authentication keys for authenticating OSPF neighbors
- ISIS passwords for authenticating ISIS neighbors

This excerpt from a router configuration file shows examples of passwords and authentication keys that are stored as clear text.

```
!
enable password O9Jb6D
!
username username1 password 0 kV9sIj3
!
key chain trees
  key 1
    key-string willow
!
interface Ethernet1/0.1
 ip address 172.16.6.1 255.255.255.0
 ip router isis
 ip rip authentication key-chain trees
 ip authentication key-chain eigrp 1 trees
 ip ospf authentication-key j7876
 no snmp trap link-status
 isis password u7865k
!
line vty 0 4
 password V9jA5M
!
```

You can encrypt these clear text passwords in the configuration file by using the **service password-encryption** command. This should be considered only a minimal level of security because the encryption algorithm used by the **service password-encryption** command to encrypt passwords creates text strings that be decrypted using tools that are publicly available. You should still protect access to any electronic or paper copies of your configuration files after you use the **service password-encryption** command.

The **service password-encryption** command does not encrypt the passwords when they are sent to the remote device. Anybody with a network traffic analyzer who has access to you network can capture these passwords from the packets as they are transmitted between the devices. See the [Configuring Password Encryption for Clear Text Passwords, on page 2214](#) for more information on encrypting clear text passwords in configuration files.

Many of the Cisco IOS XE features that use clear text passwords can also be configured to use the more secure MD5 algorithm. The MD5 algorithm creates a text string in the configuration file that is much more difficult to decrypt. The MD5 algorithm does not send the password to the remote device. This prevents people using a traffic analyzer to capture traffic on your network from being able to discover your passwords.

You can determine the type of password encryption that has been used by the number that is stored with the password string in the configuration file of the networking device. The number 5 in the configuration excerpt below indicates that the enable secret password has been encrypted using the MD5 algorithm.

```
enable secret 5 $1$fGCS$rkYbR6.Z8xo4qCl3vghWQ0
```

The number 7 in the excerpt below indicates that the enable password has been encrypted using the less secure algorithm used by the **service password-encryption** command.

```
!
```

```
enable password 7 00081204
```

Cisco IOS XE CLI Session Usernames

After you have protected access to user EXEC mode and privileged EXEC mode by configuring passwords for them you can further increase the level of security on your networking device by configuring usernames to limit access to CLI sessions to your networking device to specific users.

Usernames that are intended to be used for managing a networking device can be modified with additional options such as:

See the *Cisco IOS Security Command Reference* .

(http://www.cisco.com/en/US/docs/ios/security/command/reference/sec_book.html) for more information on how to configure the **username** command.

Cisco IOS XE Privilege Levels

The default configuration for Cisco IOS XE based networking devices uses privilege level 1 for user EXEC mode and privilege level 15 for privileged EXEC. The commands that can be run in user EXEC mode at privilege level 1 are a subset of the commands that can be run in privileged EXEC mode at privilege 15.

The **privilege** command is used to move commands from one privilege level to another. For example, some ISPs allow their first level technical support staff to enable and disable interfaces to activate new customer connections or to restart a connection that has stopped transmitting traffic. See the [Example: Configuring a Device to Allow Users to Shutdown and Enable Interfaces, on page 2231](#) for an example of how to configure this option.

The **privilege** command can also be used to assign a privilege level to a username so that when a user logs in with the username, the session will run at the privilege level specified by the **privilege** command. For example if you want your technical support staff to view the configuration on a networking device to help them troubleshoot network problems without being able to modify the configuration, you can create a username, configure it with privilege level 15, and configure it to run the **show running-config** command automatically. When a user logs in with the username the running configuration will be displayed automatically. The user's session will be logged out automatically after the user has viewed the last line of the configuration. See the [Example: Configuring a Device to Allow Users to View the Running Configuration, on page 2229](#) for an example of how to configure this option.

These command privileges can also be implemented when using AAA with TACACS+ and RADIUS. For example, TACACS+ provides two ways to control the authorization of router commands on a per-user or per-group basis. The first way is to assign privilege levels to commands and have the router verify with the TACACS+ server whether or not the user is authorized at the specified privilege level. The second way is to explicitly specify in the TACACS+ server, on a per-user or per-group basis, the commands that are allowed. For more information about implementing AAA with TACACS+ and RADIUS, see the technical note [How to Assign Privilege Levels with TACACS+ and RADIUS](#).

Cisco IOS XE Password Configuration

Cisco IOS XE software does not prompt you to repeat any passwords that you configure to verify that you have entered the passwords exactly as you intended. New passwords, and changes to existing passwords, go into effect immediately after you press the Enter key at the end of a password configuration command string. If you make a mistake when you enter a new password and have saved the configuration on the networking device to its startup configuration file and exited privileged EXEC mode before you realize that you made a mistake, you may find that you are no longer able to manage the device.

The following are common situations that can happen:

- You make a mistake configuring a password for local CLI sessions on the console port.
 - If you have properly configured access to your networking device for remote CLI sessions, you can Telnet to it and reconfigure the password on the console port.
- You make a mistake configuring a password for remote Telnet or SSH sessions.
 - If you have properly configured access to your networking device for local CLI sessions, you can connect a terminal to it and reconfigure the password for the remote CLI sessions.
- You make a mistake configuring a password for privileged EXEC mode (enable password or enable secret password).
 - You will have to perform a lost password recovery procedure.
- You make a mistake configuring your username password, and the networking device requires that you log into it with your username.
 - If you do not have access to another account name, you will have to perform a lost password recovery procedure.

To protect yourself from having to perform a lost password recovery procedure open two CLI sessions to the networking device and keep one of them in privilege EXEC mode while you reset the passwords using the other session. You can use the same device (PC or terminal) to run the two CLI sessions or two different devices. You can use a local CLI session and a remote CLI session or two remote CLI sessions for this procedure. The CLI session that you use to configure the password can also be used to verify that the password

was changed properly. The other CLI session that you keep in privileged EXEC mode can be used to change the password again if you made a mistake the first time you configured it.

You should not save password changes that you have made in the running configuration to the startup configuration until you have verified that your password was changed successfully. If you discover that you made a mistake configuring a password, and you were not able to correct the problem using the second CLI session technique described above, you can power cycle the networking device so that it returns to the previous passwords that are stored in the startup configuration.

AES Password Encryption and Master Encryption Keys

You can enable strong, reversible 128-bit Advanced Encryption Standard (AES) password encryption, also known as type-6 encryption. To start using type-6 encryption, you must enable the AES password encryption feature and configure a master encryption key, which is used to encrypt and decrypt passwords. After you enable AES password encryption and configure a master key, all existing and newly created clear-text passwords for supported applications are stored in type-6 encrypted format, unless you disable type-6 password encryption. You can also configure the device to convert all existing weakly encrypted passwords to type-6 encrypted passwords.

Type 0 and type 7 passwords can be autoconverted to type 6 if the AES password encryption feature and master encryption key are configured.

Note Type 6 username and password are backward compatible to the Cisco IOS release 16.10.1 only. If you downgrade to any release version lower than Cisco IOS release 16.10.1, type 6 username and password will be rejected. After autoconversion, to avoid an administrator password getting rejected during a downgrade, migrate the passwords.

How To Configure Security with Passwords Privileges and Logins

Protecting Access to User Exec Mode

Configuring and Verifying a Password for Remote CLI Sessions

This task will assign a password for remote CLI sessions. After you have completed this task the networking device will prompt you for a password the next time that you start a remote CLI session with it.

Cisco IOS XE based networking devices require that you have a password configured for remote CLI sessions. If you attempt to start a remote CLI session with a device that doesn't have a password configured for remote CLI sessions you will see a message that a password is required and has not been set. The remote CLI session will be terminated by the remote host.

Before you begin

If you have not previously configured a password for remote CLI sessions, you must perform this task over a local CLI session using a terminal or a PC running a terminal emulation application, attached to the console port.

Your terminal, or terminal emulation application, must be configured with the settings that are used by the console port on the networking device. The console ports on most Cisco networking devices require the following settings: 9600 baud, 8 data bits, 1 stop bit, no parity, and flow control is set to "none." See the documentation for your networking device if these settings do not work for your terminal.

To perform the verification step (Step 6) for this task, your networking device must have an interface that is in an operational state. The interface must have a valid IP address.

Note If you have not previously configured a password for remote CLI sessions, you must perform this task over a local CLI session using a terminal attached to the console port.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **line vty** *line-number* [*ending-line-number*]
4. **password** *password*
5. **end**
6. **telnet** *ip-address*
7. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	line vty <i>line-number</i> [<i>ending-line-number</i>] Example: Device(config)# line vty 0 4	Enters line configuration mode.

	Command or Action	Purpose
Step 4	<p>password <i>password</i></p> <p>Example:</p> <pre>Device(config-line)# password H7x3U8</pre>	<p>The argument <i>password</i> is a character string that specifies the line password. The following rules apply to the <i>password</i> argument:</p> <ul style="list-style-type: none"> • The first character cannot be a number. • The string can contain any alphanumeric characters, including spaces, up to 80 characters. You cannot specify the password in the format number-space-anything. • Passwords are case sensitive.
Step 5	<p>end</p> <p>Example:</p> <pre>Device(config-line)# end</pre>	<p>Exits the current configuration mode and returns to privileged EXEC mode.</p>
Step 6	<p>telnet <i>ip-address</i></p> <p>Example:</p> <pre>Device# telnet 172.16.1.1</pre>	<p>Start a remote CLI session with the networking device from your current CLI session using the IP address of an interface in the networking device that is in an operational state (interface up, line protocol up).</p> <ul style="list-style-type: none"> • Enter the password that you configured in step 4 when prompted. <p>Note This procedure is often referred to as starting a recursive Telnet session because you are initiating a remote Telnet session with the networking device from the networking device itself.</p>
Step 7	<p>exit</p> <p>Example:</p> <pre>Device# exit</pre>	<p>Terminates the remote CLI session (recursive Telnet session) with the networking device.</p>

Troubleshooting Tips

To display information for all users who have access to a lawful intercept view, issue the **show users lawful-intercept** command. (This command is available only to authorized lawful intercept view users.)

What to Do Next

Proceed to the [Configuring and Verifying a Password for Local CLI Sessions, on page 2210](#).

Configuring and Verifying a Password for Local CLI Sessions

This task will assign a password for local CLI sessions over the console port. After you have completed this task, the networking device will prompt you for a password the next time that you start a local CLI session on the console port.

This task can be performed over a local CLI session using the console port or a remote CLI session. If you want to perform the optional step of verifying that you configured the password correctly you should perform this task using a local CLI session using the console port.

Before you begin

If you want to perform the optional step of verifying the local CLI session password, you must perform this task using a local CLI session. You must have a terminal or a PC running a terminal emulation program, connected to the console port of the networking device. Your terminal must be configured with the settings that are used by the console port on the networking device. The console ports on most Cisco networking devices require the following settings: 9600 baud, 8 data bits, 1 stop bit, no parity, and flow control is set to "none." See the documentation for your networking device if these settings do not work for your terminal.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **line console 0**
4. **password** *password*
5. **end**
6. **exit**
7. Press the Enter key.

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	line console 0 Example: <pre>Device(config)# line console 0</pre>	Enters line configuration mode and selects the console port as the line that you are configuring.
Step 4	password <i>password</i> Example: <pre>Device(config-line)# password Ji8F5Z</pre>	The argument <i>password</i> is a character string that specifies the line password. The following rules apply to the <i>password</i> argument: <ul style="list-style-type: none"> • The first character cannot be a number. • The string can contain any alphanumeric characters, including spaces, up to 80 characters. You cannot

	Command or Action	Purpose
		specify the password in the format number-space-anything. <ul style="list-style-type: none"> • Passwords are case sensitive.
Step 5	end Example: Device(config-line)# end	Exits the current configuration mode and returns to privileged EXEC mode.
Step 6	exit Example: Device# exit	Exits privileged EXEC mode.
Step 7	Press the Enter key.	(Optional) Initiates the local CLI session on the console port. <ul style="list-style-type: none"> • Enter the password that you configured in step 4 when prompted to verify that it was configured correctly. Note This step can be performed only if you are using a local CLI session to perform this task.

Troubleshooting Tips

If your new password is not accepted proceed to the Configuration Examples for Configuring Security with Passwords Privileges and Logins for instructions on what to do next.

What to Do Next

Proceed to the [Protecting Access to Privileged EXEC Mode, on page 2212](#).

Protecting Access to Privileged EXEC Mode

Configuring and Verifying the Enable Password

Cisco no longer recommends that you use the **enable password** command to configure a password for privileged EXEC mode. The password that you enter with the **enable password** command is stored as plain text in the configuration file of the networking device. You can encrypt the password for the **enable password** command in the configuration file of the networking device using the **service password-encryption** command. However the encryption level used by the **service password-encryption** command can be decrypted using tools available on the Internet.

Instead of using the **enable password** command, Cisco recommends using the **enable secret** command because it encrypts the password that you configure with it with strong encryption. For more information on password encryption issues see the [Cisco IOS XE Password Encryption Levels, on page 2205](#). For information on configuring the **enable secret** command see the [Configuring and Verifying the Enable Secret Password, on page 2215](#).

Note The networking device must not have a password configured by the **enable secret** command in order to perform this task successfully. If you have already configured a password for privileged EXEC mode using the **enable secret** command, the password configured takes precedences over the password that you configure in this task using the **enable password** command.

You cannot use the same password for the **enable secret** command and the **enable password** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **enable password** *password*
4. **end**
5. **exit**
6. **enable**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	enable password <i>password</i> Example: <pre>Device(config)# enable password t6D77CdKq</pre>	The argument <i>password</i> is a character string that specifies the enable password. The following rules apply to the <i>password</i> argument: <ul style="list-style-type: none"> • Must contain from 1 to 25 uppercase and lowercase alphanumeric characters. • Must not have a number as the first character. • Can have leading spaces, but they are ignored. However, intermediate and trailing spaces are recognized. • Can contain the question mark (?) character if you precede the question mark with the key combination Crtl-v when you create the password; for example, to create the password abc?123, do the following: <ul style="list-style-type: none"> • Enter abc • Type Crtl-v

	Command or Action	Purpose
		<ul style="list-style-type: none"> • Enter ?123
Step 4	end Example: Device(config)# end	Exits the current configuration mode and returns to privileged EXEC mode.
Step 5	exit Example: Device# exit	Exits privileged EXEC mode.
Step 6	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter the password you configured in step 3.

Troubleshooting Tips

If your new password is not accepted, proceed to the Recovering from Lost or Misconfigured Passwords for Privileged EXEC Mode section for instructions on what to do next.

What to Do Next

Encrypt the clear text enable password in the configuration file of the networking device using the procedure described in [Configuring Password Encryption for Clear Text Passwords, on page 2214](#).

Configuring Password Encryption for Clear Text Passwords

Cisco IOS XE stores passwords in clear text in network device configuration files for several features such as passwords for local and remote CLI sessions, and passwords for neighbor authentication for routing protocols. Clear text passwords are a security risk because anybody with access to archived copies of the configuration files can discover the passwords that are stored as clear text. The **service password-encryption** command can be used to encrypt clear text commands in the configuration files of networking devices. See the [Cisco IOS XE Password Encryption Levels, on page 2205](#) for more information.

Perform the following steps to configure password encryption for passwords that are stored as clear text in the configuration files of your networking device.

Before you begin

You must have at least one feature that uses clear text passwords configured on your networking device for this command to have any immediate effect.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **service password-encryption**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	service password-encryption Example: Device(config)# service password-encryption	Enables Password encryption for all passwords clear text passwords, including username passwords, authentication key passwords, the privileged command password, console and virtual terminal line access passwords, and Border Gateway Protocol neighbor passwords.
Step 4	end Example: Device(config)# end	Exits the current configuration mode and returns to privileged EXEC mode.

Configuring and Verifying the Enable Secret Password

Cisco recommends that you use the **enable secret** command, instead of the **enable password** command to configure a password for privileged EXEC mode. The password created by the **enable secret** command is encrypted with the more secure MD5 algorithm.

Note You cannot use the same password for the **enable secret** command and the **enable password** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. Perform one of the following steps:
 - **enable secret** *password*
 - **enable secret** **5** *previously-encrypted-password*
4. **end**
5. **exit**
6. **enable**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	Perform one of the following steps: <ul style="list-style-type: none"> • enable secret <i>password</i> • enable secret 5 <i>previously-encrypted-password</i> Example: <pre>Device(config)# enable secret t6D77CdKq</pre> Example: <pre>Device(config)# enable secret 5 \$1\$/x6H\$RhnDI3yLC4GA01aJnHLQ4/</pre>	The argument <i>password</i> is a character string that specifies the enable secret password. The following rules apply to the <i>password</i> argument: <ul style="list-style-type: none"> • Must contain from 1 to 25 uppercase and lowercase alphanumeric characters. • Must not have a number as the first character. • Can have leading spaces, but they are ignored. However, intermediate and trailing spaces are recognized. • Can contain the question mark (?) character if you precede the question mark with the key combination Crtl-v when you create the password; for example, to create the password abc?123, do the following: <ul style="list-style-type: none"> • Enter abc • Type Crtl-v • Enter ?123 or Sets a previously encrypted password for privileged EXEC mode by entering the number 5 before the previously encrypted string. You must enter an exact copy of a password from a configuration file that was previously encrypted by the enable secret command to use this method.
Step 4	end Example: <pre>Device(config)# end</pre>	Exits the current configuration mode and returns to privileged EXEC mode.
Step 5	exit Example:	Exits privileged EXEC mode.

	Command or Action	Purpose
	Device# exit	
Step 6	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter the password that you configured in Step 3.

Troubleshooting Tips

If your new password is not accepted proceed to the Configuration Examples for Configuring Security with Passwords Privileges and Logins for instructions on what to do next.

What to Do Next

If you have finished configuring passwords for local and remote CLI sessions and you want to configure additional security features, such as usernames, and privilege levels proceed to the [Configuring Security Options to Manage Access to CLI Sessions and Commands, on page 2219](#).

Configuring a Device to Allow Users to View the Running Configuration

To access the running configuration of a device using the **show running-config** command at a privilege level lower than level 15, perform the following task.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **privilege exec all level *level command-string***
4. **file privilege *level***
5. **privilege configure all level *level command-string***
6. **end**
7. **show privilege**
8. **show running-config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	privilege exec all level <i>level command-string</i> Example: <pre>Device(config)# privilege exec all level 5 show running-config</pre>	Changes the privilege level of the specified command from one privilege level to another.
Step 4	file privilege <i>level</i> Example: <pre>Device(config)# file privilege 5</pre>	Allows a user of the privilege level to execute commands that involve the file system on a device.
Step 5	privilege configure all level <i>level command-string</i> Example: <pre>Device(config)# privilege configure all level 5 logging</pre>	Allows a user of a privilege level to see specific configuration commands. For example, allows the user of privilege level 5 to see the logging configuration commands in the running configuration.
Step 6	end Example: <pre>Device(config)# end</pre>	Exits global configuration mode and returns to privileged EXEC mode.
Step 7	show privilege Example: <pre>Device# show privilege</pre>	Displays the current privilege level.
Step 8	show running-config Example: <pre>Device# show running-config</pre>	Displays the current running configuration for the specified privilege level.

Example

The following output for the **show running-config** command displays the logging configuration commands in the running configuration. Users with a privilege level below 15 can view the running configuration after configuring the **privilege configure all level *level command-string*** command.

```
Device# show running-config

Building configuration...

Current configuration : 128 bytes
!
boot-start-marker
boot-end-marker
!
no logging queue-limit
logging buffered 1000000
```

```
no logging rate-limit
!  
!  
!  
end
```

Configuring Security Options to Manage Access to CLI Sessions and Commands

The tasks in this section describe how to configure your networking device to permit the use of a subset of privileged EXEC mode commands by users who should not have access to all of the commands available in privileged EXEC mode.

These tasks are beneficial for companies that have multiple levels of network support staff and the company wants the staff at each level to have access to a different subset of the privileged EXEC mode commands.

In this task the users who should not have access to all of the commands available in privileged EXEC mode are referred to as the first-line technical support staff.

This section contains the following procedures:

Configuring the Networking Device for the First-Line Technical Support Staff

This task describes how to configure the networking device for first-line technical support users. First-line technical support staff are usually not allowed to run all of the commands available in privileged EXEC mode (privilege level 15) on a networking device. They are prevented from running commands that they are not authorized for by not being granted access to the password assigned to privileged EXEC mode or to other roles that have been configured on the networking device.

The **privilege** command is used to move commands from one privilege level to another in order to create the additional levels of administration of a networking device that is required by companies that have different levels of network support staff with different skill levels.

The default configuration of a Cisco IOS XE device permits two types of users to access the CLI. The first type of user is a person who is only allowed to access user EXEC mode. The second type of user is a person who is allowed access to privileged EXEC mode. A user who is only allowed to access user EXEC mode is not allowed to view or change the configuration of the networking device, or to make any changes to the operational status of the networking device. On the other hand, a user who is allowed access to privileged EXEC mode can make any change to a networking device that is allowed by the CLI.

In this task the two commands that normally run at privilege level 15 are reset to privilege level 7 using the **privilege** command in order that first-line technical support users will be allowed to run the two commands. The two commands for which the privilege levels will be reset are the **clear counters** command and **reload** command.

- The **clear counters** command is used to reset the counter fields on interfaces for statistics such as packets received, packets transmitted, and errors. When a first-line technical support user is troubleshooting an interface related connectivity issue between networking devices, or with remote users connecting to the network, it is useful to reset the interface statistics to zero and then monitor the interfaces for a period of time to see if the values in the interface statistics counters change.
- The **reload** command is used to initiate a reboot sequence for the networking device. One common use of the reload command by first-line technical support staff is to cause the networking device to reboot during a maintenance window so that it loads a new operating system that was previously copied onto the networking device's file system by a user with a higher level of authority.

Any user that is permitted to know the **enable secret** password that is assigned to the first-line technical support user role privilege level can access the networking device as a first-line technical support user. You can add an additional level of security by configuring a username on the networking device and requiring that the users know the username and the password. Configuring a username as an additional level of security is described in the [. Configuring a Device to Require a Username for the First-Line Technical Support Staff, on page 2223](#)

Note You must not have the **aaa new-model** command enabled on the networking device. You must not have the **login local** command configured for the local CLI sessions over the console port or the remote CLI sessions.

Note For clarity, only the arguments and keywords that are relevant for each step are shown in the steps in this task. See the Cisco IOS command reference book for your Cisco IOS release for information on the additional arguments and keywords that can be used with these commands.

Caution Do not use the no form of the **privilege** command to reset the privilege level of a command because it might not return the configuration to the correct default state. Use the **reset** keyword with the **privilege** command instead to return a command to its default privilege level. For example, to reset the **exec level reload** command from the configuration and return the **reload** command to its default privilege level of 15, use the **privilege exec reset reload** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **enable secret level** *level password*
4. **privilege exec level** *level command-string*
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enters privileged EXEC mode. Enter the password when prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	enable secret level <i>level password</i> Example:	Configures a new enable secret password for privilege level 7.

	Command or Action	Purpose
	Device(config)# enable secret level 7 Zy72sKj	
Step 4	<p>privilege exec level <i>level command-string</i></p> <p>Example:</p> <pre>Device(config)# privilege exec level 7 clear counters</pre>	Changes the privilege level of the clear counters command from privilege level 15 to privilege level 7.
Step 5	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	Exits global configuration mode.

Verifying the Configuration for the First-Line Technical Support Staff

This task describes how to verify that the network device is configured correctly for the first-line technical support staff.

Before you begin

The following commands must have been modified to run at privilege level 7 for this task:

- clear counters
- reload

SUMMARY STEPS

1. enable *level password*
2. show privilege
3. clear counters
4. clear ip route *
5. reload in time
6. reload cancel
7. disable
8. show privilege

DETAILED STEPS

Step 1 enable *level password*

Logs the user into the networking device at the privilege level specified for the level argument.

Example:

```
Device> enable 7 Zy72sKj
```

Step 2 **show privilege**

Displays the privilege level of the current CLI session

Example:

```
Device# show privilege
Current privilege level is 7
```

Step 3 **clear counters**

The `clear counters` command clears the interface counters. This command has been changed from privilege level 15 to privilege level 7.

Example:

```
Device# clear counters
Clear "show interface" counters on all interfaces [confirm]
Device#
02:41:37: %CLEAR-5-COUNTERS: Clear counter on all interfaces by console
```

Step 4 **clear ip route ***

The `ip route` argument string for the `clear` command should not be allowed because it was not changed from privilege level 15 to privilege level 7.

Example:

```
Device# clear ip route *
% Invalid input detected at '^' marker.
```

Step 5 **reload in time**

The `reload` command causes the networking device to reboot.

Example:

```
Device# reload in
10
Reload scheduled in 10 minutes by console
Proceed with reload? [confirm]
Device#
***
*** --- SHUTDOWN in 0:10:00 ---
***
02:59:50: %SYS-5-SCHEDULED_RELOAD: Reload requested for 23:08:30 PST Sun Mar 20
```

Step 6 **reload cancel**

The `reload cancel` terminates a reload that was previously setup with the the `reload in time` command.

Example:

```
Device# reload cancel

***
*** --- SHUTDOWN ABORTED ---
***
04:34:08: %SYS-5-SCHEDULED_RELOAD_CANCELLED: Scheduled reload cancelled at 15:38:46 PST Sun Mar 27
2005
```

Step 7 **disable**

Exits the current privilege level and returns to privilege level 1.

Example:

```
Device# disable
```

Step 8 **show privilege**

Displays the privilege level of the current CLI session

Example:

```
Device> show privilege

Current privilege level is 1
```

Troubleshooting Tips

If your configuration does not work the way that you want it to and you want to remove the privilege commands from the configuration, use the **reset** keyword for the **privilege** command to return the commands to their default privilege level. For example, to remove the command **privilege exec level reload** command from the configuration and return the **reload** command to its default privilege of 15 use the **privilege exec reset reload** command.

What to Do Next

If you want to add an additional level of security by requiring that the first level technical staff use a login name, proceed to the [Configuring a Device to Require a Username for the First-Line Technical Support Staff](#), on page 2223.

Configuring a Device to Require a Username for the First-Line Technical Support Staff

This task configures the networking device to require that the first-line technical support staff login to the networking device with a login name of admin. The admin username configured in this task is assigned the privilege level of 7 which will allow users who log in with this name to run the commands that were reassigned to privilege level 7 in the previous task. When a user successfully logs in with the admin username, the CLI session will automatically enter privilege level 7.

Before Cisco IOS XE Release 2.3, two types of passwords were associated with usernames: Type 0, which is a clear text password visible to any user who has access to privileged mode on the router, and type 7, which has a password encrypted by the **service password encryption** command.

In Cisco IOS XE Release 2.3 and later releases, the new **secret** keyword for the **username** command allows you to configure Message Digest 5 (MD5) encryption for username passwords.

Before you begin

The following commands must have been modified to run at privilege level 7 for this task:

- **clear counters**
- **reload**

See the [Configuring the Networking Device for the First-Line Technical Support Staff, on page 2219](#) for instructions on how to change the privilege level for a command.

Note MD5 encryption for the **username** command is not supported in versions of Cisco IOS software prior to Cisco IOS XE Release 2.3.

You must not have the **aaa-new model** command enabled on the networking device. You must not have the **login local** command configured for the local CLI sessions over the console port or the remote CLI sessions.

Note For clarity, only the arguments and keywords that are relevant for each step are shown in the steps in this task. Refer to the Cisco IOS command reference book for your Cisco IOS XE version for information on the additional arguments and keywords that can be used with these commands.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **username *username* privilege *level* secret *password***
4. **end**
5. **disable**
6. **login *username***
7. **show privilege**
8. **clear counters**
9. **clear *ip route* ***
10. **reload in *time***
11. **reload cancel**
12. **disable**
13. **show privilege**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enters privileged EXEC mode. Enter the password when prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	username <i>username</i> privilege <i>level</i> secret <i>password</i> Example: Device(config)# username admin privilege 7 secret Kd65xZa	Creates a username and applies MD5 encryption to the <i>password</i> text string.
Step 4	end Example: Device(config)# end	Exits global configuration mode.
Step 5	disable Example: Device# disable	Exits the current privilege level and returns to user EXEC mode.
Step 6	login <i>username</i> Example: Device> login admin	Logs in the user. Enter the username and password you configured in step 3 when prompted.
Step 7	show privilege Example: Device# show privilege Current privilege level is 7	The show privilege command displays the privilege level of the CLI session.
Step 8	clear counters Example: Device# clear counters Clear "show interface" counters on all interfaces [confirm] Device# 02:41:37: %CLEAR-5-COUNTERS: Clear counter on all interfaces by console	The clear counters command clears the interface counters. This command has been changed from privilege level 15 to privilege level 7.

	Command or Action	Purpose
Step 9	<p>clear ip route *</p> <p>Example:</p> <pre>Device# clear ip route * ^ % Invalid input detected at '^' marker.</pre>	The <i>ip route</i> argument string for the clear command is not allowed because it was not changed from privilege level 15 to privilege level 7.
Step 10	<p>reload in time</p> <p>Example:</p> <pre>Device# reload in 10 Reload scheduled in 10 minutes by console Proceed with reload? [confirm] Device# *** *** --- SHUTDOWN in 0:10:00 --- *** 02:59:50: %SYS-5-SCHEDULED_RELOAD: Reload requested for 23:08:30 PST Sun Mar 20</pre>	The reload command causes the networking device to reboot.
Step 11	<p>reload cancel</p> <p>Example:</p> <pre>Device# reload cancel *** *** --- SHUTDOWN ABORTED --- *** 04:34:08: %SYS-5-SCHEDULED_RELOAD_CANCELLED: Scheduled reload cancelled at 15:38:46 PST Sun Mar 27 2005</pre>	The reload cancel command terminates a reload that was previously setup with the the reload in time command.
Step 12	<p>disable</p> <p>Example:</p> <pre>Device# disable</pre>	Exits the current privilege level and returns to user EXEC mode.
Step 13	<p>show privilege</p> <p>Example:</p> <pre>Device> show privilege Current privilege level is 1</pre>	Displays the privilege level of the current CLI session

Recovering from a Lost or Misconfigured Password for Local Sessions

There are three methods that can be used to recover from a lost or misconfigured password for local CLI sessions over console port. The method that you will use depends on the current configuration of your networking device.

Networking Device Is Configured to Allow Remote CLI Sessions

The fastest method to recover from a lost, or misconfigured password for local CLI sessions is to establish a remote CLI session with the networking device and repeat the [Configuring and Verifying a Password for Local CLI Sessions, on page 2210](#). Your networking device must be configured to allow remote CLI sessions and you must know the remote CLI session password to perform this procedure.

Networking Device Is Not Configured to Allow Remote CLI Sessions

- If you cannot establish a remote session to your networking device, and you have not saved the misconfigured local CLI session password to the startup configuration, you can restart the networking device. When the networking device starts up again it will read the startup configuration file. The previous local CLI session password is restored.

**Caution**

Restarting a networking device will cause it to stop forwarding traffic. This will also cause an interruption in any services that are running on the networking device, such as a DHCP server service, to stop. You should only restart a networking device during a period of time that has been allocated for network maintenance.

Recovering from a Lost or Misconfigured Password for Remote Sessions

There are three methods that can be used to recover from a lost, or misconfigured remote CLI session password. The method that you will use depends on the current configuration of your networking device.

Networking Device Is Configured to Allow Local CLI Sessions

The fastest method to recover from a lost, or misconfigured password for remote CLI sessions is to establish a local CLI session with the networking device and repeat the [Configuring and Verifying a Password for Remote CLI Sessions, on page 2208](#). Your networking device must be configured to allow local CLI sessions and you must know the local CLI session password to perform this procedure.

Networking Device Is Not Configured to Allow Local CLI Sessions

- If you cannot establish a local CLI session to your networking device, and you have not saved the misconfigured remote CLI session password to the startup configuration, you can restart the networking device. When the networking device starts up again it will read the startup configuration file. The previous remote CLI session password is restored.

**Caution**

Restarting a networking device will cause it to stop forwarding traffic. This will also cause an interruption in any services that are running on the networking device, such as a DHCP server service, to stop. You should only restart a networking device during a period of time that has been allocated for network maintenance.

Recovering from Lost or Misconfigured Passwords for Privileged EXEC Mode

There are two methods that can be used to recover from a lost, or misconfigured Privileged EXEC Mode password. The method that you will use depends on the current configuration of your networking device.

A Misconfigured Privileged EXEC Mode Password Has Not Been Saved

- If you have not saved the misconfigured privileged EXEC mode password to the startup configuration, you can restart the networking device. When the networking device starts up again it will read the startup configuration file. The previous privileged EXEC mode password is restored.

Caution

Restarting a networking device will cause it to stop forwarding traffic. This will also cause an interruption in any services that are running on the networking device, such as a DHCP server service, to stop. You should only restart a networking device during a period of time that has been allocated for network maintenance.

Configuration Examples for Configuring Security with Passwords Privileges and Logins

Example: Configuring an Encrypted Preshared Key

The following is an example of a configuration for which a type 6 preshared key has been encrypted. It includes the prompts and messages that a user might see.

```
Device(config)# password encryption aes
New key:
Confirm key:
Device (config)#

01:46:40: TYPE6_PASS: New Master key configured, encrypting the keys with
the new master key
Device (config)# exit
```

Example: Configuring a Device to Allow Users to Clear Remote Sessions

The following example shows how to configure a networking device to allow a non administrative user to clear remote CLI session virtual terminal (VTY) lines.

The first section is an excerpt of the running configuration for this example. The following sections show you how this example is used.

The following section is an excerpt of the running-configuration:

```
!
privilege exec level 7 clear line
!
no aaa new-model
!
!
username admin privilege 7 secret 5 $1$tmIw$1aM7sadKhWMPkVTzxNw1J.
```

```

!
privilege exec level 7 clear line
!
! the privilege exec level 7 clear command below is entered automatically
! when you enter the privilege exec level 7 clear line command above, do
! not enter it again
!
privilege exec level 7 clear
!

```

The following section using the **login** command shows the user logging in to the networking device with the username of admin:

```

R1> login
Username: admin
Password:

```

The following section using the **show privilege** command shows that the current privilege level is 7:

```

R1# show privilege

Current privilege level is 7
R1#

```

The following section using the **show user** command shows that two users (admin and root) are currently logged in to the networking device:

```

R1# show user

  Line      User      Host(s)      Idle      Location
*  0 con 0   admin      idle       00:00:00
  2 vty 0   root       idle       00:00:17 172.16.6.2
  Interface  User      Mode      Idle      Peer Address

```

The following section using the **clear line 2** command terminates the remote CLI session in use by the username root:

```

R1# clear line 2

[confirm]
[OK]

```

The following section using the **show user** command shows that admin is the only user currently logged in to the networking device:

```

R1# show user

  Line      User      Host(s)      Idle      Location
*  0 con 0   admin      idle       00:00:00
  Interface  User      Mode      Idle      Peer Address

```

Example: Configuring a Device to Allow Users to View the Running Configuration

For Users With Privilege Level 15

The following example shows how to configure the networking device to allow a non administrative users (no access to privileged EXEC mode) to view the running configuration automatically. This example requires

that the username is configured for privilege level 15 because many of the commands in the configuration file can be viewed only by users who have access to privilege level 15.

The solution is to temporarily allow the user access to privilege level 15 while running the **show running-config** command and then terminating the CLI session when the end of the configuration file has been viewed. In this example the networking device will automatically terminate the CLI session when the end of the configuration file has been viewed. No further configuration steps are required.

Caution You must include the **noescape** keyword for the **username** command to prevent the user from entering an escape character that will terminate viewing the configuration file and leave the session running at privilege level 15.

```
!
!
username viewconf privilege 15 noescape secret 5 $1$zA9C$TDWD/Q0zwp/5xRwRqdgC/.
username viewconf autocommand show running-config
!
```

For Users With Privilege Level Lower Than Level 15

The following example shows how to configure a networking device to allow a user with privilege level lower than level 15 to view the running configuration.

```
Device> enable
Device# configure terminal
Device(config)# privilege exec all level 5 show running-config
Device(config)# file privilege 5
Device(config)# privilege configure all level 5 logging
Device(config)# end
Device# show privilege

Current privilege level is 5

Device# show running-config

Building configuration...

Current configuration : 128 bytes
!
boot-start-marker
boot-end-marker
!
no logging queue-limit
logging buffered 10000000
no logging rate-limit
!
!
!
end
```

Example: Configuring a Device to Allow Users to Shutdown and Enable Interfaces

The following example shows how to configure a networking device to allow non administrative users to shutdown and enable interfaces.

The first section is an excerpt of the running configuration for this example. The following sections show you how this example is used.

The following section is an excerpt of the running-configuration:

```
!
no aaa new-model
!
username admin privilege 7 secret 5 $1$tmIw$1aM7sadKhWMpkVTzxNw1J.
!
privilege interface all level 7 shutdown
privilege interface all level 7 no shutdown
privilege configure level 7 interface
privilege exec level 7 configure terminal
!
! the privilege exec level 7 configure command below is entered automatically
! when you enter the privilege exec level 7 configure terminal command above, do
! not enter it again
!
privilege exec level 7 configure
!
```

The following section using the **login** command shows the user logging in to the networking device with the username of admin:

```
R1> login
Username: admin
Password:
```

The following section using the **show privilege** command shows that the current privilege level is 7:

```
R1# show privilege
Current privilege level is 7
```

The following section using the **show user** command shows that admin is the only user currently logged in to the networking device:

```
R1# show user
      Line      User      Host(s)      Idle      Location
*  0 con 0      admin      idle         00:00:00
      Interface  User      Mode         Idle      Peer Address
```

The following section shows that the admin user is permitted to shutdown and enable an interface:

```
R1# configure terminal
Enter configuration commands, one per line.  End with CNTL/Z.
R1(config)# interface ethernet 1/0
R1(config-if)# shutdown
R1(config-if)# no shutdown
R1(config-if)# exit
R1#
```

Where to Go Next

Once you have established a baseline of security for your networking devices you can consider more advanced options such as:

- **Role-Based CLI Access**--The role-based CLI access feature offers a more comprehensive set of options than the **privilege** command (described in this document) for network managers who want to allow different levels of technical support staff to have different levels of access to CLI commands.
- **AAA Security**--Many Cisco networking devices offer an advanced level of security using authentication, authorization and accounting (AAA) features. All of the tasks described in this document, and other - more advanced security features - can be implemented using AAA on the networking device in conjunction with a remote TACACS+ or RADIUS server. For information how to configure AAA security features that can be run locally on a networking device, or for information on how to configure remote AAA security using TACACS+ or RADIUS servers, see the *Cisco IOS XE Security Configuration Guide: Securing User Services* , Release 2.

Additional References

The following sections provide references related to Configuring Security with Passwords and, Login Usernames for CLI Sessions on Networking Devices.

Feature Information for Configuring Security with Passwords Privileges and Logins

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 224: Feature Information for Configuring Security with Passwords, Privilege Levels, and Login Usernames for CLI Sessions on Networking Devices

Feature Name	Releases	Feature Configuration Information
Enhanced Password Security		Using the Enhanced Password Security feature, you can configure MD5 encryption for username passwords. MD5 encryption is a one-way hash function that makes reversal of an encrypted password impossible, providing strong encryption protection. Using MD5 encryption, you cannot retrieve clear text passwords. MD5 encrypted passwords cannot be used with protocols that require that the clear text password be retrievable, such as Challenge Handshake Authentication Protocol (CHAP).

CHAPTER 170

Role-Based CLI Access

The Role-Based CLI Access feature allows the network administrator to define views, which are a set of operational commands and configuration capabilities that provide selective or partial access to Cisco IOS EXEC and configuration (config) mode commands. Views restrict user access to Cisco IOS command-line interface (CLI) and configuration information; that is, a view can define what commands are accepted and what configuration information is visible. Thus, network administrators can exercise better control over access to Cisco networking devices.

- [Prerequisites for Role-Based CLI Access, on page 2235](#)
- [Restrictions for Role-Based CLI Access, on page 2235](#)
- [Information About Role-Based CLI Access, on page 2236](#)
- [How to Use Role-Based CLI Access, on page 2237](#)
- [Configuration Examples for Role-Based CLI Access, on page 2242](#)
- [Additional References for Role-Based CLI Access, on page 2245](#)
- [Feature Information for Role-Based CLI Access, on page 2245](#)

Prerequisites for Role-Based CLI Access

Your image must support CLI views.

Restrictions for Role-Based CLI Access

Lawful Intercept Images Limitation

CLI views are a part of all platforms and Cisco IOS images because they are a part of the Cisco IOS parser. However, the lawful intercept view is available only in images that contain the lawful intercept subsystem.

Maximum Number of Allowed Views

The maximum number of CLI views and superviews, including one lawful intercept view, that can be configured is 15. (This does not include the root view.)

Parse View Profiles

When you configure Parse View profiles, the 'no' or 'default' commands in combination with any configuration commands are not saved to the startup-configuration file. The configuration is accepted and is persistent until the device is reloaded. Examples of commands which are not saved to the startup-configuration:

- **command configure include all no**
- **command interface include all no**
- **command configure include all default**

Information About Role-Based CLI Access

Benefits of Using CLI Views

Although users can control CLI access via both privilege levels and enable mode passwords, these functions do not provide network administrators with the necessary level of detail needed when working with Cisco IOS devices. CLI views provide a more detailed access control capability for network administrators, thereby improving the overall security and accountability of Cisco IOS software.

As of Cisco IOS Release 12.3(11)T, network administrators can also specify an interface or a group of interfaces to a view; thereby, allowing access on the basis of specified interfaces.

Root View

When a system is in root view, it has all of the access privileges as a user who has level 15 privileges. If the administrator wishes to configure any view to the system (such as a CLI view, a superview, or a lawful intercept view), the system must be in root view.

The difference between a user who has level 15 privileges and a root view user is that a root view user can configure a new view and add or remove commands from the view. Also, when you are in a CLI view, you have access only to the commands that have been added to that view by the root view user.

Lawful Intercept View

Like a CLI view, a lawful intercept view restricts access to specified commands and configuration information. Specifically, a lawful intercept view allows a user to secure access to lawful intercept commands that are held within the TAP-MIB, which is a special set of simple network management protocol (SNMP) commands that store information about calls and users.

Commands available in lawful intercept view belong to one of the these categories:

- Lawful intercept commands that should not be made available to any other view or privilege level
- CLI views that are useful for lawful intercept users but do not have to be excluded from other views or privilege levels

Superview

A superview consists of one or more CLI views, which allow users to define what commands are accepted and what configuration information is visible. Superviews allow a network administrator to easily assign all users within configured CLI views to a superview instead of having to assign multiple CLI views to a group of users.

Superviews contain these characteristics:

- A CLI view can be shared among multiple superviews.
- Commands cannot be configured for a superview; that is, you must add commands to the CLI view and add that CLI view to the superview.
- Users who are logged into a superview can access all of the commands that are configured for any of the CLI views that are part of the superview.
- Each superview has a password that is used to switch between superviews or from a CLI view to a superview.
- If a superview is deleted, its associated CLI views are not deleted.

View Authentication via a New AAA Attribute

View authentication is performed by an external authentication, authorization, and accounting (AAA) server via the new attribute **cli-view-name**.

AAA authentication associates only one view name to a particular user; that is, only one view name can be configured for a user in an authentication server.

How to Use Role-Based CLI Access

Configuring a CLI View

Perform this task to create a CLI view and add commands or interfaces to the view, as appropriate.

Before you begin

Before you create a view, you must perform the following tasks:

- Enable AAA using the **aaa new-model** command.
- Ensure that your system is in root view-not privilege level 15.

SUMMARY STEPS

1. **enable view**
2. **configure terminal**
3. **parser view** *view-name* [**inclusive**]
4. **secret** [**0** | **5**] *encrypted-password*

5. **commands** *parser-mode* {**exclude** | **include-exclusive** | **include**} [**all**] [**interface** *interface-name* | *command*]
6. **end**
7. **enable** [*privilege-level* | **view** *view-name*]
8. **show parser view all**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable view Example: <pre>Device> enable view</pre>	Enables root view. <ul style="list-style-type: none"> • Enter your privilege level 15 password (for example, root password) if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	parser view <i>view-name</i> [inclusive] Example: <pre>Device(config)# parser view first inclusive Device(config-view)#</pre>	Creates a view including all commands by default. If the inclusive keyword option is not selected, it creates a view excluding all commands by default. You are in the view configuration mode.
Step 4	secret [0 5] <i>encrypted-password</i> Example: <pre>Device(config-view)# secret 5 secret</pre>	Associates a CLI view or superview with a password. <p>Note You must issue this command before you can configure additional attributes for the view.</p> <p>Note With CSCts50236, the password can be removed or overwritten. Use the no secret command to remove the configured password.</p>
Step 5	commands <i>parser-mode</i> { exclude include-exclusive include } [all] [interface <i>interface-name</i> <i>command</i>] Example: <pre>Device(config-view)# commands exec include show version</pre>	Adds commands or interfaces to a view and specifies the mode in which the specified command exists. <p>Note While configuring parser view profiles, the following no or default commands are not saved to the startup configuration. These commands are in use until the device is reloaded. Once the device is reloaded, reapply these commands to get the required results.</p> <ul style="list-style-type: none"> • commands configure include all no • commands interface include all no • commands configure include all default

	Command or Action	Purpose
Step 6	end Example: <pre>Device(config-view)# end</pre>	Exits view configuration mode and returns to privileged EXEC mode.
Step 7	enable [<i>privilege-level</i> view <i>view-name</i>] Example: <pre>Device# enable view first</pre>	Prompts you for a password to access a configured CLI view, and you can switch from one view to another view. Enter the password to access the CLI view.
Step 8	show parser view all Example: <pre>Device# show parser view all</pre>	(Optional) Displays information for all views that are configured on the device. Note Although this command is available for both root and lawful intercept users, the all keyword is available only to root users. However, the all keyword can be configured by a user in root view to be available for users in lawful intercept view and CLI view.

Troubleshooting Tips

You must associate a password with a view. If you do not associate a password, and you attempt to add commands to the view using the **commands** command, a system message such as the following is displayed:

```
%Password not set for view <viewname>.
```

Configuring a Lawful Intercept View

Perform this task to initialize and configure a view for lawful-intercept-specific commands and configuration information.

Before you begin

Before you initialize a lawful intercept view, ensure that the privilege level is set to 15 using the **privilege** command.

Note Only an administrator or a user who has level 15 privileges can initialize a lawful intercept view.

SUMMARY STEPS

1. **enable view**
2. **configure terminal**
3. **li-view** *li-password* **user** *username* **password** *password*
4. **username** **lawful-intercept** [*name*] [**privilege** *privilege-level* | **view** *view-name*] **password** *password*

5. **parser view** *view-name*
6. **secret 5** *encrypted-password*
7. **name** *new-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable view Example: Device> enable view	Enables root view. <ul style="list-style-type: none"> • Enter your privilege level 15 password (for example, root password) if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	li-view <i>li-password</i> user <i>username</i> password <i>password</i> Example: Device(config)# li-view lipass user li_admin password li_adminpass	Initializes a lawful intercept view. After the li-view is initialized, you must specify at least one user via user <i>username</i> password <i>password</i> options.
Step 4	username lawful-intercept [<i>name</i>] [privilege <i>privilege-level</i> view <i>view-name</i>] password <i>password</i> Example: Device(config)# username lawful-intercept li-user1 password li-user1pass	Configures lawful intercept users on a Cisco device.
Step 5	parser view <i>view-name</i> Example: Device(config)# parser view li view name	(Optional) Enters view configuration mode, which allows you to change the lawful intercept view password or the lawful intercept view name.
Step 6	secret 5 <i>encrypted-password</i> Example: Device(config-view)# secret 5 secret	(Optional) Changes an existing password for a lawful intercept view.
Step 7	name <i>new-name</i> Example: Device(config-view)# name second	(Optional) Changes the name of a lawful intercept view. If this command is not issued, the default name of the lawful intercept view is “li-view.”

Troubleshooting Tips

To display information for all users who have access to a lawful intercept view, issue the **show users lawful-intercept** command. (This command is available only to authorized lawful intercept view users.)

Configuring a Superview

Perform this task to create a superview and add at least one CLI view to the superview.

Before you begin

Before adding a CLI view to a superview, ensure that the CLI views that are added to the superview are valid views in the system; that is, the views have been successfully created using the **parser view** command.

Note You can add a view to a superview only after you configure a password for the superview (using the **secret 5** command). Thereafter, issue the **view** command in view configuration mode to add at least one CLI view to the superview.

SUMMARY STEPS

1. **enable view**
2. **configure terminal**
3. **parser view *superview-name* superview**
4. **secret 5 *encrypted-password***
5. **view *view-name***
6. **end**
7. **show parser view all**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable view Example: Device> enable view	Enables root view. <ul style="list-style-type: none"> • Enter your privilege level 15 password (for example, root password) if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	parser view <i>superview-name</i> superview Example: Device(config)# parser view su_view1 superview	Creates a superview and enters view configuration mode.
Step 4	secret 5 <i>encrypted-password</i> Example: Device(config-view)# secret 5 secret	Associates a CLI view or superview with a password. Note You must issue this command before you can configure additional attributes for the view.
Step 5	view <i>view-name</i>	Adds a normal CLI view to a superview.

	Command or Action	Purpose
	Example: Device(config-view)# view view_three	Issue this command for each CLI view that is to be added to a given superview.
Step 6	end Example: Device(config-view)# end Device#	Exits view configuration mode and returns to privileged EXEC mode.
Step 7	show parser view all Example: Device# show parser view	(Optional) Displays information for all views that are configured on the device. Note Although this command is available for both root and lawful intercept users, the all keyword is available only to root users. However, the all keyword can be configured by a user in root view to be available for users in lawful intercept view and CLI view.

Monitoring Views and View Users

To display debug messages for all views-root, CLI, lawful intercept, and superview-use the **debug parser view** command in privileged EXEC mode.

Configuration Examples for Role-Based CLI Access

Example: Configuring a CLI View

The following example shows how to configure two CLI views, “first” and “second”. Thereafter, you can verify the CLI view in the running configuration.

```

Device(config)# parser view first inclusive
Device(config-view)# secret 5 firstpass
Device(config-view)# command exec exclude show version
Device(config-view)# command exec exclude configure terminal
Device(config-view)# command exec exclude all show ip
Device(config-view)# exit
Device(config)# parser view second
Device(config-view)# secret 5 secondpass
Device(config-view)# command exec include-exclusive show ip interface
Device(config-view)# command exec include logout
Device(config-view)# exit
!
!
Device(config-view)# do show running-config | beg view

parser view first inclusive
secret 5 $1$Mcmh$QuZaU8PIMP1ff9sFCZvgW/

```

```

commands exec exclude configure terminal
commands exec exclude configure
commands exec exclude all show ip
commands exec exclude show version
commands exec exclude show
!
parser view second
secret 5 $1$iP2M$R16BXKecMEiQesxLyqygW.
commands exec include-exclusive show ip interface
commands exec include show ip
commands exec include show
commands exec include logout
!
```

Example: Verifying a CLI View

After you have configured the CLI views “first” and “second”, you can issue the **enable view** command to verify which commands are available in each view. The following example shows which commands are available inside the CLI view “first” after the user has logged into this view. (Because the **show ip** command is configured with the all option, a complete set of suboptions is shown, except the **show ip interface** command, which is using the **include-exclusive** keyword in the second view.)

```

Device# enable view first
Password:
Device# ?
Exec commands:
  configure  Enter configuration mode
  enable     Turn on privileged commands
  exit       Exit from the EXEC
  show       Show running system information
Device# show ?
  ip         IP information
  parser     Display parser information
  version    System hardware and software status
Device# show ip ?

  access-lists      List IP access lists
  accounting         The active IP accounting database
  aliases            IP alias table
  arp                IP ARP table
  as-path-access-list  List AS path access lists
  bgp                BGP information
  cache              IP fast-switching route cache
  casa               display casa information
  cef                Cisco Express Forwarding
  community-list     List community-list
  dfp                DFP information
  dhcp               Show items in the DHCP database
  drp                Director response protocol
  dvmrp              DVMRP information
  eigrp              IP-EIGRP show commands
  extcommunity-list List extended-community list
  flow               NetFlow switching
  helper-address     helper-address table
  http               HTTP information
  igmp               IGMP information
  irdp               ICMP Device Discovery Protocol
  .
  .
  .
```

Example: Configuring a Lawful Intercept View

The following example shows how to configure a lawful intercept view, add users to the view, and verify the users that were added:

```
!Initialize the LI-View.
Device(config)# li-view lipass user li_admin password li_adminpass
Device(config)# end
! Enter the LI-View; that is, check to see what commands are available within the view.
Device# enable view li-view
Password:
Device# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Device(config)# parser view li-view

Device(config-view)# ?
View commands:
  commands  Configure commands for a view
  default   Set a command to its defaults
  exit      Exit from view configuration mode
  name      New LI-View name
  no        Negate a command or set its defaults
  password  Set a password associated with CLI views
Device(config-view)#
! NOTE:LI View configurations are never shown as part of 'running-configuration'.
! Configure LI Users.
Device(config)# username lawful-intercept li-user1 password li-user1pass

Device(config)# username lawful-intercept li-user2 password li-user2pass
! Displaying LI User information.
Device# show users lawful-intercept
li_admin
li-user1
li-user2
Device#
```

Note The lawful intercept view is available only on specific images and the view name option is available only in the LI view.

Example: Configuring a Superview

The following sample output from the **show running-config** command shows that “view_one” and “view_two” have been added to superview “su_view1”, “view_three”, and “view_four” have been added to superview “su_view2”:

```
Device# show running-config
!
parser view su_view1 superview
secret 5 <encoded password>
view view_one
view view_two
!
parser view su_view2 superview
secret 5 <encoded password>
view view_three
```

```
view view_four
!
```

Feature Information for Role-Based CLI Access

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 225: Feature Information for Role-Based CLI Access

Feature Name	Releases	Feature Information
Role-Based CLI Access		<p>The Role-Based CLI Access feature enables network administrators to restrict user access to CLI and configuration information.</p> <p>The CLI view capability was extended to restrict user access on a per-interface level, and additional CLI views were introduced to support the extended view capability. Also, support to group configured CLI views into a superview was introduced.</p> <p>The following commands were introduced or modified: commands (view), enable, li-view, name (view), parser view, parser view superview, secret, show parser view, show users, username, and view.</p>
Role-Based CLI Inclusive Views		<p>The Role-Based CLI Inclusive Views feature enables a standard CLI view including all commands by default.</p> <p>The following command was modified: parser view inclusive.</p>

CHAPTER 171

Information About Secure Storage

Secure Storage feature allows you to secure critical configuration information by encrypting it. It encrypts VPN, IPSec, and other asymmetric key-pairs, pre-shared secrets, the type 6 password encryption key and certain credentials. An instance-unique encryption key is stored in the hardware trust anchor to prevent it from being compromised.

By default, this feature is enabled on platforms that come with a hardware trust anchor. This feature is not supported on platforms that do not have hardware trust anchor.

- [Supported Platforms, on page 2247](#)
- [Enabling Secure Storage , on page 2250](#)
- [Disabling Secure Storage , on page 2251](#)
- [Verifying the Status of Encryption, on page 2252](#)
- [Downgrading the Platform Image to an Older Version, on page 2252](#)
- [Feature Information for Overview of Secure Storage, on page 2252](#)

Supported Platforms

Starting from Cisco IOS Release 15.6(3) M1, the following Cisco 880 Series platforms support Secure Storage:

Table 226: Secure Storage Supported Platforms - Cisco Integrated Services Router 880 PID

C881-K9
C887VA-K9
C886VA-K9
C887VAM-K9
C886VAJ-K9
C888-K9

Starting from Cisco IOS Release 15.6(3) M1, the following Cisco 890 Series platforms support Secure Storage:

Enabling Secure Storage

Before you begin

By default, this feature is enabled on a platform. Use this procedure on a platform where it is disabled.

SUMMARY STEPS

1. Config terminal
2. service private-config-encryption
3. do write memory

DETAILED STEPS

	Command or Action	Purpose
Step 1	Config terminal Example: router#config terminal	Enters the configuration mode.

	Command or Action	Purpose
Step 2	service private-config-encryption Example: <pre>router(config)# service private-config-encryption</pre>	Enables the Secure Storage feature on your platform.
Step 3	do write memory Example: <pre>router(config)# do write memory</pre>	Encrypts the private-config file and saves the file in an encrypted format.

Example

The following example shows how to enable Secure Storage:

```
router#config terminal
router(config)# service private-config-encryption
router(config)# do write memory
```

Disabling Secure Storage

Before you begin

To disable Secure Storage feature on a platform, perform this task:

SUMMARY STEPS

1. Config terminal
2. no service private-config-encryption
3. do write memory

DETAILED STEPS

	Command or Action	Purpose
Step 1	Config terminal Example: <pre>router#config terminal</pre>	Enters the configuration mode.
Step 2	no service private-config-encryption Example: <pre>router(config)# no service private-config-encryption</pre>	Disables the Secure Storage feature on your platform.
Step 3	do write memory Example: <pre>router(config)# do write memory</pre>	Decrypts the private-config file and saves the file in plane format.

Example

The following example shows how to disable Secure Storage:

```
router#config terminal
router(config)# no service private-config-encryption
router(config)# do write memory
```

Verifying the Status of Encryption

Use the **show parser encrypt file status** command to verify the status of encryption. The following command output indicates that the feature is available but the file is not encrypted. The file is in 'plain text' format.

```
router#show parser encrypt file status
Feature: Enabled
File Format: Plain Text
Encryption Version: Ver1
```

The following command output indicates that the feature is enabled and the file is encrypted. The file is in 'cipher text' format.

```
router#show parser encrypt file status
Feature: Enabled
File Format: Cipher Text
Encryption Version: Ver1
```

Downgrading the Platform Image to an Older Version

Before you downgrade the platform image to an older version where the Secure Storage is not supported, you have to disable the feature in the version where it is supported.

If you do not disable this feature before downgrading to an older image, the private-config file will be in encrypted format. The following Syslog message will be generated to indicate that the file is in encrypted format:

```
%PARSER-4-BADCFG: Unexpected end of configuration file.
```

If the file is in 'plain text', no Syslog message will be generated.

Feature Information for Overview of Secure Storage

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 232: Feature Information for Overview of Cisco TrustSec

Feature Name	Releases	Feature Information
Secure Storage	Cisco IOS XE Fuji 16.9.1	The support for Secure Storage is introduced for ASR and ISR platforms.

CHAPTER 172

AutoSecure

The AutoSecure feature secures a router by using a single CLI command to disable common IP services that can be exploited for network attacks, enable IP services and features that can aid in the defense of a network when under attack, and simplify and harden the security configuration of the router.

AutoSecure enhances secure access to the router by configuring a required minimum password length to eliminate common passwords that can be common on many networks, such as “lab” and “company name.” Syslog messages are generated after the number of unsuccessful attempts exceeds the configured threshold.

AutoSecure also allows a router to revert (roll) back to its pre-AutoSecure configuration state if the AutoSecure configuration fails.

When AutoSecure is enabled, a detailed audit trail of system logging messages capture any changes or tampering of the AutoSecure configuration that may have been applied to the running configuration.

- [Restrictions for AutoSecure, on page 2255](#)
- [Information About AutoSecure, on page 2255](#)
- [How to Configure AutoSecure, on page 2259](#)
- [Configuration Example for AutoSecure, on page 2261](#)
- [Additional References, on page 2264](#)
- [Feature Information for AutoSecure, on page 2265](#)

Restrictions for AutoSecure

The AutoSecure configuration can be configured at run time or setup time. If any related configuration is modified after AutoSecure has been enabled, the AutoSecure configuration may not be fully effective.

Information About AutoSecure

Securing the Management Plane

The management plane is secured by turning off certain global and interface services that can be potentially exploited for security attacks and turning on global services that help mitigate the threat of attacks. Secure access and secure logging are also configured for the router.

Caution If your device is managed by a network management (NM) application, securing the management plane could turn off some services like the HTTP server and disrupt the NM application support.

The following subsections define how AutoSecure helps to secure the management plane:

Disabling Global Services

After enabling this feature (through the **auto secure** command), the following global services are disabled on the router without prompting the user:

- Finger--Collects information about the system (reconnaissance) before an attack. If enabled, the information can leave your device vulnerable to attacks.
- PAD--Enables all packet assembler and disassembler (PAD) commands and connections between PAD devices and access servers. If enabled, it can leave your device vulnerable to attacks.
- Small Servers--Causes TCP and User Datagram Protocol (UDP) diagnostic port attacks: a sender transmits a volume of fake requests for UDP diagnostic services on the router, consuming all CPU resources.
- Bootp Server--Bootp is an insecure protocol that can be exploited for an attack.
- HTTP Server--Without secure-http or authentication embedded in the HTTP server with an associated ACL, the HTTP server is insecure and can be exploited for an attack. (If you must enable the HTTP server, you are prompted for the proper authentication or access list.)

Note If you are using Cisco Configuration Professional (CCP), you must manually enable the HTTP server through the **ip http server** command.

- Identification Service--An insecure protocol, defined in RFC 1413, that allows one to query a TCP port for identification. An attacker can access private information about the user from the ID server.
- CDP--If a large number of Cisco Discovery Protocol (CDP) packets are sent to the router, the available memory of the router can be consumed, causing the router to crash.

Caution NM applications that use CDP to discover network topology are not able to perform discovery.

- NTP--Without authentication or access-control, Network Time Protocol (NTP) is insecure and can be used by an attacker to send NTP packets to crash or overload the router. (If you want to turn on NTP, you must configure NTP authentication using Message Digest 5 (MD5) and the **ntp access-group** command. If NTP is enabled globally, disable it on all interfaces on which it is not needed.)
- Source Routing--Provided only for debugging purposes, so source routing should be disabled in all other cases. Otherwise, packets may slip away from some of the access control mechanisms that they should have gone through.

Disabling Per Interface Services

After enabling this feature, the following per interface services are disabled on the router without prompting the user:

- ICMP redirects--Disabled on all interfaces. Does not add a useful functionality to a correctly configured to network, but it could be used by attackers to exploit security holes.
- ICMP unreachable--Disabled on all interfaces. Internet Control Management Protocol (ICMP) unreachable are a known cause for some ICMP-based denial of service (DoS) attacks.
- ICMP mask reply messages--Disabled on all interfaces. ICMP mask reply messages can give an attacker the subnet mask for a particular subnetwork in the internetwork.
- Proxy-Arp--Disabled on all interfaces. Proxy-Arp requests are a known cause for DoS attacks because the available bandwidth and resources of the router can be consumed in an attempt to respond to the repeated requests that are sent by an attacker.
- Directed Broadcast--Disabled on all interfaces. Potential cause of SMURF attacks for DoS.
- Maintenance Operations Protocol (MOP) service--Disabled on all interfaces.

Enabling Global Services

After AutoSecure is enabled, the following global services are enabled on the router without prompting the user:

- The **service password-encryption** command--Prevents passwords from being visible in the configuration.
- The **service tcp-keepalives-in** and **service tcp-keepalives-out** commands--Ensures that abnormally terminated TCP sessions are removed.

Securing Access to the Router

Caution If your device is managed by an NM application, securing access to the router could turn off vital services and may disrupt the NM application support.

After enabling this feature, the following options in which to secure access to the router are available to the user:

- If a text banner does not exist, users are prompted to add a banner. This feature provides the following sample banner:

Authorized access only

```
This system is the property of ABC Enterprise
Disconnect IMMEDIATELY if you are not an authorized user!
Contact abc@xyz.com +99 876 543210 for help.
```

- The login and password (preferably a secret password, if supported) are configured on the console, AUX, vty, and tty lines. The **transport input** and **transport output** commands are also configured on all of these lines. (Telnet and secure shell (SSH) are the only valid transport methods.) The **exec-timeout** command is configured on the console and AUX as 10.

- When the image on the device is a crypto image, AutoSecure enables SSH and secure copy (SCP) for access and file transfer to and from the router. The **timeout seconds** and **authentication-retries integer** options for the **ip ssh** command are configured to a minimum number. (Telnet and FTP are not affected by this operation and remain operational.)
- If the AutoSecure user specifies that their device does not use Simple Network Management Protocol (SNMP), one of the following functions occur:
 - In interactive mode, the user is asked whether to disable SNMP regardless of the values of the community strings, which act like passwords to regulate access to the agent on the router.
 - In non-interact mode, SNMP is disabled if the community string is “public” or “private.”

Note After AutoSecure has been enabled, tools that use SNMP to monitor or configure a device is unable to communicate with the device through SNMP.

- If authentication, authorization, and accounting (AAA) is not configured, configure local AAA. AutoSecure prompts users to configure a local username and password on the router.

Security Logging

The following logging options are available after AutoSecure is enabled. These options identify security incidents and provide ways to respond to them.

- Sequence numbers and time stamps for all debug and log messages. This option is useful when auditing logging messages.
- Logging messages can be generated for login-related events; for example, the message “Blocking Period when Login Attack Detected” is displayed when a login attack is detected and the router enters “quiet mode.” (Quiet mode means that the router does not allow any login attempts through Telnet, HTTP, or SSH.)

For more information on login system messages, see the Cisco IOS Release 12.3(4)T feature module Cisco IOS Login Enhancements .

- The **logging console critical** command, which sends system logging (syslog) messages to all available TTY lines and limits messages based on severity.
- The **logging buffered** command, which copies logging messages to an internal buffer and limits messages logged to the buffer based on severity.
- The **logging trap debugging** command, which allows all commands with a severity higher than debugging to be sent to the logging server.

Securing the Forwarding Plane

To minimize the risk of attacks on the router forward plane, AutoSecure provides the following functions:

- Cisco Express Forwarding (CEF)--AutoSecure enables CEF or distributed CEF (dCEF) on the router whenever possible. Because there is no need to build cache entries when traffic starts arriving for new destinations, CEF behaves more predictably than other modes when presented with large volumes of

traffic addressed to many destinations. Thus, routers configured for CEF perform better under SYN attacks than routers using the traditional cache.

Note CEF consumes more memory than a traditional cache.

- If the TCP intercept feature is available, it can be configured on the router for connection timeout.
- If strict Unicast Reverse Path Forwarding (uRPF) is available, it can be configured on the router to help mitigate problems that are caused by the introduction of forged (spoofed) IP source addresses. uRPF discards IP packets that lack a verifiable IP source address.
- If the router is being used as a firewall, it can be configured for context-based access control (CBAC) on public interfaces that are facing the Internet.

Note At the beginning of the AutoSecure dialogue, you are prompted for a list of public interfaces.

How to Configure AutoSecure

Configuring AutoSecure

Caution Although the **auto secure** command helps to secure a router, it does not guarantee the complete security of the router.

SUMMARY STEPS

1. **enable**
2. **auto secure** [management | forwarding] [no-interact | full] [ntp | login | ssh | firewall | tcp-intercept]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables higher privilege levels, such as privileged EXEC mode. Enter your password if prompted.
Step 2	auto secure [management forwarding] [no-interact full] [ntp login ssh firewall tcp-intercept] Example:	A semi-interactive dialogue session begins to secure either the management or forwarding planes on the router when the management or forwarding keyword is selected. If neither option is selected, then the dialogue asks for both

	Command or Action	Purpose
	<pre>Router# auto secure</pre>	<p>planes to be configured. If the management keyword is selected, then the management plane is secured only. If the forwarding keyword is selected, then the forwarding plane is secured only.</p> <p>If the no-interact keyword is selected, then the user is not prompted for any interactive configurations.</p> <p>If the full keyword is selected, then user is prompted for all interactive questions, which is the default.</p>

Configuring Enhanced Security Access to the Router

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **enable password** *{password} [encryption-type] encrypted-password }*
4. **security authentication failure rate** *threshold-rate log*
5. **exit** *threshold-rate log*
6. **show auto secure config**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables higher privilege levels, such as privileged EXEC mode.</p> <p>Enter your password if prompted.</p>
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	<p>Enters global configuration mode.</p>
Step 3	<p>enable password <i>{password} [encryption-type] encrypted-password }</i></p> <p>Example:</p> <pre>Router(config)# enable password elephant</pre>	<p>Sets a local password to control access to various privilege levels.</p>
Step 4	<p>security authentication failure rate <i>threshold-rate log</i></p> <p>Example:</p> <pre>Router(config)# security authentication failure rate 10 log</pre>	<p>Configures the number of allowable unsuccessful login attempts.</p> <ul style="list-style-type: none"> • <i>threshold-rate</i> --Number of allowable unsuccessful login attempts.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • log --Syslog authentication failures if the rate exceeds the threshold.
Step 5	exit threshold-rate log Example: Router(config)# exit	Exits configuration mode and enters privileged EXEC mode.
Step 6	show auto secure config Example: Router# show auto secure config	(Optional) Displays all configuration commands that have been added as part of the AutoSecure configuration.

Configuration Example for AutoSecure

The following example is a sample AutoSecure dialogue. After you enable the **auto secure** command, the feature automatically prompts you with a similar dialogue unless you enable the **no-interact** keyword. (For information on which services are disabled and which features are enabled, see the sections, [Securing the Management Plane, on page 2255](#) and [Securing the Forwarding Plane, on page 2258](#) earlier in this document.)

```

Router# auto secure
      --- AutoSecure Configuration ---
*** AutoSecure configuration enhances the security of the router but it will not make router
    absolutely secure from all security attacks ***
All the configuration done as part of AutoSecure will be shown here. For more details of
why and how this configuration is useful, and any possible side effects, please refer to
Cisco documentation of AutoSecure.
At any prompt you may enter '?' for help.
Use ctrl-c to abort this session at any prompt.

CHAPTER 173

Configuring Kerberos

- [Information About Kerberos, on page 2267](#)
- [How to Configure Kerberos, on page 2271](#)
- [Kerberos Configuration Examples, on page 2278](#)
- [Additional References, on page 2279](#)
- [Feature Information for Configuring Kerberos, on page 2280](#)

Information About Kerberos

Kerberos is a secret-key network authentication protocol, developed at the Massachusetts Institute of Technology (MIT), that uses the Data Encryption Standard (DES) cryptographic algorithm for encryption and authentication. Kerberos was designed to authenticate requests for network resources. Kerberos, like other secret-key systems, is based on the concept of a trusted third party that performs secure verification of users and services. In the Kerberos protocol, this trusted third party is called the key distribution center (KDC).

The primary use of Kerberos is to verify that users and the network services they use are really who and what they claim to be. To accomplish this, a trusted Kerberos server issues tickets to users. These tickets, which have a limited lifespan, are stored in a user's credential cache and can be used in place of the standard username-and-password authentication mechanism.

The Kerberos credential scheme embodies a concept called "single logon." This process requires authenticating a user once, and then allows secure authentication (without encrypting another password) wherever that user's credential is accepted.

Cisco IOS XE software includes Kerberos 5 support, which allows organizations already deploying Kerberos 5 to use the same Kerberos authentication database on their routers that they are already using on their other network hosts (such as UNIX servers and PCs).

The following network services are supported by the Kerberos authentication capabilities in Cisco IOS XE software:

- Telnet
- rlogin
- rsh
- rcp

Note Cisco Systems' implementation of Kerberos client support is based on code developed by CyberSafe, which was derived from the MIT code. As a result, the Cisco Kerberos implementation has successfully undergone full compatibility testing with the CyberSafe Challenger commercial Kerberos server and MIT's server code, which is freely distributed.

The table below lists common Kerberos-related terms and their definitions.

Table 234: Kerberos Terminology

Term	Definition
authentication	A process by which a user or service identifies itself to another service. For example, a client can authenticate to a router or a router can authenticate to another router.
authorization	A means by which the router determines what privileges you have in a network or on the router and what actions you can perform.
credential	A general term that refers to authentication tickets, such as ticket granting tickets (TGTs) and service credentials. Kerberos credentials verify the identity of a user or service. If a network service decides to trust the Kerberos server that issued a ticket, it can be used in place of retyping in a username and password. Credentials have a default lifespan of eight hours.
instance	An authorization level label for Kerberos principals. Most Kerberos principals are of the form user@REALM (for example, smith@EXAMPLE.COM). A Kerberos principal with a Kerberos instance has the form user/instance@REALM (for example, smith/admin@EXAMPLE.COM). The Kerberos instance can be used to specify the authorization level for the user if authentication is successful. It is up to the server of each network service to implement and enforce the authorization mappings of Kerberos instances. Note that the Kerberos realm name must be in uppercase characters.
Kerberized	Applications and services that have been modified to support the Kerberos credential infrastructure.
Kerberos realm	A domain consisting of users, hosts, and network services that are registered to a Kerberos server. The Kerberos server is trusted to verify the identity of a user or network service to another user or network service. Kerberos realms must always be in uppercase characters.
Kerberos server	A daemon running on a network host. Users and network services register their identity with the Kerberos server. Network services query the Kerberos server to authenticate to other network services.
key distribution center (KDC)	A Kerberos server and database program running on a network host.
principal	Also known as a Kerberos identity, this is who you are or what a service is according to the Kerberos server.

Term	Definition
service credential	A credential for a network service. When issued from the KDC, this credential is encrypted with the password shared by the network service and the KDC, and with the user's TGT.
SRVTAB	A password that a network service shares with the KDC. The network service authenticates an encrypted service credential by using the SRVTAB (also known as a KEYTAB) to decrypt it.
ticket granting ticket (TGT)	A credential that the key distribution center (KDC) issues to authenticated users. When users receive a TGT, they can authenticate to network services within the Kerberos realm represented by the KDC.

Kerberos Client Support Operation

This section describes how the Kerberos security system works with a Cisco router functioning as the security server. Although (for convenience or technical reasons) you can customize Kerberos in a number of ways, remote users attempting to access network services must pass through three layers of security before they can access network services.

Authenticating to the Boundary Router

This section describes the first layer of security that remote users must pass through when they attempt to access a network. The first step in the Kerberos authentication process is for users to authenticate themselves to the boundary router. The following process describes how users authenticate to a boundary router:

1. The remote user opens a PPP connection to the corporate site router.
2. The router prompts the user for a username and password.
3. The router requests a TGT from the KDC for this particular user.
4. The KDC sends an encrypted TGT to the router that includes (among other things) the user's identity.
5. The router attempts to decrypt the TGT using the password the user entered. If the decryption is successful, the remote user is authenticated to the router.

A remote user who successfully initiates a PPP session and authenticates to the boundary router is inside the firewall but still must authenticate to the KDC directly before being allowed to access network services. This is because the TGT issued by the KDC is stored on the router and is not useful for additional authentication unless the user physically logs on to the router.

Obtaining a TGT from a KDC

This section describes how remote users who are authenticated to the boundary router authenticate themselves to a KDC.

When a remote user authenticates to a boundary router, that user technically becomes part of the network; that is, the network is extended to include the remote user and the user's machine or network. To gain access to network services, however, the remote user must obtain a TGT from the KDC. The following process describes how remote users authenticate to the KDC:

1. The remote user, at a workstation on a remote site, launches the KINIT program (part of the client software provided with the Kerberos protocol).
2. The KINIT program finds the user's identity and requests a TGT from the KDC.
3. The KDC creates a TGT, which contains the identity of the user, the identity of the KDC, and the expiration time of the TGT.
4. Using the user's password as a key, the KDC encrypts the TGT and sends the TGT to the workstation.
5. When the KINIT program receives the encrypted TGT, it prompts the user for a password (this is the password that is defined for the user in the KDC).
6. If the KINIT program can decrypt the TGT with the password the user enters, the user is authenticated to the KDC, and the KINIT program stores the TGT in the user's credential cache.

At this point, the user has a TGT and can communicate securely with the KDC. In turn, the TGT allows the user to authenticate to other network services.

Authenticating to Network Services

The following process describes how a remote user with a TGT authenticates to network services within a given Kerberos realm. Assume the user is on a remote workstation (Host A) and wants to log in to Host B.

1. The user on Host A initiates a Kerberized application (such as Telnet) to Host B.
2. The Kerberized application builds a service credential request and sends it to the KDC. The service credential request includes (among other things) the user's identity and the identity of the desired network service. The TGT is used to encrypt the service credential request.
3. The KDC tries to decrypt the service credential request with the TGT it issued to the user on Host A. If the KDC can decrypt the packet, it is assured that the authenticated user on Host A sent the request.
4. The KDC notes the network service identity in the service credential request.
5. The KDC builds a service credential for the appropriate network service on Host B on behalf of the user on Host A. The service credential contains the client's identity and the desired network service's identity.
6. The KDC then encrypts the service credential twice. It first encrypts the credential with the SRVTAB that it shares with the network service identified in the credential. It then encrypts the resulting packet with the TGT of the user (who, in this case, is on Host A).
7. The KDC sends the twice-encrypted credential to Host A.
8. Host A attempts to decrypt the service credential with the user's TGT. If Host A can decrypt the service credential, it is assured the credential came from the real KDC.
9. Host A sends the service credential to the desired network service. Note that the credential is still encrypted with the SRVTAB shared by the KDC and the network service.
10. The network service attempts to decrypt the service credential using its SRVTAB.
11. If the network service can decrypt the credential, it is assured the credential was in fact issued from the KDC. Note that the network service trusts anything it can decrypt from the KDC, even if it receives it indirectly from a user. This is because the user first authenticated with the KDC.

At this point, the user is authenticated to the network service on Host B. This process is repeated each time a user wants to access a network service in the Kerberos realm.

How to Configure Kerberos

For hosts and the KDC in your Kerberos realm to communicate and mutually authenticate, you must identify them to each other. To do this, you add entries for the hosts to the Kerberos database on the KDC and add SRVTAB files generated by the KDC to all hosts in the Kerberos realm. You also make entries for users in the KDC database.

This section describes how to set up a Kerberos-authenticated server-client system and contains the following topics:

This section assumes that you have installed the Kerberos administrative programs on a UNIX host, known as the KDC, initialized the database, and selected a Kerberos realm name and password. For instructions about completing these tasks, refer to documentation that came with your Kerberos software.

Note Write down the host name or IP address of the KDC, the port number you want the KDC to monitor for queries, and the name of the Kerberos realm it will serve. You need this information to configure the router.

Configuring the KDC Using Kerberos Commands

After you set up a host to function as the KDC in your Kerberos realm, you must make entries to the KDC database for all principals in the realm. Principals can be network services on Cisco routers and hosts or they can be users.

To use Kerberos commands to add services to the KDC database (and to modify existing database information), complete the tasks in the following sections:

Note All Kerberos command examples are based on Kerberos 5 Beta 5 of the original MIT implementation. Later versions use a slightly different interface.

Adding Users to the KDC Database

To add users to the KDC and create privileged instances of those users, use the **su** command to become root on the host running the KDC and use the `kdb5_edit` program to use the following commands in privileged EXEC mode:

SUMMARY STEPS

1. Router# **ankusername@REALM**
2. Router# **ankusername/instance@REALM**

DETAILED STEPS

	Command or Action	Purpose
Step 1	Router# ankusername@REALM	Use the ank (add new key) command to add a user to the KDC. This command prompts for a password, which the user must enter to authenticate to the router.
Step 2	Router# ankusername/instance@REALM	Use the ank command to add a privileged instance of a user.

What to do next

For example, to add user *loki* of Kerberos realm CISCO.COM, enter the following Kerberos command:

```
ank loki@CISCO.COM
```

Note The Kerberos realm name must be in uppercase characters.

You might want to create privileged instances to allow network administrators to connect to the router at the enable level, for example, so that they need not enter a clear text password (and compromise security) to enter enable mode.

To add an instance of *loki* with additional privileges (in this case, enable, although it could be anything) enter the following Kerberos command:

```
ank loki/enable@CISCO.COM
```

In each of these examples, you are prompted to enter a password, which you must give to user *loki* to use at login.

The [Enabling Kerberos Instance Mapping, on page 2277](#) describes how to map Kerberos instances to various Cisco IOS XE privilege levels.

Creating SRVTABs on the KDC

All routers that you want to authenticate to use the Kerberos protocol must have an SRVTAB. For more information on extracting SRVTABs, see *Extracting SRVTABs*

To make SRVTAB entries on the KDC, use the following command in privileged EXEC mode:

Command	Purpose
Router# ark SERVICE/HOSTNAME@REALM	Use the ark (add random key) command to add a network service supported by a host or router to the KDC.

For example, to add a Kerberized authentication service for a Cisco router called *router1* to the Kerberos realm CISCO.COM, enter the following Kerberos command:

```
ark host/router1.cisco.com@CISCO.COM
```

Make entries for all network services on all Kerberized hosts that use this KDC for authentication.

Extracting SRVTABs

SRVTABs contain (among other things) the passwords or randomly generated keys for the service principals you entered into the KDC database. Service principal keys must be shared with the host running that service. To do this, you must save the SRVTAB entries to a file, then copy the file to the router and all hosts in the Kerberos realm. Saving SRVTAB entries to a file is called *extracting* SRVTABs. To extract SRVTABs, use the following command in privileged EXEC mode:

Command	Purpose
Router# xst router-name host	Use the kdb5_edit command xst to write an SRVTAB entry to a file.

For example, to write the host/router1.cisco.com@CISCO.COM SRVTAB to a file, enter the following Kerberos command:

```
xst router1.cisco.com@CISCO.COM host
```

Use the **quit** command to exit the kdb5_edit program.

Configuring the Router to Use the Kerberos Protocol

Defining a Kerberos Realm

For a router to authenticate a user defined in the Kerberos database, it must know the host name or IP address of the host running the KDC, the name of the Kerberos realm and, optionally, be able to map the host name or Domain Name System (DNS) domain to the Kerberos realm.

To configure the router to authenticate to a specified KDC in a specified Kerberos realm, use the following commands in global configuration mode. Note that DNS domain names must begin with a leading dot (.):

SUMMARY STEPS

1. Router(config)# **kerberos local-realm**kerberos-realm
2. Router(config)# **kerberos server**kerberos-realm {hostname | ip-address } [port-number]
3. Router(config)# **kerberos realm** {dns-domain | host } kerberos-realm

DETAILED STEPS

	Command or Action	Purpose
Step 1	Router(config)# kerberos local-realm kerberos-realm	Defines the default realm for the router.
Step 2	Router(config)# kerberos server kerberos-realm {hostname ip-address } [port-number]	Specifies to the router which KDC to use in a given Kerberos realm and, optionally, the port number that the KDC is monitoring. (The default is 88.)
Step 3	Router(config)# kerberos realm {dns-domain host } kerberos-realm	(Optional) Maps a host name or DNS domain to a Kerberos realm.

What to do next

Note Because the machine running the KDC and all Kerberized hosts must interact within a 5-minute window or authentication fails, all Kerberized machines, and especially the KDC, should be running the Network Time Protocol (NTP).

The **kerberos local-realm**, **kerberos realm**, and **kerberos server** commands are equivalent to the UNIX krb.conf file. The table below identifies mappings from the Cisco IOS XE configuration commands to a Kerberos 5 configuration file (krb5.conf).

Table 235: Kerberos 5 Configuration File and Commands

krb5.conf File	Cisco IOS XE Configuration Command
[libdefaults] default_realm = DOMAIN.COM	(in configuration mode) kerberos local-realm DOMAIN.COM
[domain_realm] .domain.com = DOMAIN.COM domain.com = DOMAIN.COM	(in configuration mode) kerberos realm .domain.com DOMAIN.COM kerberos realm domain.com DOMAIN.COM
[realms] kdc = DOMAIN.PIL.COM:750 admin_server = DOMAIN.PIL.COM default_domain = DOMAIN.COM	(in configuration mode) kerberos server DOMAIN.COM 172.65.44.2 (172.65.44.2 is the example IP address for DOMAIN.PIL.COM)

For an example of defining a Kerberos realm, see the Defining a Kerberos Realm Examples module.

Copying SRVTAB Files

To make it possible for remote users to authenticate to the router using Kerberos credentials, the router must share a secret key with the KDC. To do this, you must give the router a copy of the SRVTAB you extracted on the KDC.

The most secure method to copy SRVTAB files to the hosts in your Kerberos realm is to copy them onto physical media and go to each host in turn and manually copy the files onto the system. To copy SRVTAB files to the router, which does not have a physical media drive, you must transfer them via the network using TFTP.

To remotely copy SRVTAB files to the router from the KDC, use the following command in global configuration mode:

Command	Purpose
<pre>Router(config)# kerberos srvtab remote {hostname ip-address } {filename }</pre>	Retrieves an SRVTAB file from the KDC.

When you copy the SRVTAB file from the router to the KDC, the **kerberos srvtab remote** command parses the information in this file and stores it in the router's running configuration in the **kerberos srvtab entry** format. To ensure that the SRVTAB is available (does not need to be acquired from the KDC) when you reboot the router, use the **write memory** configuration command to write your running configuration (which contains the parsed SRVTAB file) to NVRAM.

For an example of copying SRVTAB files, see the [SRVTAB File Copying Example, on page 2278](#).

Specifying Kerberos Authentication

You have now configured Kerberos on your router. This makes it possible for the router to authenticate using Kerberos. The next step is to tell it to do so. Because Kerberos authentication is facilitated through AAA, you need to enter the **aaa authentication** command, specifying Kerberos as the authentication method. For more information, refer to the chapter "Configuring Authentication".

Enabling Credentials Forwarding

With Kerberos configured thus far, a user authenticated to a Kerberized router has a TGT and can use it to authenticate to a host on the network. However, if the user tries to list credentials after authenticating to a host, the output will show no Kerberos credentials present.

You can optionally configure the router to forward users' TGTs with them as they authenticate from the router to Kerberized remote hosts on the network when using Kerberized Telnet, rcp, rsh, and rlogin (with the appropriate flags).

To force all clients to forward users' credentials as they connect to other hosts in the Kerberos realm, use the following command in global configuration mode:

Command	Purpose
<pre>Router(config)# kerberos credentials forward</pre>	Forces all clients to forward user credentials upon successful Kerberos authentication.

With credentials forwarding enabled, users' TGTs are automatically forwarded to the next host they authenticate to. In this way, users can connect to multiple hosts in the Kerberos realm without running the KINIT program each time to get a new TGT.

Opening a Telnet Session to the Router

To use Kerberos to authenticate users opening a Telnet session to the router from within the network, use the following command in global configuration mode:

Command	Purpose
<pre>Router(config)# aaa authentication login {default <i>list-name</i> } krb5_telnet</pre>	Sets login authentication to use the Kerberos 5 Telnet authentication protocol when using Telnet to connect to the router.

Although Telnet sessions to the router are authenticated, users must still enter a clear text password if they want to enter enable mode. The **kerberos instance map** command, discussed in a later section, allows them to authenticate to the router at a predefined privilege level.

Establishing an Encrypted Kerberized Telnet Session

Another way for users to open a secure Telnet session is to use Encrypted Kerberized Telnet. With Encrypted Kerberized Telnet, users are authenticated by their Kerberos credentials before a Telnet session is established. The Telnet session is encrypted using 56-bit Data Encryption Standard (DES) encryption with 64-bit Cipher Feedback (CFB). Because data sent or received is encrypted, not clear text, the integrity of the dialed router or access server can be more easily controlled.

Note This feature is available only if you have the 56-bit encryption image. 56-bit DES encryption is subject to U.S. Government export control regulations.

To establish an encrypted Kerberized Telnet session from a router to a remote host, use either of the following commands in EXEC command mode:

Command	Purpose
<pre>Router(config)# connect <i>host</i> [<i>port</i>] /encrypt kerberos</pre> <p>or</p> <pre>Router(config)# telnet <i>host</i> [<i>port</i>] /encrypt kerberos</pre>	Establishes an encrypted Telnet session.

When a user opens a Telnet session from a Cisco router to a remote host, the router and remote host negotiate to authenticate the user using Kerberos credentials. If this authentication is successful, the router and remote host then negotiate whether or not to use encryption. If this negotiation is successful, both inbound and outbound traffic is encrypted using 56-bit DES encryption with 64-bit CFB.

When a user dials in from a remote host to a Cisco router configured for Kerberos authentication, the host and router will attempt to negotiate whether or not to use encryption for the Telnet session. If this negotiation is successful, the router will encrypt all outbound data during the Telnet session.

If encryption is not successfully negotiated, the session will be terminated and the user will receive a message stating that the encrypted Telnet session was not successfully established.

For information about enabling bidirectional encryption from a remote host, refer to the documentation specific to the remote host device.

For an example of using encrypted Kerberized Telnet to open a secure Telnet session, see the [Encrypted Telnet Session Example, on page 2279](#).

Enabling Mandatory Kerberos Authentication

As an added layer of security, you can optionally configure the router so that, after remote users authenticate to it, these users can authenticate to other services on the network only with Kerberized Telnet, rlogin, rsh, and rcp. If you do not make Kerberos authentication mandatory and Kerberos authentication fails, the application attempts to authenticate users using the default method of authentication for that network service; for example, Telnet and rlogin prompt for a password, and rsh attempts to authenticate using the local rhost file.

To make Kerberos authentication mandatory, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos clients mandatory	Sets Telnet, rlogin, rsh, and rcp to fail if they cannot negotiate the Kerberos protocol with the remote server.

Enabling Kerberos Instance Mapping

As mentioned in the [Creating SRVTABs on the KDC, on page 2272](#), you can create administrative instances of users in the KDC database. The **kerberos instance map** command allows you to map those instances to Cisco IOS XE privilege levels so that users can open secure Telnet sessions to the router at a predefined privilege level, obviating the need to enter a clear text password to enter enable mode.

To map a Kerberos instance to a Cisco IOS XE privilege level, use the following command in global configuration mode:

Command	Purpose
Router(config)# kerberos instance map <i>instance</i> <i>privilege-level</i>	Maps a Kerberos instance to a Cisco IOS XE privilege level.

If there is a Kerberos instance for user *loki* in the KDC database (for example, *loki/admin*), user *loki* can now open a Telnet session to the router as *loki/admin* and authenticate automatically at privilege level 15, assuming instance “admin” is mapped to privilege level 15. (See the [Opening a Telnet Session to the Router, on page 2275](#).)

Cisco IOS XE commands can be set to various privilege levels using the **privilege level** command.

After you map a Kerberos instance to a Cisco IOS XE privilege level, you must configure the router to check for Kerberos instances each time a user logs in. To run authorization to determine if a user is allowed to run an EXEC shell based on a mapped Kerberos instance, use the **aaa authorization** command with the **krb5-instance** keyword. For more information, refer to the chapter “Configuring Authorization.”

Monitoring and Maintaining Kerberos

To display or remove a current user’s credentials, use the following commands in EXEC mode:

SUMMARY STEPS

1. Router# **show kerberos creds**
2. Router# **clear kerberos creds**

DETAILED STEPS

	Command or Action	Purpose
Step 1	Router# show kerberos creds	Lists the credentials in a current user's credentials cache.
Step 2	Router# clear kerberos creds	Destroys all credentials in a current user's credentials cache, including those forwarded.

Kerberos Configuration Examples

Kerberos Realm Definition Examples

To define CISCO.COM as the default Kerberos realm, use the following command:

```
kerberos local-realm CISCO.COM
```

To tell the router that the CISCO.COM KDC is running on host 10.2.3.4 at port number 170, use the following Kerberos command:

```
kerberos server CISCO.COM 10.2.3.4 170
```

To map the DNS domain cisco.com to the Kerberos realm CISCO.COM, use the following command:

```
kerberos realm.cisco.com CISCO.COM
```

SRVTAB File Copying Example

To copy over the SRVTAB file on a host named host123.cisco.com for a router named router1.cisco.com, the command would look like this:

```
kerberos srvtab remote host123.cisco.com router1.cisco.com-new-srvtab
Valid Starting      Expires      Service Principal
13-May-1996 14:59:44  13-May-1996 23:00:45  krbtgt/CISCO.COM@CISCO.COM
chet-2500# show privilege
Current privilege level is 15
chet-2500# q
Connection closed by foreign host.
chet-ss20% telnet chet-2500
Trying 172.16.0.0 ...
Connected to chet-2500.cisco.com.
Escape character is '^]'.
User Access Verification
Username: chet/restricted
Password:
chet-2500# show kerberos creds
Default Principal: chet/restricted@CISCO.COM
```

```

Valid Starting          Expires          Service Principal
13-May-1996 15:00:32   13-May-1996 23:01:33   krbtgt/CISCO.COM@CISCO.COM
chet-2500# show privilege
Current privilege level is 3
chet-2500# q
Connection closed by foreign host.
chet-ss20%

```

Encrypted Telnet Session Example

The following example shows how to establish an encrypted Telnet session from a router to a remote host named “host1”:

```
Router> telnet host1 /encrypt kerberos
```

CHAPTER 174

Lawful Intercept Architecture

The Lawful Intercept (LI) feature supports service providers in meeting the requirements of law enforcement agencies (LEA) to provide electronic surveillance as authorized by a judicial or administrative order. The surveillance is performed using wiretaps to intercept Voice-over-Internet protocol (VoIP) or data traffic going through the edge routers. The LEA delivers a request for a wiretap to the target's service provider, who is responsible for intercepting data communication to and from the individual using IP sessions.

This document explains LI architecture, including Cisco Service Independent Intercept architecture and PacketCable Lawful Intercept architecture. It also describes the components of the LI feature and provides instructions on how to configure the LI feature in your system.

Before Cisco IOS XE Release 2.5, PPP sessions were tapped based on the accounting session. Circuit-ID based tapping was introduced in Cisco IOS XE Release 2.5.

In Cisco IOS XE Release 2.6, a user session is tapped based on the unique PPP over Ethernet (PPPoE) circuit ID tag. This circuit ID tag serves as a unique parameter for the PPPoE user session on the device. The tapped user session is provisioned through SNMP, and user session data packets and RADIUS authentication data packets are tapped.

- [Prerequisites for Lawful Intercept, on page 2283](#)
- [Restrictions for Lawful Intercept, on page 2284](#)
- [Information About Lawful Intercept, on page 2284](#)
- [How to Configure Lawful Intercept, on page 2291](#)
- [Configuration Examples for Lawful Intercept, on page 2300](#)
- [Additional References, on page 2301](#)
- [Feature Information for Lawful Intercept, on page 2302](#)

Prerequisites for Lawful Intercept

Access to the Cisco LI MIB view should be restricted to the mediation device and to system administrators who need to be aware of lawful intercepts on the router. To access the MIB, users must have level-15 access rights on the router.

Communication with Mediation Device

For the router to communicate with the mediation device to execute a lawful intercept, the following configuration requirements must be met:

- The domain name for both the router and the mediation device must be registered in the Domain Name System (DNS).

In DNS, the router IP address is typically the address of the FastEthernet0/0/0 interface on the router.

- The mediation device must have an access function (AF) and an access function provisioning interface (AFPI).
- You must add the mediation device to the Simple Network Management Protocol (SNMP) user group that has access to the CISCO-TAP2-MIB view. Specify the username of the mediation device as the user to add to the group.

When you add the mediation device as a CISCO-TAP2-MIB user, you can include the mediation device's authorization password if you want. The password must be at least eight characters in length.

Restrictions for Lawful Intercept

General Restrictions

There is no command-line interface (CLI) available to configure LI on the router. All error messages are sent to the mediation device as SNMP notifications. All intercepts are provisioned using SNMPv3 only.

Lawful Intercept does not support SUP HA. LI configuration needs to be reapplied after SUP switchover. An SNMP trap will be generated for this event.

Lawful Intercept MIBs

Only the mediation device and users who need to know about lawful intercepts are allowed to access the LI MIBs.

Due to its sensitive nature, the Cisco LI MIBs are only available in software images that support the LI feature. These MIBs are not accessible through the Network Management Software MIBs Support page (<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>).

SNMP Notifications

SNMP notifications for LI must be sent to User Datagram Protocol (UDP) port 161 on the mediation device, not port 162 (which is the SNMP default).

Information About Lawful Intercept

Introduction to Lawful Intercept

LI is the process by which law enforcement agencies (LEAs) conduct electronic surveillance as authorized by judicial or administrative order. Increasingly, legislation is being adopted and regulations are being enforced that require service providers (SPs) and Internet service providers (ISPs) to implement their networks to explicitly support authorized electronic surveillance. The types of SPs or ISPs that are subject to LI mandates vary greatly from country to country. LI compliance in the United States is specified by the Commission on Accreditation for Law Enforcement Agencies (CALEA).

Cisco supports two architectures for LI: PacketCable and Service Independent Intercept. The LI components by themselves do not ensure customer compliance with applicable regulations but rather provide tools that can be used by SPs and ISPs to construct an LI-compliant network.

Cisco Service Independent Intercept Architecture

The [Cisco Service Independent Intercept Architecture Version 3.0](#) document describes implementation of LI for VoIP networks using the Cisco BTS 10200 Softswitch call agent, version 5.0, in a non-PacketCable network. Packet Cable Event Message specification version 1.5-I01 is used to deliver the call identifying information along with version 2.0 of the Cisco Tap MIB for call content.

The [Cisco Service Independent Intercept Architecture Version 2.0](#) document describes implementation of LI for VoIP networks using the Cisco BTS 10200 Softswitch call agent, versions 4.4 and 4.5, in a non-PacketCable network. Although not a PacketCable network, PacketCable Event Messages Specification version I08 is still used to deliver call identifying information, along with version 1.0 or version 2.0 of the Cisco Tap MIB for call content. The *Cisco Service Independent Intercept Architecture Version 2.0* document adds additional functionality for doing data intercepts by both IP address and session ID, which are both supported in version 2.0 of the Cisco Tap MIB (CISCO-TAP2-MIB).

The [Cisco Service Independent Intercept Architecture Version 1.0](#) document describes implementation of LI for VoIP networks that are using the Cisco BTS 10200 Softswitch call agent, versions 3.5 and 4.1, in a non-PacketCable network. Although not a PacketCable network, PacketCable Event Message Specification version I03 is still used to deliver call identifying information, along with version 1.0 of the Cisco Tap MIB (CISCO-TAP-MIB) for call content. Simple data intercepts by IP address are also discussed.

PacketCable Lawful Intercept Architecture

The *PacketCable Lawful Intercept Architecture for BTS Version 5.0* document describes the implementation of LI for VoIP using Cisco BTS 10200 Softswitch call agent, version 5.0, in a PacketCable network that conforms to PacketCable Event Messages Specification version 1.5-I01.

The *PacketCable Lawful Intercept Architecture for BTS Versions 4.4 and 4.5* document describes the implementation of LI for VoIP using Cisco BTS 10200 Softswitch call agent, versions 4.4 and 4.5, in a PacketCable network that conforms to PacketCable Event Messages Specification version I08.

The [PacketCable Lawful Intercept Architecture for BTS Versions 3.5 and 4.1](#) document describes the implementation of LI for voice over IP (VoIP) using Cisco Broadband Telephony Softswitch (BTS) 10200 Softswitch call agent, versions 3.5 and 4.1, in a PacketCable network that conforms to PacketCable Event Message Specification version I03.

The *PacketCable Control Point Discovery Interface Specification* document defines an IP-based protocol that can be used to discover a control point for a given IP address. The control point is the place where Quality of Service (QoS) operations, LI content tapping operations, or other operations may be performed.

CISCO ASR 1000 Series Routers

The Cisco ASR 1000 Series Aggregation Services Routers support two types of LI: regular and broadband (per-subscriber). Broadband wiretaps are executed on access subinterfaces and tunnel interfaces. Regular wiretaps are executed on access subinterfaces, tunnel interfaces, and physical interfaces. Wiretaps are not required, and are not executed, on internal interfaces. The router determines which type of wiretap to execute based on the interface that the target's traffic is using.

LI on the Cisco ASR 1000 series routers can intercept traffic based on a combination of one or more of the following fields:

- Destination IP address and mask (IPv4 or IPv6 address)
- Destination port or destination port range
- Source IP address and mask (IPv4 or IPv6 address)
- Source port or source port range
- Protocol ID
- Type of Service (TOS)
- Virtual routing and forwarding (VRF) name, which is translated to a *vrf-tableid* value within the router.
- Subscriber (user) connection ID

The LI implementation on the Cisco ASR 1000 series routers is provisioned using SNMP3 and supports the following functionality:

- RADIUS session intercepts, which can occur in one of the following ways:
 - Interception through Access-Accept packets allows interception to start at the beginning of a session.
 - Interception through CoA-Request packets enables the router to start or stop interception during a session.
- Interception of communication content. The router duplicates each intercepted packet and then places the copy of the packet within a UDP-header encapsulated packet (with a configured CCCid). The router sends the encapsulated packet to the LI mediation device. Even if multiple lawful intercepts are configured on the same data flow, only one copy of the packet is sent to the mediation device. If necessary, the mediation device can duplicate the packet for each LEA.
- Interception of IPv4, IPv4 multicast, IPv6, and IPv6 multicast flows.

VRF Aware LI

VRF Aware LI is the ability to provision a LI wiretap on IPv4 data in a particular Virtual Private Network (VPN). This feature allows a LEA to lawfully intercept targeted data within that VPN. Only IPv4 data within that VPN is subject to the VRF-based LI tap.

VRF Aware LI is available for the following types of traffic:

- ip2ip
- ip2tag (IP to MPLS)
- tag2ip (MPLS to IP)

To provision a VPN-based IPv4 tap, the LI administrative function (running on the mediation device) uses the CISCO-IP-TAP-MIB to identify the name of the VRF table that the targeted VPN uses. The VRF name is used to select the VPN interfaces on which to enable LI in order to execute the tap.

The router determines which traffic to intercept and which mediation device to send the intercepted packets based on the VRF name (along with the source and destination address, source and destination port, and protocol).

Note When using the Cisco-IP-TAP-MIB, if the VRF name is not specified in the stream entry, the global IP routing table is used by default.

Lawful Intercept MIBs

Due to its sensitive nature, the Cisco LI MIBs are only available in software images that support the LI feature. These MIBs are not accessible through the Network Management Software MIBs Support page (<http://www.cisco.com/public/sw-center/netmgmt/cmtk/mibs.shtml>).

Restricting Access to the Lawful Intercept MIBs

Only the mediation device and users who need to know about lawful intercepts should be allowed to access the LI MIBs. To restrict access to these MIBs, you must:

1. Create a view that includes the Cisco LI MIBs.
2. Create an SNMP user group that has read-and-write access to the view. Only users assigned to this user group can access information in the MIBs.
3. Add users to the Cisco LI user groups to define who can access the MIBs and any information related to lawful intercepts. Be sure to add the mediation device as a user in this group; otherwise, the router cannot perform lawful intercepts.

For more information, see the Creating a Restricted SNMP View of Lawful Intercept MIBs module.

Note Access to the Cisco LI MIB view should be restricted to the mediation device and to system administrators who need to be aware of lawful intercepts on the router. To access the MIB, users must have level-15 access rights on the router.

RADIUS-Based Lawful Intercept

A RADIUS-based lawful intercept solution enables intercept requests to be sent (through Access-Accept packets or Change of Authorization (CoA)-Request packets) to the network access server (NAS) or to the Layer 2 Tunnel Protocol access concentrator (LAC) from the RADIUS server. All traffic data going to or from a PPP or L2TP session is passed to a mediation device. Another advantage of RADIUS-based lawful intercept is the synchronicity of the solution—the tap is set with Access-Accept packets so that all target traffic is intercepted.

Intercept requests are initiated by the mediation device via SNMPv3 messages, and all traffic data going to or from a given IP address is passed to a mediation device. Interception based on IP addresses prevents a session from being tapped until an IP address has been assigned to the session.

The RADIUS-based lawful intercept feature provides High Availability (HA) support for LI for the following modes:

- Access-Accept based LI for the new session
- CoA based LI for existing session

The RADIUS-based LI HA supports only the RADIUS based provisioning. The SNMP-based provisioning is not supported.

Intercept Operation

How Intercept Requests Work Within Access-Accept Packets

When an intercept target begins to establish a connection, an Access-Request packet is sent to the RADIUS server. The RADIUS server responds with an Access-Accept packet containing the four RADIUS attributes.

The NAS or the LAC receives the LI-Action attribute with the value 1, allowing the NAS or LAC to duplicate the traffic data at the start of the new session and forward the duplicated data to the mediation device that was specified through the attributes, MD-IP-Address and MD-Port-Number.

Note If the NAS or LAC cannot start intercepting traffic data for a new session, the session does not get established.

If accounting is enabled (through the **aaa accounting network** command and the **aaa accounting send stop-record authentication failure** command), an Accounting-Stop packet must be sent with the Acct-Termination-Cause attribute (49) set to 15, which means that service is not available.

How Intercept Requests Work Within CoA-Request Packets

After a session has been established for the intercept target, CoA-Request packets can be used for the following tasks:

- Starting the interception of an existing session. The LI-Action attribute is set to 1.
- Stopping the interception of an existing session. The LI-Action attribute is set to 0.
- Issuing a dummy intercept request. The LI-Action attribute is set to 2. The NAS or LAC should not perform any session interception; instead, it searches the session on the basis of the Acct-Session-ID attribute value that was specified in the CoA-Request packets. If a session is found, the NAS or LAC sends a CoA acknowledgment (ACK) response to the RADIUS server. If a session is not found, the NAS or LAC issues a “session not found” error message.

In each case, the RADIUS server must send CoA-Request packets with the identified attributes and the Acct-Session-ID attribute. Each of these attributes must be in the packet.

The Acct-Session-ID attribute identifies the session that will be intercepted. The Acct-Session-ID attribute can be obtained from either the Access-Request packet or the Accounting-Stop packet.

When a session is being tapped and the session terminates, the tap stops. The session does not start when the subscriber logs back in unless the Access-Accept indicates a start tap or a CoA-Request is sent to start the session.

Note The frequency of CoA-Request packets should not exceed a rate of one request every 10 minutes.

Service Independent Intercept (SII)

Cisco developed the Service Independent Intercept (SII) architecture in response to requirements that support lawful intercept for service provider customers. The SII architecture offers well-defined, open interfaces between the Cisco equipment acting as the content Intercept Access Point (IAP) and the mediation device. The modular nature of the SII architecture allows the service provider to choose the most appropriate mediation device to meet specific network requirements and regional, standards-based requirements for the interface to the law enforcement collection function.

The mediation device uses SNMPv3 to instruct the call connect (CC) IAP to replicate the CC and send the content to the mediation device. The CC IAP can be either an edge router or a trunking gateway for voice, and either an edge router or an access server for data.

To increase the security and to mitigate any SNMPv3 vulnerability, the following tasks are required:

Restricting Access to Trusted Hosts (without Encryption)

SNMPv3 provides support for both security models and security levels. A security model is an authentication strategy that is set up for a user and the group in which the user resides. A security level is the permitted level of security within a security model. A combination of a security model and a security level will determine the security mechanism employed when handling an SNMP packet.

Additionally, the SNMP Support for the Named Access Lists feature adds support for standard named access control lists (ACLs) to several SNMP commands.

To configure a new SNMP group or a table that maps SNMP users to SNMP views, use the **snmp-server group** command in global configuration mode.

```
access-list my-list permit ip host 10.10.10.1
snmp-server group my-group v3 auth access my-list
```

In this example, the access list named **my-list** allows SNMP traffic only from 10.10.10.1. This access list is then applied to the SNMP group called **my-group**.

Encrypting Lawful Intercept Traffic and Restricting Access to Trusted Hosts

Encryption of intercepted traffic between the router (the content Intercept Access Point (IAP)) and the Mediation Device (MD) is highly recommended.

The following configuration is required:

- Configuring encryption in the router and either an encryption client in the MD or a router associated with the MD to decrypt the traffic.
- Restricting access to trusted hosts.
- Configuring the VPN client.

Configuring encryption in the Router

First configure Authentication, Authorization and Accounting (AAA) parameters. The following example shows how to configure the parameters:

```
aaa authentication login userauthen local
username <username> password 0 <password>
```

The following example uses the internal database; however, external authentication servers can also be specified to perform the authentication.

After configuring the AAA parameters, configure the Internet Security Association and Key Management Protocol (ISAKMP) policy and the crypto map. The following example uses pre-shared keys, Diffie-Hellman (DH) group 2 and AES 256 as the encryption protocol for phase 1 (Internet Key Exchange (IKE)). The crypto map is called dynamic-map and the VPN group is called LI-group. Access-list 108 defines the traffic that is allowed to the router (in this case the ip pool is 10.1.1.1 through 10.1.1.254).

```
crypto isakmp policy 1
encr aes 256
authentication pre-share
group 2
!
crypto isakmp client configuration group LI-group
key <password>
dns 10.10.10.10
wins 10.10.10.20
domain cisco.com
pool ippool
acl 108
!
!
crypto ipsec transform-set myset esp-3des esp-sha-hmac
!
crypto dynamic-map dynmap 10
set transform-set myset
!
!
crypto map clientmap client authentication list userauthen
crypto map clientmap isakmp authorization list groupauthor
crypto map clientmap client configuration address respond
crypto map clientmap 10 ipsec-isakmp dynamic dynmap
!
!
interface GigabitEthernet0/3
ip address <IP address of LI-enabled router> 255.255.255.0
crypto map clientmap
!
!
ip local pool ippool 10.1.1.1 10.1.1.254
!
!
access-list 108 permit ip 10.1.1.0 0.0.0.255 host 10.0.24.4 <IP address of LI-enabled
router>
```

Restricting Access to Trusted Hosts (with Encryption)

The following example shows how to create an ACL that allows only the IP pool (10.1.1.0/24) for VPN clients, and assign that ACL to the SNMPv3 group.

```
access-list my-list permit ip 10.1.1.0 0.0.0.255
snmp-server group my-group v3 auth access my-list
```

Configuring the VPN Client

See the [Installing the VPN Client](#) document to download and configure the Cisco VPN Client for Solaris. See the

[Cisco VPN Client installation instructions](#)

document to download and configure the Cisco VPN Client for other operating systems.

How to Configure Lawful Intercept

Although there are no direct user commands to provision lawful intercept on the router, you do need to perform some configuration tasks, such as providing access to LI MIBs, setting up SNMP notifications, and enabling the LI RADIUS session feature. This section describes how to perform the required tasks.

Creating a Restricted SNMP View of Lawful Intercept MIBs

To create and assign users to an SNMP view that includes the Cisco lawful intercept MIBs, perform the steps in this section.

Before you begin

- You must issue the commands in global configuration mode with level-15 access rights.
- SNMPv3 must be configured on the device.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa intercept**
4. **snmp-server view** *view-name MIB-name* **included**
5. **snmp-server view** *view-name MIB-name* **included**
6. **snmp-server view** *view-name MIB-name* **included**
7. **snmp-server group** *group-name v3 noauth read view-name write view-name*
8. **snmp-server user** *user-name group-name v3 auth md5 auth-password*
9. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	aaa intercept Example:	Enables lawful intercept on the device.

	Command or Action	Purpose
	<pre>Device(config)# aaa intercept</pre>	<ul style="list-style-type: none"> Associate this command with a high administrative security to ensure that unauthorized users cannot stop intercepts if this command is removed. <p>Note The aaa intercept command is required to set up the wiretap using an IP session.</p>
Step 4	<p>snmp-server view <i>view-name MIB-name</i> included</p> <p>Example:</p> <pre>Device(config)# snmp-server view exampleView ciscoTap2MIB included</pre>	<p>Creates an SNMP view that includes the CISCO-TAP2-MIB (where <i>exampleView</i> is the name of the view to create for the MIB).</p> <ul style="list-style-type: none"> This MIB is required for both regular and broadband lawful intercept.
Step 5	<p>snmp-server view <i>view-name MIB-name</i> included</p> <p>Example:</p> <pre>Device(config)# snmp-server view exampleView ciscoIpTapMIB included</pre>	<p>Adds the CISCO-IP-TAP-MIB to the SNMP view.</p>
Step 6	<p>snmp-server view <i>view-name MIB-name</i> included</p> <p>Example:</p> <pre>Device(config)# snmp-server view exampleView cisco802TapMIB included</pre>	<p>Adds the CISCO-802-TAP-MIB to the SNMP view.</p>
Step 7	<p>snmp-server group <i>group-name</i> v3 noauth read <i>view-name</i> write <i>view-name</i></p> <p>Example:</p> <pre>Device(config)# snmp-server group exampleGroup v3 noauth read exampleView write exampleView</pre>	<p>Creates an SNMP user group that has access to the LI MIB view and defines the group's access rights to the view.</p>
Step 8	<p>snmp-server user <i>user-name group-name</i> v3 auth md5 <i>auth-password</i></p> <p>Example:</p> <pre>Device(config)# snmp-server user exampleUser exampleGroup v3 auth md5 examplePassword</pre>	<p>Adds users to the specified user group.</p>
Step 9	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	<p>Exits the current configuration mode and returns to privileged EXEC mode.</p>

Where to Go Next

The mediation device can now access the lawful intercept MIBs and issue SNMP **set** and **get** requests to configure and run lawful intercepts on the router. To configure the router to send SNMP notification to the mediation device, see the Enabling SNMP Notifications for Lawful Intercept.

Enabling SNMP Notifications for Lawful Intercept

SNMP automatically generates notifications for lawful intercept events. To configure the router to send lawful intercept notifications to the mediation device, perform the steps in this section.

Before you begin

- You must issue the commands in global configuration mode with level-15 access rights.
- SNMPv3 must be configured on the router.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server host** *ip-address* **community-string** **udp-port** *port notification-type*
4. **snmp-server enable traps snmp authentication linkup linkdown coldstart warmstart** *and* **snmp-server enable traps rf**
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	snmp-server host <i>ip-address</i> community-string udp-port <i>port notification-type</i> Example: Device(config)# snmp-server 10.2.2.1 community-string udp-port 161 udp	Specifies the IP address of the mediation device and the password-like community-string that is sent with a notification request. <ul style="list-style-type: none"> • For lawful intercept, the udp-port must be 161 and not 162 (the SNMP default).
Step 4	snmp-server enable traps snmp authentication linkup linkdown coldstart warmstart <i>and</i> snmp-server enable traps rf	Configures the router to send RFC 1157 notifications to the mediation device.

	Command or Action	Purpose
	Example: Device(config)# snmp-server enable traps snmp authentication linkup linkdown coldstart warmstart Device(config)# snmp-server enable traps rf	These notifications indicate authentication failures, link status (up or down), and router restarts.
Step 5	end Example: Device(config)# end	Exits the current configuration mode and returns to privileged EXEC mode.

Disabling SNMP Notifications

To disable SNMP notifications on the router, perform the steps in this section.

Note To disable lawful intercept notifications, use SNMPv3 to set the CISCO-TAP2-MIB object cTap2MediationNotificationEnable to false(2). To reenble lawful intercept notifications through SNMPv3, reset the object to true(1).

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no snmp-server enable traps**
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	no snmp-server enable traps Example: Device(config)# no snmp-server enable traps	Disables all SNMP notification types that are available on your system.

	Command or Action	Purpose
Step 4	end Example: <pre>Device(config)# end</pre>	Exits the current configuration mode and returns to privileged EXEC mode.

Enabling RADIUS Session Intercepts

There are no user CLI commands available to provision the mediation device or taps. However, to enable the intercepts through the CISCO-TAP-MIB you must configure the system to make the account-session-id value available to the mediation device. To enable RADIUS session intercepts on the router, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa intercept**
4. **aaa authentication ppp default group radius**
5. **aaa accounting delay-start all**
6. **aaa accounting send stop-record authentication failure**
7. **aaa accounting network default start-stop group radius**
8. **radius-server attribute 44 include-in-access-req**
9. **radius-server host *host-name***
10. **aaa server radius dynamic-author**
11. **client *ip-address***
12. **domain {*delimiter character*|stripping [right-to-left]}**
13. **server-key *word***
14. **port *port-number***
15. **exit**
16. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	aaa intercept	Enables lawful intercept on the router.

	Command or Action	Purpose
	Example: Device(config)# aaa intercept	<ul style="list-style-type: none"> Associate this command with a high administrative security to ensure that unauthorized users cannot stop intercepts if this command is removed.
Step 4	aaa authentication ppp default group radius Example: Device(config)# aaa authentication ppp default group radius	Specifies the authentication method to use on the serial interfaces that are running Point-to-Point protocol (PPP). Note This command is required because tap information resides only on the RADIUS server. You can authenticate with locally configured information, but you cannot specify a tap with locally configured information.
Step 5	aaa accounting delay-start all Example: Device(config)# aaa accounting delay-start all	Delays the generation of accounting start records until the user IP address is established. Specifying the all keyword ensures that the delay applies to all VRF and non-VRF users. Note This command is required so that the mediation device can see the IP address assigned to the target.
Step 6	aaa accounting send stop-record authentication failure Example: Device(config)# aaa accounting send stop-record authentication failure	(Optional) Generates accounting stop records for users who fail to authenticate while logging into or during session negotiation. Note If a lawful intercept action of 1 does not start the tap, the stop record contains Acct-Termination-Cause, attribute 49, set to 15 (Service Unavailable).
Step 7	aaa accounting network default start-stop group radius Example: Device(config)# aaa accounting network default start-stop group radius	(Optional) Enables accounting for all network-related service requests. Note This command is required only to determine the reason why a tap did not start.
Step 8	radius-server attribute 44 include-in-access-req Example: Device(config)# radius-server attribute 44 include-in-access-req	(Optional) Sends RADIUS attribute 44 (Accounting Session ID) in access request packets before user authentication (including requests for preauthentication). Note Enter this command to obtain attribute 44 from the Access-Request packet. Otherwise you will have to wait for the accounting packets to be received before you can determine the value of attribute 44.
Step 9	radius-server host host-name Example:	(Optional) Specifies the RADIUS server host.

	Command or Action	Purpose
	Device(config)# radius-server host host1	
Step 10	<p>aaa server radius dynamic-author</p> <p>Example:</p> <pre>Device(config)# aaa server radius dynamic-author</pre>	<p>Configures a device as an Authentication, Authorization, and Accounting (AAA) server to facilitate interaction with an external policy server and enters dynamic authorization local server configuration mode.</p> <p>Note This is an optional command if taps are always started with a session starts. The command is required if CoA-Requests are used to start and stop taps in existing sessions.</p>
Step 11	<p>client <i>ip-address</i></p> <p>Example:</p> <pre>Device(config-locsvr-da-radius)# client 10.0.0.2</pre>	(Optional) Specifies a RADIUS client from which the device will accept CoA-Request packets.
Step 12	<p>domain {delimiter <i>character</i> stripping [right-to-left]}</p> <p>Example:</p> <pre>Device(config-locsvr-da-radius)# domain stripping right-to-left</pre> <p>Example:</p> <pre>Device(config-locsvr-da-radius)# domain delimiter @</pre>	<p>(Optional) Configures username domain options for the RADIUS application.</p> <ul style="list-style-type: none"> • The delimiter keyword specifies the domain delimiter. One of the following options can be specified for the <i>character</i> argument: @, /, \$, %, \, # or - • The stripping keyword compares the incoming username with the names oriented to the left of the @ domain delimiter. • The right-to-left keyword terminates the string at the first delimiter going from right to left.
Step 13	<p>server-key <i>word</i></p> <p>Example:</p> <pre>Device(config-locsvr-da-radius)# server-key samplekey</pre>	(Optional) Configures the RADIUS key to be shared between a device and RADIUS clients.
Step 14	<p>port <i>port-number</i></p> <p>Example:</p> <pre>Device(config-locsvr-da-radius)# port 1600</pre>	(Optional) Specifies a RADIUS client from which the device will accept CoA-Request packets.
Step 15	<p>exit</p> <p>Example:</p> <pre>Device(config-locsvr-da-radius)# exit</pre>	Exits dynamic authorization local server configuration mode and returns to global configuration mode.

	Command or Action	Purpose
Step 16	end Example: Device(config)# end	Exits the current configuration mode and returns to privileged EXEC mode.

Configuring Circuit ID Based Tapping

To configure circuit ID based tapping of user session data packets and RADIUS authentication data packets on the router, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **subscriber access pppoe unique-key circuit-id**
4. **end**
5. **show pppoe session all**
6. **show idmgr session key circuit-id *circuit-id***

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	subscriber access pppoe unique-key circuit-id Example: Device(config)#subscriber access pppoe unique-key circuit-id	Specifies a unique circuit ID tag for a PPPoE user session to be tapped on the router.
Step 4	end Example: Device(config)# end	Exits the current configuration mode and returns to privileged EXEC mode.
Step 5	show pppoe session all Example:	Displays the circuit-id tag in the PPPoE session, which is used in the next step to verify the user session.

	Command or Action	Purpose
	Device# show pppoe session all	
Step 6	<p>show idmgr session key circuit-id <i>circuit-id</i></p> <p>Example:</p> <pre>Device# show idmgr session key circuit-id Ethernet4/0.100:PPPoE-Tag-1</pre> <p>Example:</p> <pre>session-handle = AA000007</pre> <p>Example:</p> <pre>aaa-unique-id = 0000000E</pre> <p>Example:</p> <pre>circuit-id-tag = Ethernet4/0.100:PPPoE-Tag-1</pre> <p>Example:</p> <pre>interface = nas-port:0.0.0.0:0/1/1/100</pre> <p>Example:</p> <pre>authen-status = authen</pre> <p>Example:</p> <pre>username = user1@cisco.com</pre> <p>Example:</p> <pre>addr = 106.1.1.3</pre> <p>Example:</p> <pre>session-guid = 650101020000000E</pre> <p>The session hdl AA000007 in the record is valid</p> <p>Example:</p> <pre>The session hdl AA000007 in the record is valid</pre> <p>Example:</p> <pre>No service record found</pre>	Verifies the user session information in the ID Manager (IDMGR) database by specifying the unique circuit ID tag.

Configuration Examples for Lawful Intercept

Example: Enabling Mediation Device Access Lawful Intercept MIBs

The following example shows how to enable the mediation device to access the lawful intercept MIBs. It creates an SNMP view (tapV) that includes four LI MIBs (CISCO-TAP2-MIB, CISCO-IP-TAP-MIB, CISCO-802-TAP-MIB, and CISCO-USER-CONNECTION-TAP-MIB). It also creates a user group that has read, write, and notify access to MIBs in the tapV view.

```
aaa intercept
snmp-server view tapV ciscoTap2MIB included
snmp-server view tapV ciscoIpTapMIB included
snmp-server view tapV cisco802TapMIB included
snmp-server view tapV ciscoUserConnectionTapMIB included
snmp-server group tapGrp v3 noauth read tapV write tapV notify tapV
snmp-server user MDuser tapGrp v3 auth md5 MDpasswd
snmp-server engineID local 1234
```

Example: Enabling RADIUS Session Lawful Intercept

The following example shows the configuration of a RADIUS-Based Lawful Intercept solution on a router acting as a network access server (NAS) device employing an Ethernet PPP connection over Ethernet (PPPoE) link:

```
aaa new-model
!
aaa intercept
!
aaa group server radius SG
server 10.0.56.17 auth-port 1645 acct-port 1646
!

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for Lawful Intercept

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 237: Feature Information for Lawful Intercept

Feature Name	Releases	Feature Information
Lawful Intercept	Cisco IOS XE Release 2.4 Cisco IOS XE Release 3.15S	The Lawful Intercept (LI) feature supports service providers in meeting the requirements of law enforcement agencies to provide the ability to intercept VoIP or data traffic going through the edge routers. In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. In Cisco IOS XE Release 3.15S, the Lawful Intercept feature was introduced on tunnel interfaces for the Cisco ASR 1000 Series Aggregation Services Routers.
VRF Aware LI (Lawful Intercept)	Cisco IOS XE Release 2.4	VRF Aware LI is the ability to provision a LI wiretap on IPv4 data in a particular Virtual Private Network (VPN). In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers.

Feature Name	Releases	Feature Information
RADIUS-based Lawful Intercept	Cisco IOS XE Release 2.4 Cisco IOS XE Release 3.5S	The LI implementation is provisioned using SNMP3 and supports RADIUS session intercepts. In Cisco IOS XE Release 2.4, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. In Cisco IOS XE Release 3.5, High Availability support was added for RADIUS-Based Lawful Intercept.
Circuit ID based tapping of PPP session for Lawful Intercept.	Cisco IOS XE Release 2.5	In Cisco IOS XE Release 2.5, circuit ID based tapping of a PPP session is introduced. Circuit ID based tapping works only if the tap is provisioned after the user session is active. It is assumed in this instance that the user session is uniquely identified by a circuit ID tag.
Circuit ID based tapping for Lawful Intercept	Cisco IOS XE Release 2.6	In Cisco IOS XE Release 2.6, pre-provisioning of circuit-ID based tapping of a PPP session is introduced. If the tap is provisioned before a user session is active, then the tap is effective whenever the user session becomes active. Also, corresponding RADIUS authentication and accounting packets are tapped. It is assumed in this instance that the user session is uniquely identified by a circuit ID tag.
Non-Lawful Intercept (Non-LI) Images	Cisco IOS XE Release 3.10S	In Cisco IOS XE Release 3.10S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. The Non-LI images will be available from Cisco IOS XE Release 3.10S onwards and will not contain the LI subsystems.

CHAPTER 175

LI Support for IPoE Sessions

The LI Support for IPoE Sessions feature extends support for provisioning lawful intercept (LI) to IP over Ethernet (IPoE) sessions in accordance with RFC 2866. This document describes RADIUS-based LI for IPoE. See the “Lawful Intercept Architecture” module for information on LI architecture and components and for configuration tasks and examples.

- [Restrictions for LI Support for IPoE Sessions, on page 2305](#)
- [Additional References for LI Support for IPoE Sessions, on page 2305](#)
- [Feature Information for LI Support for IPoE Sessions, on page 2307](#)

Restrictions for LI Support for IPoE Sessions

The following restrictions apply to RADIUS-based LI for IPoE sessions:

- You cannot use Access-Accept packets to start TAP for a RADIUS proxy session when the LI parameters are encrypted.
- The **aaa intercept** command must be configured to accept attribute value pairs (AVPs) associated with RADIUS-based LI. The frequency of change of authentication (CoA) requests to start, stop, or no-action, should not exceed a rate of 1 per 10 minutes.
- Intercepted traffic from different users is sent to the same mediation device (MD). You must use a unique stream ID (made up of the first four digits of the eight-digit intercept ID) for each MD.
- The format of intercepted packets captured using RADIUS-based LI include the L2 header; this is different from the format of SNMP-based LI.
- Per-flow tapping is not supported through RADIUS-based LI; it is supported with SNMP-based LI.

Additional References for LI Support for IPoE Sessions

Feature Name	Releases	Feature Information
LI Support for IPoE Sessions	Cisco IOS XE Release 3.10S	Extends support for provisioning LI to IPoE sessions in accordance with RFC 2866.

CHAPTER 176

Image Verification

The Image Verification feature allows users to automatically verify the integrity of Cisco IOS XE images and provisioning files. Thus, users can be sure that an image or provisioning file is protected from accidental corruption, which can occur at any time during transit, starting from the moment the files are generated by Cisco until they reach the user.

- [Restrictions for Image Verification, on page 2309](#)
- [Information About Image Verification, on page 2309](#)
- [How to Use Image Verification, on page 2310](#)
- [Configuration Examples for Image Verification, on page 2313](#)
- [Additional References, on page 2314](#)
- [Feature Information for Image Verification, on page 2315](#)

Restrictions for Image Verification

Image Verification is applied to and attempted on any file; however, if the file is not an image file or provisioning file, image verification will not occur and you will see the following error, “SIGNATURE-4-NOT_PRESENT.”

Note The Image Verification feature can only be used to check the integrity of a Cisco IOS XE software image or provisioning file that is stored on a Cisco IOS XE device. It cannot be used to check the integrity of an image on a remote file system or an image running in memory.

Information About Image Verification

Note Throughout this document, any references to Cisco IOS XE images, also applies to provisioning files.

Benefits of Image Verification

The efficiency of Cisco IOS XE routers is improved because the routers can now automatically detect when the integrity of an image or provisioning file is accidentally corrupted as a result of transmission errors or disk corruption.

How Image Verification Works

Because a production image undergoes a sequence of transfers before it is copied into the memory of a router, the integrity of the image is at risk of accidental corruption every time a transfer occurs. When downloading an image from Cisco.com, a user can run a message-digest5 (MD5) hash on the downloaded image and verify that the MD5 digest posted on Cisco.com is the same as the MD5 digest that is computed on the user's server. However, many users choose not to run an MD5 digest because it is 128-bits long and the verification is manual. Image verification allows the user to automatically validate the integrity of all downloaded images, thereby, significantly reducing user interaction.

How to Use Image Verification

Globally Verifying the Integrity of an Image

The **file verify auto** command enables image verification globally; that is, all images that are to be copied (via the **copy** command) or reloaded (via the **reload** command) are automatically verified. Although both the **copy** and **reload** commands have a **/verify** keyword that enables image verification, you must issue the keyword each time you want to copy or reload an image. The **file verify auto** command enables image verification by default, so you no longer have to specify image verification multiple times.

If you have enabled image verification by default but prefer to disable verification for a specific image copy or reload, the **/noverify** keyword, along with either the **copy** or the **reload** command, will override the **file verify auto** command.

Use this task to enable automatic image verification.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **file verify auto**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	file verify auto Example: Device(config)# file verify auto	Enables automatic image verification.
Step 4	exit Example: Device(config)# exit	Exits global configuration mode. You must exit global configuration mode if you are going to copy or reload an image.

What to Do Next

After issuing the **file verify auto** command, you do not have to issue the **/verify** keyword with the **copy** or the **reload** command because each image that is copied or reloaded will be automatically verified.

Verifying the Integrity of an Image That Is About to Be Copied

When issuing the **copy** command, you can verify the integrity of the copied file by entering the **/verify** keyword. If the integrity check fails, the copied file will be deleted. If the file that is about to be copied does not have an embedded hash (an old image), you will be prompted whether or not to continue with the copying process. If you choose to continue, the file will be successfully copied; if you choose not to continue, the copied file will be deleted.

Without the **/verify** keyword, the **copy** command could copy a file that is not valid. Thus, after the **copy** command has been successfully executed, you can issue the **verify** command at any time to check the integrity of the files that are in the storage of the router.

Use this task to verify the integrity of an image before it is copied onto a router.

SUMMARY STEPS

1. **enable**
2. **copy** [/erase] [/verify|/noverify] *source-url destination-url*
3. **verify** [/md5 [*md5-value*]], *filesystem: file-url*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	copy [/erase] [/verify] [/noverify] <i>source-url destination-url</i> Example: <pre>Device# copy /verify tftp://10.1.1.1/cat3k_caa-universalk9.SSA.16.1.0.EFT3-1.bin flash:</pre>	Copies any file from a source to a destination. <ul style="list-style-type: none"> • /verify --Verifies the signature of the destination file. If verification fails, the file will be deleted. • /noverify --Does not verify the signature of the destination file before the image is copied. Note /noverify is often issued if the file verify auto command is enabled, which automatically verifies the signature of all images that are copied.
Step 3	verify [/md5 [<i>md5-value</i>]] <i>filesystem: file-url</i> Example: <pre>Device# flash: tftp://10.1.1.1/cat3k_caa-universalk9.SSA.16.1.0.EFT3-1.bin flash:</pre>	(Optional) Verifies the integrity of the images in the Device's storage.

Verifying the Integrity of an Image That Is About to Be Reloaded

By issuing the **reload** command with the **/verify** keyword, the image that is about to be loaded onto your system will be checked for integrity. If the **/verify** keyword is specified, image verification will occur before the system initiates the reboot. Thus, if verification fails, the image will not be loaded.

Note Because different platforms obtain the file that is to be loaded in various ways, the file specified in BOOTVAR will be verified. If a file is not specified, the first file on each subsystem will be verified. On certain platforms, because of variables such as the configuration register, the file that is verified may not be the file that is loaded.

Use this task to verify the integrity of an image before it is reloaded onto a router.

SUMMARY STEPS

1. **enable**
2. **reload** [[warm] [/verify] [/noverify] *text* | [warm] [/verify] [/noverify] **in** [*hh* : *mm* [*text*] | [warm] [/verify] [/noverify] **at** [*hh* : *mm* [*month day* | *day month*] [*text*] | [warm] [/verify] [/noverify] **cancel**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	<p>reload [[warm] [/verify /noverify] <i>text</i> [warm] [/verify /noverify] in [<i>hh</i> : <i>mm</i> [<i>text</i>] [warm] [/verify /noverify] at [<i>hh</i> : <i>mm</i> [<i>month day</i> <i>day month</i>] [<i>text</i>] [warm] [/verify /noverify] cancel]</p> <p>Example:</p> <pre>Device# reload /verify</pre>	<p>Reloads the operating system.</p> <ul style="list-style-type: none"> • /verify--Verifies the signature of the destination file. If verification fails, the file will be deleted. • /noverify --Does not verify the signature of the destination file before the image is reloaded. <p>Note /noverify is often issued if the file verify auto command is enabled, which automatically verifies the signature of all images that are copied.</p>

Configuration Examples for Image Verification

Global Image Verification Example

The following example shows how to enable automatic image verification. After enabling this command, image verification will automatically occur for all images that are either copied (via the **copy** command) or reloaded (via the **reload** command).

```
Device(config)# file verify auto
```

Image Verification via the copy Command Example

The following example shows how to specify image verification before copying an image:

```
Device# copy /verify tftp://10.1.1.1/jdoe/c7200-js-mz disk0:
Destination filename [c7200-js-mz]?
Accessing tftp://10.1.1.1/jdoe/c7200-js-mz...
Loading jdoe/c7200-js-mz from 10.1.1.1 (via FastEthernet0/0):!!!!!!!!!!!!!!
!!!!!!!!!!!!!!
!!!!!!!!!!!!!!
[OK - 19879944 bytes]
19879944 bytes copied in 108.632 secs (183003 bytes/sec)
Verifying file integrity of disk0:/c7200-js-mz
.....
.....
.....Done!
Embedded Hash MD5 :CFA258948C4ECE52085DCF428A426DCD
Computed Hash MD5 :CFA258948C4ECE52085DCF428A426DCD
CCO Hash MD5 :44A7B9BDDD9638128C35528466318183
Signature Verified
```

Image Verification via the reload Command Example

The following example shows how to specify image verification before reloading an image onto the Device:

```

Device# reload /verify
Verifying file integrity of bootflash:c7200-kboot-mz.121-8a.E
%ERROR:Signature not found in file bootflash:c7200-kboot-mz.121-8a.E.
Signature not present. Proceed with verify? [confirm]
Verifying file disk0:c7200-js-mz
.....Done!
Embedded Hash      MD5 :CFA258948C4ECE52085DCF428A426DCD
Computed Hash      MD5 :CFA258948C4ECE52085DCF428A426DCD
CCO Hash           MD5 :44A7B9BDDD9638128C35528466318183
Signature Verified
Proceed with reload? [confirm]n

```

Verify Command Sample Output Example

The following example shows how to specify image verification via the **verify** command:

```

Device# verify disk0:c7200-js-mz
%Filesystem does not support verify operations
Verifying file integrity of disk0:c7200-js-mz.....Done!
.....Done!
Embedded Hash      MD5 :CFA258948C4ECE52085DCF428A426DCD
Computed Hash      MD5 :CFA258948C4ECE52085DCF428A426DCD
CCO Hash           MD5 :44A7B9BDDD9638128C35528466318183
Signature Verified

```

CHAPTER 177

IPsec Anti-Replay Window Expanding and Disabling

Cisco IP security (IPsec) authentication provides anti-replay protection against an attacker duplicating encrypted packets by assigning a unique sequence number to each encrypted packet. The decryptor keeps track of which packets it has seen on the basis of these numbers. Currently, the default window size is 64 packets. Generally, this number (window size) is sufficient, but there are times when you may want to expand this window size. The IPsec Anti-Replay Window: Expanding and Disabling feature allows you to expand the window size, allowing the decryptor to keep track of more than 64 packets.

- [Prerequisites for IPsec Anti-Replay Window Expanding and Disabling, on page 2319](#)
- [Information About IPsec Anti-Replay Window Expanding and Disabling, on page 2320](#)
- [How to Configure IPsec Anti-Replay Window Expanding and Disabling, on page 2320](#)
- [Configuration Examples for IPsec Anti-Replay Window Expanding and Disabling, on page 2322](#)
- [IPsec Anti Replay Mechanism for QoS, on page 2324](#)
- [Additional References, on page 2330](#)
- [Feature Information for IPsec Anti-Replay Window Expanding and Disabling, on page 2331](#)

Prerequisites for IPsec Anti-Replay Window Expanding and Disabling

- Before configuring this feature, you should have already created a crypto map or crypto profile.
- To configure the IPsec Anti-Replay Window: Expanding and Disabling feature, you should understand the following concept: [IPsec Anti-Replay Window, on page 2320](#)

Information About IPsec Anti-Replay Window Expanding and Disabling

IPsec Anti-Replay Window

Cisco IPsec authentication provides anti-replay protection against an attacker duplicating encrypted packets by assigning a unique sequence number to each encrypted packet. (Security association [SA] anti-replay is a security service in which the receiver can reject old or duplicate packets to protect itself against replay attacks.) The decryptor checks off the sequence numbers that it has seen before. The encryptor assigns sequence numbers in an increasing order. The decryptor remembers the value X of the highest sequence number that it has already seen. N is the window size, and the decryptor also remembers whether it has seen packets having sequence numbers from $X-N+1$ through X . Any packet with the sequence number $X-N$ is discarded. Currently, N is set at 64, so only 64 packets can be tracked by the decryptor.

At times, however, the 64-packet window size is not sufficient. For example, Cisco quality of service (QoS) gives priority to high-priority packets, which could cause some low-priority packets to be discarded when they arrive outside of the 64 packet replay window at the decryptor. The IPsec Anti-Replay Window: Expanding and Disabling feature allows you to expand the window size, allowing the decryptor to keep track of more than 64 packets.

Increasing the anti-replay window size has no impact on throughput and security. The impact on memory is insignificant because only an extra 128 bytes per incoming IPsec SA is needed to store the sequence number on the decryptor. It is recommended that you use the full 1024 window size to eliminate any future anti-replay problems.

How to Configure IPsec Anti-Replay Window Expanding and Disabling

Configuring IPsec Anti-Replay Window Expanding and Disabling Globally

To configure IPsec Anti-Replay Window: Expanding and Disabling globally (so that it affects all SAs that are created), perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec security-association replay window-size $[N]$**
4. **crypto ipsec security-association replay disable**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: <pre>Router> enable</pre>	<ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto ipsec security-association replay window-size [N] Example: <pre>Router (config)# crypto ipsec security-association replay window-size 256</pre>	Sets the size of the SA replay window globally. Note Configure this command or the crypto ipsec security-association replay disable command. The two commands are not used at the same time.
Step 4	crypto ipsec security-association replay disable Example: <pre>Router (config)# crypto ipsec security-association replay disable</pre>	Disables checking globally. Note Configure this command or the crypto ipsec security-association replay window-size command. The two commands are not used at the same time.

Configuring IPsec Anti-Replay Window Expanding and Disabling on a Crypto Map

To configure IPsec Anti-Replay Window: Expanding and Disabling on a crypto map so that it affects those SAs that have been created using a specific crypto map or profile, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num* [**ipsec-isakmp**]
4. **set security-association replay window-size** [*N*]
5. **set security-association replay disable**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto map map-name seq-num [ipsec-isakmp] Example: Router (config)# crypto map ETH0 17 ipsec-isakmp	Enters crypto map configuration mode and creates a crypto profile that provides a template for configuration of dynamically created crypto maps.
Step 4	set security-association replay window-size [N] Example: Router (crypto-map)# set security-association replay window-size 128	Controls the SAs that are created using the policy specified by a particular crypto map, dynamic crypto map, or crypto profile. Note Configure this command or the set security-association replay disable command. The two commands are not used at the same time.
Step 5	set security-association replay disable Example: Router (crypto-map)# set security-association replay disable	Disables replay checking for a particular crypto map, dynamic crypto map, or crypto profile. Note Configure this command or the set security-association replay window-size command. The two commands are not used at the same time.

Troubleshooting Tips

- If your replay window size has not been set to a number that is high enough for the number of packets received, you will receive a system message such as the following:

```
*Nov 17 19:27:32.279: %CRYPTO-4-PKT_REPLAY_ERR: decrypt: replay check failed connection id=1
```

The above message is generated when a received packet is judged to be outside the anti-replay window.

Configuration Examples for IPsec Anti-ReplayWindow Expanding and Disabling

Global Expanding and Disabling of an Anti-Replay Window Example

The following example shows that the anti-replay window size has been set globally to 1024:

```
version 2.1
service timestamps debug datetime msec
service timestamps log datetime msec
```

```
no service password-encryption
!
hostname VPN-Gateway1
!
boot-start-marker
boot-end-marker
!
!
clock timezone EST 0
no aaa new-model
ip subnet-zero
!

IPsec Anti Replay Mechanism for QoS

It is normal for packets to be reordered in IP networks, where QoS mechanisms (on the egress interface of the encrypting device or on other network elements in the path), loadbalancing mechanisms or routing / path selection mechanisms (that send different flows over different paths) are used.

The above diagram shows how anti-replay protection system causes problems when QoS reorders packets. The encryption engine adds sequence numbers. After these numbers are added, packets are enqueued in egress queues depending on the application within that packet. In the example in the diagram, packets are already present in the bandwidth queues (data and class-default), when packets with the sequence numbers 101 and 102 are enqueued in the priority queue. The priority packets will be scheduled first. When the decrypting device receives the packet with the sequence number 101, the history in the sliding window is moved to 101, implying that the sliding window creates a history of sequence numbers 30-101. When the next packet which has the sequence number 102 is received, the history in the sliding window is changed to 39-102. Now, that there are no more packets in the priority queue, packets from one of the other queue is taken – for example, packet with the sequence number 1. Although this is the first time the decrypting device is receiving a packet with sequence number 1, the packet is dropped because of the history maintained in the sliding window.

Moving QoS scheduling before the encryption may solve the anti-replay issue but would render the QoS functionality useless. In addition, scheduling needs to be driven by the congestion of the egress interface (or a shaper on that interface). Increasing the size of the anti-replay window places a huge load on the memory of the devices that handles this functionality.

Hence, the solution of maintaining multiple sequence number spaces per security association was introduced. The number spaces would be aligned with the egress queuing scheme such that all packets in a given queue would receive a sequence number from the same sequence number space. Since all packets within a sequence number space would go through the same queue, the possibility of egress QoS causing reordering within those packets is eliminated. It is still possible (but unlikely) that reordering within a number space could happen elsewhere in the network. If packets are tail dropped rather than enqueued out of sequence (not out of order), sequence numbers will still be received on the receiving side. Hence, we still maintain a history window per sequence number space but that history is considerably shorter.

The image shows that the sequence number consists of two parts, namely the selector and the sequence number. The receiving side would use the selector to choose the correct history to use and the sequence number would operate as always.

Note IPsec Anti-Replay feature does not support Group Encrypted Transport VPN (GETVPN) when multiple sequence number space (multi-SNS) is enabled.

IPsec Anti-Replay Packet Loss Avoidance

The IPsec Anti-Replay Packet Loss Avoidance feature avoids unnecessary IPsec Anti-Replay packet drops when QoS is configured with IPsec. However, some packet drops can happen under certain circumstances when QoS is used together with IPsec Anti-Replay enabled. Anti-Replay drops are seen for a second or two with multi-SNS enabled when a class-map is added or removed while crypto interface is attached on the peer router. The traffic recovers after a couple of seconds and no drops are seen after that.

The Anti-Replay drops can occur in the following situations:

- When a packet is in transit, a class is deleted from the QoS policymap. The packets that belong to this class are exhausted and the incoming packets are queued behind all the packets in the class-default queue. This can cause disruption in the sequence number space causing Anti-Replay drops. The queue becomes empty and the system recovers soon enough to resume normal behavior.
- When an ESP-based High Availability is configured and the over-subscribed traffic is sent through all the sequence number spaces Anti-Replay drops occur. With over-subscribed traffic on the sender side, traffic is shaped based on QoS policy. As a result, the receiving router gets packets with out of order sequence numbers. These drops are momentary and are recovered soon.
- During rekeying of security associations (SA), a router keeps both the old and new inbound Security Parameter Index (SPI) for a short period of time. Old SA is deleted after a short period. After the old SA is deleted, if router receives any packet with old SPI (which can happen when there is a QoS policy), it drops the packet with invalid SPI error.

Configuring IPsec Anti-Replay for QoS

Given below is the command to enable multiple sequence number space per IPsec SA:

```
Device(config)#crypto ipsec security-association multi-sn
```

Caution All existing sessions need to be cleared before configuring this feature. Else, traffic from the existing sessions will be dropped.

Caution This feature needs to be configured on both the tunnel routers in an IPsec connection. If this feature is only enabled on one router, the other router will drop packets.

Show Commands

show platform hardware qfp active feature ipsec datapath crypto-sa

This command displays the mapping between the sequence number spaces and the sequence numbers in an IPsec SA in QFP:

```

Feature Information for IPsec Anti-Replay Window Expanding and Disabling

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 240: Feature Information for IPsec Anti-Replay Window: Expanding and Disabling

Feature Name	Releases	Feature Information
IPsec Anti-Replay Window: Expanding and Disabling	Cisco IOS XE Release 2.1 IPsec Anti-Replay Window Expanding and Disabling, on page 2319	The following commands were introduced or modified: crypto ipsec security-association replay disable , ipsec security-association replay window-size , security-association replay disable , security-association replay window-size .
IPSec anti-replay should work when QoS is enabled in CSR platforms.	Cisco IOS XE Release 16.6.1	This feature enables support for IPSec anti-replay mechanism when QoS is enabled in Cisco Cloud Services Router 1000V Series. The following commands were introduced or modified: show platform hardware qfp active feature ipsec , show platform software ipsec fp active flow , show crypto ipsec sa .
IPSec anti-replay should work when QoS is enabled in ISR 4300/4200 platforms.	Cisco IOS XE Release 16.7.1	This feature ensures that IPSec anti-replay mechanism works when QoS is enabled in ISR platforms except ISR 44xx.
Anti-replay QoS/IPSec packet loss avoidance	Cisco IOS XE Release 16.8.1	This feature avoids IPSec anti-replay packet drops when QoS is used with IPSec anti-replay enabled. This support is added on Octeon-based ASR platforms only.

CHAPTER 178

Pre-Fragmentation for IPsec VPNs

The Pre-Fragmentation for IPsec VPNs feature increases performance between Cisco IOS XE routers and VPN clients by delivering encryption throughput at maximum encryption hardware accelerator speeds for packets that are near the maximum transmission unit (MTU) size. Packets are fragmented into equally sized units to prevent further downstream fragmentation.

- [Restrictions for Pre-Fragmentation for IPsec VPNs, on page 2333](#)
- [Information About Pre-Fragmentation for IPsec VPNs, on page 2334](#)
- [How to Configure Pre-Fragmentation for IPsec VPNs, on page 2335](#)
- [Additional References, on page 2336](#)
- [Feature Information for Pre-Fragmentation for IPsec VPNs, on page 2336](#)

Restrictions for Pre-Fragmentation for IPsec VPNs

Take the following information into consideration before this feature is configured:

- Pre-fragmentation for IPsec VPNs operates in IPsec tunnel mode and IPsec tunnel mode with GRE, but not with IPsec transport mode.
- Pre-fragmentation for IPsec VPNs configured on the decrypting router in a unidirectional traffic scenario does not improve the performance or change the behavior of either of the peers.
- Pre-fragmentation for IPsec VPNs occurs before the transform is applied if compression is turned on for outgoing packets.
- Pre-fragmentation for IPsec VPNs functionality depends on the egress interface **crypto ipsec df-bit** configuration and the incoming packet “do not fragment” (DF) bit state. See the table below.

Table 241: Pre-Fragmentation for IPsec VPNs Dependencies

Pre-Fragmentation for IPsec VPNs Feature State (Enabled/Disabled)	Egress Interface “crypto ipsec df-bit” Configuration	Incoming Packet DF Bit State	Result
Enabled	crypto ipsec df-bit clear	0	Fragmentation occurs before encryption.
Enabled	crypto ipsec df-bit clear	1	Fragmentation occurs before encryption.

Pre-Fragmentation for IPsec VPNs Feature State (Enabled/Disabled)	Egress Interface "crypto ipsec df-bit" Configuration	Incoming Packet DF Bit State	Result
Disabled	crypto ipsec df-bit clear	0	Fragmentation occurs after encryption and packets are reassembled before decryption.
Disabled	crypto ipsec df-bit clear	1	Fragmentation occurs after encryption and packets are reassembled before decryption.
Enabled	crypto ipsec df-bit set	0	Fragmentation occurs before encryption.
Enabled	crypto ipsec df-bit set	1	Packets are dropped.
Disabled	crypto ipsec df-bit set	0	Fragmentation occurs after encryption and packets are reassembled before decryption.
Disabled	crypto ipsec df-bit set	1	Packets are dropped.
Enabled	crypto ipsec df-bit copy	0	Fragmentation occurs before encryption.
Enabled	crypto ipsec df-bit copy	1	Packets are dropped.
Disabled	crypto ipsec df-bit copy	0	Fragmentation occurs after encryption, and packets are reassembled before decryption.
Disabled	crypto ipsec df-bit copy	1	Packets are dropped.

Information About Pre-Fragmentation for IPsec VPNs

Pre-fragmentation for IPsec VPNs

When a packet is nearly the size of the MTU of the outbound link of the encrypting router and it is encapsulated with IPsec headers, it is likely to exceed the MTU of the outbound link. This causes packet fragmentation after encryption. The decrypting router must then reassemble these packets in the process path, which decreases the decrypting router's performance.

The Pre-fragmentation for IPsec VPNs feature increases the decrypting router's performance by enabling it to operate in the high-performance CEF path instead of the process path. An encrypting router can predetermine the encapsulated packet size from information available in transform sets, which are configured as part of the IPsec security association (SA). If it is predetermined that the packet exceeds the MTU of the output interface, the packet is fragmented before encryption. This function avoids process-level reassembly before decryption and helps improve decryption performance and overall IPsec traffic throughput.

Note The pre-fragmentation feature is turned off by default for tunnel interfaces. To receive pre-fragmentation performance benefits, turn pre-fragmentation on after ensuring that the tunnel interfaces have the same MTU on both ends.

Crypto maps are no longer used to define fragmentation behavior that occurred before and after encryption. Now, IPsec Virtual Tunnel Interface (also referred to as Virtual-Template interface) (VTI) fragmentation behavior is determined by the IP MTU settings that are configured on the VTI.

See the IPsec Virtual Tunnel Interface feature document for more information on VTIs.

Note If fragmentation after-encryption behavior is desired, then set the VTI IP MTU to a value that is greater than the egress router interface IP MTU. Use the **show ip interface tunnel** command to display the IP MTU value.

How to Configure Pre-Fragmentation for IPsec VPNs

Configuring Pre-Fragmentation for IPsec VPNs

Perform this task to configure Pre-Fragmentation for IPsec VPNs.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip mtu** *bytes*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: Router(config-if)# interface tunnel0	Specifies the interface on which the VTI is configured and enters interface configuration mode.

	Command or Action	Purpose
Step 4	ip mtu <i>bytes</i> Example: <pre>Router(config-if)# ip mtu 1500</pre> Example:	Specifies the VTI MTU size in bytes of IP packets on the egress interface for IPsec VPNs. Note If after-encryption fragmentation behavior is desired, then set the VTI IP MTU to a value that is greater than the egress router interface IP MTU. Use the show ip interface tunnel command to display the IP MTU value.

CHAPTER 179

Invalid Security Parameter Index Recovery

When an invalid security parameter index error (shown as “Invalid SPI”) occurs in IP Security (IPsec) packet processing, the Invalid Security Parameter Index Recovery feature allows for an Internet Key Exchange (IKE) security association (SA) to be established. The “IKE” module sends notification of the “Invalid SPI” error to the originating IPsec peer so that Security Association Databases (SADBs) can be resynchronized and successful packet processing can be resumed.

Prerequisites for Invalid Security Parameter Index Recovery

Before configuring the Invalid Security Parameter Index Recovery feature, you must have enabled IKE and IPsec on your router.

Restrictions for Invalid Security Parameter Index Recovery

If an IKE SA is being initiated to notify an IPsec peer of an “Invalid SPI” error, there is the risk that a denial-of-service (DoS) attack can occur. The Invalid Security Parameter Index Recovery feature has a built-in mechanism to minimize such a risk, but because there is a risk, the Invalid Security Parameter Index Recovery feature is not enabled by default. You must enable the command using command-line interface (CLI).

Information About Invalid Security Parameter Index Recovery

How the Feature Works

An IPsec “black hole” occurs when one IPsec peer “dies” (for example, a peer can “die” if a reboot occurs or if an IPsec peer somehow gets reset). Because one of the peers (the receiving peer) is completely reset, it loses

its IKE SA with the other peer. Generally, when an IPsec peer receives a packet for which it cannot find an SA, it tries to send an IKE “INVALID SPI NOTIFY” message to the data originator. This notification is sent using the IKE SA. If there is no IKE SA available, the receiving peer drops the packet.

Note A single SA has only two peers. However, a SADB can have multiple SAs, whereby each SA has an association with a different peer.

When an invalid security parameter index (SPI) is encountered, the Invalid Security Parameter Index feature provides for the setting up of an IKE SA with the originator of the data, and the IKE “INVALID SPI NOTIFY” message is sent. The peer that originated the data “sees” the “INVALID SPI NOTIFY” message and deletes the IPsec SA that has the invalid SPI. If there is further traffic from the originating peer, there will not be any IPsec SAs, and new SAs will be set up. Traffic will flow again. The default behavior (that is, without configuring the Invalid Security Parameter Index Recovery feature) is that the data packet that caused the invalid SPI error is dropped. The originating peer keeps on sending the data using the IPsec SA that has the invalid SPI, and the receiving peer keeps dropping the traffic (thus creating the “black hole”).

The IPsec module uses the IKE module to send an IKE “INVALID SPI NOTIFY” message to the other peer. Once the invalid SPI recovery is in place, there should not be any significant dropping of packets although the IPsec SA setup can itself result in the dropping of a few packets.

To configure your router for the Invalid Security Parameter Index Recovery feature, use the **crypto isakmp invalid-spi-recovery** command. The IKE SA will not be initiated unless you have configured this command.

How to Configure Invalid Security Parameter Index Recovery

Configuring Invalid Security Parameter Index Recovery

To configure the Invalid Security Parameter Index Recovery feature, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp invalid-spi-recovery**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Router# configure terminal	
Step 3	crypto isakmp invalid-spi-recovery Example: Router (config)# crypto isakmp invalid-spi-recovery	Initiates the IKE module process whereby the IKE module notifies the receiving peer that an “Invalid SPI” error has occurred.

Verifying a Preshared Configuration

To determine the status of the IPsec SA for traffic between two peers, you can use the **show crypto ipsec sa** command. If the IPsec SA is available on one peer and not on the other, there is a “black hole” situation, in which case you will see the invalid SPI errors being logged for the receiving peer. If you turn console logging on or check the syslog server, you will see that these errors are also being logged.

The diagram below shows the topology of a typical preshared configuration setup. Host 1 is the initiating peer (initiator), and Host 2 is the receiving peer (responder).

Figure 89: Preshared Configuration Topology

SUMMARY STEPS

1. Initiate the IKE and IPsec SAs between Host 1 and Host 2
2. Clear the IKE and IPsec SAs on Router B
3. Send traffic from Host 1 to Host 2 and ensure that new IKE and IPsec SAs are correctly established
4. Check for an invalid SPI message on Router B

DETAILED STEPS

Step 1 Initiate the IKE and IPsec SAs between Host 1 and Host 2

Router A

Example:

```
Router# show crypto isakmp sa
  f_vrf/i_vrf  dst          src          state      conn-id slot
  / 10.2.2.2          10.1.1.1    QM_IDLE    1         0
```

Router B

Example:

```
Router# show crypto isakmp sa
  f_vrf/i_vrf  dst          src          state      conn-id slot
  /            10.1.1.1    10.2.2.2    QM_IDLE    1         0
```

Router A

Example:

```

Router# show crypto ipsec sa interface fastethernet0/0
interface: FastEthernet0/0
  Crypto map tag: testtag1, local addr. 10.1.1.1
  protected vrf:
  local ident (addr/mask/prot/port): (10.0.0.1/255.255.255.255/0/0)
  remote ident (addr/mask/prot/port): (10.0.2.2/255.255.255.255/0/0)
  current_peer: 10.2.2.2:500
    PERMIT, flags={origin_is_acl,}
    #pkts encaps: 10, #pkts encrypt: 10, #pkts digest: 10

Step 2 Clear the IKE and IPsec SAs on Router B

Example:

```

Router# clear crypto isakmp
Router# clear crypto sa
Router# show crypto isakmp sa
  f_vrf/i_vrf   dst          src          state          conn-id slot
  /            10.2.2.2.    10.1.1.1    MM_NO_STATE    1        0 (deleted)
Router# show crypto ipsec sa
interface: FastEthernet1/0
  Crypto map tag: testtag1, local addr. 10.2.2.2
  protected vrf:
  local ident (addr/mask/prot/port): (10.0.2.2/255.255.255.255/0/0)
  remote ident (addr/mask/prot/port): (10.0.0.1/255.255.255.255/0/0)

```

```

current_peer: 10.1.1.1:500
  PERMIT, flags={origin_is_acl,}
#pkts encaps: 0, #pkts encrypt: 0, #pkts digest: 0
#pkts decaps: 0, #pkts decrypt: 0, #pkts verify: 0
#pkts compressed: 0, #pkts decompressed: 0
#pkts not compressed: 0, #pkts compr. failed: 0
#pkts not decompressed: 0, #pkts decompress failed: 0
#send errors 0, #recv errors 0
local crypto endpt.: 10.2.2.2, remote crypto endpt.: 10.1.1.1
path mtu 1500, media mtu 1500
current outbound spi: 0
inbound esp sas:
inbound ah sas:
inbound pcp sas:
outbound esp sas:
outbound ah sas:
outbound pcp sas:

```

Step 3 Send traffic from Host 1 to Host 2 and ensure that new IKE and IPsec SAs are correctly established

Example:

```

ping
Protocol [ip]: ip
Target IP address: 10.0.2.2
Repeat count [5]: 30
Datagram size [100]: 100
Timeout in seconds [2]:
Extended commands [n]: no
Sweep range of sizes [n]: n
Type escape sequence to abort.
Sending 30, 100-byte ICMP Echos to 10.0.2.2, timeout is 2 seconds:
..!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
Success rate is 93 percent (28/30), round-trip min/avg/max = 1/3/8 ms
RouterB# show crypto isakmp sa
   f_vrf/i_vrf   dst          src          state          conn-id slot
   /            /            /            /            /      /
   /            /            /            /            /      /
   /            /            /            /            /      /
   /            /            /            /            /      /
   /            /            /            /            /      /

<p>The Cisco Support website provides extensive online resources, including documentation and tools for troubleshooting and resolving technical issues with Cisco products and technologies.</p> <p>To receive security and technical information about your products, you can subscribe to various services, such as the Product Alert Tool (accessed from Field Notices), the Cisco Technical Services Newsletter, and Really Simple Syndication (RSS) Feeds.</p> <p>Access to most tools on the Cisco Support website requires a Cisco.com user ID and password.</p>	http://www.cisco.com/techsupport

Feature Information for Invalid Security Parameter Index Recovery

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 243: Feature Information for Invalid Security Parameter Index Recovery

Feature Name	Releases	Feature Information
Invalid Special Parameter Index (SPI) Recovery	Cisco IOS XE Release 2.1	<p>When an invalid SPI occurs in IPsec packet processing, the Invalid Security Parameter Index Recovery feature allows for an IKE SA to be established. The “IKE” module sends notification of the “Invalid SPI” error to the originating IPsec peer so that Security Association Databases (SADBs) can be resynchronized and successful packet processing can be resumed.</p> <p>The following command was introduced or modified: crypto isakmp invalid-spi-recovery.</p>

CHAPTER 180

IPsec Dead Peer Detection Periodic Message Option

The IPsec Dead Peer Detection Periodic Message Option feature allows you to configure your router to query the liveliness of its Internet Key Exchange (IKE) peer at regular intervals. The benefit of this approach over the default approach (on-demand dead peer detection) is earlier detection of dead peers.

- [Prerequisites for IPsec Dead Peer Detection Periodic Message Option, on page 2355](#)
- [Restrictions for IPsec Dead Peer Detection Periodic Message Option, on page 2355](#)

- [Additional References, on page 2363](#)
- [Feature Information for Dead Peer Detection Periodic Message Option, on page 2364](#)

Prerequisites for IPsec Dead Peer Detection Periodic Message Option

Before configuring the IPsec Dead Peer Detection Periodic Message Option feature, you should have the following:

- Familiarity with configuring IP Security (IPsec).
- An IKE peer that supports DPD (dead peer detection). Implementations that support DPD include the Cisco VPN 3000 concentrator, Cisco PIX Firewall, Cisco VPN Client, and Cisco IOS XE software in all modes of operation--site-to-site and Easy VPN server.

Restrictions for IPsec Dead Peer Detection Periodic Message Option

Using periodic DPD potentially allows the router to detect an unresponsive IKE peer with better response time when compared to on-demand DPD. However, use of periodic DPD incurs extra overhead. When communicating to large numbers of IKE peers, you should consider using on-demand DPD instead.

Information About IPsec Dead Peer Detection Periodic Message Option

How DPD and Cisco IOS XE Keepalive Features Work

DPD and Cisco IOS XE keepalives function on the basis of the timer. If the timer is set for 10 seconds, the router will send a “hello” message every 10 seconds (unless, of course, the router receives a “hello” message from the peer). The benefit of IOS keepalives and periodic DPD is earlier detection of dead peers. However, IOS keepalives and periodic DPD rely on periodic messages that have to be sent with considerable frequency. The result of sending frequent messages is that the communicating peers must encrypt and decrypt more packets.

DPD also has an on-demand approach. The contrasting on-demand approach is the default. With on-demand DPD, messages are sent on the basis of traffic patterns. For example, if a router has to send outbound traffic and the liveliness of the peer is questionable, the router sends a DPD message to query the status of the peer. If a router has no traffic to send, it never sends a DPD message. If a peer is dead, and the router never has any traffic to send to the peer, the router will not find out until the IKE or IPsec security association (SA) has to be rekeyed (the liveliness of the peer is unimportant if the router is not trying to communicate with the peer). On the other hand, if the router has traffic to send to the peer, and the peer does not respond, the router will initiate a DPD message to determine the state of the peer.

Using the IPsec Dead Peer Detection Periodic Message Option

With the IPsec Dead Peer Detection Periodic Message Option feature, you can configure your router so that DPD messages are “forced” at regular intervals. This forced approach results in earlier detection of dead peers. For example, if a router has no traffic to send, a DPD message is still sent at regular intervals, and if a peer is dead, the router does not have to wait until the IKE SA times out to find out.

If you want to configure the DPD periodic message option, you should use the **crypto isakmp keepalive** command with the **periodic** keyword. If you do not configure the **periodic** keyword, the router defaults to the on-demand approach.

Note When the **crypto isakmp keepalive** command is configured, the Cisco IOS software negotiates the use of Cisco IOS keepalives or DPD, depending on which protocol the peer supports.

Using DPD and Cisco IOS XE Keepalive Features with Multiple Peers in the Crypto Map

DPD and Cisco IOS XE keepalive features can be used in conjunction with multiple peers in the crypto map to allow for stateless failover. DPD allows the router to detect a dead IKE peer, and when the router detects the dead state, the router deletes the IPsec and IKE SAs to the peer. If you configure multiple peers, the router will switch over to the next listed peer for a stateless failover.

How to Configure IPsec Dead Peer Detection Periodic Message Option

Configuring a Periodic DPD Message

To configure a periodic DPD message, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp keepalive** *seconds* [*retries*] [**periodic** | **on-demand**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto isakmp keepalive <i>seconds</i> [<i>retries</i>] [periodic on-demand] Example: <pre>Router (config)# crypto isakmp keepalive 10 periodic</pre>	Allows the gateway to send DPD messages to the peer. <ul style="list-style-type: none"> • <i>seconds</i> --When the periodic keyword is used, this argument is the number of seconds between DPD messages; the range is from 10 to 3600 seconds. <p>When the on-demand keyword is used, this argument is the number of seconds during which traffic is not received from the peer before DPD retry messages are sent if there is data (IPSec) traffic to send; the range is from 10 to 3600 seconds.</p> <p>Note If you do not specify a time interval, an error message appears.</p> <ul style="list-style-type: none"> • <i>retry-seconds</i> --(Optional) Number of seconds between DPD retry messages if the DPD retry message is missed by the peer; the range is from 2 to 60 seconds. <p>Once 1 DPD message is missed by the peer, the router moves to a more aggressive state and sends the DPD retry</p>

	Command or Action	Purpose
		<p>message at the faster retry interval, which is the number of seconds between DPD retries if the DPD message is missed by the peer. The default DPD retry message is sent every 2 seconds. Five aggressive DPD retry messages can be missed before the tunnel is marked as down.</p> <p>Note To configure DPD with IPsec High Availability (HA), the recommendation is to use a value other than the default (which is 2 seconds). A keepalive timer of 10 seconds with 5 retries seems to work well with HA because of the time that it takes for the router to get into active mode.</p> <ul style="list-style-type: none"> • periodic --(Optional) DPD messages are sent at regular intervals. • on-demand --(Optional) The default behavior. DPD retries are sent on demand. <p>Note Because this option is the default, the on-demand keyword does not appear in configuration output.</p>

Configuring DPD and Cisco IOS XE Keepalives with Multiple Peers in the Crypto Map

To configure DPD and IOS keepalives to be used in conjunction with the crypto map to allow for stateless failover, perform the following steps. This configuration will cause a router to cycle through the peer list when it detects that the first peer is dead.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num ipsec-isakmp*
4. **set peer** *{host-name [dynamic] | ip-address}*
5. **set transform-set** *transform-set-name*
6. **match address** *[access-list-id | name]*

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto map map-name seq-num ipsec-isakmp Example: Router (config)# crypto map green 1 ipsec-isakmp	Enters crypto map configuration mode and creates or modifies a crypto map entry. <ul style="list-style-type: none"> The ipsec-isakmp keyword indicates that IKE will be used to establish the IPsec SAs for protecting the traffic specified by this crypto map entry.
Step 4	set peer {host-name [dynamic] ip-address} Example: Router (config-crypto-map)# set peer 10.12.12.12	Specifies an IPsec peer in a crypto map entry. <ul style="list-style-type: none"> You can specify multiple peers by repeating this command.
Step 5	set transform-set transform-set-name Example: Router (config-crypto-map)# set transform-set txfm	Specifies which transform sets can be used with the crypto map entry. <ul style="list-style-type: none"> You can specify more than one transform set name by repeating this command.
Step 6	match address [access-list-id name] Example: Router (config-crypto-map)# match address 101	Specifies an extended access list for a crypto map entry.

Verifying That DPD Is Enabled

DPD allows the router to clear the IKE state when a peer becomes unreachable. If DPD is enabled and the peer is unreachable for some time, you can use the **clear crypto session** command to manually clear IKE and IPsec SAs.

The **debug crypto isakmp** command can be used to verify that DPD is enabled.

SUMMARY STEPS

1. **enable**
2. **clear crypto session [local ip-address [port local-port]] [remote ip-address [port remote-port]] | [fvrf vrf-name] [ivrf vrf-name]**
3. **debug crypto isakmp**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: Router> enable	<ul style="list-style-type: none"> Enter your password if prompted.
Step 2	clear crypto session [<i>local ip-address</i> [<i>port local-port</i>]] [<i>remote ip-address</i> [<i>port remote-port</i>]] [<i>fvr</i> <i>vrf-name</i>] [<i>ivrf vrf-name</i>] Example: Router# clear crypto session	Deletes crypto sessions (IPsec and IKE SAs).
Step 3	debug crypto isakmp Example: Router# debug crypto isakmp	Displays messages about IKE events.

Configuration Examples for IPsec Dead Peer Detection Periodic Message Option

Site-to-Site Setup with Periodic DPD Enabled Example

The following configurations are for a site-to-site setup with periodic DPD enabled. The configurations are for the IKE Phase 1 policy and for the IKE preshared key.

IKE Phase 1 Policy

```
crypto isakmp policy 1
  encryption aes
  authentication pre-share
  group 14
!
```

IKE Preshared Key

```
crypto isakmp key kd94j1ksldz address 10.2.80.209 255.255.255.0
crypto isakmp keepalive 10 periodic
crypto ipsec transform-set Trans1 esp-aes esp-sha-hmac

!
!
interface
  ip address 10.1.32.14 255.255.255.0
  speed auto

!
```

Verifying DPD Configuration Using the debug crypto isakmp Command Example

The following sample output from the **debug crypto isakmp** command verifies that IKE DPD is enabled:

```
*Mar 25 15:17:14.131: ISAKMP:(0:1:HW:2):IKE_DPD is enabled, initializing timers
```

To see that IKE DPD is enabled (and that the peer supports DPD): when periodic DPD is enabled, you should see the following debug messages at the interval specified by the command:

```
*Mar 25 15:18:52.107: ISAKMP:(0:1:HW:2): sending packet to 10.2.80.209 my_port
500 peer_port 500 (I) QM_IDLE
*Mar 25 15:18:52.107: ISAKMP:(0:1:HW:2):purging node 899852982 *Mar 25 15:18:52.111:
ISAKMP:(0:1:HW:2):Input = IKE_MSG_FROM_TIMER,
IKE_TIMER_IM_ALIVE
*Mar 25 15:18:52.111: ISAKMP:(0:1:HW:2):Old State = IKE_P1_COMPLETE New State =
IKE_P1_COMPLETE
```

The above message corresponds to sending the DPD R_U_THERE message.

```
*Mar 25 15:18:52.123: ISAKMP (0:268435457): received packet from 10.2.80.209
dport 500 sport 500 Global (I) QM_IDLE
*Mar 25 15:18:52.123: ISAKMP: set new node -443923643 to QM_IDLE *Mar 25 15:18:52.131:
ISAKMP:(0:1:HW:2): processing HASH payload. message ID =
-443923643
*Mar 25 15:18:52.131: ISAKMP:(0:1:HW:2): processing NOTIFY R_U_THERE_ACK protocol 1
spi 0, message ID = -443923643, sa = 81BA4DD4
*Mar 25 15:18:52.135: ISAKMP:(0:1:HW:2): DPD/R_U_THERE_ACK received from peer
10.2.80.209, sequence 0x9
*Mar 25 15:18:52.135: ISAKMP:(0:1:HW:2):deleting node -443923643 error FALSE
reason "informational (in) state 1"
*Mar 25 15:18:52.135: ISAKMP:(0:1:HW:2):Input = IKE_MSG_FROM_PEER, IKE_INFO_NOTIFY *Mar
25 15:18:52.135: ISAKMP:(0:1:HW:2):Old State = IKE_P1_COMPLETE New State =
IKE_P1_COMPLETE
```

The above message corresponds to receiving the acknowledge (ACK) message from the peer.

```
Router#
*Mar 25 15:47:35.335: ISAKMP: set new node -90798077 to QM_IDLE *Mar 25 15:47:35.343:

```

The above message shows what happens when the remote peer is unreachable. The router sends one DPD R_U_THERE message and four retransmissions before it finally deletes the IPsec and IKE SAs.

DPD and Cisco IOS XE Keepalives Used in Conjunction with Multiple Peers in a Crypto Map Example

The following example shows that DPD and Cisco IOS XE keepalives are used in conjunction with multiple peers in a crypto map configuration when IKE will be used to establish the security associations (SAs). In this example, an SA could be set up to the IPsec peer at 10.0.0.1, 10.0.0.2, or 10.0.0.3.

```
crypto isakmp keepalive 10 periodic
crypto map green 1 ipsec-isakmp
  set peer 10.0.0.1
  set peer 10.0.0.2
  set peer 10.0.0.3
  set transform-set txfm
  match address 101
```

Table 244: Feature Information for Dead Peer Detection

Feature Name	Releases	Feature Information
Dead Peer Detection Periodic Message Option	Cisco IOS XE Release 2.1	<p>This feature allows you to configure your router to query the liveliness of its IKE peer at regular intervals. The benefit of this approach over the default approach (on-demand dead peer detection) is earlier detection of dead peers.</p> <p>The following command was introduced or modified: crypto isakmp keepalive.</p>

CHAPTER 181

IPsec NAT Transparency

The IPsec NAT Transparency feature introduces support for IP Security (IPsec) traffic to travel through Network Address Translation (NAT) or Port Address Translation (PAT) points in the network by addressing many known incompatibilities between NAT and IPsec.

- [Restrictions for IPsec NAT Transparency, on page 2367](#)
- [Information About IPsec NAT Transparency, on page 2368](#)
- [How to Configure NAT and IPsec, on page 2371](#)
- [Configuration Examples for IPsec and NAT, on page 2373](#)
- [Additional References, on page 2374](#)
- [Feature Information for IPsec NAT Transparency, on page 2375](#)
- [Glossary, on page 2376](#)

Restrictions for IPsec NAT Transparency

Although this feature addresses many incompatibilities between NAT and IPsec, the following problems still exist:

Internet Key Exchange (IKE) IP Address and NAT

This incompatibility applies only when IP addresses are used as a search key to find a preshared key. Modification of the IP source or destination addresses by NAT or reverse NAT results in a mismatch between the IP address and the preshared key.

Embedded IP Addresses and NAT

Because the payload is integrity protected, any IP address enclosed within IPsec packets cannot be translated by NAT. Protocols that use embedded IP addresses include FTP, Internet Relay Chat (IRC), Simple Network Management Protocol (SNMP), Lightweight Directory Access Protocol (LDAP), H.323, and Session Initiation Protocol (SIP).

Information About IPsec NAT Transparency

Benefit of IPsec NAT Transparency

Before the introduction of this feature, a standard IPsec virtual private network (VPN) tunnel would not work if there were one or more NAT or PAT points in the delivery path of the IPsec packet. This feature makes NAT IPsec-aware, thereby, allowing remote access users to build IPsec tunnels to home gateways.

Feature Design of IPsec NAT Traversal

The IPsec NAT Transparency feature introduces support for IPsec traffic to travel through NAT or PAT points in the network by encapsulating IPsec packets in a User Datagram Protocol (UDP) wrapper, which allows the packets to travel across NAT devices. The following sections define the details of NAT traversal:

IKE Phase 1 Negotiation NAT Detection

During Internet Key Exchange (IKE) phase 1 negotiation, two types of NAT detection occur before IKE Quick Mode begins--NAT support and NAT existence along the network path.

To detect NAT support, you should exchange the vendor identification (ID) string with the remote peer. During Main Mode (MM) 1 and MM 2 of IKE phase 1, the remote peer sends a vendor ID string payload to its peer to indicate that this version supports NAT traversal. Thereafter, NAT existence along the network path can be determined.

Detecting whether NAT exists along the network path allows you to find any NAT device between two peers and the exact location of NAT. A NAT device can translate the private IP address and port to public value (or from public to private). This translation changes the IP address and port if the packet goes through the device. To detect whether a NAT device exists along the network path, the peers should send a payload with hashes of the IP address and port of both the source and destination address from each end. If both ends calculate the hashes and the hashes match, each peer knows that a NAT device does not exist on the network path between them. If the hashes do not match (that is, someone translated the address or port), then each peer needs to perform NAT traversal to get the IPsec packet through the network.

The hashes are sent as a series of NAT discovery (NAT-D) payloads. Each payload contains one hash; if multiple hashes exist, multiple NAT-D payloads are sent. In most environments, there are only two NAT-D payloads--one for the source address and port and one for the destination address and port. The destination NAT-D payload is sent first, followed by the source NAT-D payload, which implies that the receiver should expect to process the local NAT-D payload first and the remote NAT-D payload second. The NAT-D payloads are included in the third and fourth messages in Main Mode and in the second and third messages in Aggressive Mode (AM).

IKE Phase 2 Negotiation NAT Traversal Decision

While IKE phase 1 detects NAT support and NAT existence along the network path, IKE phase 2 decides whether or not the peers at both ends will use NAT traversal. Quick Mode (QM) security association (SA) payload in QM1 and QM2 is used to for NAT traversal negotiation.

Because the NAT device changes the IP address and port number, incompatibilities between NAT and IPsec can be created. Thus, exchanging the original source address bypasses any incompatibilities.

UDP Encapsulation of IPsec Packets for NAT Traversal

In addition to allowing IPsec packets to traverse across NAT devices, UDP encapsulation also addresses many incompatibility issues between IPsec and NAT and PAT. The resolved issues are as follows:

Incompatibility Between IPsec ESP and PAT Resolved

If PAT found a legislative IP address and port, it would drop the Encapsulating Security Payload (ESP) packet. To prevent this scenario, UDP encapsulation is used to hide the ESP packet behind the UDP header. Thus, PAT treats the ESP packet as a UDP packet, processing the ESP packet as a normal UDP packet.

Incompatibility Between Checksums and NAT Resolved

In the new UDP header, the checksum value is always assigned to zero. This value prevents an intermediate device from validating the checksum against the packet checksum, thereby, resolving the TCP UDP checksum issue because NAT changes the IP source and destination addresses.

Incompatibility Between Fixed IKE Destination Ports and PAT Resolved

PAT changes the port address in the new UDP header for translation and leaves the original payload unchanged. To see how UDP encapsulation helps to send IPsec packets see the figures below.

Figure 90: Standard IPsec Tunnel Through a NAT/PAT Point (No UDP Encapsulation)

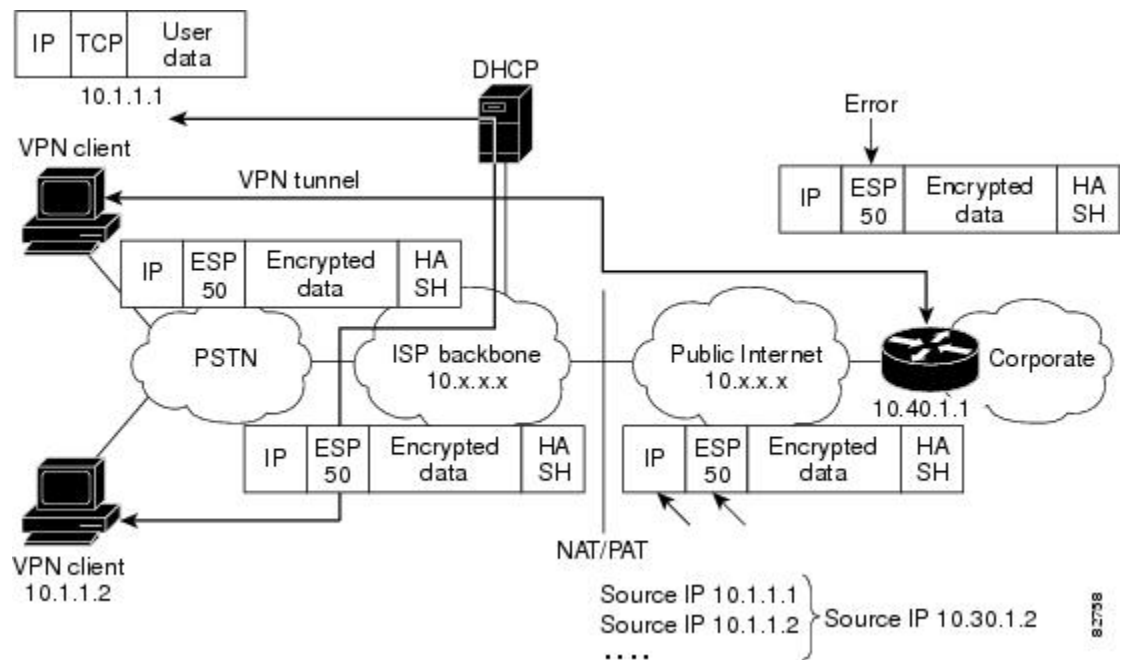

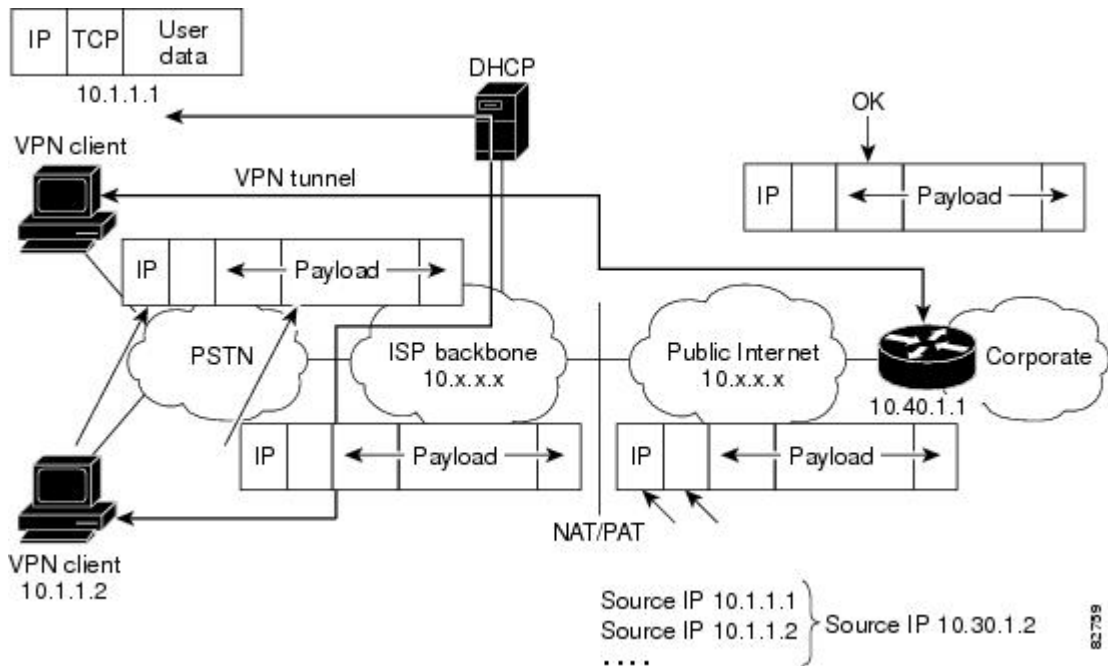

Figure 91: IPsec Packet with UDP Encapsulation

UDP Encapsulated Process for Software Engines Transport Mode and Tunnel Mode ESP Encapsulation

After the IPsec packet is encrypted by a hardware accelerator or a software crypto engine, a UDP header and a non-IKE marker (which is 8 bytes in length) are inserted between the original IP header and ESP header. The total length, protocol, and checksum fields are changed to match this modification. The first figure below shows an IPsec packet before and after transport mode is applied; the second figure below shows an IPsec packet before and after tunnel mode is applied.

Figure 92: Transport Mode--IPsec Packet Before and After ESP Encapsulation

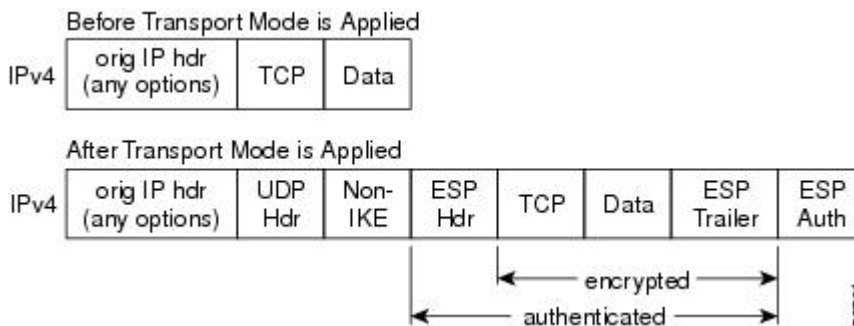

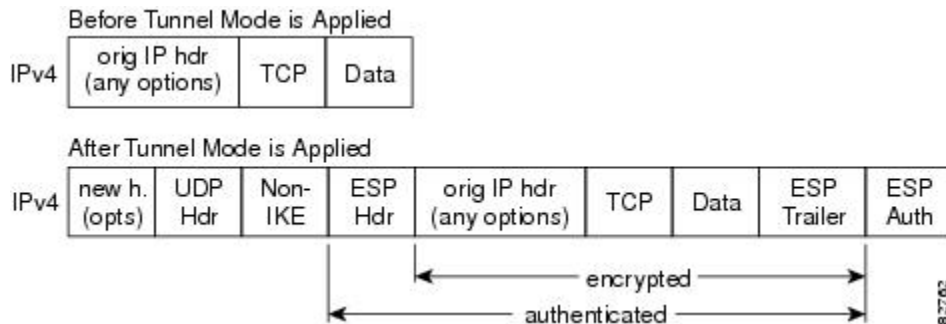

Figure 93: Tunnel Mode--IPsec Packet Before and After ESP Encapsulation

NAT Keepalives

NAT keepalives are enabled to keep the dynamic NAT mapping alive during a connection between two peers. NAT keepalives are UDP packets with an unencrypted payload of 1 byte. Although the current dead peer detection (DPD) implementation is similar to NAT keepalives, there is a slight difference: DPD is used to detect peer status, while NAT keepalives are sent if the IPsec entity did not send or receive the packet at a specified period of time--valid range is between 5 to 3600 seconds.

If NAT keepalives are enabled (via the **crypto isakmp nat keepalive** command), users should ensure that the idle value is shorter than the NAT mapping expiration time, which is 20 seconds.

How to Configure NAT and IPsec

Configuring NAT Traversal

NAT Traversal is a feature that is auto detected by VPN devices. There are no configuration steps for a router running Cisco IOS XE Release 2.1. If both VPN devices are NAT-T capable, NAT Traversal is auto detected and auto negotiated.

Disabling NAT Traversal

You may wish to disable NAT traversal if you already know that your network uses IPsec-awareness NAT (spi-matching scheme). To disable NAT traversal, use the following commands:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no crypto ipsec nat-transparency udp-encapsulation**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables higher privilege levels, such as privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	no crypto ipsec nat-transparency udp-encapsulation Example: <pre>Router(config)# no crypto ipsec nat-transparency udp-encapsulation</pre>	Disables NAT traversal.

Configuring NAT Keepalives

To configure your router to send NAT keepalives, use the following commands:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp nat keepalive** *seconds*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables higher privilege levels, such as privileged EXEC mode. Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto isakmp nat keepalive <i>seconds</i> Example: <pre>Router(config)# crypto isakmp nat keepalive 20</pre>	Allows an IPsec node to send NAT keepalive packets. <ul style="list-style-type: none"> • <i>seconds</i> --The number of seconds between keepalive packets; range is between 5 to 3,600 seconds.

	Command or Action	Purpose
		<p>Note When the timer is modified, it is modified for every Internet Security Association Key Management Protocol (ISAKMP) security association (SA) when the keepalive for that SA is sent based on the existing timer.</p> <p>Note A five-percent jitter mechanism value is applied to the timer to avoid security association rekey collisions. If there are many peer routers, and the timer is configured too low, then the router can experience high CPU usage.</p>

Verifying IPsec Configuration

To verify your configuration, perform the following optional steps:

SUMMARY STEPS

1. `enable`
2. `show crypto ipsec sa [map map-name | address | identity] [detail]`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables higher privilege levels, such as privileged EXEC mode.</p> <p>Enter your password if prompted.</p>
Step 2	<p><code>show crypto ipsec sa [map map-name address identity] [detail]</code></p> <p>Example:</p> <pre>Router# show crypto ipsec sa</pre>	<p>Displays the settings used by current SAs.</p>

Configuration Examples for IPsec and NAT

NAT Keepalives Configuration Example

The following example shows how to enable NAT keepalives to be sent every 20 seconds:

```
crypto isakmp policy 1
 authentication pre-share
crypto isakmp key 1234 address 10.0.0.1
```

```

crypto isakmp nat keepalive 20
!
!
crypto ipsec transform-set t2 esp-des esp-sha-hmac
!
crypto map test2 10 ipsec-isakmp
 set peer 10.0.0.1
 set transform-set t2
 match address 101

```

Glossary

IKE --Internet Key Exchange. Hybrid protocol that implements Oakley key exchange and Skeme key exchange inside the Internet Security Association Key Management Protocol (ISAKMP) framework. Although IKE can be used with other protocols, its initial implementation is with IPsec. IKE provides authentication of the IPsec peers, negotiates IPsec keys, and negotiates IPsec security associations (SAs).

IPsec --IP Security. Framework of open standards developed by the Internet Engineering Task Force (IETF). IPsec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPsec acts at the network layer, protecting and authenticating IP packets between participating IPsec devices (“peers”), such as Cisco routers.

NAT --Network Address Translation. Translates a private IP address used inside the corporation to a public, routable address for use on the outside of the corporation, such as the Internet. NAT is considered a one-to-one mapping of addresses from private to public.

PAT --Port Address Translation. Like NAT, PAT also translated private IP address to public, routable addresses. Unlike NAT, PAT provides a many-to-one mapping of private addresses to a public address; each instance of the public address is associated with a particular port number to provide uniqueness. PAT can be used in environments where the cost of obtaining a range of public addresses is too expensive for an organization.

CHAPTER 182

IPsec Extended Sequence Number

The Extended Sequence Number (ESN) is an addition to the IPsec standard sequence number that is used to assist high-speed IPsec implementations. IPsec packets have 32 bit sequence numbers, and rekey is mandatory for IKE-keyed IPsec Security Association (SA) after a sequence number rollover. ESN attempts to reduce this high IPsec SA rekey rate by extending the sequence number to 64 bits, this would increase the time before mandatory rekeys.

- [Prerequisites for IPsec Extended Sequence Number](#) , on page 2377
- [Restrictions for IPsec Extended Sequence Number](#) , on page 2377
- [Information About IPsec Extended Sequence Number](#), on page 2378
- [How to Configure IPsec Extended Sequence Number](#), on page 2378
- [Additional References](#), on page 2379
- [Feature Information for IPsec ESN support](#) , on page 2379

Prerequisites for IPsec Extended Sequence Number

- ESN must be supported by both IPsec peers involved in establishing a secure connection. This feature will not function if either one of the peers does not support ESN
- Anti-replay configuration is required, when using ESN. For more details see, [IPsec Anti-Replay Window Expanding and Disabling](#).

Restrictions for IPsec Extended Sequence Number

- ESN is only supported on Cisco Catalyst 8500 Series Edge Platforms and Cisco ASR 1000 Series ESP 100-X and ESP 200-X.
- ESN feature is not supported with DES or 3DES algorithms.

Information About IPsec Extended Sequence Number

IPsec Extended Sequence Number

The Extended Sequence Number (ESN) is an addition to the IPsec standard sequence number that is used to assist high-speed IPsec implementations. ESN uses a larger sequence number space than the standard sequence number and it allows the customer to transmit large volumes of data at a high speed without rekeying.

IPSec packets have 32 bit sequence numbers, and rekey is mandatory for IKE-keyed IPSec Security Association (SA) after a sequence number rollover. ESN attempts to reduce this high IPsec SA rekey rate by extending the sequence number to 64 bits, this would increase the time before mandatory rekeys and prevents sequence number rollover. As a result, it lowers the usage of system resources and prevents frequent rekeying on high speed IPsec connections or IPsec implementations that require long IPsec SA lifetime.

How to Configure IPsec Extended Sequence Number

Configuring IPsec Extended Sequence Number

To configure IPsec Extended Sequence Number support, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec transform-set** *transform-set-name transform1* [*transform2*]
4. **esn**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto ipsec transform-set <i>transform-set-name transform1</i> [<i>transform2</i>] Example: Router (config)# crypto ipsec transform-set foo esp-aes esp-sha-hmac	Configures Transform Sets for IPsec. <ul style="list-style-type: none"> • There are complex rules defining the entries that you can use for transform arguments. These rules are explained in the command description for the crypto ipsec transform-set command, and the table in “About

	Command or Action	Purpose
		Transform Sets ” section provides a list of allowed transform combinations.
Step 4	esn Example: <pre>Router(cfg-crypto-trans)#[no] esn [optional]</pre>	(Optional) Enables IPsec ESN.

DF Bit Override Functionality with IPsec Tunnels

The DF Bit Override Functionality with IPsec Tunnels feature allows you to configure the setting of the DF bit when encapsulating tunnel mode IPsec traffic on a global or per-interface level. Thus, if the DF bit is set to clear, routers can fragment packets regardless of the original DF bit setting.

- [Prerequisites for DF Bit Override Functionality with IPsec Tunnels, on page 2381](#)
- [Restrictions for DF Bit Override Functionality with IPsec Tunnels, on page 2381](#)

- [Additional References, on page 2384](#)
- [Feature Information for DF Bit Override Functionality with IPsec Tunnels, on page 2385](#)

Prerequisites for DF Bit Override Functionality with IPsec Tunnels

IPsec must be enabled on your router.

Restrictions for DF Bit Override Functionality with IPsec Tunnels

Performance Impact

Because each packet is reassembled at the process level, a significant performance impact occurs at a high data rate. Two major caveats are as follows:

- The reassemble queue can fill up and force fragments to be dropped.
- The traffic is slower because of the process switching.

DF Bit Setting Requirement

If several interfaces share the same crypto map using the local address feature, these interfaces must share the same DF bit setting.

Feature Availability

This feature is available only for IPsec tunnel mode. (IPsec transport mode is not affected because it does not provide an encapsulating IP header.)

Information About DF Bit Override Functionality with IPsec Tunnels

Feature Overview

The DF Bit Override Functionality with IPsec Tunnels feature allows you to specify whether your router can clear, set, or copy the Don't Fragment (DF) bit from the encapsulated header. A DF bit is a bit within the IP header that determines whether a router is allowed to fragment a packet.

Some user configurations have hosts that perform the following functions:

- Set the DF bit in packets they send
- Use firewalls that block Internet Control Message Protocol (ICMP) errors from outside the firewall, preventing hosts from learning about the maximum transmission unit (MTU) size outside the firewall
- Use IP Security (IPsec) to encapsulate packets, reducing the available MTU size

If your configurations have hosts that prevent you from learning about the available MTU size, you can configure your router to clear the DF bit and fragment the packet.

Note In compliance with RFC 2401, this feature can be configured globally or per interface. If both levels are configured, the interface configuration will override the global configuration.

How to Configure DF Bit Override Functionality with IPsec Tunnels

Configuring the DF Bit for the Encapsulating Header in Tunnel Mode

To set the DF bit for the encapsulating header in tunnel mode, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec df-bit** [clear | set | copy]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto ipsec df-bit [clear set copy] Example: Router (config)# crypto ipsec df-bit set	Sets the DF bit for the encapsulating header in tunnel mode for all interfaces. To set the DF bit for a specified interface, use the crypto ipsec df-bit command in interface configuration mode. Note DF bit interface configuration settings override all DF bit global configuration settings.

Verifying DF Bit Setting

To verify the current DF Bit settings on your router, use the **show running-config** command in EXEC mode.

Configuration Examples for DF Bit Override Functionality with IPsec Tunnels

DF Bit Setting Configuration Example

In following example, the router is configured to globally clear the setting for the DF bit and copy the DF bit on the interface named FastEthernet. Thus, all interfaces except FastEthernet will allow the router to send packets larger than the available MTU size; FastEthernet will allow the router to fragment the packet.

CHAPTER 184

IPsec Security Association Idle Timers

When a router running the Cisco IOS XE software creates an IPsec security association (SA) for a peer, resources must be allocated to maintain the SA. The SA requires both memory and several managed timers. For idle peers, these resources are wasted. If enough resources are wasted by idle peers, the router could be prevented from creating new SAs with other peers. The IPsec Security Association Idle Timers feature introduces a configurable idle timer to monitor SAs for activity, allowing SAs for idle peers to be deleted. Benefits of this feature include:

- Increased availability of resources
- Improved scalability of Cisco IOS XE IPsec deployments. Because this feature prevents the wasting of resources by idle peers, more resources will be available to create new SAs as required.
- [Prerequisites for IPsec Security Association Idle Timers, on page 2387](#)
- [Information About IPsec Security Association Idle Timers, on page 2387](#)
- [How to Configure IPsec Security Association Idle Timers, on page 2388](#)
- [Configuration Examples for IPsec Security Association Idle Timers, on page 2389](#)
- [Additional References, on page 2390](#)
- [Feature Information for IPsec Security Association Idle Timers, on page 2391](#)

Prerequisites for IPsec Security Association Idle Timers

You must configure Internet Key Exchange (IKE) as described in the “Configuring Internet Key Exchange Security Protocol” chapter of the *Cisco IOS XE Security Configuration Guide*.

Information About IPsec Security Association Idle Timers

Lifetimes for IPsec Security Associations

The Cisco IOS software currently allows the configuration of lifetimes for IPsec SAs. Lifetimes can be configured globally or per crypto map. There are two lifetimes: a “timed” lifetime and a “traffic-volume” lifetime. A security association expires after the first of these lifetimes is reached.

IPsec Security Association Idle Timers

The IPsec SA idle timers are different from the global lifetimes for IPsec SAs. The expiration of the global lifetime is independent of peer activity. The IPsec SA idle timer allows SAs associated with inactive peers to be deleted before the global lifetime has expired.

If the IPsec SA idle timers are not configured, only the global lifetimes for IPsec SAs are applied. SAs are maintained until the global timers expire, regardless of peer activity.

Note If the last IPsec SA to a given peer is deleted due to idle timer expiration, the Internet Key Exchange (IKE) SA to that peer will also be deleted.

How to Configure IPsec Security Association Idle Timers

Configuring the IPsec SA Idle Timer Globally

This task configures the IPsec SA idle timer globally. The idle timer configuration will be applied to all SAs.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec security-association idle-time *seconds***

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto ipsec security-association idle-time <i>seconds</i> Example: Router(config)# crypto ipsec security-association idle-time 600	Configures the IPsec SA idle timer. <ul style="list-style-type: none"> • The <i>seconds</i> argument specifies the time, in seconds, that the idle timer will allow an inactive peer to maintain an SA. Valid values for the <i>seconds</i> argument range from 60 to 86400.

Configuring the IPsec SA Idle Timer per Crypto Map

This task configures the IPsec SA idle timer for a specified crypto map. The idle timer configuration will be applied to all SAs under the specified crypto map.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-number ipsec-isakmp*
4. **set security-association idle-time** *seconds*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto map <i>map-name seq-number ipsec-isakmp</i> Example: <pre>Router(config)# crypto map test 1 ipsec-isakmp</pre>	Creates or modifies a crypto map entry and enters crypto map configuration mode.
Step 4	set security-association idle-time <i>seconds</i> Example: <pre>Router(config-crypto-map)# set security-association idle-time 600</pre>	Specifies the maximum amount of time for which the current peer can be idle before the default peer is used. <ul style="list-style-type: none"> • The <i>seconds</i> argument is the number of seconds for which the current peer can be idle before the default peer is used. Valid values are 60 to 86400.

Configuration Examples for IPsec Security Association Idle Timers

Configuring the IPsec SA Idle Timer Globally Example

The following example globally configures the IPsec SA idle timer to drop SAs for inactive peers after 600 seconds:

```
crypto ipsec security-association idle-time 600
```

Configuring the IPsec SA Idle Timer per Crypto Map Example

The following example configures the IPsec SA idle timer for the crypto map named test to drop SAs for inactive peers after 600 seconds:

```
crypto map test 1 ipsec-isakmp
 set security-association idle-time 600
```

CHAPTER 185

IPv6 IPsec Quality of Service

The IPv6 IPsec QoS feature allows the quality of service (QoS) policies to be applied to IPv6 IPsec.

- [Information About IPv6 IPsec QoS, on page 2393](#)
- [How to Configure IPv6 IPsec QoS, on page 2393](#)
- [Configuration Examples for QoS, on page 2398](#)
- [Additional References for IPv6 IPsec QoS, on page 2400](#)
- [Feature Information for IPv6 IPsec QoS, on page 2400](#)

Information About IPv6 IPsec QoS

IPv6 IPsec QoS Overview

The IPv6 IPsec QoS feature applies the quality of service (QoS) policies to IPv6 IPsec. This feature supports the following functionalities:

- **Crypto LLQ QoS**—Traffic that is classified by QoS and marked as priority level 1 or 2 by traditional Cisco Modular QoS CLI (MQC) QoS configuration, for example PAK priority, is enqueued to the priority queue before the crypto processor. The low latency queuing (LLQ) for IPsec encryption engines helps reduce packet latency for priority traffic.
- **IPsec QoS Pre-Classify**—QoS pre-classify is configured under a crypto map to enable IPsec to save the original Layer 3 and Layer 4 header before the encryption so that QoS can do the classification using the saved header.
- **QoS group-based LLQ**—The QoS group-based LLQ feature allows IPsec to check the LLQ QoS group setting to determine whether a packet is a high priority packet before it is enqueued to low latency queuing (LLQ).

How to Configure IPv6 IPsec QoS

Configuring Crypto LLQ QoS

When IPsec and QoS are configured on a physical interface and if the QoS policy has priority class, IPsec will classify the packet based on the policy attached to the interface. It will enqueue the packet matching

priority class into Low Latency Queue. The high-priority packet will be enqueued to low latency queuing (LLQ).

Perform this task to attach a service policy to the output interface and enable LLQ for IPsec encryption engines.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *physical-interface-name*
4. **ipv6 address** *{ipv6-address /prefix-length | prefix-name sub-bits/prefix-length}*
5. **service-policy output** *policy-map*
6. **ipv6 crypto map** *map-name*
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>physical-interface-name</i> Example: Device(config)# interface GigabitEthernet0/0/1	Specifies the interface using the LLQ for IPsec encryption engines.
Step 4	ipv6 address <i>{ipv6-address /prefix-length prefix-name sub-bits/prefix-length}</i> Example: Device(config-if)# ipv6 address 2001:DB8:FFFF::2/64	Configures an IPv6 address on an interface.
Step 5	service-policy output <i>policy-map</i> Example: Device(config-if)# service-policy output p1	Attaches the specified service policy map to the output interface and enables LLQ for IPsec encryption engines.
Step 6	ipv6 crypto map <i>map-name</i> Example: Device(config-if)# ipv6 crypto map CMAP_1	Enables an IPv6 crypto map on an interface.

	Command or Action	Purpose
Step 7	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring QoS Pre-classify

Configuring Pre-classify on the Crypto Map

The **qos pre-classify** command is applied on the crypto map, allowing configuration on a per-tunnel basis. QoS policy is applied to Packets based on the L3 and L4 Header before encryption.

Perform this task to apply the QoS pre-classify on the crypto map.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ipv6 crypto map *map-name***
4. **qos pre-classify**
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	ipv6 crypto map <i>map-name</i> Example: Device(config-if)# ipv6 crypto map CM_V6	Enters crypto map configuration mode and specifies the crypto map to be configured.
Step 4	qos pre-classify Example: Device(config-if)# qos pre-classify	Enables QoS pre-classify on the crypto map.

	Command or Action	Purpose
Step 5	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring Pre-classify on the Tunnel Interface

The **qos pre-classify** command is applied on the IPv6 IPsec tunnel interface, making QoS a configuration option on a per-tunnel basis.

Perform this task to apply the QoS pre-classify on the tunnel interface.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *tunnel-interface-name*
4. **ipv6 address** *{ipv6-address /prefix-length | prefix-name sub-bits/prefix-length}*
5. **qos pre-classify**
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>tunnel-interface-name</i> Example: Device(config)# interface Tunnel1	Enters interface configuration mode and specifies the tunnel or virtual interface to configure.
Step 4	ipv6 address <i>{ipv6-address /prefix-length prefix-name sub-bits/prefix-length}</i> Example: Device(config-if)# ipv6 address 2001:DB8:FFFF::2/64	Configures an IPv6 address on an interface.
Step 5	qos pre-classify Example:	Enables QoS pre-classify on the tunnel interface.

	Command or Action	Purpose
	<code>Device(config-if)# qos pre-classify</code>	
Step 6	end Example: <code>Device(config-if)# end</code>	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring LLQ QoS Group

The **platform ipsec llq qos-group** command enables low latency queuing for traffic that matches the QoS groups configured with this command.

Perform this task to enable LLQ for QoS groups.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **platform ipsec llq qos-group** *group-number*
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <code>Device> enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <code>Device# configure terminal</code>	Enters global configuration mode.
Step 3	platform ipsec llq qos-group <i>group-number</i> Example: <code>Device(config)# platform ipsec llq qos-group 1</code>	Specifies the QoS group to enable LLQ. Valid values are from 1 to 99.
Step 4	end Example: <code>Device(config-if)# end</code>	Exits interface configuration mode and returns to privileged EXEC mode.

Configuration Examples for QoS

Example: Configuring Crypto LLQ QoS

The following example shows how to specify the service policy map to the output interface and enable an IPv6 crypto map on an interface.

```
!
class-map match-all c2
  match precedence 5 6 7
class-map match-all c1
  match precedence 0 1 2 3

policy-map p1
  class c1
    priority percent 10
  class c2
    bandwidth remaining percent 3

crypto map ipv6 CMAP_1 1 ipsec-isakmp
  set peer address 2001:DB8:FFFF::1
  set transform-set ESP-3DES-SHA
  match address 102

interface GigabitEthernet0/0/1
  ipv6 address 2001:DB8:FFFF::2/64
  ipv6 crypto map CMAP_1
  service-policy output p1
```

Example: Configuring Pre-classify on the Crypto Map

The following example shows how to enable QoS pre-classification using the **qos pre-classify** command on the crypto map CM_V6.

```
!
crypto map ipv6 CM_V6 10 ipsec-isakmp
  match address ACL_IPV6_1
  set transform-set set1
  set peer 2001:DB8:FFFF::1
  qos pre-classify
!
interface GigabitEthernet0/0/1
  ipv6 address 2001:DB8:FFFF::2/64
  service-policy output policy1
  ipv6 crypto map CM_V6
```

Example: Configuring Pre-classify on the Tunnel Interface

The following example shows how to enable QoS pre-classification using the **qos pre-classify** command on the tunnel interface tunnel1.

```

interface GigabitEthernet1/1/2
  ipv6 address 2001:DB8:1::F/64
  service-policy output policy1
!
interface Tunnel1
  ipv6 address 2001:DB8:2::F/64
  qos pre-classify

CHAPTER 186

IPv6 Virtual Tunnel Interface

Cisco IOS IPv6 security features for your Cisco networking devices can protect your network against degradation or failure and also against data loss or compromise resulting from intentional attacks and from unintended but damaging mistakes by well-meaning network users.

Cisco IOS IPsec functionality provides network data encryption at the IP packet level, offering robust, standards-based security. IPsec provides data authentication and antireplay services in addition to data confidentiality services.

IPsec is a mandatory component of IPv6 specification. IPv6 IPsec tunnel mode and encapsulation is used to protect IPv6 unicast and multicast traffic. This document provides information about implementing IPsec in IPv6 security.

Information About IPv6 Virtual Tunnel Interface

IPsec for IPv6

IP Security, or IPsec, is a framework of open standards developed by the Internet Engineering Task Force (IETF) that provide security for transmission of sensitive information over unprotected networks such as the Internet. IPsec acts at the network layer, protecting and authenticating IP packets between participating IPsec devices (peers), such as Cisco routers. IPsec provides the following optional network security services. In general, local security policy will dictate the use of one or more of these services:

- Data confidentiality--The IPsec sender can encrypt packets before sending them across a network.
- Data integrity--The IPsec receiver can authenticate packets sent by the IPsec sender to ensure that the data has not been altered during transmission.
- Data origin authentication--The IPsec receiver can authenticate the source of the IPsec packets sent. This service depends upon the data integrity service.
- Antireplay--The IPsec receiver can detect and reject replayed packets.

With IPsec, data can be sent across a public network without observation, modification, or spoofing. IPsec functionality is similar in both IPv6 and IPv4; however, site-to-site tunnel mode only is supported in IPv6.

In IPv6, IPsec is implemented using the AH authentication header and the ESP extension header. The authentication header provides integrity and authentication of the source. It also provides optional protection against replayed packets. The authentication header protects the integrity of most of the IP header fields and authenticates the source through a signature-based algorithm. The ESP header provides confidentiality, authentication of the source, connectionless integrity of the inner packet, antireplay, and limited traffic flow confidentiality.

The Internet Key Exchange (IKE) protocol is a key management protocol standard that is used in conjunction with IPsec. IPsec can be configured without IKE, but IKE enhances IPsec by providing additional features, flexibility, and ease of configuration for the IPsec standard.

IKE is a hybrid protocol that implements the Oakley key exchange and Skeme key exchange inside the Internet Security Association Key Management Protocol (ISAKMP) framework (ISAKMP, Oakley, and Skeme are security protocols implemented by IKE) (see the figure below). This functionality is similar to the security gateway model using IPv4 IPsec protection.

IPv6 IPsec Site-to-Site Protection Using Virtual Tunnel Interface

The IPsec virtual tunnel interface (VTI) provides site-to-site IPv6 crypto protection of IPv6 traffic. Native IPv6 IPsec encapsulation is used to protect all types of IPv6 unicast and multicast traffic.

The IPsec VTI allows IPv6 routers to work as security gateways, establish IPsec tunnels between other security gateway routers, and provide crypto IPsec protection for traffic from internal networks when it is sent across the public IPv6 Internet (see the figure below). This functionality is similar to the security gateway model using IPv4 IPsec protection.

Figure 94: IPsec Tunnel Interface for IPv6

When the IPsec tunnel is configured, IKE and IPsec security associations (SAs) are negotiated and set up before the line protocol for the tunnel interface is changed to the UP state. The remote IKE peer is the same as the tunnel destination address; the local IKE peer will be the address picked from tunnel source interface which has the same IPv6 address scope as tunnel destination address.

The following figures shows the IPsec packet format.

Figure 95: IPv6 IPsec Packet Format

How to Configure IPv6 Virtual Tunnel Interface

Configuring a VTI for Site-to-Site IPv6 IPsec Protection

Defining an IKE Policy and a Preshared Key in IPv6

Because IKE negotiations must be protected, each IKE negotiation begins by agreement of both peers on a common (shared) IKE policy. This policy states which security parameters will be used to protect subsequent IKE negotiations and mandates how the peers are authenticated.

After the two peers agree upon a policy, the security parameters of the policy are identified by an SA established at each peer, and these SAs apply to all subsequent IKE traffic during the negotiation.

You can configure multiple, prioritized policies on each peer--each with a different combination of parameter values. However, at least one of these policies must contain exactly the same encryption, hash, authentication, and Diffie-Hellman parameter values as one of the policies on the remote peer. For each policy that you create, you assign a unique priority (1 through 10,000, with 1 being the highest priority).

Note If you are interoperating with a device that supports only one of the values for a parameter, your choice is limited to the value supported by the other device. Aside from this limitation, there is often a trade-off between security and performance, and many of these parameter values represent such a trade-off. You should evaluate the level of security risks for your network and your tolerance for these risks.

When the IKE negotiation begins, IKE searches for an IKE policy that is the same on both peers. The peer that initiates the negotiation will send all its policies to the remote peer, and the remote peer will try to find a match. The remote peer looks for a match by comparing its own highest priority policy against the policies received from the other peer. The remote peer checks each of its policies in order of its priority (highest priority first) until a match is found.

A match is made when both policies from the two peers contain the same encryption, hash, authentication, and Diffie-Hellman parameter values, and when the remote peer's policy specifies a lifetime that is less than or equal to the lifetime in the policy being compared. (If the lifetimes are not identical, the shorter lifetime--from the remote peer's policy--will be used.)

If a match is found, IKE will complete negotiation, and IPsec security associations will be created. If no acceptable match is found, IKE refuses negotiation and IPsec will not be established.

Note Depending on which authentication method is specified in a policy, additional configuration might be required. If a peer's policy does not have the required companion configuration, the peer will not submit the policy when attempting to find a matching policy with the remote peer.

You should set the ISAKMP identity for each peer that uses preshared keys in an IKE policy.

When two peers use IKE to establish IPsec SAs, each peer sends its identity to the remote peer. Each peer sends either its hostname or its IPv6 address, depending on how you have set the ISAKMP identity of the router.

By default, a peer's ISAKMP identity is the IPv6 address of the peer. If appropriate, you could change the identity to be the peer's hostname instead. As a general rule, set the identities of all peers the same way--either all peers should use their IPv6 addresses or all peers should use their hostnames. If some peers use their hostnames and some peers use their IPv6 addresses to identify themselves to each other, IKE negotiations could fail if the identity of a remote peer is not recognized and a DNS lookup is unable to resolve the identity.

Perform this task to create an IKE policy and a preshared key in IPv6.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp policy** *priority*
4. **authentication** {*rsa-sig* | *rsa-encr* | **pre-share**}
5. **hash** {*sha* | **md5**}
6. **group** {**1** | **2** | **5**}
7. **encryption** {*des* | **3des** | **aes** | **aes 192** | **aes 256**}
8. **lifetime** *seconds*
9. **exit**
10. **crypto isakmp key** *password-type* *keystring* *keystring* { **address** *peer-address* | **ipv6** {*ipv6-address* / *ipv6-prefix*} | **hostname** *hostname*} [**no-xauth**]
11. **crypto keyring** *keyring-name* [**vrf** *vrf-name*]
12. **pre-shared-key** {**address** *address* [*mask*] | **hostname** *hostname* | **ipv6** {*ipv6-address* | *ipv6-prefix*}}
key *key*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto isakmp policy <i>priority</i> Example: <pre>Router(config)# crypto isakmp policy 15</pre>	Defines an IKE policy, and enters ISAKMP policy configuration mode. <ul style="list-style-type: none"> Policy number 1 indicates the policy with the highest priority. The smaller the <i>priority</i> argument value, the higher the priority.
Step 4	authentication { <i>rsa-sig</i> <i>rsa-encr</i> <i>pre-share</i> } Example: <pre>Router(config-isakmp-policy)# authentication pre-share</pre>	Specifies the authentication method within an IKE policy. <ul style="list-style-type: none"> The <i>rsa-sig</i> and <i>rsa-encr</i> keywords are not supported in IPv6.
Step 5	hash { <i>sha</i> <i>md5</i> } Example: <pre>Router(config-isakmp-policy)# hash md5</pre>	Specifies the hash algorithm within an IKE policy.
Step 6	group { <i>1</i> <i>2</i> <i>5</i> } Example: <pre>Router(config-isakmp-policy)# group 2</pre>	Specifies the Diffie-Hellman group identifier within an IKE policy.
Step 7	encryption { <i>des</i> <i>3des</i> <i>aes</i> <i>aes 192</i> <i>aes 256</i> } Example: <pre>Router(config-isakmp-policy)# encryption 3des</pre>	Specifies the encryption algorithm within an IKE policy.
Step 8	lifetime <i>seconds</i> Example: <pre>Router(config-isakmp-policy)# lifetime 43200</pre>	Specifies the lifetime of an IKE SA. <ul style="list-style-type: none"> Setting the IKE lifetime value is optional.
Step 9	exit Example: <pre>Router(config-isakmp-policy)# exit</pre>	Exits ISAKMP policy configuration mode and enter global configuration mode.
Step 10	crypto isakmp key <i>password-type</i> <i>keysting</i> <i>keysting</i> { address <i>peer-address</i> } ipv6 { <i>ipv6-address</i> / <i>ipv6-prefix</i> } hostname <i>hostname</i> } [no-xauth] Example: <pre>Router(config)# crypto isakmp key 0 my-preshare-key-0 address ipv6 3ffe:1001::2/128</pre>	Configures a preshared authentication key.
Step 11	crypto keyring <i>keyring-name</i> [vrf <i>fvrif-name</i>] Example:	Defines a crypto keyring to be used during IKE authentication and enters config-keyring mode.

	Command or Action	Purpose
	Router(config)# crypto keyring keyring1	
Step 12	<p>pre-shared-key {address <i>address</i> [<i>mask</i>] hostname <i>hostname</i> ipv6 {<i>ipv6-address</i> <i>ipv6-prefix</i>}} key <i>key</i></p> <p>Example:</p> <pre>Router (config-keyring)# pre-shared-key ipv6 3FFE:2002::A8BB:CCFF:FE01:2C02/128</pre>	Defines a preshared key to be used for IKE authentication.

Configuring ISAKMP Aggressive Mode

You likely do not need to configure aggressive mode in a site-to-site scenario. The default mode is typically used.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp peer** {address {*ipv4-address* | **ipv6** *ipv6-address* *ipv6-prefix-length*} | hostname *fqdn-hostname*}
4. **set aggressive-mode client-endpoint** {*client-endpoint* | **ipv6** *ipv6-address*}
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	<p>crypto isakmp peer {address {<i>ipv4-address</i> ipv6 <i>ipv6-address</i> <i>ipv6-prefix-length</i>} hostname <i>fqdn-hostname</i>}</p> <p>Example:</p> <pre>Router(config)# crypto isakmp peer address ipv6 3FFE:2002::A8BB:CCFF:FE01:2C02/128</pre>	Enables an IPsec peer for IKE querying for tunnel attributes.
Step 4	<p>set aggressive-mode client-endpoint {<i>client-endpoint</i> ipv6 <i>ipv6-address</i>}</p> <p>Example:</p>	Defines the remote peer's IPv6 address, which will be used by aggressive mode negotiation. The remote peer's address is usually the client side's end-point address.

	Command or Action	Purpose
	<pre>Router(config-isakmp-peer)# set aggressive mode client-endpoint ipv6 3FFE:2002::A8BB:CCFF:FE01:2C02/128</pre>	
Step 5	<p>end</p> <p>Example:</p> <pre>Router(config-isakmp-peer)# end</pre>	Exits crypto ISAKMP peer configuration mode and returns to privileged EXEC mode.

Defining an IPsec Transform Set and IPsec Profile

Perform this task to define an IPsec transform set. A transform set is a combination of security protocols and algorithms that is acceptable to the IPsec routers.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec transform-set** *transform-set-name transform1* [*transform2*] [*transform3*] [*transform4*]
4. **crypto ipsec profile** *name*
5. **set transform-set** *transform-set-name* [*transform-set-name2...transform-set-name6*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	<p>crypto ipsec transform-set <i>transform-set-name transform1</i> [<i>transform2</i>] [<i>transform3</i>] [<i>transform4</i>]</p> <p>Example:</p> <pre>Router(config)# crypto ipsec transform-set myset0 ah-sha-hmac esp-3des</pre>	Defines a transform set, and places the router in crypto transform configuration mode.
Step 4	<p>crypto ipsec profile <i>name</i></p> <p>Example:</p> <pre>Router(config)# crypto ipsec profile profile0</pre>	Defines the IPsec parameters that are to be used for IPsec encryption between two IPsec routers.

	Command or Action	Purpose
Step 5	set transform-set <i>transform-set-name</i> [<i>transform-set-name2...transform-set-name6</i>] Example: Router (config-crypto-transform)# set-transform-set myset0	Specifies which transform sets can be used with the crypto map entry.

Defining an ISAKMP Profile in IPv6

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp profile** *profile-name* [**accounting** *aaalist*]
4. **self-identity** {**address** | **address ipv6**] | **fqdn** | **user-fqdn** *user-fqdn*}
5. **match identity** {**group** *group-name* | **address** {*address* [*mask*] [*fvrfl*] | **ipv6** *ipv6-address*} | **host** *host-name* | **host domain** *domain-name* | **user** *user-fqdn* | **user domain** *domain-name*}
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp profile <i>profile-name</i> [accounting <i>aaalist</i>] Example: Router(config)# crypto isakmp profile profile1	Defines an ISAKMP profile and audits IPsec user sessions.
Step 4	self-identity { address address ipv6] fqdn user-fqdn <i>user-fqdn</i> }	Defines the identity that the local IKE uses to identify itself to the remote peer.
	Example: Router(config-isakmp-profile)# self-identity address ipv6	

	Command or Action	Purpose
Step 5	<p>match identity {group <i>group-name</i> address {<i>address</i> [<i>mask</i>] [<i>vrf</i>] ipv6 <i>ipv6-address</i>} host <i>host-name</i> host domain <i>domain-name</i> user <i>user-fqdn</i> user domain <i>domain-name</i>}</p> <p>Example:</p> <pre>Router(config-isakmp-profile)# match identity address ipv6 3FFE:2002::A8BB:CCFF:FE01:2C02/128</pre>	Matches an identity from a remote peer in an ISAKMP profile.
Step 6	<p>end</p> <p>Example:</p> <pre>Router(config-isakmp-profile)# end</pre>	Exits ISAKMP profile configuration mode and returns to privileged EXEC mode.

Configuring IPv6 IPsec VTI

Before you begin

Use the **ipv6 unicast-routing** command to enable IPv6 unicast routing.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ipv6 unicast-routing**
4. **interface tunnel** *tunnel-number*
5. **ipv6 address** *ipv6-address/prefix*
6. **ipv6 enable**
7. **tunnel source** {*ip-address* | *ipv6-address* | *interface-type interface-number*}
8. **tunnel destination** {*host-name* | *ip-address* | *ipv6-address*}
9. **tunnel mode** {**aurp** | **cayman** | **dvmrp** | **eon** | **gre** | **gre multipoint** | **gre ipv6** | **ipip** [**decapsulate-any**] | **ipsec ipv4** | **iptalk** | **ipv6** | **ipsec ipv6** | **mpls** | **nos** | **rbscp**}
10. **tunnel protection ipsec profile** *name* [**shared**]
11. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p>	Enters global configuration mode.

	Command or Action	Purpose
	Router# configure terminal	
Step 3	ipv6 unicast-routing Example: Router(config)# ipv6 unicast-routing	Enables IPv6 unicast routing. You only need to enable IPv6 unicast routing once, not matter how many interface tunnels you want to configure.
Step 4	interface tunnel <i>tunnel-number</i> Example: Router(config)# interface tunnel 0	Specifies a tunnel interface and number, and enters interface configuration mode.
Step 5	ipv6 address <i>ipv6-address/prefix</i> Example: Router(config-if)# ipv6 address 3FFE:C000:0:7::/64 eui-64	Provides an IPv6 address to this tunnel interface, so that IPv6 traffic can be routed to this tunnel.
Step 6	ipv6 enable Example: Router(config-if)# ipv6 enable	Enables IPv6 on this tunnel interface.
Step 7	tunnel source {<i>ip-address</i> <i>ipv6-address</i> <i>interface-type interface-number</i>} Example: Router(config-if)# tunnel source ethernet0	Sets the source address for a tunnel interface.
Step 8	tunnel destination {<i>host-name</i> <i>ip-address</i> <i>ipv6-address</i>} Example: Router(config-if)# tunnel destination 2001:DB8:1111:2222::1	Specifies the destination for a tunnel interface.
Step 9	tunnel mode {<i>aurp</i> <i>cayman</i> <i>dvmrp</i> <i>eon</i> <i>gre</i> gre multipoint gre ipv6 ipip [<i>decapsulate-any</i>] ipsec ipv4 <i>iptalk</i> <i>ipv6</i> ipsec ipv6 <i>mpls</i> <i>nos</i> <i>rbscp</i>} Example: Router(config-if)# tunnel mode ipsec ipv6	Sets the encapsulation mode for the tunnel interface. For IPsec, only the ipsec ipv6 keywords are supported.
Step 10	tunnel protection ipsec profile <i>name</i> [<i>shared</i>] Example: Router(config-if)# tunnel protection ipsec profile profile1	Associates a tunnel interface with an IPsec profile. IPv6 does not support the shared keyword.

	Command or Action	Purpose
Step 11	end Example: Router(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Verifying IPsec Tunnel Mode Configuration

SUMMARY STEPS

1. **show adjacency** [**summary** [*interface-type interface-number*]] | [**prefix**] [**interface** *interface-number*] [**connectionid** *id*] [**link** {**ipv4** **ipv6** | **mpls**}] [**detail**]
2. **show crypto engine** {**accelerator** | **brief** | **configuration** | **connections** [**active** | **dh** | **dropped-packet** | **show**] | **qos**}
3. **show crypto ipsec sa** [**ipv6**] [*interface-type interface-number*] [**detailed**]
4. **show crypto isakmp peer** [**config** | **detail**]
5. **show crypto isakmp policy**
6. **show crypto isakmp profile** [**tag** *profilename* | **vrf** *vrfname*]
7. **show crypto map** [**interface** *interface* | **tag** *map-name*]
8. **show crypto session** [**detail**] | [**local** *ip-address* [**port** *local-port*]] | [**remote** *ip-address* [**port** *remote-port*]] | [**detail**] | [**fvfr** *vrf-name* | **ivrf** *vrf-name*]
9. **show crypto socket**
10. **show ipv6 access-list** [*access-list-name*]
11. **show ipv6 cef** [*ipv6-prefix / prefix-length*] | [*interface-type interface-number*] [**longer-prefixes** | **similar-prefixes** | **detail** | **internal** | **platform** | **epoch** | **source**]
12. **show interface** *type number* **stats**

DETAILED STEPS

	Command or Action	Purpose
Step 1	show adjacency [summary [<i>interface-type interface-number</i>]] [prefix] [interface <i>interface-number</i>] [connectionid <i>id</i>] [link { ipv4 ipv6 mpls }] [detail] Example: Router# show adjacency detail	Displays information about the Cisco Express Forwarding adjacency table or the hardware Layer 3-switching adjacency table.
Step 2	show crypto engine { accelerator brief configuration connections [active dh dropped-packet show] qos } Example: Router# show crypto engine connection active	Displays a summary of the configuration information for the crypto engines.
Step 3	show crypto ipsec sa [ipv6] [<i>interface-type interface-number</i>] [detailed]	Displays the settings used by current SAs in IPv6.

	Command or Action	Purpose
	Example: <pre>Router# show crypto ipsec sa ipv6</pre>	
Step 4	show crypto isakmp peer [<i>config</i> <i>detail</i>] Example: <pre>Router# show crypto isakmp peer detail</pre>	Displays peer descriptions.
Step 5	show crypto isakmp policy Example: <pre>Router# show crypto isakmp policy</pre>	Displays the parameters for each IKE policy.
Step 6	show crypto isakmp profile [<i>tag profilename</i> <i>vrf vrfname</i>] Example: <pre>Router# show crypto isakmp profile</pre>	Lists all the ISAKMP profiles that are defined on a router.
Step 7	show crypto map [<i>interface interface</i> <i>tag map-name</i>] Example: <pre>Router# show crypto map</pre>	Displays the crypto map configuration. The crypto maps shown in this command output are dynamically generated. The user does not have to configure crypto maps.
Step 8	show crypto session [<i>detail</i>] [<i>local ip-address</i> [<i>port local-port</i>] [<i>remote ip-address</i> [<i>port remote-port</i>]] <i>detail</i>] <i>fvfr vrf-name</i> <i>ivrf vrf-name</i>] Example: <pre>Router# show crypto session</pre>	Displays status information for active crypto sessions. IPv6 does not support the fvfr or ivrf keywords or the <i>vrf-name</i> argument.
Step 9	show crypto socket Example: <pre>Router# show crypto socket</pre>	Lists crypto sockets.
Step 10	show ipv6 access-list [<i>access-list-name</i>] Example: <pre>Router# show ipv6 access-list</pre>	Displays the contents of all current IPv6 access lists.
Step 11	show ipv6 cef [<i>ipv6-prefix / prefix-length</i>] [<i>interface-type interface-number</i>] [<i>longer-prefixes</i> <i>similar-prefixes</i> <i>detail</i> <i>internal</i> <i>platform</i> <i>epoch</i> <i>source</i>] Example: <pre>Router# show ipv6 cef</pre>	Displays entries in the IPv6 Forwarding Information Base (FIB).

	Command or Action	Purpose
Step 12	show interface <i>type number</i> stats Example: Router# show interface fddi 3/0/0 stats	Displays numbers of packets that were process switched, fast switched, and distributed switched.

Troubleshooting IPsec for IPv6 Configuration and Operation

SUMMARY STEPS

1. enable
2. debug crypto ipsec
3. debug crypto engine packet [detail]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	debug crypto ipsec Example: Router# debug crypto ipsec	Displays IPsec network events.
Step 3	debug crypto engine packet [detail] Example: Router# debug crypto engine packet	Displays the contents of IPv6 packets. Caution Using this command could flood the system and increase CPU usage if several packets are being encrypted.

Configuration Examples for IPv6 Virtual Tunnel Interface

Example: Configuring a VTI for Site-to-Site IPv6 IPsec Protection

```

crypto isakmp policy 1
  encryption aes
  authentication pre-share
  group 14
!
crypto isakmp key myPreshareKey0 address ipv6 3FFE:2002::A8BB:CCFF:FE01:2C02/128
crypto isakmp keepalive 30 30
!

```

```

crypto ipsec transform-set Trans1 ah-sha-hmac esp-aes
!
crypto ipsec profile profile0
  set transform-set Trans1
!
ipv6 cef
!
interface Tunnel0
  ipv6 address 3FFE:1001::/64 eui-64
  ipv6 enable
  ipv6 cef
  tunnel source Ethernet2/0
  tunnel destination 3FFE:2002::A8BB:CCFF:FE01:2C02
  tunnel mode ipsec ipv6
  tunnel protection ipsec profile profile0

CHAPTER 187

IP Security VPN Monitoring

The IP Security VPN Monitoring feature provides VPN session monitoring enhancements that will allow you to troubleshoot the Virtual Private Network (VPN) and monitor the end-user interface. Session monitoring enhancements include the following:

- Ability to specify an Internet Key Exchange (IKE) peer description in the configuration file
- Summary listing of crypto session status
- Syslog notification for crypto session up or down status
- Ability to clear both IKE and IP Security (IPsec) security associations (SAs) using one command-line interface (CLI)
- [Prerequisites for IP Security VPN Monitoring, on page 2421](#)
- [Restrictions for IP Security VPN Monitoring, on page 2421](#)
- [Information About IPsec VPN Monitoring, on page 2422](#)
- [How to Configure IP Security VPN Monitoring, on page 2423](#)
- [Configuration Examples for IP Security VPN Monitoring, on page 2426](#)
- [Additional References, on page 2426](#)
- [Feature Information for IP Security VPN Monitoring, on page 2427](#)

Prerequisites for IP Security VPN Monitoring

- You should be familiar with IPsec and encryption.
- Your router must support IPsec, and before using the IP Security VPN Monitoring feature, you must have configured IPsec on your router.

Restrictions for IP Security VPN Monitoring

- You must be running Cisco IOS XE k8 or k9 crypto images on your router.

Information About IPsec VPN Monitoring

Background Crypto Sessions

A crypto session is a set of IPsec connections (flows) between two crypto endpoints. If the two crypto endpoints use IKE as the keying protocol, they are IKE peers to each other. Typically, a crypto session consists of one IKE security association (for control traffic) and at least two IPsec security associations (for data traffic--one per each direction). There may be duplicated IKE security associations (SAs) and IPsec SAs or duplicated IKE SAs or IPsec SAs for the same session in the duration of rekeying or because of simultaneous setup requests from both sides.

Per-IKE Peer Description

The Per-IKE Peer Description function allows you to enter a description of your choosing for an IKE peer. The unique peer description, which can include up to 80 characters, can be used whenever you are referencing that particular IKE peer. To add the peer description, use the **description** command.

Note IKE peers that “sit” behind a Network Address Translation (NAT) device cannot be uniquely identified; therefore, they have to share the same peer description.

The primary application of this description field is for monitoring purposes (for example, when using **show** commands or for logging [syslog messages]). The description field is purely informational (for example, it cannot act as a substitute for the peer address or FQDN when defining crypto maps).

Summary Listing of Crypto Session Status

You can get a list of all the active VPN sessions by entering the **show crypto session** command. The listing will include the following:

- Interface
- IKE peer description, if available
- IKE SAs that are associated with the peer by whom the IPsec SAs are created
- IPsec SAs serving the flows of a session

Multiple IKE or IPsec SAs may be established for the same peer (for the same session), in which case IKE peer descriptions will be repeated with different values for the IKE SAs that are associated with the peer and for the IPsec SAs that are serving the flows of the session.

You can also use the **show crypto session detail** variant of this command to obtain more detailed information about the sessions.

Syslog Notification for Crypto Session Up or Down Status

The Syslog Notification for Crypto Session Up or Down Status function provides syslog notification every time the crypto session comes up or goes down.

The following is a sample syslog notification showing that a crypto session is up:

```
%CRYPTO-5-SESSION_STATUS: Crypto session is UP. Peer 10.6.6.1:500 fvrf=name10 ivrf=name20
Description: SJC24-2-VPN-Gateway Id: 10.5.5.2
```

The following is a sample syslog notification showing that a crypto session is down:

```
%CRYPTO-5-SESSION_STATUS: Crypto session is DOWN. Peer 10.6.6.1:500 fvrf=name10 ivrf=name20
Description: SJC24-2-VPN-Gateway Id: 10.5.5.2
```

IKE and IPsec Security Exchange Clear Command

The **clear crypto session** command allows you to clear both IKE and IPsec with a single command. To clear a specific crypto session or a subset of all the sessions (for example, a single tunnel to one remote site), you need to provide session-specific parameters, such as a local or remote IP address, a local or remote port, a front door VPN routing and forwarding (FVRF) name, or an inside VRF (IVRF) name. Typically, the remote IP address will be used to specify a single tunnel to be deleted.

If a local IP address is provided as a parameter when you use the **clear crypto session** command, all the sessions (and their IKE SAs and IPsec SAs) that share the IP address as a local crypto endpoint (IKE local address) will be cleared. If you do not provide a parameter when you use the **clear crypto session** command, all IPsec SAs and IKE SAs that are in the router will be deleted.

How to Configure IP Security VPN Monitoring

Adding the Description of an IKE Peer

To add the description of an IKE peer to an IPsec VPN session, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp peer {ip-address ip-address}**
4. **description**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp peer {ip-address ip-address} Example: Router (config)# crypto isakmp peer address 10.2.2.9	Enables an IPsec peer for IKE querying of authentication, authorization, and accounting (AAA) for tunnel attributes in aggressive mode and enters ISAKMP peer configuration mode.
Step 4	description Example: Router (config-isakmp-peer)# description connection from site A	Adds a description for an IKE peer.

Verifying Peer Descriptions

To verify peer descriptions, use the **show crypto isakmp peer** command.

SUMMARY STEPS

1. **enable**
2. **show crypto isakmp peer**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto isakmp peer Example: Router# show crypto isakmp peer	Displays peer descriptions.

Examples

The following output example verifies that the description “connection from site A” has been added for IKE peer 10.2.2.9:

```
Router# show crypto isakmp peer
Peer: 10.2.2.9 Port: 500
```

```
Description: connection from site A
flags: PEER_POLICY
```

When the peer at address 10.2.2.9 connects and the session comes up, the syslog status will be shown as follows:

```
%CRYPTO-5-SESSION_STATUS: Crypto tunnel is UP. Peer 10.2.2.9:500 Description: connection
from site A Id: ezvpn
```

The following output example verifies that the description “connection from site A” has been added for IKE peer 10.2.2.9:

```
Router# show crypto isakmp peer
Peer: 10.2.2.9 Port: 500
Description: connection from site A
flags: PEER_POLICY
```

When the peer at address 10.2.2.9 connects and the session comes up, the syslog status will be shown as follows:

```
%CRYPTO-5-SESSION_STATUS: Crypto tunnel is UP. Peer 10.2.2.9:500 Description: connection
from site A Id: ezvpn
```

Clearing a Crypto Session

To clear a crypto session, use the **clear crypto session** command from the router command line. No configuration statements are required in the configuration file to use this command.

SUMMARY STEPS

1. **enable**
2. **clear crypto session**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	clear crypto session Example: Router# clear crypto session	Deletes crypto sessions (IPSec and IKE SAs).

Configuration Examples for IP Security VPN Monitoring

show crypto session Command Output Examples

The following is sample output for the **show crypto session** output without the **detail** keyword:

```
Router# show crypto session
Crypto session current status
Interface: FastEthernet0/1
Session status: UP-ACTIVE
Peer: 172.0.0.2/500
  IKE SA: local 172.0.0.1/500 remote 172.0.0.2/500 Active
  IPSEC FLOW: permit ip 10.10.10.0/255.255.255.0 10.30.30.0/255.255.255.0
    Active SAs: 2, origin: crypto map
```

The following is sample output using the **show crypto session command and the detail** keyword:

```
Router# show crypto session detail
Interface: Tunnel0
Session status: UP-ACTIVE
Peer: 10.1.1.3 port 500 fvrf: (none) ivrf: (none)
  Desc: this is my peer at 10.1.1.3:500 Green
  Phase1_id: 10.1.1.3
  IKE SA: local 10.1.1.4/500 remote 10.1.1.3/500 Active
    Capabilities:(none) connid:3 lifetime:22:03:24
  IPSEC FLOW: permit 47 host 10.1.1.4 host 10.1.1.3
    Active SAs: 0, origin: crypto map
    Inbound: #pkts dec'ed 0 drop 0 life (KB/Sec) 0/0
    Outbound: #pkts enc'ed 0 drop 0 life (KB/Sec) 0/0
  IPSEC FLOW: permit ip host 10.1.1.4 host 10.1.1.3
    Active SAs: 4, origin: crypto map
    Inbound: #pkts dec'ed 4 drop 0 life (KB/Sec) 4605665/2949
    Outbound: #pkts enc'ed 4 drop 1 life (KB/Sec) 4605665/2949
```

Feature Information for IP Security VPN Monitoring

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 251: Feature Information for IP Security VPN Monitoring

Feature Name	Releases	Feature Information
IP Security VPN Monitoring	Cisco IOS XE Release 2.1	<p>The IP Security VPN Monitoring feature provides VPN session monitoring enhancements that will allow you to troubleshoot the VPN and monitor the end-user interface. Session monitoring enhancements include the following:</p> <ul style="list-style-type: none"> • Ability to specify an IKE peer description in the configuration file • Summary listing of crypto session status • Syslog notification for crypto session up or down status <p>Ability to clear both IKE and IPsec SAs using one CLI</p> <ul style="list-style-type: none"> • The following commands were introduced or modified: clear crypto session, description (isakmp peer), show crypto isakmp peer, show crypto session.

CHAPTER 188

IPsec and IKE MIB Support for Cisco VRF-Aware IPsec

The IPsec and IKE MIB Support for the Virtual Private Network routing and forwarding- (VRF-) aware IP security (IPsec) feature allows VRF-aware IPsec to be managed with MIBs, which provide the details of IPsec statistics and performance metrics on a per VRF basis.

- [Prerequisites for IPsec and IKE MIB Support for Cisco VRF-Aware IPsec, on page 2429](#)
- [Information About IPsec and IKE MIB Support for Cisco VRF-Aware IPsec, on page 2429](#)
- [How to Configure IPsec and IKE MIB Support for Cisco VRF-Aware IPsec, on page 2430](#)
- [Configuration Example for IPsec and IKE MIB Support for Cisco VRF-Aware IPsec, on page 2431](#)
- [Additional References, on page 2443](#)
- [Feature Information for IPsec and IKE MIB Support for Cisco VRF-Aware IPsec, on page 2444](#)

Prerequisites for IPsec and IKE MIB Support for Cisco VRF-Aware IPsec

- You should be familiar with configuring Simple Network Management Protocol (SNMP).

Information About IPsec and IKE MIB Support for Cisco VRF-Aware IPsec

MIBs Supported by the IPsec and IKE MIB Support for Cisco VRF-Aware IPsec Feature

- CISCO-IPSEC-FLOW-MONITOR-MIB supports IKE and IPSEC per-tunnel history and failure information. The length of this history and failure information can be configured and must be maintained on a per-VRF basis. The table sizes are controlled by using the **crypto mib ipsec flowmib history tunnel size number** and **crypto mib ipsec flowmib history failure size** commands in global configuration mode.

- CISCO-IPSEC-MIB
- CISCO-IPSEC-POLICY-MAP-MIB is supported. However, because this MIB applies to the entire router rather than to a specific VPN VRF instance, it is not VRF aware; therefore, polling of the object identifiers (OIDs) that belong to this MIB is accomplished with respect to the global VRF context.

SNMP Traps Supported by the IPsec and IKE MIB Support for Cisco VRF-Aware IPsec Feature

The following IKE and IPsec tunnel start and stop traps must go with their corresponding VRF:

- IPSEC_TUNNEL_STOP
- IKE_TUNNEL_STOP
- IPSEC_TUNNEL_START
- IKE_TUNNEL_START

The following traps are global traps that have been modified for the Cisco VRF-Aware IPsec feature:

- TOO_MANY_SAS_CREATED
- CRYPTOMAP_ADDED
- CRYPTOMAPSET_ATTACHED
- CRYPTOMAP_DELETED
- CRYPTOMAPSET_DELETED
- ISAKMP_POLICY_ADDED
- ISAKMP_POLICY_DELETED

How to Configure IPsec and IKE MIB Support for Cisco VRF-Aware IPsec

No special configuration is needed for this feature. The SNMP framework can be used to manage VRF-aware IPsec using MIBs. See the Configuration Examples for IPsec and IKE MIB Support for Cisco VRF-Aware IPsec section for more information.

The following section provides information about troubleshooting this feature:

How to Troubleshoot the IPsec and IKE MIB Support for Cisco VRF-Aware IPsec Feature

The following **debug crypto mib** command and keywords may be used to display information about the IPsec and Internet Key Exchange (IKE) MIB as it relates to Cisco VRF-aware IPsec.

SUMMARY STEPS

1. **enable**
2. **debug crypto mib detail**
3. **debug crypto mib error**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	debug crypto mib detail Example: Router# debug crypto mib detail	Displays different events as they occur in the IPsec MIB subsystem. <ul style="list-style-type: none"> • Due consideration should be given to enabling debug crypto mib detail because the output for the detail keyword can be quite long.
Step 3	debug crypto mib error Example: Router# debug crypto mib error	Displays error events in the MIB agent.

Configuration Example for IPsec and IKE MIB Support for Cisco VRF-Aware IPsec

Configuration That Has Two VRFs Examples

The following output example is for a typical hub configuration that has two VRFs. The output is what you would see if you were to poll for the IPsec security association (SA). Router 3745b is the VRF-aware router.

Two VRFs Configured

The following output shows that two VRFs have been configured (vrf1 and vrf2).

```
Router3745b# show running-config

Both VRFs Cleared

The following output, for abc1 and abc2, shows that both VRFs have been “cleared” to ensure that all the counters are initialized to a known value.

The following output shows that VRF abc1 has been cleared:

```

VRF abc1 Pinged

The following output shows that VRF abc1 has been pinged:

```

Router3745a# ping
Protocol [ip]:
Target IP address: 10.22.1.1
Repeat count [5]:
Datagram size [100]:
Timeout in seconds [2]:
Extended commands [n]: y
Source address or interface: 10.20.1.1
Type of service [0]:
Set DF bit in IP header? [no]:
Validate reply data? [no]:
Data pattern [0xABCD]:
Loose, Strict, Record, Timestamp, Verbose[none]:
Sweep range of sizes [n]:
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.22.1.1, timeout is 2 seconds:
Packet sent with a source address of 10.20.1.1

```

VRF abc1 Polled

Polling VRF abc1 results in the following output:

Note After the ping, the counters should show some nonzero values.

```

CHAPTER 189

IPsec SNMP Support

The IP Security (IPsec) SNMP Support feature introduces support for industry-standard IPsec MIBs and Cisco IOS XE-software specific IPsec MIBs.

The commands in this feature allow you to examine the version of the IPsec MIB feature, to enable and disable SNMP traps, and to monitor and control the size of the buffers used by this feature.

Note This document focuses on Cisco IOS XE CLI support for the Cisco IPsec MIBs. This document also lists which elements of the MIBs are currently supported. This document does not describe SNMP configuration (from a Network Management Station) of the Cisco IPsec MIBs.

- [Restrictions for IPsec SNMP Support, on page 2447](#)
- [Information About IPsec SNMP Support, on page 2448](#)
- [How to Configure IPsec SNMP Support, on page 2448](#)
- [Configuration Examples for IPsec SNMP Support, on page 2452](#)
- [Additional References, on page 2453](#)
- [Feature Information for IPsec SNMP Support, on page 2454](#)
- [Glossary, on page 2454](#)

Restrictions for IPsec SNMP Support

- Only the following tunnel setup failure logs are supported with the IPsec--SNMP Support feature:
 - NOTIFY_MIB_IPSEC_PROPOSAL_INVALID
 - “A tunnel could not be established because the peer did not supply an acceptable proposal.”
 - NOTIFY_MIB_IPSEC_ENCRYPT_FAILURE
 - “A tunnel could not be established because it failed to encrypt a packet to be sent to a peer.”
 - NOTIFY_MIB_IPSEC_SYSCAP_FAILURE
 - “A tunnel could not be established because the system ran out of resources.”
 - NOTIFY_MIB_IPSEC_LOCAL_FAILURE
 - “A tunnel could not be established because of an internal error.”

Note that these failure notices are recorded in the failure tables, but are not available as SNMP notifications (traps).

- The following functions are not supported with the IPsec MIB feature:
 - Checkpointing
 - The Dynamic Cryptomap table of the CISCO-IPSEC-MIB
- The CISCO-IPSEC-POLICY-MAP-MIB (ciscoIpSecPolMap) defines no notifications (the “IPSec Policy Map Notifications Group” is empty).

Information About IPsec SNMP Support

The IP Security (IPsec) SNMP Support feature introduces support for industry-standard IPsec MIBs and Cisco IOS XE-software specific IPsec MIBs.

The IPsec MIBs allow IPsec configuration monitoring and IPsec status monitoring using SNMP, and can be integrated in a variety of Virtual Private Network (VPN) management solutions.

For example, this feature allows you to specify the desired size of a tunnel history table or a tunnel failure table using the Cisco IOS XE CLI. The history table archives attribute and statistic information about the tunnel; the failure table archives tunnel failure reasons along with the time failure occurred. A failure history table can be used as a simple method to distinguish between a normal and an abnormal tunnel termination. That is, if a tunnel entry in the tunnel history table has no associated failure record, the tunnel must have terminated normally. However, a tunnel history table does not accompany every failure table because every failure does not correspond to a tunnel. Thus, supported setup failures are recorded in the failure table, but an associated history table is not recorded because a tunnel was never set up.

This feature also provides IPsec Simple Network Management Protocol (SNMP) notifications for use with network management systems.

Related Features and Technologies

The IPsec--SNMP Support feature was designed to support the VPN Device Manager (VDM). VDM enables network administrators to manage and configure site-to-site VPNs on a single device from a web browser and to see the effects of changes in real time. VDM implements a wizard-based graphical user interface (GUI) to simplify the process of configuring site-to-site VPNs using the IPsec protocol. VDM software is installed directly on Cisco VPN routers, and is designed for use and compatibility with future Device Manager products.

How to Configure IPsec SNMP Support

Enabling IPsec SNMP Notifications

To enable IPsec SNMP notifications, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server enable traps ipsec cryptomap [add | delete | attach | detach]**
4. **snmp-server enable traps isakmp [policy {add | delete} | tunnel {start | stop}]**

5. `snmp-server host host-address traps community-string ipsec`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	snmp-server enable traps ipsec cryptomap [add delete attach detach] Example: <pre>Router (config)# snmp-server enable traps ipsec cryptomap add</pre>	Enables a router to send IPsec SNMP notifications.
Step 4	snmp-server enable traps isakmp [policy {add delete} tunnel {start stop}] Example: <pre>Router (config)# snmp-server enable traps isakmp policy add</pre>	Enables a router to send IPsec ISAKMP SNMP notifications.
Step 5	snmp-server host host-address traps community-string ipsec Example: <pre>Router (config)# snmp-server host my.example.com traps version2c</pre>	Specifies the recipient of IPsec SNMP notification operations.

What to do next

For more information on configuring SNMP, refer to the chapter “Configuring SNMP Support” in the *Cisco IOS XE Configuration Fundamentals Configuration Guide* .

Configuring IPsec Failure History Table Size

The default failure history table size is 200. To change the size of the failure history table, perform the following steps.

SUMMARY STEPS

1. `enable`

2. `configure terminal`
3. `crypto mib ipsec flowmib history failure size number`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto mib ipsec flowmib history failure size number Example: <pre>Router (config)# crypto mib ipsec flowmib history failure size 220</pre>	Changes the size of the IPsec failure history table.

Configuring IPsec Tunnel History Table Size

The default tunnel history table size is 200. To change the size of the tunnel history table, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto mib ipsec flowmib history tunnel size number`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto mib ipsec flowmib history tunnel size <i>number</i> Example: <pre>Router (config)# crypto mib ipsec flowmib history tunnel size</pre>	Changes the size of the IPsec tunnel history table.

Verifying IPsec MIB Configuration

To verify that the IPsec MIB feature is configured properly, perform the following tasks:

- Enter the **show crypto mib ipsec flowmib history failure size** privileged EXEC command to display the size of the failure history table:

```
Router# show crypto mib ipsec flowmib history failure size
IPSec Failure Window Size: 140
```

- Enter the **show crypto mib ipsec flowmib history tunnel size** privileged EXEC command to display the size of the tunnel history table:

```
Router# show crypto mib ipsec flowmib history tunnel size
IPSec History Window Size: 130
```

- Enter the **show crypto mib ipsec flowmib version** privileged EXEC command to display the MIB version used by the management applications to identify the feature set:

```
Router# show crypto mib ipsec flowmib version
IPSec Flow MIB version: 1
```

- Enter the **debug crypto mib** command to display the IPsec MIB debug message notifications:

```
Router# debug crypto mib
Crypto IPsec Mgmt Entity debugging is on
```

Monitoring and Maintaining IPsec MIB

To monitor the status of IPsec MIB information, use any of the following commands.

SUMMARY STEPS

1. **enable**
2. **show crypto mib ipsec flowmib history failure size**
3. **show crypto mib ipsec flowmib history tunnel size**
4. **show crypto mib ipsec flowmib version**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto mib ipsec flowmib history failure size Example: <pre>Router# show crypto mib ipsec flowmib history failure size</pre>	Displays the size of the IPsec failure history table.
Step 3	show crypto mib ipsec flowmib history tunnel size Example: <pre>Router# show crypto mib ipsec flowmib history tunnel size</pre>	Displays the size of the IPsec tunnel history table.
Step 4	show crypto mib ipsec flowmib version Example: <pre>Router# show crypto mib ipsec flowmib version</pre>	Displays the IPsec Flow MIB version used by the router.

Configuration Examples for IPsec SNMP Support

Enabling IPsec Notifications Examples

In the following example, IPsec notifications are enabled:

```
snmp-server enable traps ipsec isakmp
```

In the following example, the router is configured to send IPsec notifications to the host nms1.example.com:

```
snmp-server host nms1.example.com public ipsec isakmp
Translating "nms1.example.com"...domain server (172.00.0.01) [OK]
```

Specifying History Table Size Examples

In the following example, the specified failure history table size is 140:

```
crypto mib ipsec flowmib history failure size 140
```

In the following example, the specified tunnel history table size is 130:

```
crypto mib ipsec flowmib history tunnel size 130
```

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for IPsec SNMP Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 253: Feature Information for IPsec SNMP Support

Feature Name	Releases	Feature Information
IPsec SNMP Support	Cisco IOS XE Release 2.1	<p>The IP Security (IPsec) SNMP Support feature introduces support for industry-standard IPsec MIBs and Cisco IOS XE-software specific IPsec MIBs.</p> <p>The following commands were introduced or modified: crypto mib ipsec flowmib history failure size, crypto mib ipsec flowmib history tunnel size, debug crypto mib, show crypto mib ipsec flowmib history failure size, show crypto mib ipsec flowmib history tunnel size, show crypto mib ipsec flowmib version, snmp-server enable traps ipsec, snmp-server enable traps isakmp, snmp-server host.</p>

Glossary

CA --certificate authority. A certificate authority (CA) is an entity in a network that issues and manages security credentials and public keys (in the form of X509v3 certificates) for message encryption. As part of a public key infrastructure (PKI), a CA checks with a registration authority (RA) to verify information provided by the requestor of a digital certificate. If the RA verifies the requestor's information, the CA can then issue a certificate. Certificates generally include the owner's public key, the expiration date of the certificate, the owner's name, and other information about the public key owner.

IP Security --See IPsec.

IPsec --Internet Protocol Security. A framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPsec provides these security services at the IP layer. IPsec uses Internet Key Exchange (IKE) to handle negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPsec. IPsec can be used to protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

Management Information Base --See MIB.

MIB --Management Information Base. Database of network management information that is used and maintained by a network management protocol such as Simple Network Management Protocol (SNMP) or Common Management Information Protocol (MIP). The value of a MIB object can be changed or retrieved using SNMP or CMIP commands, usually through a graphical user interface (GUI) network management system (NMS). MIB objects are organized in a tree structure that includes public (standard) and private (proprietary) branches.

Simple Network Management Protocol --See SNMP.

SNMP --Simple Network Management Protocol. An application-layer protocol that provides a message format for communication between SNMP managers and agents.

trap --Message sent by an SNMP agent to a network management system, console, or terminal to indicate the occurrence of a significant event, such as a specifically defined condition or a threshold that was reached.

CHAPTER 190

IPsec VPN Accounting

The IPsec VPN Accounting feature allows for a session to be accounted for by indicating when the session starts and when it stops.

A VPN session is defined as an Internet Key Exchange (IKE) security association (SA) and the one or more SA pairs that are created by the IKE SA. The session starts when the first IP Security (IPsec) pair is created and stops when all IPsec SAs are deleted.

Session identifying information and session usage information is passed to the Remote Authentication Dial-In User Service (RADIUS) server through standard RADIUS attributes and vendor-specific attributes (VSAs).

- [Glossary, on page 2473](#)

Prerequisites for IPsec VPN Accounting

- Understand how to configure RADIUS and authentication, authorization, and accounting (AAA) accounting.
- Understand how to configure IPsec accounting.

Information About IPsec VPN Accounting

RADIUS Accounting

For many large networks, it is required that user activity be recorded for auditing purposes. The method that is used most is RADIUS accounting.

RADIUS accounting allows for a session to be accounted for by indicating when the session starts and when it stops. Additionally, session identifying information and session usage information is passed to the RADIUS server through RADIUS attributes and VSAs.

RADIUS Start Accounting

The RADIUS Start packet contains many attributes that generally identify who is requesting the service and of what the property of that service consists. The table below represents the attributes required for the start.

Table 254: RADIUS Accounting Start Packet Attributes

RADIUS Attributes Value	Attribute	Description
1	user-name	Username used in extended authentication (XAUTH). The username may be NULL when XAUTH is not used.
4	nas-ip-address	Identifying IP address of the network access server (NAS) that serves the user. It should be unique to the NAS within the scope of the RADIUS server.
5	nas-port	Physical port number of the NAS that serves the user.
8	framed-ip-address	Private address allocated for the IP Security (IPsec) session.
40	acct-status-type	Status type. This attribute indicates whether this accounting request marks the beginning (start), the end (stop), or an update of the session.
41	acct-delay-time	Number of seconds the client has been trying to send a particular record.
44	acct-session-id	Unique accounting identifier that makes it easy to match start and stop records in a log file.
26	vrf-id	String that represents the name of the Virtual Route Forwarder (VRF).
26	isakmp-initiator-ip	Endpoint IP address of the remote Internet Key Exchange (IKE) initiator (V4).
26	isakmp-group-id	Name of the VPN group profile used for accounting.
26	isakmp-phase1-id	Phase 1 identification (ID) used by IKE (for example, domain name [DN], fully qualified domain name [FQDN], IP address) to help identify the session initiator.

RADIUS Stop Accounting

The RADIUS Stop packet contains many attributes that identify the usage of the session. Table 2 represents the additional attributes required for the RADIUS stop packet. It is possible that only the stop packet is sent without the start if configured to do so. If only the stop packet is sent, this allows an easy way to reduce the number of records going to the AAA server.

Table 255: RADIUS Accounting Stop Packet Attributes

RADIUS Attributes Value	Attribute	Description
42	acct-input-octets	Number of octets that have been received from the Unity client over the course of the service that is being provided.
43	acct-output-octets	Number of octets that have been sent to the Unity client in the course of delivering this service.
46	acct-session-time	Length of time (in seconds) that the Unity client has received service.
47	acct-input-packets	Quantity of packets that have been received from the Unity client in the course of delivering this service.
48	acct-output-packets	Quantity of packets that have been sent to the Unity client in the course of delivering this service.
49	acct-terminate-cause	For future use.
52	acct-input-gigawords	How many times the Acct-Input-Octets counter has wrapped around the 232 (2 to the 32nd power) over the course of this service.
52	acct-output-gigawords	How many times the Acct-Input-Octets counter has wrapped around the 232 (2 to the 32nd power) over the course of this service.

RADIUS Update Accounting

RADIUS accounting updates are supported. Packet and octet counts are shown in the updates.

IKE and IPsec Subsystem Interaction

Accounting Start

If IPsec accounting is configured, after IKE phases are complete, an accounting start record is generated for the session. New accounting records are not generated during a rekeying.

The following is an account start record that was generated on a router and that is to be sent to the AAA server that is defined:

```
*Aug 23 04:06:20.131: RADIUS(00000002): sending
*Aug 23 04:06:20.131: RADIUS(00000002): Send Accounting-Request to 10.1.1.4:1646 id 4, len
220
*Aug 23 04:06:20.131: RADIUS:   authenticator 38 F5 EB 46 4D BE 4A 6F - 45 EB EF 7D B7 19
FB 3F
*Aug 23 04:06:20.135: RADIUS:   Acct-Session-Id      [44] 10 "00000001"

9D 5D

```

Accounting Stop

An accounting stop packet is generated when there are no more flows (IPsec SA pairs) with the remote peer.

The accounting stop records contain the following information:

- Packets out
- Packets in
- Octets out
- Gigawords in
- Gigawords out

Below is an account start record that was generated on a router. The account start record is to be sent to the AAA server that is defined.

```

*Aug 23 04:20:16.519: RADIUS(00000003): Using existing nas_port 0
*Aug 23 04:20:16.519: RADIUS(00000003): Config NAS IP: 100.1.1.147
*Aug 23 04:20:16.519: RADIUS(00000003): sending
*Aug 23 04:20:16.519: RADIUS(00000003): Send Accounting-Request to 100.1.1.4:1646 id 19,
len 238
*Aug 23 04:20:16.519: RADIUS: authenticator 82 65 5B 42 F0 3F 17 C3 - 23 F3 4C 35 A2 8A

*Aug 23 04:20:16.523: RADIUS: Received from id 21645/19 100.1.1.4:1646, Accounting-response,
len 20
*Aug 23 04:20:16.523: RADIUS: authenticator F1 CA C1 28 CE A0 26 C9 - 3E 22 C9 DA EA B8
22 A0
```

Accounting Updates

If accounting updates are enabled, accounting updates are sent while a session is “up.” The update interval is configurable. To enable the accounting updates, use the **aaa accounting update** command.

The following is an accounting update record that is being sent from the router:

```
Router#
*Aug 23 21:46:05.263: RADIUS(00000004): Using existing nas_port 0
*Aug 23 21:46:05.263: RADIUS(00000004): Config NAS IP: 100.1.1.147
*Aug 23 21:46:05.263: RADIUS(00000004): sending
*Aug 23 21:46:05.263: RADIUS(00000004): Send Accounting-Request to 100.1.1.4:1646 id 22,
len 200
*Aug 23 21:46:05.263: RADIUS: authenticator 30 FA 48 86 8E 43 8E 4B - F9 09 71 04 4A F1
52 25
*Aug 23 21:46:05.263: RADIUS: Acct-Session-Id [44] 10 "00000003"

How to Configure IPsec VPN Accounting

Configuring IPsec VPN Accounting

Before you begin

IPsec must be configured first before configuring IPsec VPN accounting.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa authentication login** *list-name method*
5. **aaa authorization network** *list-name method*
6. **aaa accounting network list-name start-stop** [**broadcast**] **group** *group-name*
7. **aaa session-id common**
8. **crypto isakmp profile** *profile-name*
9. **vrf** *ivrf*
10. **match identity group** *group-name*
11. **client authentication list** *list-name*
12. **isakmp authorization list** *list-name*
13. **client configuration address** [**initiate** | **respond**]
14. **accounting** *list-name*
15. **exit**
16. **crypto dynamic-map** *dynamic-map-name dynamic-seq-num*
17. **set transform-set** *transform-set-name*
18. **set isakmp-profile** *profile-name*
19. **reverse-route** [**remote-peer**]
20. **exit**
21. **crypto map** *map-name ipsec-isakmp dynamic dynamic-template-name*
22. **radius-server host** *ip-address* [**auth-port** *port-number*] [**acct-port** *port-number*]
23. **radius-server key** *string*
24. **radius-server vsa send accounting**
25. **interface** *type slot / port*
26. **crypto map** *map-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Router (config)# aaa new-model	Enables periodic interim accounting records to be sent to the accounting server.

	Command or Action	Purpose
Step 4	aaa authentication login <i>list-name method</i> Example: <pre>Router (config)# aaa authentication login cisco-client group radius</pre>	Enforces authentication, authorization, and accounting (AAA) authentication for extended authorization (XAUTH) through RADIUS or local.
Step 5	aaa authorization network <i>list-name method</i> Example: <pre>Router (config)# aaa authorization network cisco-client group radius</pre>	Sets AAA authorization parameters on the remote client from RADIUS or local.
Step 6	aaa accounting network list-name start-stop [broadcast] group group-name Example: <pre>Router (config)# aaa accounting network acc start-stop broadcast group radius</pre>	Enables AAA accounting of requested services for billing or security purposes when RADIUS or TACACS+ is used.
Step 7	aaa session-id common Example: <pre>Router (config)# aaa session-id common</pre>	Specifies whether the same session ID is used for each AAA accounting service type within a call or whether a different session ID is assigned to each accounting service type.
Step 8	crypto isakmp profile profile-name Example: <pre>Route (config)# crypto isakmp profile cisco</pre>	Audits IP security (IPsec) user sessions and enters isakmp-profile submode.
Step 9	vrf ivrf Example: <pre>Router (conf-isa-prof)# vrf cisco</pre>	Associates the on-demand address pool with a Virtual Private Network (VPN) routing and forwarding (VRF) instance name.
Step 10	match identity group group-name Example: <pre>Router(conf-isa-prof)# match identity group cisco</pre>	Matches an identity from a peer in an ISAKMP profile.
Step 11	client authentication list list-name Example: <pre>Router(conf-isa-prof)# client authentication list cisco</pre>	Configures Internet Key Exchange (IKE) extended authentication (XAUTH) in an Internet Security Association and Key Management Protocol (ISAKMP) profile.
Step 12	isakmp authorization list list-name Example:	Configures an IKE shared secret and other parameters using the AAA server in an ISAKMP profile. The shared

	Command or Action	Purpose
	Router(conf-isa-prof)# isakmp authorization list cisco-client	secret and other parameters are generally pushed to the remote peer through mode configuration (MODECFG).
Step 13	client configuration address [initiate respond] Example: Router(conf-isa-prof)# client configuration address respond	Configures IKE mode configuration (MODECFG) in the ISAKMP profile.
Step 14	accounting list-name Example: Router(conf-isa-prof)# accounting acc	Enables AAA accounting services for all peers that connect through this ISAKMP profile.
Step 15	exit Example: Router(conf-isa-prof)# exit	Exits isakmp-profile submenu.
Step 16	crypto dynamic-map dynamic-map-name dynamic-seq-num Example: Router(config)# crypto dynamic-map mymap 10 ipsec-isakmp	Creates a dynamic crypto map template and enters the crypto map configuration command mode.
Step 17	set transform-set transform-set-name Example: Router(config-crypto-map)# set transform-set aswan	Specifies which transform sets can be used with the crypto map template.
Step 18	set isakmp-profile profile-name Example: Router(config-crypto-map)# set isakmp-profile cisco	Sets the ISAKMP profile name.
Step 19	reverse-route [remote-peer] Example: Router(config-crypto-map)# reverse-route	Allows routes (ip addresses) to be injected for destinations behind the VPN remote tunnel endpoint and may include a route to the tunnel endpoint itself (using the remote-peer keyword for the crypto map).
Step 20	exit Example: Router(config-crypto-map)# exit	Exits dynamic crypto map configuration mode.

	Command or Action	Purpose
Step 21	crypto map <i>map-name</i> ipsec-isakmp dynamic <i>dynamic-template-name</i> Example: <pre>Router(config)# crypto map mymap ipsec-isakmp dynamic dmap</pre>	Enters crypto map configuration mode
Step 22	radius-server host <i>ip-address</i> [auth-port <i>port-number</i>] [acct-port <i>port-number</i>] Example: <pre>Router(config)# radius-server host 172.16.1.4</pre>	Specifies a RADIUS server host.
Step 23	radius-server key <i>string</i> Example: <pre>Router(config)# radius-server key nsite</pre>	Sets the authentication and encryption key for all RADIUS communications between the router and the RADIUS daemon.
Step 24	radius-server vsa send accounting Example: <pre>Router(config)# radius-server vsa send accounting</pre>	Configures the network access server to recognize and use vendor-specific attributes.
Step 25	interface <i>type slot / port</i> Example: <pre>Router(config)# interface FastEthernet 1/0</pre>	Configures an interface type and enters interface configuration mode.
Step 26	crypto map <i>map-name</i> Example: <pre>Router(config-if)# crypto map mymap</pre>	Applies a previously defined crypto map set to an interface.

Configuring Accounting Updates

To send accounting updates while a session is “up,” perform the following optional task:

Before you begin

IPsec VPN accounting must be configured before accounting updates are configured. See [Configuring IPsec VPN Accounting, on page 2461](#) for more information.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa accounting update periodic** *number*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	aaa accounting update periodic number Example: Router (config)# aaa accounting update periodic 1-2147483647	(Optional) Enables periodic interim accounting records to be sent to the accounting server.

Troubleshooting for IPsec VPN Accounting

To display messages about IPsec accounting events, perform the following optional task:

SUMMARY STEPS

1. enable
2. debug crypto isakmp aaa

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	debug crypto isakmp aaa Example: Router# debug crypto isakmp aaa	Displays messages about Internet Key Exchange (IKE) events. <ul style="list-style-type: none"> • The aaa keyword specifies accounting events.

Technical Assistance

Description	Link
<p>The Cisco Support website provides extensive online resources, including documentation and tools for troubleshooting and resolving technical issues with Cisco products and technologies.</p> <p>To receive security and technical information about your products, you can subscribe to various services, such as the Product Alert Tool (accessed from Field Notices), the Cisco Technical Services Newsletter, and Really Simple Syndication (RSS) Feeds.</p> <p>Access to most tools on the Cisco Support website requires a Cisco.com user ID and password.</p>	http://www.cisco.com/cisco/web/support/index.html

Feature Information for IPsec VPN Accounting

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 256: Feature Information for IPsec VPN Accounting

Feature Name	Releases	Feature Information
IPsec VPN Accounting	Cisco IOS XE Release 2.1	<p>The IPsec VPN Accounting feature allows for a session to be accounted for by indicating when the session starts and when it stops.</p> <p>A VPN session is defined as an IKE SA and the one or more SA pairs that are created by the IKE SA. The session starts when the first IPsec pair is created and stops when all IPsec SAs are deleted.</p> <p>Session identifying information and session usage information is passed to the RADIUS server through standard RADIUS attributes and VSAs.</p> <p>The following commands were introduced or modified: client authentication list, client configuration address, crypto isakmp profile, crypto map (global IPsec), debug crypto isakmp, isakmp authorization list, match identity, set isakmp-profile, vrf.</p>

Glossary

IKE --Internet Key Exchange. IKE establishes a shared security policy and authenticates keys for services (such as IP security [IPsec]) that require keys. Before any IPsec traffic can be passed, each router, firewall, and host must verify the identity of its peer. This can be done by manually entering preshared keys into both hosts or by a certification authority (CA) service.

IPsec --IP security. IPsec is A framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPsec provides these security services at the IP layer. IPsec uses IKE to handle the negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPsec. IPsec can protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

ISAKMP --Internet Security Association and Key Management Protocol. ISAKMP is an Internet IPsec protocol (RFC 2408) that negotiates, establishes, modifies, and deletes security associations. It also exchanges key generation and authentication data (independent of the details of any specific key generation technique), key establishment protocol, encryption algorithm, or authentication mechanism.

L2TP session --Layer 2 Transport Protocol. L2TP are communications transactions between the L2TP access concentrator (LAC) and the L2TP network server (LNS) that support tunneling of a single PPP connection. There is a one-to-one relationship among the PPP connection, L2TP session, and L2TP call.

NAS --network access server. A NAS is a Cisco platform (or collection of platforms, such as an AccessPath system) that interfaces between the packet world (for example, the Internet) and the circuit world (for example, the public switched telephone network [PSTN]).

PFS --perfect forward secrecy. PFS is a cryptographic characteristic associated with a derived shared secret value. With PFS, if one key is compromised, previous and subsequent keys are not compromised because subsequent keys are not derived from previous keys.

QM --Queue Manager. The Cisco IP Queue Manager (IP QM) is an intelligent, IP-based, call-treatment and routing solution that provides powerful call-treatment options as part of the Cisco IP Contact Center (IPCC) solution.

RADIUS --Remote Authentication Dial-In User Service. RADIUS is a database for authenticating modem and ISDN connections and for tracking connection time.

RSA --Rivest, Shamir, and Adelman. Rivest, Shamir, and Adelman are the inventors of the Public-key cryptographic system that can be used for encryption and authentication.

SA --security association. A SA is an instance of security policy and keying material that is applied to a data flow.

TACACS+ --Terminal Access Controller Access Control System Plus. TACACS+ is a security application that provides centralized validation of users attempting to gain access to a router or network access server.

VPN --Virtual Private Network. A VPN enables IP traffic to travel securely over a public TCP/IP network by encrypting all traffic from one network to another. A VPN uses "tunneling" to encrypt all information at the IP level.

VRF --A VPN routing/forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router.

VSA --vendor-specific attribute. A VSA is an attribute that has been implemented by a particular vendor. It uses the attribute Vendor-Specific to encapsulate the resulting AV pair: essentially, Vendor-Specific = protocol:attribute = value.

XAUTH --Extended authentication. XAUTH is an optional exchange between IKE Phase 1 and IKE Phase 2, in which the router demands additional authentication information in an attempt to authenticate the actual user (as opposed to authenticating the peer).

CHAPTER 191

IPsec Usability Enhancements

The IPsec Usability Enhancements feature introduces functionality that eases the configuration and monitoring of your IPsec virtual private network (VPN). Benefits of this feature include intelligent defaults for IPsec and Internet Key Exchange (IKE) and the ability to easily verify and troubleshoot IPsec VPNs.

Prerequisites for IPsec Usability Enhancements

- You must be familiar with IPsec, IKE, and encryption.
- You must have configured IPsec and enabled IKE on your router.
- You must be running Cisco IOS XE k9 crypto image on your router.

Information About IPsec Usability Enhancements

IPsec Overview

IPsec is a framework of open standards developed by the Internet Engineering Task Force (IETF), which provides security for transmission of sensitive information over public networks. IPsec acts at the network layer, protecting and authenticating IP packets between participating IPsec devices (peers), such as Cisco routers.

IPsec provides secure tunnels between two peers. You may define which packets are considered sensitive and should be sent through these secure tunnels. You may also define the parameters that should be used to protect these sensitive packets by specifying characteristics of the tunnels. When an IPsec peer detects a sensitive packet, it sets up the appropriate secure tunnel and sends the packet through the tunnel to the remote peer.

IPsecOperation

An IPsec operation involves five basic steps: identifying interesting traffic, IKE phase-1, IKE phase-2, establishing the tunnel or IPsec session, and finally tearing down the tunnel.

Step 1: Identifying Interesting Traffic

The VPN devices recognize the traffic, or sensitive packets, to detect. IPsec is either applied to the sensitive packet, the packet is bypassed, or the packet is dropped. Based on the traffic type, if IPsec is applied then IKE phase-1 is initiated.

Step 2: IKE Phase-1

There are three exchanges between the VPN devices to negotiate an IKE security policy and establish a secure channel.

During the first exchange, the VPN devices negotiate matching IKE transform sets to protect the IKE exchange resulting in establishing an Internet Security Association and Key Management Protocol (ISAKMP) policy to utilize. The ISAKMP policy consists of an encryption algorithm, a hash algorithm, an authentication algorithm, a Diffie-Hellman (DH) group, and a lifetime parameter.

There are eight default ISAKMP policies supported. For more information on default ISAKMP policies, see the [Verifying IKE Phase-1 ISAKMP Default Policies, on page 2477](#).

The second exchange consists of a Diffie-Hellman exchange, which establishes a shared secret.

The third exchange authenticates peer identity. After the peers are authenticated, IKE phase-2 begins.

Step 3: IKE Phase-2

The VPN devices negotiate the IPsec security policy used to protect the IPsec data. IPsec transform sets are negotiated.

A transform set is a combination of algorithms and protocols that enact a security policy for network traffic. For more information on default transform sets, see the [Verifying Default IPsec Transform-Sets, on page 2480](#). A VPN tunnel is ready to be established.

Step 4: Establishing the Tunnel--IPsec Session

The VPN devices apply security services to IPsec traffic and then transmit the IPsec data. Security associations (SAs) are exchanged between peers. The negotiated security services are applied to the tunnel traffic while the IPsec session is active.

Step 5: Terminating the Tunnel

The tunnel is torn down when an IPsec SA lifetime time-out occurs or if the packet counter is exceeded. The IPsec SA is removed.

How to Utilize IPsec Usability Enhancements

Verifying IKE Phase-1 ISAKMP Default Policies

When IKE negotiation begins, the peers try to find a common policy, starting with the highest priority policy as specified on the remote peer. The peers negotiate the policy sets until there is a match. If peers have more than one policy set in common, the lowest priority number is used.

There are three groups of IKE phase-1, ISAKMP, policies as defined by policy priority ranges and behavior:

- Default ISAKMP policies, which are automatically enabled.
- User configured ISAKMP policies, which you may configure with the **crypto isakmp policy** command.
- Easy VPN ISAKMP policies, which are made available during Easy VPN configuration.

This section describes the three groups of ISAKMP policies, how they behave in relationship to one another, how to determine which policies are in use with the appropriate **show** command, and how to disable the default ISAKMP policies.

Default IKE Phase-1 Policies

There are eight default IKE phase-1, ISAKMP, policies supported (see the table below) that are enabled automatically. If you have neither manually configured IKE policies with the **crypto isakmp policy** command nor disabled the default IKE policies with the **no crypto isakmp default policy** command, the default IKE policies will be used during peer IKE negotiations. You can verify that the default IKE policies are in use by issuing either the **show crypto isakmp policy** command or the **show crypto isakmp default policy** command.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

The default IKE policies define the following policy set parameters:

- The priority, 65507-65514, where 65507 is the highest priority and 65514 is the lowest priority.
- The authentication method, Rivest, Shamir, and Adelman (RSA) or preshared keys (PSK).
- The encryption method, Advanced Encryption Standard (AES) or Triple Data Encryption Standard (3DES).
- The hash function, Secure Hash Algorithm (SHA-1) or Message-Digest algorithm 5 (MD5).
- The DH group specification DH2 or DH5
 - DH2 specifies the 768-bit DH group.
 - DH5 specifies the 1536-bit DH group.

Note Cisco no longer recommends using 3DES, MD5 and DH groups 1, 2 and 5. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper. To learn more about IKE configuration, read the chapter “Configuring Internet Key Exchange for IPsec VPNs” in *Internet Key Exchange for IPsec VPNs Configuration Guide*.

Table 257: Default IKE Phase-1, ISAKMP, Policies

Priority	Authentication	Encryption	Hash	Diffie-Hellman
65507	RSA	AES	SHA	DH5
65508	PSK	AES	SHA	DH5
65509	RSA	AES	MD5	DH5
65510	PSK	AES	MD5	DH5
65511	RSA	3DES	SHA	DH2
65512	PSK	3DES	SHA	DH2
65513	RSA	3DES	MD5	DH2
65514	PSK	3DES	MD5	DH2

User Configured IKE Policies

You may configure IKE policies with the **crypto isakmp policy** command. User configured IKE policies are uniquely identified and configured with a priority number ranging from 1-10000, where 1 is the highest priority and 10000 the lowest priority.

Once you have configured one or more IKE policies with a priority of 1-10000:

- The user configured policies will be used during peer IKE negotiations.
- The default IKE policies will no longer used during peer IKE negotiations.
- The user configured policies may be displayed by issuing the **show crypto isakmp policy** command.

Easy VPN ISAKMP Policies

If you have configured Easy VPN, the default Easy VPN ISAKMP policies in use are uniquely identified with a priority number ranging from 65515-65535, where 65515 is the highest priority and 65535 is the lowest priority.

Once a user has configured Easy VPN:

- The default Easy VPN ISAKMP policies and the default IKE policies will be used during peer IKE negotiations.
- The Easy VPN ISAKMP policies and the default IKE policies will be displayed by issuing the **show crypto isakmp policy** command.

- Default ISAKMP policies will be displayed by issuing the **show crypto isakmp default policy** command unless they have been disabled by issuing the **no crypto isakmp default policy** command.

SUMMARY STEPS

1. **enable**
2. **show crypto isakmp default policy**
3. **configure terminal**
4. **no crypto isakmp default policy**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto isakmp default policy Example: Router# show crypto isakmp default policy	(Optional) Displays default ISAKMP policies if no policy with a priority of 1-10000 is configured.
Step 3	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 4	no crypto isakmp default policy Example: Router(config)# no crypto isakmp default policy	(Optional) Turns off default ISAKMP policies with priorities 65507-65514.

Examples

The following is sample output of the **show crypto isakmp default policy** command. The default policies are displayed because the default policies have not been disabled.

```
Router# show crypto isakmp default policy

Default IKE policy
Default protection suite of priority 65507
  encryption algorithm:  AES - Advanced Encryption Standard (128 bit key).
  hash algorithm:        Secure Hash Standard
  authentication method: Rivest-Shamir-Adleman Signature
  Diffie-Hellman group:  #5 (1536 bit)
  lifetime:              86400 seconds, no volume limit
Default protection suite of priority 65508
  encryption algorithm:  AES - Advanced Encryption Standard (128 bit key).
  hash algorithm:        Secure Hash Standard
```

```

authentication method: Pre-Shared Key
Diffie-Hellman group: #5 (1536 bit)
lifetime: 86400 seconds, no volume limit
Default protection suite of priority 65509
encryption algorithm: AES - Advanced Encryption Standard (128 bit key).
hash algorithm: Message Digest 5
authentication method: Rivest-Shamir-Adleman Signature
Diffie-Hellman group: #5 (1536 bit)
lifetime: 86400 seconds, no volume limit
Default protection suite of priority 65510
encryption algorithm: AES - Advanced Encryption Standard (128 bit key).
hash algorithm: Message Digest 5
authentication method: Pre-Shared Key
Diffie-Hellman group: #5 (1536 bit)
lifetime: 86400 seconds, no volume limit
Default protection suite of priority 65511
encryption algorithm: Three key triple DES
hash algorithm: Secure Hash Standard
authentication method: Rivest-Shamir-Adleman Signature
Diffie-Hellman group: #2 (1024 bit)
lifetime: 86400 seconds, no volume limit
Default protection suite of priority 65512
encryption algorithm: Three key triple DES
hash algorithm: Secure Hash Standard
authentication method: Pre-Shared Key
Diffie-Hellman group: #2 (1024 bit)
lifetime: 86400 seconds, no volume limit
Default protection suite of priority 65513
encryption algorithm: Three key triple DES
hash algorithm: Message Digest 5
authentication method: Rivest-Shamir-Adleman Signature
Diffie-Hellman group: #2 (1024 bit)
lifetime: 86400 seconds, no volume limit
Default protection suite of priority 65514
encryption algorithm: Three key triple DES
hash algorithm: Message Digest 5
authentication method: Pre-Shared Key
Diffie-Hellman group: #2 (1024 bit)
lifetime: 86400 seconds, no volume limit

```

The following example disables the default IKE policies then shows the resulting output of the **show crypto isakmp default policy** command, which is blank:

```

Router# configure terminal
Router(config)# no crypto isakmp default policy
Router(config)# exit
Router# show crypto isakmp default policy
Router#
!There is no output since the default IKE policies have been disabled.

```

The following is an example system log message that is generated whenever the default ISAKMP policies are in use:

```
%CRYPTO-6-IKMP_POLICY_DEFAULT: Using ISAKMP Default policies
```

Verifying Default IPsec Transform-Sets

A transform set represents a certain combination of security protocols and algorithms. During the IPsec SA negotiation, the peers agree to use a particular transform set for protecting a particular data flow.

During IPsec SA negotiations with IKE, the peers search for a transform set that is the same at both peers. When such a transform set is found, it is selected and is applied to the protected traffic as part of the IPsec SAs of both peers.

Default Transform Sets

A default transform set will be used by any crypto map or IPsec profile where no other transform set has been configured and if the following is true:

- The default transform sets have not been disabled with the **no crypto ipsec default transform-set** command.
- The crypto engine in use supports the encryption algorithm.

The two default transform sets each define an Encapsulation Security Protocol (ESP) encryption transform type and an ESP authentication transform type as shown in the table below.

Table 258: Default Transform Sets and Parameters

Default Transform Name	ESP Encryption Transform and Description	ESP Authentication Transform and Description
#!default_transform_set_0	esp-3des (ESP with the 168-bit 3DES or Triple DES encryption algorithm)	esp-sha-hmac
#!default_transform_set_1	esp-aes (ESP with the 128-bit AES encryption algorithm)	esp-sha-hmac (ESP with the SHA-1, hash message authentication code [HMAC] variant authentication algorithm)

SUMMARY STEPS

1. **enable**
2. **show crypto ipsec default transform-set**
3. **configure terminal**
4. **no crypto ipsec default transform-set**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	show crypto ipsec default transform-set Example: Router# show crypto ipsec default transform-set	(Optional) Displays the default IPsec transform sets currently in use by IKE.

	Command or Action	Purpose
Step 3	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 4	no crypto ipsec default transform-set Example: Router(config)# no crypto ipsec default transform-set	(Optional) Disables the default IPsec transform sets.

Examples

The following example displays output from the **show crypto ipsec default transform-set** command when the default transform sets are enabled, the default setting:

```
Router# show crypto ipsec default transform-set
Transform set #${default_transform_set_1}: { esp-aes esp-sha-hmac }
    will negotiate = { Transport, },

Transform set #${default_transform_set_0}: { esp-3des esp-sha-hmac }
    will negotiate = { Transport, },
```

The following example displays output from the **show crypto ipsec default transform-set** command when the default transform sets have been disabled with the **no crypto ipsec default transform-set** command.

```
Router(config)# no crypto ipsec default transform-set
Router(config)# exit
Router#
Router# show crypto ipsec default transform-set
! There is no output.
Router#
```

The following is an example system log message that is generated whenever IPsec SAs have negotiated with a default transform set:

```
%CRYPTO-5-IPSEC_DEFAULT_TRANSFORM: Using Default IPsec transform-set
```

Verifying and Troubleshooting IPsec VPNs

Perform one of the following optional tasks in this section, depending on whether you want to verify IKE phase-1 or IKE phase-2 tunnels or troubleshoot your IPsec VPN:

Verifying IKE Phase-1 ISAKMP

To display statistics for ISAKMP tunnels, use the following optional commands.

SUMMARY STEPS

1. **show crypto mib isakmp flowmib failure [vrf vrf-name]**

2. **show crypto mib isakmp flowmib global** [vrf vrf-name]
3. **show crypto mib isakmp flowmib history** [vrf vrf-name]
4. **show crypto mib isakmp flowmib peer** [index peer-mib-index][vrf vrf-name]
5. **show crypto mib isakmp flowmib tunnel** [index tunnel-mib-index][vrf vrf-name]

DETAILED STEPS

Step 1 **show crypto mib isakmp flowmib failure** [vrf vrf-name]

For ISAKMP tunnel failures, this command displays event information. The following is sample output for this command:

Example:

```
Router# show crypto mib isakmp flowmib failure
vrf Global
Index:                1
Reason:               peer lost
Failure time since reset: 00:07:27
Local type:           ID_IPV4_ADDR
Local value:          192.0.2.1
Remote type:          ID_IPV4_ADDR
Remote Value:         192.0.2.2
Local Address:        192.0.2.1
Remote Address:       192.0.2.2
Index:                2
Reason:               peer lost
Failure time since reset: 00:07:27
Local type:           ID_IPV4_ADDR
Local value:          192.0.3.1
Remote type:          ID_IPV4_ADDR
Remote Value:         192.0.3.2
Local Address:        192.0.3.1
Remote Address:       192.0.3.2
Index:                3
Reason:               peer lost
Failure time since reset: 00:07:32
Local type:           ID_IPV4_ADDR
Remote type:          ID_IPV4_ADDR
Remote Value:         192.0.2.2
Local Address:        192.0.2.1
Remote Address:       192.0.2.2
```

Step 2 **show crypto mib isakmp flowmib global** [vrf vrf-name]

Global ISAKMP tunnel statistics are displayed by issuing this command. The following is sample output for this command:

Example:

```
Router# show crypto mib isakmp flowmib global
vrf Global
Active Tunnels:       3
Previous Tunnels:     0
In octets:            2856
Out octets:           3396
In packets:           16
Out packets:          19
In packets drop:     0
Out packets drop:    0
In notifys:           4
Out notifys:          7
```

```

In P2 exchg:                3
Out P2 exchg:               6
In P2 exchg invalids:      0
Out P2 exchg invalids:     0
In P2 exchg rejects:       0
Out P2 exchg rejects:      0
In IPSEC delete:           0
Out IPSEC delete:          0
SAs locally initiated:     3
SAs locally initiated failed: 0
SAs remotely initiated failed: 0
System capacity failures:  0
Authentication failures:  0
Decrypt failures:          0
Hash failures:             0
Invalid SPI:               0

```

Step 3 `show crypto mib isakmp flowmib history [vrf vrf-name]`

For information about ISAKMP tunnels that are no longer active, this command displays event information including the reason that the tunnel was terminated. The following is sample output for this command:

Example:

```

Router# show crypto mib isakmp flowmib history
vrf Global
Reason:                peer lost
Index:                 2
Local type:            ID_IPV4_ADDR
Local address:         192.0.2.1
Remote type:           ID_IPV4_ADDR
Remote address:        192.0.2.2
Negotiation mode:     Main Mode
Diffie Hellman Grp:   2
Encryption algo:      des
Hash algo:             sha
Auth method:          psk
Lifetime:              86400
Active time:           00:06:30
Policy priority:      1
Keepalive enabled:    Yes
In octets:             3024
In packets:           22
In drops:              0
In notifys:           18
In P2 exchanges:     1
In P2 exchg invalids: 0
In P2 exchg rejected: 0
In P2 SA delete reqs: 0
Out octets:            4188
Out packets:          33
Out drops:             0
Out notifys:          28
Out P2 exchgs:        2
Out P2 exchg invalids: 0
Out P2 exchg rejects: 0
Out P2 Sa delete requests: 0
Reason:                peer lost
Index:                 3
Local type:            ID_IPV4_ADDR
Local address:         192.0.3.1
Remote type:           ID_IPV4_ADDR
Remote address:        192.0.3.2
Negotiation mode:     Main Mode

```

```

Diffie Hellman Grp:          2
Encryption algo:            des
Hash algo:                  sha
Auth method:                psk
Lifetime:                   86400
Active time:                 00:06:25
Policy priority:            1
Keepalive enabled:          Yes
In octets:                   3140
In packets:                  23
In drops:                    0
In notifys:                  19
In P2 exchanges:            1
In P2 exchg invalids:       0
In P2 exchg rejected:       0
In P2 SA delete reqs:       0
Out octets:                  4304
Out packets:                 34
Out drops:                   0
Out notifys:                 29
Out P2 exchgs:               2
Out P2 exchg invalids:       0
Out P2 exchg rejects:        0
Out P2 Sa delete requests:   0

```

Step 4 `show crypto mib isakmp flowmib peer [index peer-mib-index][vrf vrf-name]`

For active ISAKMP peer associations, this command displays information including indexes, type of connection, and IP addresses. The following is sample output for this command:

Example:

```

Router# show crypto mib isakmp flowmib peer
vrf Global
  Index:          1
  Local type:     ID_IPV4_ADDR
  Local address:  192.0.2.1
  Remote type:    ID_IPV4_ADDR
  Remote address: 192.0.2.2
  Index:          2
  Local type:     ID_IPV4_ADDR
  Local address:  192.0.3.1
  Remote type:    ID_IPV4_ADDR
  Remote address: 192.0.3.1
  Index:          3
  Local type:     ID_IPV4_ADDR
  Local address:  192.0.4.1
  Remote type:    ID_IPV4_ADDR
  Remote address: 192.0.4.1

```

Step 5 `show crypto mib isakmp flowmib tunnel [index tunnel-mib-index][vrf vrf-name]`

For active ISAKMP tunnels, this command displays tunnel statistics. The following is sample output for this command:

Example:

```

Router# show crypto mib isakmp flowmib tunnel
vrf Global
  Index:          1
  Local type:     ID_IPV4_ADDR
  Local address:  192.0.2.1
  Remote type:    ID_IPV4_ADDR
  Remote address: 192.0.2.2

```

```

Negotiation mode:           Main Mode
Diffie Hellman Grp:        2
Encryption algo:           des
Hash algo:                  sha
Auth method:                psk
Lifetime:                   86400
Active time:                00:03:08
Policy priority:           1
Keepalive enabled:         Yes
In octets:                  2148
In packets:                 15
In drops:                   0
In notifys:                 11
In P2 exchanges:           1
In P2 exchg invalids:      0
In P2 exchg rejected:      0
In P2 SA delete reqs:     0
Out octets:                 2328
Out packets:                16
Out drops:                  0
Out notifys:                12
Out P2 exchgs:              2
Out P2 exchg invalids:     0
Out P2 exchg rejects:      0
Out P2 Sa delete requests: 0

```

Verifying IKE Phase-2

To display statistics for IPsec phase-2 tunnels, use the following optional commands.

SUMMARY STEPS

1. `show crypto mib ipsec flowmib endpoint [vrf vrf-name]`
2. `show crypto mib ipsec flowmib failure [vrf vrf-name]`
3. `show crypto mib ipsec flowmib global [vrf vrf-name]`
4. `show crypto mib ipsec flowmib history [vrf vrf-name]`
5. `show crypto mib ipsec flowmib spi [vrf vrf-name]`
6. `show crypto mib ipsec flowmib tunnel [index tunnel-mib-index] [vrf vrf-name]`

DETAILED STEPS

Step 1 `show crypto mib ipsec flowmib endpoint [vrf vrf-name]`

Information for each active endpoint, local or remote device, associated with an IPsec phase-2 tunnel is displayed by issuing this command. The following is sample output for this command:

Example:

```

Router# show crypto mib ipsec flowmib endpoint
vrf Global
  Index:                1
  Local type:           Single IP address
  Local address:        192.1.1.1
  Protocol:             0
  Local port:           0

```

```

Remote type:          Single IP address
Remote address:       192.1.2.2
Remote port:          0
Index:                2
Local type:           Subnet
Local address:        192.1.3.0 255.255.255.0
Protocol:             0
Local port:           0
Remote type:          Subnet
Remote address:       192.1.3.0 255.255.255.0
Remote port:          0

```

Step 2 **show crypto mib ipsec flowmib failure [vrf vrf-name]**

For ISAKMP tunnel failures, this command displays event information. The following is sample output for this command:

Example:

```

Router# show crypto mib ipsec flowmib failure
vrf Global
Index:                1
Reason:               Operation request
Failure time since reset: 00:25:18
Src address:          192.1.2.1
Destination address:  192.1.2.2
SPI:                  0

```

Step 3 **show crypto mib ipsec flowmib global [vrf vrf-name]**

Global IKE phase-2 tunnel statistics are displayed by issuing this command. The following is sample output for this command:

Example:

```

Router# show crypto mib ipsec flowmib global
vrf Global
Active Tunnels:       2
Previous Tunnels:     0
In octets:            800
Out octets:           1408
In packets:           8
Out packets:          8
Uncompressed encrypted bytes: 1408
In packets drops:    0
Out packets drops:   2
In replay drops:     0
In authentications:  8
Out authentications: 8
In decrypts:         8
Out encrypts:        8
Compressed bytes:    0
Uncompressed bytes:  0
In uncompressed bytes: 0
Out uncompressed bytes: 0
In decrypt failures:  0
Out encrypt failures: 0
No SA failures:      0
! Number of SA Failures.
Protocol use failures: 0
System capacity failures: 0
In authentication failures: 0
Out authentication failures: 0

```

Step 4 `show crypto mib ipsec flowmib history [vrf vrf-name]`

For information about IKE phase-2 tunnels that are no longer active, this command displays event information including the reason that the tunnel was terminated. The following is sample output for this command:

Example:

```
Router# show crypto mib ipsec flowmib history
vrf Global
Reason:                               Operation request
Index:                                 1
Local address:                         192.1.2.1
Remote address:                        192.1.2.2
IPSEC keying:                           IKE
Encapsulation mode:                    1
Lifetime (KB):                          4608000
Lifetime (Sec):                         3600
Active time:                            00:24:32
Lifetime threshold (KB):                423559168
Lifetime threshold (Sec):               3590000
Total number of refreshes:              0
Expired SA instances:                   4
Current SA instances:                   4
In SA DH group:                         14
In sa encrypt algorithm                 aes
In SA auth algorithm:                   rsig
In SA ESP auth algo:                    ESP_HMAC_SHA
In SA uncompress algorithm:             None
Out SA DH group:                        14
Out SA encryption algorithm:            aes
Out SA auth algorithm:                   ESP_HMAC_SHA
Out SA ESP auth algorithm:               ESP_HMAC_SHA
Out SA uncompress algorithm:             None
In octets:                              400
Decompressed octets:                    400
In packets:                             4
In drops:                               0
In replay drops:                        0
In authentications:                     4
In authentication failures:              0
In decrypts:                            4
In decrypt failures:                    0
Out octets:                              704
Out uncompressed octets:                 704
Out packets:                             4
Out drops:                               1
Out authentications:                     4
Out authentication failures:              0
Out encryptions:                         4
Out encryption failures:                 0
Compressed octets:                       0
Decompressed octets:                     0
Out uncompressed octets:                 704
```

Step 5 `show crypto mib ipsec flowmib spi [vrf vrf-name]`

The security protection index (SPI) table contains an entry for each active and expiring security IKE phase-2 association. The following is sample output for this command, which displays the SPI table:

Example:

```
Router# show crypto mib ipsec flowmib spi
vrf Global
```

```

Tunnel Index:          1
SPI Index:             1
SPI Value:             0xCC57D053
SPI Direction:        In
SPI Protocol:         AH
SPI Status:           Active
SPI Index:            2
SPI Value:            0x68612DF
SPI Direction:        Out
SPI Protocol:         AH
SPI Status:           Active
SPI Index:            3
SPI Value:            0x56947526

Troubleshooting IPsec VPNs

The **show tech-support ipsec** command simplifies the collection of the IPsec related information if you are troubleshooting a problem.

SUMMARY STEPS

1. **show tech-support ipsec**

DETAILED STEPS

show tech-support ipsec

There are three variations of the **show tech-support ipsec** command:

- **show tech-support ipsec**
- **show tech-support ipsec peer** *ipv4address*
- **show tech-support ipsec vrf** *vrf-name*

For a sample display of the output from the **show tech-support ipsec** command for the individual **show** commands listed below for each variation see the following sections.

Output of the show tech-support ipsec Command

If you enter the **show tech-support ipsec** command without any keywords, the command output displays the following **show** commands, in order of output:

- **show version**
- **show running-config**
- **show crypto isakmp sa count**
- **show crypto ipsec sa count**
- **show crypto session summary**
- **show crypto session detail**
- **show crypto isakmp sa detail**
- **show crypto ipsec sa detail**
- **show crypto isakmp peers**

- **show crypto ruleset detail**
- **show processes memory | include Crypto IKMP**
- **show processes cpu | include Crypto IKMP**
- **show crypto eli**
- **show crypto engine accelerator statistic**

Output of the show tech-support ipsec peer Command

If you enter the **show tech-support ipsec** command with the **peer** keyword and the *ipv4address* argument, the output displays the following **show** commands, in order of output for the specified peer:

- **show version**
- **show running-config**
- **show crypto session remote *ipv4address* detail**
- **show crypto isakmp sa peer *ipv4address* detail**
- **show crypto ipsec sa peer *ipv4address* detail**
- **show crypto isakmp peers *ipv4address***
- **show crypto ruleset detail**
- **show processes memory | include Crypto IKMP**
- **show processes cpu | include Crypto IKMP**
- **show crypto eli**
- **show crypto engine accelerator statistic**

Output of the show tech-support ipsec vrf Command

If you enter the **show tech-support ipsec** command with the **vrf** keyword and the *vrf-name* argument, the output displays the following **show** commands, in order of output for the specified Virtual Routing and Forwarding (VRF):

- **show version**
- **show running-config**
- **show crypto isakmp sa count vrf *vrf-name***
- **show crypto ipsec sa count vrf *vrf-name***
- **show crypto session ivrf *ivrf-name* detail**
- **show crypto session fvrf *fvrf-name* detail**
- **show crypto isakmp sa vrf *vrf-name* detail**
- **show crypto ipsec sa vrf *vrf-name* detail**
- **show crypto ruleset detail**
- **show processes memory | include Crypto IKMP**

- show processes cpu | include Crypto IKMP
- show crypto eli
- show crypto engine accelerator statistic

Example:

Configuration Examples for IPsec Usability Enhancements

IKE Default Policies Example

In the following example, crypto maps are configured on RouterA and RouterB and default IKE policies are in use. Traffic is routed from Pagent A to Pagent B. Checking the system log on Peer A and Peer B confirms that the default IKE policies are in use on both peers (see the figure below).

Figure 96: Example Site to Site Topology

```

! Configuring RouterA.
RouterA(config)# crypto isakmp key identity address 209.165.200.226
RouterA(config)# crypto map testmap 10 ipsec-isakmp
% NOTE: This new crypto map will remain disabled until a peer
and a valid access list have been configured.
RouterA(config-crypto-map)# set peer 209.165.200.226
RouterA(config-crypto-map)# match address 101
RouterA(config-crypto-map)# exit
RouterA(config)# ip route 209.165.200.225 255.255.255.224 209.165.200.226

```

Default Transform Sets Example

In the following example, static crypto maps are configured on RouterA and dynamic crypto maps are configured on RouterB. Traffic is routed from Pagent A to Pagent B. The IPsec SAs negotiate with default transform sets and the traffic is encrypted. Executing the **show crypto map** command on both peers verifies that the default transform sets are in use.

```

! Configuring RouterA.
RouterA(config)# crypto isakmp key identify address 209.165.200.225
RouterA(config)# crypto map testmap 10 ipsec-isakmp
% NOTE: This new crypto map will remain disabled until a peer
and a valid access list have been configured.
RouterA(config-crypto-map)# set peer 209.165.200.225
RouterA(config-crypto-map)# match address 101
RouterA(config-crypto-map)# exit
RouterA(config)# ip route 209.165.200.226 255.255.255.255 209.165.200.225
RouterA(config)# access-list 101 permit ip host 209.165.200.227 host 209.165.200.226
RouterA(config)# end
RouterA(config)# interface FastEthernet1/2
RouterA(config-if)# crypto map testmap
RouterA(config-if)# end
RouterA(config)# crypto isakmp policy 10
RouterA(config-isakmp)# encryption aes
RouterA(config-isakmp)# authentication pre-share
RouterA(config-isakmp)# hash sha
RouterA(config-isakmp)# group 5
RouterA(config-isakmp)# end
! Configuring RouterB.
RouterB(config)# crypto isakmp key identity address 209.165.200.229
RouterB(config)# crypto dynamic-map dyn_testmap 10

Glossary

peer--In the context of this module, a router or other device that participates in IPsec.

SA--security association. Description of how two or more entities use security services in the context of a particular security protocol (AH or ESP) to communicate securely on behalf of a particular data flow. The transform and the shared secret keys are used for protecting the traffic.

transform--List of operations performed on a dataflow to provide data authentication, data confidentiality, and data compression. For example, one transform is the ESP protocol with the HMAC-MD5 authentication algorithm; another transform is the AH protocol with the 56-bit DES encryption algorithm and the ESP protocol with the HMAC-SHA authentication algorithm.

tunnel--In the context of this module, a secure communication path between two peers, such as two routers. It does not refer to using IPsec in tunnel mode.

CHAPTER 192

Reverse Route Injection

Reverse route injection (RRI) is the ability for static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint. These protected hosts and networks are known as remote proxy identities.

Each route is created on the basis of the remote proxy network and mask, with the next hop to this network being the remote tunnel endpoint. By using the remote Virtual Private Network (VPN) router as the next hop, the traffic is forced through the crypto process to be encrypted.

- [Configuration Examples for Reverse Route Injection, on page 2502](#)
- [Additional References, on page 2503](#)
- [Feature Information for Reverse Route Injection, on page 2503](#)

Prerequisites for Reverse Route Injection

- IP routing should be enabled and static routes should be redistributed if dynamic routing protocols are to be used to propagate RRI-generated static routes.

Restrictions for Reverse Route Injection

- RRI is not supported for IPv6 crypto maps.
- For static crypto maps, routes are always present if RRI is configured on an applied crypto map. The default behavior (of routes always being present for a static map) will not apply unless the **static** keyword is added to the **reverse-route** command.
- For a prefix in the RIB, if you have manually configured a static route with a tag and a route without a tag inserted through RRI, the route selection may be inconsistent. In this scenario, either the manually configured route or the RRI route may be chosen. To prevent such an inconsistency, perform one of the following actions:
 - Disable RRI by removing reverse route configuration from the crypto map, if you are manually configuring static routes to all the peer VPN networks of the router.

- Set an identical tag in the crypto map for the route inserted through RRI.

Information About Reverse Route Injection

Reverse Route Injection

RRI is the ability for static routes to be automatically inserted into the routing process for those networks and hosts that are protected by a remote tunnel endpoint. These protected hosts and networks are known as remote proxy identities.

Each route is created on the basis of the remote proxy network and mask, with the next hop to this network being the remote tunnel endpoint. By using the remote VPN router as the next hop, the traffic is forced through the crypto process to be encrypted.

After the static route is created on the VPN router, this information is propagated to upstream devices, allowing them to determine the appropriate VPN router to which to send returning traffic in order to maintain IPsec state flows. Being able to determine the appropriate VPN router is particularly useful if multiple VPN routers are used at a site to provide load balancing or failover or if the remote VPN devices are not accessible via a default route. Routes are created in either the global routing table or the appropriate virtual route forwarding (VRF) table.

RRI is applied on a per-crypto map basis, whether this is via a static crypto map or a dynamic crypto map template. The default behavior for the two map types is as follows:

- In the case of a dynamic crypto map, routes are created upon the successful establishment of IPsec security associations (SAs) for those remote proxies. The next hop back to those remote proxies is via the remote VPN router whose address is learned and applied during the creation of the dynamic crypto map template. The routes are deleted after the SAs are deleted. Routes created on the basis of IPsec source proxies on static crypto maps is the default behavior on static maps and overrides the creation of routes on the basis of crypto ACLs (see the next bullet).
- For static crypto maps, routes are created on the basis of the destination information defined in the crypto access list. The next hop is taken from the first set peer statement that is attached to the crypto map. If at any time, RRI, the peer, or the access list is removed from the crypto map, routes will be deleted. This behavior changes with the addition of the RRI enhancements, as explained in the sections below.

How to Configure Reverse Route Injection

Configuring RRI Under a Static Crypto Map

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** { *map-name* } { *seq-name* } **ipsec-isakmp**
4. **reverse-route** [**static** | **tag** *tag-id* [**static**] | **remote-peer**[**static**] | **remote-peer** *ip-address* [**static**]]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto map { map-name } { seq-name} ipsec-isakmp Example: <pre>Router (config)# crypto map mymap 1 ipsec-isakmp</pre>	Creates or modifies a crypto map entry and enters crypto map configuration mode.
Step 4	reverse-route [static tag tag-id [static] remote-peer[static] remote-peer ip-address [static]] Example: <pre>Router (config-crypto-map)# reverse-route remote peer 10.1.1.1</pre>	Creates source proxy information for a crypto map entry.

Configuring RRI Under a Dynamic Map Template

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto dynamic-map** *dynamic-map-name* *dynamic-seq-name*
4. **reverse-route** [static | tag *tag-id* [static] | remote-peer[static] | remote-peer *ip-address* [static]]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto dynamic-map <i>dynamic-map-name</i> <i>dynamic-seq-name</i> Example: Router (config)# crypto dynamic-map mymap 1	Creates a dynamic crypto map entry and enters the crypto map configuration command mode.
Step 4	reverse-route [static tag <i>tag-id</i> [static] remote-peer [static] remote-peer <i>ip-address</i> [static]] Example: Router (config-crypto-map)# reverse-route remote peer 10.1.1.1	Creates source proxy information for a crypto map entry.

Configuration Examples for Reverse Route Injection

Configuring RRI When Crypto ACLs Exist Example

The following example shows that all remote VPN gateways connect to the router via 192.168.0.3. RRI is added on the static crypto map, which creates routes on the basis of the source network and source netmask that are defined in the crypto access control list (ACL):

```
crypto map mymap 1 ipsec-isakmp
  set peer 10.1.1.1
  reverse-route
  set transform-set esp-3des-sha
  match address 102
Interface FastEthernet 0/0/1
  ip address 192.168.0.2 255.255.255.0
  standby name group1
  standby ip 192.168.0.3
  crypto map mymap redundancy group1
access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255
```

Configuring RRI When Two Routes Are Created One for the Remote Endpoint and One for Route Recursion Example

In the following example, two routes are created, one for the remote endpoint and one for route recursion to the remote endpoint via the interface on which the crypto map is configured:

```
reverse-route remote-peer
```

Information About IPsec VPN High Availability Enhancements

Reverse Route Injection

Reverse Route Injection (RRI) simplifies network design for Virtual Private Networks (VPNs) in which there is a requirement for redundancy or load balancing. RRI works with both dynamic and static crypto maps.

RRI provides the following benefits:

- Enables routing of IPsec traffic to a specific VPN headend device in environments that have multiple (redundant) VPN headend devices.
- Ensures predictable failover time of remote sessions between headend devices when using IKE keepalives, especially in environments in which remote device route flapping is common (not taking into consideration the effects of route convergence, which may vary depending on the routing protocol used and the size of the network).
- Eliminates the need for the administration of static routes on upstream devices, as routes are dynamically learned by these devices.

In the dynamic case, as remote peers establish IPsec security associations (SAs) with an RRI-enabled router, a static route is created for each subnet or host protected by that remote peer. For static crypto maps, a static route is created for each destination of an extended access list rule. When RRI is used on a static crypto map with an access control list (ACL), routes will always exist, even without the negotiation of IPsec SAs.

Note The use of any keyword in ACLs with RRI is not supported.

When routes are created, they are injected into any dynamic routing protocol and distributed to surrounding devices. This traffic flows, requiring IPsec to be directed to the appropriate RRI router for transport across the correct SAs to avoid IPsec policy mismatches and possible packet loss.

The figure below shows an RRI configuration functionality topology. Remote A is being serviced by Router A and Remote B connected to Router B, providing load balancing across VPN gateways at the central site. RRI on the central site devices ensures that the other router on the inside of the network can automatically make the correct forwarding decision. RRI also eliminates the need to administer static routes on the inside router.

Figure 97: Topology Showing Reverse Route Injection Configuration Functionality

Hot Standby Router Protocol and IPsec

Hot Standby Router Protocol (HSRP) provides high network availability by routing IP traffic from hosts on Ethernet networks without relying on the availability of any single router. HSRP is particularly useful for hosts that do not support a router discovery protocol, such as ICMP Router Discovery Protocol (IRDP) and do not have the functionality to switch to a new router when their selected router reloads or loses power. Without this functionality, a router that loses its default gateway because of a router failure cannot communicate with the network.

HSRP is configurable on LAN interfaces using standby command-line interface (CLI) commands. You can use the standby IP address from an interface as the local IPsec identity or local tunnel endpoint.

By using the standby IP address as the tunnel endpoint, failover can be applied to VPN routers by using HSRP. Remote VPN gateways connect to the local VPN router via the standby address that belongs to the active

device in the HSRP group. In the event of failover, the standby device takes over ownership of the standby IP address and begins to service remote VPN gateways.

Failover can be applied to VPN routers through the use of HSRP. Remote VPN gateways connect to the local VPN router through the standby address that belongs to the active device in the HSRP group. This functionality reduces configuration complexity on remote peers with respect to defining gateway lists, because only the HSRP standby address needs to be defined.

The figure below shows the enhanced HSRP functionality topology. Traffic is serviced by the active Router P, which is the active device in the standby group. In the event of failover, traffic is diverted to Router S, which is the original standby device. Router S assumes the role of the new active router and takes ownership of the standby IP address.

Figure 98: Topology Showing Hot Standby Router Protocol Functionality

Note In case of a failover, HSRP does not facilitate IPsec state information transference between VPN routers. This means that without this state transference, SAs to remotes will be deleted, requiring Internet Key Exchange (IKE) and IPsec SAs to be reestablished. To make IPsec failover more efficient, it is recommended that IKE keepalives be enabled on all routers.

How to Configure IPsec VPN High Availability Enhancements

Configuring Reverse Route Injection on a Dynamic Crypto Map

Dynamic crypto map entries, like regular static crypto map entries, are grouped into sets. A set is a group of dynamic crypto map entries all with the same dynamic map name, but each with a different dynamic sequence number. Each member of the set may be configured for RRI.

To create a dynamic crypto map entry and enable RRI, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto dynamic-map** *map-name seq-num*

4. `set transform-set`
5. `reverse-route`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> <code>enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# <code>configure terminal</code>	Enters global configuration mode.
Step 3	crypto dynamic-map <i>map-name seq-num</i> Example: Router(config)# <code>crypto dynamic-map mymap</code>	Creates a dynamic crypto map entry and enters crypto map configuration mode.
Step 4	set transform-set Example: Router(config-crypto-m)# <code>set transform-set</code>	Specifies which transform sets are allowed for the crypto map entry. Lists multiple transform sets in order of priority (highest priority first). This entry is the only configuration statement required in dynamic crypto map entries.
Step 5	reverse-route Example: Router(config-crypto-m)# <code>reverse-route</code>	Creates source proxy information.

Configuring Reverse Route Injection on a Static Crypto Map

Before configuring RRI on a static crypto map, note that:

- Routes are not created based on access list 102, as `reverse-route` is not enabled on `mymap 2`. RRI is not enabled by default and is not displayed in the router configuration.
- Enable a routing protocol to distribute the VPN routes to upstream devices.
- If Cisco Express Forwarding (CEF) is run on a VPN router configured for RRI, adjacencies need to be formed for each RRI injected network through the next hop device. As the next hop is not explicitly defined in the routing table for these routes, proxy-ARP should be enabled on the next hop router, which allows the CEF adjacency to be formed using the Layer 2 addresses of that device. In cases where there are many RRI injected routes, adjacency tables may become quite large, as an entry is created for each device from each of the subnets represented by the RRI route.

To add RRI to a static crypto map set, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num ipsec-isakmp*
4. **set peer** *ip-address*
5. **reverse-route**
6. **match address**
7. **set transform-set** *transform-set-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto map <i>map-name seq-num ipsec-isakmp</i> Example: Router(config)# crypto map mymap 3 ipsec-isakmp	Adds a dynamic crypto map set to a static crypto map set and enters interface configuration mode.
Step 4	set peer <i>ip-address</i> Example: Router(config-if)# set peer 209.165.200.248	Specifies an IPsec peer IP address in a crypto map entry.
Step 5	reverse-route Example: Router (config-if)# reverse-route	Creates dynamic static routes based on crypto access control lists (ACLs).
Step 6	match address Example: Router(config-if)# match address	Specifies an extended access list for a crypto map entry.
Step 7	set transform-set <i>transform-set-name</i> Example: Router (config-if)# set transform-set my_t_set1	Specifies which transform sets are allowed for the crypto map entry. List multiple transform sets in order of priority (highest priority first).

Configuring HSRP with IPsec

When configuring HSRP with IPsec, the following conditions may apply:

- When HSRP is applied to a crypto map on an interface, the crypto map must be reapplied if the standby IP address or the standby name is changed on that interface.
- If HSRP is applied to a crypto map on an interface, and you delete the standby IP address or the standby name from that interface, the crypto tunnel endpoint is reinitialized to the actual IP address of that interface.
- If you add the standby IP address and the standby name to an interface with the requirement IPsec failover, the crypto map must be reapplied with the appropriate redundancy information.
- Standby priorities should be equal on active and standby routers. If they are not, the higher priority router takes over as the active router. If the old active router comes back up and immediately assumes the active role before having time to report itself, standby and sync connections will be dropped.
- The IP addresses on the HSRP-tracked interfaces on the standby and active routers should both be either lower or higher on one router than the other. In the case of equal priorities (an HA requirement), HSRP will assign the active state-based IP address. If an addressing scheme exists so that the public IP address of router A is lower than the public IP address of router B, but the opposite is true for their private interfaces, an active/standby-standby/active split condition could exist, which will break connectivity.

Note To configure HSRP without IPsec, refer to the “Configuring IP Services” module in the *IP Application Services Configuration Guide*.

To apply a crypto map set to an interface, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type slot / port*
4. **standby name** *group-name*
5. **standby ip** *ip-address*
6. **crypto map** *map-name* **redundancy** [*standby-name*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Router# <code>configure terminal</code>	
Step 3	<code>interface</code> <i>type slot / port</i> Example: Router(config)# <code>interface GigabitEthernet 0/0</code>	Specifies an interface and enters interface configuration mode.
Step 4	<code>standby name</code> <i>group-name</i> Example: Router(config-if)# <code>standby name mygroup</code>	Specifies the standby group name.
Step 5	<code>standby ip</code> <i>ip-address</i> Example: Router(config-if)# <code>standby ip 209.165.200.249</code>	Specifies the IP address of the standby groups <ul style="list-style-type: none"> • This command is required for one device in the group.
Step 6	<code>crypto map</code> <i>map-name</i> redundancy [<i>standby-name</i>] Example: Router (config-if)# <code>crypto map mymap redundancy</code>	Specifies the IP redundancy address as the tunnel endpoint for IPsec.

Verifying VPN IPsec Crypto Configuration

SUMMARY STEPS

1. `enable`
2. `show crypto ipsec transform-set`
3. `show crypto map` [*interface interface* | **tag** *map-name*]
4. `show crypto ipsec sa` [**map** *map-name* | **address** | **identity**] [**detail**]
5. `show crypto dynamic-map` [**tag** *map-name*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code> Example: Router> <code>enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<code>show crypto ipsec transform-set</code> Example: Router# <code>show crypto ipsec transform-set</code>	Displays the transform set configuration.

	Command or Action	Purpose
Step 3	show crypto map [interface <i>interface</i> tag <i>map-name</i>] Example: Router# <code>show crypto map tag mycryptomap</code>	Displays your crypto map configuration.
Step 4	show crypto ipsec sa [map <i>map-name</i> address identity] [detail] Example: Router# <code>show crypto ipsec sa address detail</code>	Displays information about IPsec SAs.
Step 5	show crypto dynamic-map [tag <i>map-name</i>] Example: Router# <code>show crypto dynamic-map tag mymap</code>	Displays information about dynamic crypto maps.

Configuring High Availability Redundancy on the Virtual Tunnel Interface using HSRP

You can configure High Availability (HA) redundancy for IPsec with Virtual Tunnel Interface (VTI) using Hot Standby Router Protocol (HSRP) and establish an IPsec session between the active HSRP device and the remote device. In this topology, the remote device establishes an IPsec session with the HSRP active device based on the priority configuration. The higher priority device acts as the active device. If the active device goes down, a new IPsec session is established from the standby device.

Figure 99: Topology Showing Redundancy High Availability for Virtual Tunnel Interface Using HSRP

To configure HA redundancy for Virtual Tunnel Interface using HSRP:

- Configure the device A and B with HA configuration.
- The VTI tunnel source address should point to the VIP address of the physical interface.

- Configure the remote device to establish an IPsec session to the active device of the HSRP pair.

Configuring HA on the IPsec Virtual Tunnel Interfaces of the Device A and B

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto IPsec profile** *profile-name*
4. **set transform-set** *transform-set-name* [*transform-set-name2*...*transform-set-name6*]
5. **set ikev2 profile** *ikev2 profile-name*
6. **crypto ikev2 dpd** *interval* *retry-interval* {**on-demand** | **periodic**}
7. **exit**
8. **interface** *type number*
9. **ip address** *address mask*
10. **tunnel source** *ip address*
11. **tunnel mode ipsec ipv4**
12. **tunnel destination** *ip-address*
13. **tunnel protection IPsec profile** *profile-name*
14. **exit**
15. **interface type slot/port** *number*
16. **ip address** *address mask*
17. **standbygroup-number ip** [*IP* [**secondary**]]
18. **standbygroup-number priority** *priority name*
19. **standbygroup-number preempt**
20. **standbygroup-number name** *name*
21. **standbygroup-number track** *type* [*interface-priority*]
22. **negotiate auto**
23. **exit**
24. **interface type slot/port** *number*
25. **ip address** *address mask*
26. **standbygroup-number ip** [*IP* [**secondary**]]
27. **standbygroup-number priority** *priority name*
28. **standbygroup-number preempt**
29. **standbygroup-number track** *type* [*interface-priority*]
30. **negotiate auto**
31. **exit**
32. Repeat the same steps and configure the device B.

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto IPsec profile <i>profile-name</i> Example: Device(config)# crypto IPsec profile TUNNEL-PROFILE-SITE	Defines the IPsec parameters that are to be used for IPsec encryption between two IPsec devices, and enters IPsec profile configuration mode.
Step 4	set transform-set <i>transform-set-name</i> [<i>transform-set-name2...transform-set-name6</i>] Example: Device(config-ipsec-profile)# set transform-set tset1	Specifies which transform sets can be used .
Step 5	set ikev2 profile <i>ikev2 profile-name</i> Example: Device(config-ipsec-profile)# set ikev2-profile ikev2profile	Specifies which transform sets can be used .
Step 6	crypto ikev2 dpd <i>interval retry-interval {on-demand periodic}</i> Example: Device(config-ikev2-profile)# crypto ikev2 dpd 10 2 periodic	This step is optional. Configures Dead Peer Detection (DPD) globally for peers matching the profile. By default, the Dead Peer Detection (DPD) is disabled.
Step 7	exit Example: Device(ipsec-profile)# exit	Exits IPsec profile configuration mode, and enters global configuration mode.
Step 8	interface <i>type number</i> Example: Device(config)# interface tunnel 10	Specifies the interface on which the tunnel will be configured and enters interface configuration mode.
Step 9	ip address <i>address mask</i> Example: Device(config-if)# ip address 10.10.10.1 255.255.255.0	Specifies the IP address and mask.

	Command or Action	Purpose
Step 10	tunnel source <i>ip address</i> Example: Device(config-if)# tunnel source 2.2.2.1	Specifies the tunnel source address. For IPsec HA, this tunnel source address should point to the HSRP VIP (Virtual IP) address of the physical interface terminating the tunnel.
Step 11	tunnel mode ipsec ipv4 Example: Device(config-if)# tunnel mode ipsec ipv4	Defines the mode for the tunnel.
Step 12	tunnel destination <i>ip-address</i> Example: Device(config-if)# tunnel destination 3.3.3.5	Identifies the IP address of the tunnel destination.
Step 13	tunnel protection IPsec profile <i>profile-name</i> Example: Device(config-if)# tunnel protection IPsec profile TUNNEL-PROFILE-SITE	Associates a tunnel interface with an IPsec profile.
Step 14	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to privileged EXEC mode.
Step 15	interface type slot/port number Example: Device(config)# interface GigabitEthernet0/0/0	Specifies a gigabit ethernet interface and enters interface configuration mode.
Step 16	ip address address mask Example: Device(config-if)# ip address 2.2.2.2 255.255.255.0	Specifies the IP address and mask.
Step 17	standbygroup-number ip [IP [secondary]] Example: Device(config-if)# standby 1 ip 2.2.2.1	Specifies the standby IP address to activate the Hot Standby Router Protocol (HSRP).
Step 18	standbygroup-number priority priority name Example: Device(config-if)# standby 1 priority 105	Specifies the standby priority to activate the Hot Standby Router Protocol (HSRP).
Step 19	standbygroup-number preempt Example:	Specifies the standby preempt to activate the Hot Standby Router Protocol (HSRP).

	Command or Action	Purpose
	Device(config-if)# standby 1 preempt	
Step 20	standbygroup-number name name Example: Device(config-if)# standby 1 name IPSEC-VTI-HA	Specifies the standby name to activate the Hot Standby Router Protocol (HSRP).
Step 21	standbygroup-number track type [interface-priority] Example: Device(config-if)# standby 1 track 200 decrement 10	Specifies the interface to track other interfaces, so that if one of the other interfaces goes down, the device's Hot Standby priority is lowered.
Step 22	negotiate auto Example: Device(config-if)# negotiation auto	Enables the autonegotiation protocol to configure the speed, duplex, and automatic flow-control of the Gigabit Ethernet interface.
Step 23	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to privileged EXEC mode.
Step 24	interface type slot/port number Example: Device(config)# interface GigabitEthernet0/0/1	Specifies a gigabit ethernet interface and enters interface configuration mode.
Step 25	ip address address mask Example: Device(config-if)# ip address 1.1.1.2 255.255.255.0	Specifies the IP address and mask.
Step 26	standbygroup-number ip [IP [secondary]] Example: Device(config-if)# standby 2 ip 1.1.1.1	Specifies the standby IP address to activate the Hot Standby Router Protocol (HSRP).
Step 27	standbygroup-number priority priority name Example: Device(config-if)# standby 2 priority 105	Specifies the standby priority to activate the Hot Standby Router Protocol (HSRP).
Step 28	standbygroup-number preempt Example: Device(config-if)# standby 2 preempt	Specifies the standby preempt to activate the Hot Standby Router Protocol (HSRP).

	Command or Action	Purpose
Step 29	standbygroup-number track type [interface-priority] Example: Device(config-if)# standby 2 track 100 decrement 10	Specifies the interface to track other interfaces, so that if one of the other interfaces goes down, the device's Hot Standby priority is lowered.
Step 30	negotiate auto Example: Device(config-if)# negotiation auto	Enables the autonegotiation protocol to configure the speed, duplex, and automatic flow-control of the Gigabit Ethernet interface.
Step 31	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to privileged EXEC mode.
Step 32	Repeat the same steps and configure the device B.	

Configuring IPsec Virtual Tunnel Interface on the Remote Device

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto IPsec profile** *profile-name*
4. **set transform-set** *transform-set-name* [*transform-set-name2...transform-set-name6*]
5. **set ikev2 profile** *ikev2 profile-name*
6. **crypto ikev2 dpd** *interval retry-interval* {**on-demand** | **periodic**}
7. **exit**
8. **interface** *type number*
9. **ip address** *address mask*
10. **tunnel source** *interface-type interface-number*
11. **tunnel mode ipsec ipv4**
12. **tunnel destination** *ip-address*
13. **tunnel protection IPsec profile** *profile-name*
14. **exit**
15. **interface type slot/port** *number*
16. **ip address** *address mask*
17. **negotiate auto**
18. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: Device> enable	<ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto IPsec profile <i>profile-name</i> Example: Device(config)# crypto IPsec profile TUNNEL-PROFILE-SITE	Defines the IPsec parameters that are to be used for IPsec encryption between two IPsec devices, and enters IPsec profile configuration mode.
Step 4	set transform-set <i>transform-set-name</i> [<i>transform-set-name2...transform-set-name6</i>] Example: Device(config-ipsec-profile)# set transform-set tset1	Specifies which transform sets can be used .
Step 5	set ikev2 profile <i>ikev2 profile-name</i> Example: Device(config-ipsec-profile)# set ikev2-profile ikev2profile	Specifies which transform sets can be used .
Step 6	crypto ikev2 dpd <i>interval retry-interval</i> {on-demand periodic} Example: Device(config-ikev2-profile)# crypto ikev2 dpd 10 2 periodic	This step is optional. Configures Dead Peer Detection (DPD) globally for peers matching the profile. By default, the Dead Peer Detection (DPD) is disabled.
Step 7	exit Example: Device(ipsec-profile)# exit	Exits IPsec profile configuration mode, and enters global configuration mode.
Step 8	interface <i>type number</i> Example: Device(config)# interface tunnel 10	Specifies the interface on which the tunnel will be configured and enters interface configuration mode.
Step 9	ip address <i>address mask</i> Example: Device(config-if)# ip address 10.10.10.254 255.255.255.0	Specifies the IP address and mask.

	Command or Action	Purpose
Step 10	tunnel source <i>interface-type interface-number</i> Example: Device(config-if)# tunnel source 3.3.3.5	Specifies the tunnel source interface.
Step 11	tunnel mode ipsec ipv4 Example: Device(config-if)# tunnel mode ipsec ipv4	Defines the mode for the tunnel.
Step 12	tunnel destination <i>ip-address</i> Example: Device(config-if)# tunnel destination 2.2.2.1	Identifies the IP address of the tunnel destination.
Step 13	tunnel protection IPsec profile <i>profile-name</i> Example: Device(config-if)# tunnel protection IPsec profile TUNNEL-PROFILE-SITE	Associates a tunnel interface with an IPsec profile.
Step 14	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to privileged EXEC mode.
Step 15	interface type slot/port number Example: Device(config)# interface GigabitEthernet0/0/1	Specifies a gigabit ethernet interface and enters interface configuration mode.
Step 16	ip address <i>address mask</i> Example: Device(config-if)# ip address 3.3.3.5 255.255.255.0	Specifies the IP address and mask.
Step 17	negotiate auto Example: Device(config-if)# negotiation auto	Enables the autonegotiation protocol to configure the speed, duplex, and automatic flow-control of the Gigabit Ethernet interface.
Step 18	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to privileged EXEC mode.

Configuration Examples for IPsec VPN High Availability Enhancements

Example: Configuring Reverse Route Injection on a Dynamic Crypto Map

In the following example, using the **reverse-route** command in the definition of the dynamic crypto map template ensures that routes are created for any remote proxies (subnets or hosts), protected by the connecting remote IPsec peers.

```
crypto dynamic mydynmap 1
  set transform-set my-transform-set
  reverse-route
```

This template is then associated with a “parent” crypto map statement and then applied to an interface.

```
crypto map mymap 3 ipsec-isakmp dynamic mydynmap
interface FastEthernet 0/0
crypto map mymap
```

Example: Configuring Reverse Route Injection on a Static Crypto Map

RRI is a good solution for topologies that require encrypted traffic to be diverted to a VPN router and all other traffic to a different router. In these scenarios, RRI eliminates the need to manually define static routes on devices.

RRI is not required if a single VPN router is used, and all traffic passes through the VPN router during its path in to and out of the network.

If you choose to manually define static routes on the VPN router for remote proxies and have these routes permanently installed in the routing table, RRI should not be enabled on the crypto map instance that covers the same remote proxies. In this case, there is no possibility of user-defined static routes being removed by RRI.

Routing convergence can affect the success of a failover based on the routing protocol used to advertise routes (link state versus periodic update). We recommend that a link state routing protocol such as OSPF be used to help speed convergence time by ensuring that routing updates are sent as soon as a change in routing state is detected.

In the following example, RRI is enabled for mymap 1, but not for mymap 2. Upon the application of the crypto map to the interface, a route is created based on access-list 101 analogous to the following:

```
IP route 172.17.11.0 255.255.255.0 FastEthernet 0/0
crypto map mymap 1 ipsec-isakmp
  set peer 172.17.11.1
  reverse-route
  set transform-set my-transform-set
  match address 101
crypto map mymap 2 ipsec-isakmp
  set peer 10.1.1.1
  set transform-set my-transform-set
  match address 102
access-list 101 permit ip 192.168.1.0 0.0.0.255 172.17.11.0 0.0.0.255
```

```
access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255
interface FastEthernet 0/0
 crypto map mymap
```

Example: Configuring HSRP with IPsec

The following example shows how all remote VPN gateways connect to the router via 192.168.0.3. The crypto map on the interface binds this standby address as the local tunnel endpoint for all instances of the crypto map named *mymap* and at the same time ensures that HSRP failover is facilitated between an active and standby device belonging to the same standby group named *group1*.

Note that RRI also provides the ability for only the active device in the HSRP group to be advertising itself to inside devices as the next hop VPN gateway to the remote proxies. If there is a failover, routes are deleted on the formerly active device and created on the newly active device.

```
crypto map mymap 1 ipsec-isakmp
 set peer 10.1.1.1
 reverse-route
 set transform-set esp-aes-sha
 match address 102
Interface FastEthernet 0/0
 ip address 192.168.0.2 255.255.255.0
 standby name group1
 standby ip 192.168.0.3
 crypto map mymap redundancy group1
access-list 102 permit ip 192.168.1.0 0.0.0.255 10.0.0.0 0.0.255.255
```

The standby name needs to be configured on all devices in the standby group, and the standby address needs to be configured on at least one member of the group. If the standby name is removed from the router, the IPsec SAs will be deleted. If the standby name is added again, regardless of whether the same name or a different name is used, the crypto map (using the redundancy option) will have to be reapplied to the interface.

Example: Configuring HA Redundancy on the VTI using HSRP

The following example shows how to configure HA redundancy for VTI using HSRP and establishes and establishes an IPsec session between the devices in the inside network and the remote device.

Device A

```
crypto ipsec profile TUNNEL-PROFILE-SITE
 set transform-set tset1
 set ikev2-profile ikev2profile
crypto ikev2 dpd 10 2 periodic
!
interface Tunnel10
 ip address 10.10.10.1 255.255.255.0
 tunnel source 2.2.2.1
 tunnel mode ipsec ipv4
 tunnel destination 3.3.3.5
 tunnel protection ipsec profile TUNNEL-PROFILE-SITE
!
interface GigabitEthernet0/0/0
 ip address 2.2.2.2 255.255.255.0
 standby 1 ip 2.2.2.1
 standby 1 priority 105
 standby 1 preempt
 standby 1 name IPSEC-VTI-HA
 standby 1 track 200 decrement 10
```

```

negotiation auto
!
interface GigabitEthernet0/0/1
ip address 1.1.1.2 255.255.255.0

Feature Information for IPsec VPN High Availability Enhancements

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 261: Feature Information for IPsec VPN High Availability Enhancements

Feature Name	Releases	Feature Information
IPsec VPN High Availability Enhancements	Cisco IOS XE 3.1.0S	<p>The IPsec VPN High Availability Enhancements feature consists of two features: Reverse Route Injection (RRI) and Hot Standby Router Protocol (HSRP) with IPsec. When used together, these two features provide you with a simplified network design for VPNs and reduced configuration complexity on remote peers when defining gateway lists.</p> <p>The following commands were introduced or modified: crypto map (interface IPsec), reverse-route.</p>

CHAPTER 194

IPsec Preferred Peer

The IP Security (IPsec) Preferred Peer feature allows you to control the circumstances by which multiple peers on a crypto map are tried in a failover scenario.

This feature includes the following capabilities:

- Default peer configuration
- IPsec idle-timer usage with default peer
- [Prerequisites for IPsec Preferred Peer, on page 2525](#)
- [Restrictions for IPsec Preferred Peer, on page 2525](#)
- [Information About IPsec Preferred Peer, on page 2526](#)
- [How to Configure IPsec Preferred Peer, on page 2528](#)
- [Configuration Examples for IPsec Preferred Peer, on page 2530](#)
- [Additional References, on page 2530](#)
- [Feature Information for IPsec Preferred Peer, on page 2531](#)
- [Glossary, on page 2531](#)

Prerequisites for IPsec Preferred Peer

- You must have a properly defined, complete crypto map.

Restrictions for IPsec Preferred Peer

Default Peer

- This feature must be used in conjunction with Dead Peer Detection (DPD). It is most effective on a remote site running DPD in periodic mode. DPD detects the failure of a device quickly and resets the peer list so that the default peer is tried for the next attempted connection.
- Only one peer can be designated as the default peer in a crypto map.
- The default peer must be the first peer in the peer list.

IPsec Idle Timer Usage with Default Peer

- This feature works only on the crypto map for which it is configured. You cannot configure the capability globally for all crypto maps.
- If there is a global idle timer, the crypto map idle-timer value must be different from the global value; otherwise, the idle timer is not added to the crypto map.

IPsec Failover

IPsec on the Cisco ASR 1000 Series Router supports only stateless failover. IPsec failover is a feature that increases the total uptime (or availability) of an IPsec network. This is accomplished traditionally by employing a redundant (standby) router in addition to the original (active) router. If the active router becomes unavailable for any reason, the standby router takes over the processing of IKE and IPsec.

IPsec failover falls into two categories: stateless failover and stateful failover. Stateless failover uses protocols such as the Hot Standby Router Protocol (HSRP) to provide primary-to-secondary cutover and also allows the active and standby VPN gateways to share a common virtual IP address.

Information About IPsec Preferred Peer

IPsec

IPsec is a framework of open standards developed by the Internet Engineering Task Force (IETF). IPsec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPsec acts at the network layer, protecting and authenticating Internet Protocol (IP) packets between participating IPsec devices (peers), such as Cisco routers.

IPsec provides the following network security services. These services are optional. In general, local security policy dictates the use of one or more of these services:

- Data Confidentiality--The IPsec sender can encrypt packets before transmitting them across a network.
- Data Integrity--The IPsec receiver can authenticate packets sent by the IPsec sender to ensure that the data has not been altered during transmission.
- Data Origin Authentication--The IPsec receiver can authenticate the source of the IPsec packets sent.
- Anti-Replay--The IPsec receiver can detect and reject replayed packets.

With IPsec, data can be transmitted across a public network without fear of observation, modification, or spoofing. This enables applications such as Virtual Private Networks (VPNs), including intranets, extranets, and remote user access.

IPsec provides secure tunnels between two peers, such as two routers. You define which packets are considered sensitive and should be sent through these secure tunnels, and you define the parameters that should be used to protect these sensitive packets, by specifying characteristics of these tunnels. When the IPsec peer sees such a sensitive packet, it sets up the appropriate secure tunnel and sends the packet through the tunnel to the remote peer.

Dead Peer Detection

The VPN Client uses a keepalive mechanism called Dead Peer Detection (DPD) to check the availability of the VPN device on the other side of an IPsec tunnel. If the network is unusually busy or unreliable, you can increase the number of seconds that the VPN Client will wait before deciding whether the peer is no longer active.

Keepalive packets are not sent if traffic is received. This lowers the overhead associated with DPD, because on a heavily loaded network very few keepalive packets will be sent because traffic is being received on the tunnels. In addition, DPD sends keepalive packets only if there is user traffic to send (and no user traffic is received).

You can configure Internet Key Exchange (IKE) DPD so that DPD sends the keepalive packets whether or not there is outbound user data. That is, as long as there is no inbound user data, the keepalive packets are sent at the configured keepalive interval.

Default Peer Configuration

If a connection timeout occurs, the connection to the current peer is closed. The **set peer** command allows you to configure the first peer as the default peer. If there is a default peer, the next time a connection is initiated, the connection is directed to the default peer instead of to the next peer in the peer list. If the default peer is unresponsive, the next peer in the peer list becomes the current peer and future connections through the crypto map try that peer.

This capability is useful when traffic on a physical link stops due to the failure of a remote peer. DPD indicates that the remote peer is unavailable, but that peer remains the current peer.

A default peer facilitates the failover to a preferred peer that was previously unavailable, but has returned to service. Users can give preference to certain peers in the event of a failover. This is useful if the original failure was due to a network connectivity problem rather than failure of the remote peer.

Idle Timers

When a router creates an IPsec security association (SA) for a peer, resources must be allocated to maintain the SA. The SA requires both memory and several managed timers. For idle peers, these resources are wasted. If enough resources are wasted by idle peers, the router could be prevented from creating new SAs with other peers.

IPsec SA idle timers increase the availability of resources by deleting SAs associated with idle peers. Because IPsec SA idle timers prevent the wasting of resources by idle peers, more resources are available to create new SAs when required.

If IPsec SA idle timers are not configured, only the global lifetimes for IPsec SAs are applied. SAs are maintained until the global timers expire, regardless of peer activity.

IPsec Idle-Timer Usage with Default Peer

If all connections to the current peer time out, the next time a connection is initiated it is directed to the default peer configured in the **set peer** command. If a default peer is not configured and there is a connection timeout, the current peer remains the one that timed out.

This enhancement helps facilitate a failover to a preferred peer that was previously unavailable but is in service now.

Peers on Crypto Maps

A crypto map set can contain multiple entries, each with a different access list. The router searches the crypto map entries in order, and attempts to match the packet to the access list specified in that entry.

When a packet matches a **permit** entry in a particular access list, and the corresponding crypto map entry is tagged as Cisco, connections are established with the remote peer as specified in the set peer statements within the crypto map.

How to Configure IPsec Preferred Peer

Configuring a Default Peer

To configure a default peer, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num [ipsec-isakmp] [dynamic dynamic-map-name] [discover] [profile profile-name]*
4. **set peer** *{host-name [dynamic] [default] | ip-address [default] }*
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto map <i>map-name seq-num [ipsec-isakmp] [dynamic dynamic-map-name] [discover] [profile profile-name]</i> Example: Router(config)# crypto map mymap 10 ipsec-isakmp	Enters crypto map configuration mode. Creates or modifies a crypto map entry, creates a crypto profile that provides a template for configuration of dynamically created crypto maps, or configures a client accounting list.
Step 4	set peer <i>{host-name [dynamic] [default] ip-address [default] }</i> Example:	Specifies an IPsec peer in a crypto map entry. Ensures that the first peer specified is defined as the default peer.

	Command or Action	Purpose
	Router(config-crypto-map)# set peer 10.0.0.2 default	
Step 5	exit Example: Router(config-crypto-map)# exit	Exits crypto map configuration mode and returns to global configuration mode.

Configuring the Idle Timer

To configure the idle timer, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num* [**ipsec-isakmp**] [**dynamic** *dynamic-map-name*] [**discover**] [**profile** *profile-name*]
4. **set security-association idletime** *seconds* [**default**]
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto map <i>map-name seq-num</i> [ipsec-isakmp] [dynamic <i>dynamic-map-name</i>] [discover] [profile <i>profile-name</i>] Example: Router(config)# crypto map mymap 10 ipsec-isakmp	Enters crypto map configuration mode. Creates or modifies a crypto map entry, creates a crypto profile that provides a template for configuration of dynamically created crypto maps, or configures a client accounting list.
Step 4	set security-association idletime <i>seconds</i> [default] Example: Router(config-crypto-map)# set security-association idletime 120 default	Specifies the maximum amount of time for which the current peer can be idle before the default peer is used.

	Command or Action	Purpose
Step 5	exit Example: Router(config-crypto-map)# exit	Exits crypto map configuration mode and returns to global configuration mode.

Configuration Examples for IPsec Preferred Peer

Configuring a Default Peer Example

The following example shows that the first peer, at IP address 10.1.1.1, is the default peer:

```
crypto map tohub 1 ipsec-isakmp
 set peer 10.1.1.1 default
 set peer 10.2.2.2
```

Configuring the IPsec Idle Timer Example

In the following example, if the current peer is idle for 120 seconds, the default peer 10.1.1.1 (which was specified in the **set peer** command) is used for the next attempted connection:

```
crypto map tohub 1 ipsec-isakmp
 set peer 10.1.1.1 default
 set peer 10.2.2.2
 set security-association idletime 120 default
```

Table 262: Feature Information for IPsec Preferred Peer

Feature Name	Releases	Feature Information
IPsec Preferred Peer	Cisco IOS XE Release 2.1	The IPsec Preferred Peer feature allows you to control the circumstances by which multiple peers on a crypto map are tried in a failover scenario. The following commands were introduced or modified: set peer (IPsec) and set security-association idle-time .

Glossary

crypto access list --A list that defines which IP traffic will be protected by crypto and which traffic will not be protected by crypto.

crypto map --A map that specifies which traffic should be protected by IPsec, where IPsec-protected traffic should be sent, and what IPsec transform sets should be applied to this traffic.

dead peer detection --A feature that allows the router to detect an unresponsive peer.

keepalive message --A message sent by one network device to inform another network device that the virtual circuit between the two is still active.

peer --Router or other device that participates in IPsec and IKE. In IPsec, peers are devices or entities that communicate securely either through the exchange of keys or the exchange of digital certificates.

SA --security association. An instance of security policy and keying material applied to a data flow. Both IKE and IPsec use SAs, although SAs are independent of one another. IPsec SAs are unidirectional and are unique in each security protocol. An IKE SA is used by IKE only, and unlike the IPsec SA, it is bidirectional. IKE negotiates and establishes SAs on behalf of IPsec. A user also can establish IPsec SAs manually. A set of SAs are needed for a protected data pipe, one per direction per protocol. For example, if you have a pipe that supports Encapsulating Security Payload (ESP) between peers, one ESP SA is required for each direction. SAs are identified uniquely by destination (IPsec endpoint) address, security protocol (AH or ESP), and security parameter index (SPI).

transform set --An acceptable combination of security protocols, algorithms, and other settings to apply to IPsec-protected traffic. During the IPsec security association negotiation, the peers agree to use a particular transform set when protecting a particular data flow.

CHAPTER 195

Real-Time Resolution for IPsec Tunnel Peer

After a user specifies a host name (instead of an IP address) for remote IP Security (IPsec) peer, the Real-Time Resolution for IPsec Tunnel Peer feature allows the host name to be domain name server (DNS) resolved before the router establishes the IPsec tunnel. Thus, the router can immediately discover whether the IP address of the peer has changed.

- [Restrictions for Real-Time Resolution for IPsec Tunnel Peer, on page 2533](#)
- [Information About Real-Time Resolution for IPsec Tunnel Peer, on page 2533](#)
- [How to Configure Real-Time Resolution, on page 2534](#)
- [Configuration Examples for Real-Time Resolution, on page 2536](#)
- [Additional References, on page 2537](#)
- [Feature Information for Real-Time Resolution for IPsec Tunnel Peer, on page 2538](#)

Restrictions for Real-Time Resolution for IPsec Tunnel Peer

Secure DNS Requirement

It is recommended that you use this feature only with secure DNS and when the DNS responses can be authenticated. Otherwise, an attacker can spoof or forge DNS responses and have access to Internet Key Exchange (IKE) authentication data, such as a certificate. If an attacker has a certificate that is trusted by the initiating host, the attacker can successfully establish Phase 1 IKE security association (SA), or the attacker can try to guess the preshared key that is shared between the initiator and the actual responder.

DNS Initiator

DNS names resolution for remote IPsec peers will work only if they are used as an initiator. The first packet that is to be encrypted will trigger a DNS lookup; after the DNS lookup is complete, subsequent packets will trigger IKE.

Information About Real-Time Resolution for IPsec Tunnel Peer

Real-Time Resolution Via Secure DNS

When specifying the host name of a remote IPsec peer via the **set peer** command, you can also issue the **dynamic** keyword, which defers DNS resolution of the host name until right before the IPsec tunnel has been

established. Deferring resolution enables the software to detect whether the IP address of the remote IPsec peer has changed. Thus, the software can contact the peer at the new IP address.

If the **dynamic** keyword is not issued, the host name is resolved immediately after it is specified. So, the software cannot detect an IP address change and, therefore, attempts to connect to the IP address that it previously resolved.

DNS resolution assures users that their established IPsec tunnel is secure and authenticated.

How to Configure Real-Time Resolution

Configuring Real-Time Resolution for IPsec Peers

Use this task to configure a router to perform real-time DNS resolution with a remote IPsec peer; that is, the host name of peer is resolved via a DNS lookup right before the router establishes a connection (an IPsec tunnel) with the peer.

Before you begin

Before creating a crypto map, you should perform the following tasks:

- Define Internet Security Association Key Management Protocol (ISAKMP) policies.
- Define IPsec transform sets.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num ipsec-isakmp*
4. **match address** *access-list-id*
5. **set peer** *{host-name [dynamic] | ip-address*
6. **set transform-set** *transform-set-name1 [transform-set-name2 ... transform-set-name6]*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto map <i>map-name seq-num ipsec-isakmp</i> Example: <pre>Router(config)# crypto map secure_b 10 ipsec-isakmp</pre>	Specifies the crypto map entry to create (or modify) and enters crypto map configuration mode.
Step 4	match address <i>access-list-id</i> Example: <pre>Router(config-crypto-m)# match address 140</pre>	Names an extended access list. This access list determines which traffic should be protected by IPsec and which traffic should not be protected by IPsec in the context of this crypto map entry.
Step 5	set peer <i>{host-name [dynamic] ip-address}</i> Example: <pre>Router(config-crypto-m)# set peer b.cisco.com dynamic</pre>	Specifies a remote IPsec peer. This is the peer to which IPsec-protected traffic can be forwarded. <ul style="list-style-type: none"> • dynamic --Allows the host name to be resolved via a DNS lookup just before the router establishes the IPsec tunnel with the remote peer. If this keyword is not specified, the host name will be resolved immediately after the host name is specified. Repeat for multiple remote peers.
Step 6	set transform-set <i>transform-set-name1 [transform-set-name2 ... transform-set-name6]</i> Example: <pre>Router(config-crypto-m)# set transform-set myset</pre>	Specifies which transform sets are allowed for this crypto map entry. List multiple transform sets in order of priority (highest priority first).

Troubleshooting Tips

To display crypto map configuration information, use the **show crypto map** command.

What to Do Next

You need to apply a crypto map set to each interface through which IPsec traffic will flow. Applying the crypto map set to an interface instructs the router to evaluate all the interface's traffic against the crypto map set and to use the specified policy during connection or security association (SA) negotiation on behalf of traffic to be protected by crypto.

Configuration Examples for Real-Time Resolution

Configuring Real-Time Resolution for an IPsec Peer Example

The figure below and the following example illustrate how to create a crypto map that configures the host name of a remote IPsec peer to DNS resolved via a DNS lookup right before the software attempts to establish a connection with that peer.

Figure 100: Real-Time Resolution Sample Topology

```
! Configure the initiating router.
hostname a.cisco.com
ip domain name cisco.com
ip name server 10.0.0.1
!
crypto map secure_b 10 ipsec-isakmp
  match address 140
  set peer b.cisco.com dynamic
  set transform-set xset
interface serial1
  ip address 10.10.0.1
  crypto map secure_b
access-list 140 permit ...
!
! Configure the responding router (the remote IPsec peer).
hostname b.cisco.com
!
crypto map secure_a 10 ipsec-isakmp
  match address 150
  set peer 10.10.0.1
  set transform-set
interface serial0/1
  ip address 10.0.0.1
  crypto map secure_a
access-list 150 ...
! DNS server configuration
b.cisco.com 10.0.0.1      # the address of serial0/1 of b.cisco.com
```

CHAPTER 196

Configuring Internet Key Exchange for IPsec VPNs

This module describes how to configure the Internet Key Exchange (IKE) protocol for basic IP Security (IPsec) Virtual Private Networks (VPNs). IKE is a key management protocol standard that is used in conjunction with the IPsec standard. IPsec is an IP security feature that provides robust authentication and encryption of IP packets.

IPsec can be configured without IKE, but IKE enhances IPsec by providing additional features, flexibility, and ease of configuration for the IPsec standard.

IKE is a hybrid protocol, that implements the Oakley key exchange and Skeme key exchange inside the Internet Security Association Key Management Protocol (ISAKMP) framework. (ISAKMP, Oakley, and Skeme are security protocols implemented by IKE.)

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

- [Prerequisites for IKE Configuration, on page 2541](#)
- [Restrictions for IKE Configuration, on page 2542](#)
- [Information About Configuring IKE for IPsec VPNs, on page 2542](#)
- [How to Configure IKE for IPsec VPNs, on page 2548](#)
- [Configuration Examples for an IKE Configuration, on page 2556](#)
- [Where to Go Next, on page 2559](#)
- [Additional References, on page 2559](#)
- [Feature Information for Configuring IKE for IPsec VPNs, on page 2560](#)

Prerequisites for IKE Configuration

- You should be familiar with the concepts and tasks explained in the module [Configuring Security for VPNs with IPsec](#).
- Ensure that your Access Control Lists (ACLs) are compatible with IKE. Because IKE negotiation uses User Datagram Protocol (UDP) on port 500, your ACLs must be configured so that UDP port 500 traffic

is not blocked at interfaces used by IKE and IPsec. In some cases you might need to add a statement to your ACLs to explicitly permit UDP port 500 traffic.

Restrictions for IKE Configuration

- To avoid profiles being locked or leading to DMI degrade state, before using the **config-replace** command to replace a configuration, ensure to shut down the tunnel interface to bring down all crypto sessions, and tunnel configurations.
- The initiating router *must not* have a certificate associated with the remote peer.
- The preshared key *must* be by a fully qualified domain name (FQDN) on both peers. (To configure the preshared key, enter the **crypto isakmp key** command.)
- The communicating routers *must* have a FQDN host entry for each other in their configurations.
- The communicating routers *must* be configured to authenticate by hostname, *not* by IP address; thus, you should use the **crypto isakmp identity hostname** command.
- Use **show crypto eli** command to determine the software encryption limitations for your device. Without any hardware modules, the limitations are as follows:
 - 1000 IPsec security associations (SAs)
 - 100 IKE SAs
 - 50 Diffie-Hellman (DH) session keys
- Disable the crypto batch functionality, by using the **no crypto batch allowed** command to increase the performance of a TCP flow on a Site-to-site VPN. However, disabling the crypto batch functionality might have an impact on CPU utilization.
- Starting with Cisco IOS Release 15.0(1)SY and later, you cannot configure IPsec Network Security features using **crypto ipsec** commands on Cisco Catalyst 6500 Series switches. For IPsec support on these switches, you must use a hardware encryption engine.

Information About Configuring IKE for IPsec VPNs

Supported Standards for Use with IKE

Cisco implements the following standards:

- IPsec—IP Security Protocol. IPsec is a framework of open standards that provides data confidentiality, data integrity, and data authentication between participating peers. IPsec provides these security services at the IP layer; it uses IKE to handle negotiation of protocols and algorithms based on local policy and to generate the encryption and authentication keys to be used by IPsec. IPsec can be used to protect one or more data flows between a pair of hosts, between a pair of security gateways, or between a security gateway and a host.

- ISAKMP—Internet Security Association and Key Management Protocol. A protocol framework that defines payload formats, the mechanics of implementing a key exchange protocol, and the negotiation of a security association.
- Oakley—A key exchange protocol that defines how to derive authenticated keying material.
- Skeme—A key exchange protocol that defines how to derive authenticated keying material, with rapid key refreshment.

Note Cisco no longer recommends using DES, 3DES, MD5 (including HMAC variant), and Diffie-Hellman (DH) groups 1, 2 and 5; instead, you should use AES, SHA-256 and DH Groups 14 or higher. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

The component technologies implemented for use by IKE include the following:

- AES—Advanced Encryption Standard. A cryptographic algorithm that protects sensitive, unclassified information. AES is privacy transform for IPsec and IKE and has been developed to replace the Data Encryption Standard (DES). AES is designed to be more secure than DES: AES offers a larger key size, while ensuring that the only known approach to decrypt a message is for an intruder to try every possible key. AES has a variable key length—the algorithm can specify a 128-bit key (the default), a 192-bit key, or a 256-bit key.
- DES—Data Encryption Standard. An algorithm that is used to encrypt packet data. IKE implements the 56-bit DES-CBC with Explicit IV standard. Cipher Block Chaining (CBC) requires an initialization vector (IV) to start encryption. The IV is explicitly given in the IPsec packet.

Cisco IOS software also implements Triple DES (168-bit) encryption, depending on the software versions available for a specific platform. Triple DES (3DES) is a strong form of encryption that allows sensitive information to be transmitted over untrusted networks. It enables customers, particularly in the finance industry, to utilize network-layer encryption.

Note Cisco IOS images that have strong encryption (including, but not limited to, 56-bit data encryption feature sets) are subject to United States government export controls, and have a limited distribution. Images that are to be installed outside the United States require an export license. Customer orders might be denied or subject to delay because of United States government regulations. Contact your sales representative or distributor for more information, or send e-mail to export@cisco.com.

- SEAL—Software Encryption Algorithm. An alternative algorithm to software-based DES, 3DES, and AES. SEAL encryption uses a 160-bit encryption key and has a lower impact to the CPU when compared to other software-based algorithms.
- SHA-2 and SHA-1 family (HMAC variant)—Secure Hash Algorithm (SHA) 1 and 2. Both SHA-1 and SHA-2 are hash algorithms used to authenticate packet data and verify the integrity verification mechanisms for the IKE protocol. HMAC is a variant that provides an additional level of hashing. SHA-2 family adds the SHA-256 bit hash algorithm and SHA-384 bit hash algorithm. This functionality is part of the Suite-B requirements that comprises four user interface suites of cryptographic algorithms for use with IKE and IPsec that are described in RFC 4869. Each suite consists of an encryption algorithm, a digital signature algorithm, a key agreement algorithm, and a hash or message digest algorithm. See the

Configuring Security for VPNs with IPsec feature module for more detailed information about Cisco IOS Suite-B support.

- RSA signatures and RSA encrypted nonces—RSA is the public key cryptographic system developed by Ron Rivest, Adi Shamir, and Leonard Adleman. RSA signatures provide nonrepudiation, and RSA encrypted nonces provide repudiation. (Repudiation and nonrepudiation have to do with traceability.)
- Diffie-Hellman—A public-key cryptography protocol that allows two parties to establish a shared secret over an unsecure communications channel. Diffie-Hellman is used within IKE to establish session keys. It supports 768-bit (the default), 1024-bit, 1536-bit, 2048-bit, 3072-bit, and 4096-bit DH groups. It also supports a 2048-bit DH group with a 256-bit subgroup, and 256-bit and 384-bit elliptic curve DH (ECDH). Cisco recommends using 2048-bit or larger DH key exchange, or ECDH key exchange.
- MD5—Message Digest 5 (Hash-Based Message Authentication Code (HMAC) variant). A hash algorithm used to authenticate packet data. HMAC is a variant that provides an additional level of hashing.

IKE interoperates with the X.509v3 certificates, which are used with the IKE protocol when authentication requires public keys. This certificate support allows the protected network to scale by providing the equivalent of a digital ID card to each device. When two devices intend to communicate, they exchange digital certificates to prove their identity (thus removing the need to manually exchange public keys with each peer or to manually specify a shared key at each peer).

IKE Benefits

IKE automatically negotiates IPsec security associations (SAs) and enables IPsec secure communications without costly manual preconfiguration. Specifically, IKE provides the following benefits:

- Allows you to specify a lifetime for the IPsec SA.
- Allows encryption keys to change during IPsec sessions.
- Allows IPsec to provide antireplay services.
- Permits certification authority (CA) support for a manageable, scalable IPsec implementation.
- Allows dynamic authentication of peers.

IKE Main Mode and Aggressive Mode

IKE has two phases of key negotiation: phase 1 and phase 2. Phase 1 negotiates a security association (a key) between two IKE peers. The key negotiated in phase 1 enables IKE peers to communicate securely in phase 2. During phase 2 negotiation, IKE establishes keys (security associations) for other applications, such as IPsec.

Phase 1 negotiation can occur using main mode or aggressive mode. Main mode tries to protect all information during the negotiation, meaning that no information is available to a potential attacker. When main mode is used, the identities of the two IKE peers are hidden. Although this mode of operation is very secure, it is relatively costly in terms of the time required to complete the negotiation. Aggressive mode takes less time to negotiate keys between peers; however, it gives up some of the security provided by main mode negotiation. For example, the identities of the two parties trying to establish a security association are exposed to an eavesdropper.

The two modes serve different purposes and have different strengths. Main mode is slower than aggressive mode, but main mode is more secure and more flexible because it can offer an IKE peer more security proposals than aggressive mode. Aggressive mode is less flexible and not as secure, but much faster.

In Cisco IOS software, the two modes are not configurable. The default action for IKE authentication (rsa-sig, rsa-encr, or preshared) is to initiate main mode; however, in cases where there is no corresponding information to initiate authentication, and there is a preshared key associated with the hostname of the peer, Cisco IOS software can initiate aggressive mode. Cisco IOS software will respond in aggressive mode to an IKE peer that initiates aggressive mode.

IKE Policies Security Parameters for IKE Negotiation

An IKE policy defines a combination of security parameters to be used during the IKE negotiation. You must create an IKE policy at each peer participating in the IKE exchange.

If you do not configure any IKE policies, your router will use the default policy, which is always set to the lowest priority and which contains the default value of each parameter.

About IKE Policies

Because IKE negotiations must be protected, each IKE negotiation begins by agreement of both peers on a common (shared) IKE policy. This policy states which security parameters will be used to protect subsequent IKE negotiations and mandates how the peers are authenticated.

After the two peers agree upon a policy, the security parameters of the policy are identified by an SA established at each peer, and these SAs apply to all subsequent IKE traffic during the negotiation.

You can configure multiple, prioritized policies on each peer--each with a different combination of parameter values. However, at least one of these policies must contain exactly the same encryption, hash, authentication, and Diffie-Hellman parameter values as one of the policies on the remote peer. For each policy that you create, you assign a unique priority (1 through 10,000, with 1 being the highest priority).

Tip If you are interoperating with a device that supports only one of the values for a parameter, your choice is limited to the value supported by the other device. Aside from this limitation, there is often a trade-off between security and performance, and many of these parameter values represent such a trade-off. You should evaluate the level of security risks for your network and your tolerance for these risks.

IKE Peers Agreeing Upon a Matching IKE Policy

When the IKE negotiation begins, IKE searches for an IKE policy that is the same on both peers. The peer that initiates the negotiation will send all its policies to the remote peer, and the remote peer will try to find a match. The remote peer looks for a match by comparing its own highest priority policy against the policies received from the other peer. The remote peer checks each of its policies in order of its priority (highest priority first) until a match is found.

A match is made when both policies from the two peers contain the same encryption, hash, authentication, and Diffie-Hellman parameter values.

If a match is found, IKE will complete negotiation, and IPsec security associations will be created. If no acceptable match is found, IKE refuses negotiation and IPsec will not be established.

Note The parameter values apply to the IKE negotiations after the IKE SA is established. Depending on the authentication method specified in a policy, additional configuration might be required. For more information, see [Configuring IKE Authentication, on page 2549](#).

If a peer's policy does not have the required companion configuration, the peer will not submit the policy when attempting to find a matching policy with the remote peer.

IKE Authentication

IKE authentication consists of the following options and each authentication method requires additional configuration.

RSA Signatures

With RSA signatures, you can configure the peers to obtain certificates from a CA. (The CA must be properly configured to issue the certificates.) Using a CA can dramatically improve the manageability and scalability of your IPsec network. Additionally, RSA signature-based authentication uses only two public key operations, whereas RSA encryption uses four public key operations, making it costlier in terms of overall performance. To properly configure CA support, see the module “Deploying RSA Keys Within a PKI.

The certificates are used by each peer to exchange public keys securely. RSA signatures require that each peer has the public signature key of the remote peer. When both peers have valid certificates, they will automatically exchange public keys with each other as part of any IKE negotiation in which RSA signatures are used.

You can also exchange the public keys manually, as described in [Configuring RSA Keys Manually for RSA Encrypted Nonces, on page 2549](#).

RSA signatures provide nonrepudiation for the IKE negotiation. And, you can prove to a third party after the fact that you did indeed have an IKE negotiation with the remote peer.

RSA Encrypted Nonces

With RSA encrypted nonces, you must ensure that each peer has the public keys of the other peers.

Unlike RSA signatures, the RSA encrypted nonces method cannot use certificates to exchange public keys. Instead, ensure that each peer has the other's public keys by one of the following methods:

- Configuring RSA keys manually as described in [Configuring RSA Keys Manually for RSA Encrypted Nonces, on page 2549](#).
- Ensuring that an IKE exchange using RSA signatures with certificates has already occurred between the peers. (The peers' public keys are exchanged during the RSA-signatures-based IKE negotiations if certificates are used.) To make that the IKE exchange happens, specify two policies: a higher-priority policy with RSA encrypted nonces and a lower-priority policy with RSA signatures. When IKE negotiations occur, RSA signatures will be used the first time because the peers do not yet have each other's public keys. Then future IKE negotiations can use RSA encrypted nonces because the public keys will have been exchanged. This alternative requires that you already have CA support configured.

RSA encrypted nonces provide repudiation for the IKE negotiation; however, unlike RSA signatures, you cannot prove to a third party that you had an IKE negotiation with the remote peer.

Preshared Keys

Preshared Keys An Overview

Preshared keys are clumsy to use if your secured network is large, and they do not scale well with a growing network. However, they do not require use of a CA, as do RSA signatures, and might be easier to set up in a small network with fewer than ten nodes. RSA signatures also can be considered more secure when compared with preshared key authentication.

Note If RSA encryption is configured and signature mode is negotiated (and certificates are used for signature mode), the peer will request both signature and encryption keys. Basically, the router will request as many keys as the configuration will support. If RSA encryption is not configured, it will just request a signature key.

ISAKMP Identity Setting for Preshared Keys

You should set the ISAKMP identity for each peer that uses preshared keys in an IKE policy.

When two peers use IKE to establish IPsec SAs, each peer sends its identity to the remote peer. Each peer sends either its hostname or its IP address, depending on how you have set the ISAKMP identity of the router.

By default, a peer's ISAKMP identity is the IP address of the peer. If appropriate, you could change the identity to be the peer's hostname instead. As a general rule, set the identities of all peers the same way--either all peers should use their IP addresses or all peers should use their hostnames. If some peers use their hostnames and some peers use their IP addresses to identify themselves to each other, IKE negotiations could fail if the identity of a remote peer is not recognized and a Domain Name System (DNS) lookup is unable to resolve the identity.

Mask Preshared Keys

A mask preshared key allows a group of remote users with the same level of authentication to share an IKE preshared key. The preshared key of the remote peer must match the preshared key of the local peer for IKE authentication to occur.

A mask preshared key is usually distributed through a secure out-of-band channel. In a remote peer-to-local peer scenario, any remote peer with the IKE preshared key configured can establish IKE SAs with the local peer.

If you specify the **mask** keyword with the **crypto isakmp key** command, it is up to you to use a subnet address, which will allow more peers to share the same key. That is, the preshared key is no longer restricted to use between two users.

Note Using 0.0.0.0 as a subnet address is not recommended because it encourages group preshared keys, which allow all peers to have the same group key, thereby reducing the security of your user authentication.

Disable Xauth on a Specific IPsec Peer

Disabling Extended Authentication (Xauth) for static IPsec peers prevents the routers from being prompted for Xauth information--username and password.

IKE Mode Configuration

IKE mode configuration, as defined by the Internet Engineering Task Force (IETF), allows a gateway to download an IP address (and other network-level configuration) to the client as part of an IKE negotiation. Using this exchange, the gateway gives an IP address to the IKE client to be used as an “inner” IP address encapsulated under IPsec. This method provides a known IP address for the client that can be matched against IPsec policy.

To implement IPsec VPNs between remote access clients that have dynamic IP addresses and a corporate gateway, you have to dynamically administer scalable IPsec policy on the gateway once each client is authenticated. With IKE mode configuration, the gateway can set up a scalable policy for a very large set of clients regardless of the IP addresses of those clients.

There are two types of IKE mode configuration:

- Gateway initiation--Gateway initiates the configuration mode with the client. Once the client responds, the IKE modifies the identity of the sender, the message is processed, and the client receives a response.
- Client initiation--Client initiates the configuration mode with the gateway. The gateway responds with an IP address that it has allocated for the client.

How to Configure IKE for IPsec VPNs

If you do not want IKE to be used with your IPsec implementation, you can disable it at all IPsec peers via the **no crypto isakmp** command, skip the rest of this chapter, and begin your IPsec VPN.

IKE is enabled by default. IKE does not have to be enabled for individual interfaces, but it is enabled globally for all interfaces at the router.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

Perform the following tasks to provide authentication of IPsec peers, negotiate IPsec SAs, and establish IPsec keys:

Troubleshooting Tips

- Clear (and reinitialize) IPsec SAs by using the **clear crypto sa EXEC** command.

Using the **clear crypto sa** command without parameters will clear out the full SA database, which will clear out active security sessions. You may also specify the **peer**, **map**, or **entry** keywords to clear out only a subset of the SA database. For more information, see the **clear crypto sa** command in the Cisco IOS Security Command Reference.

- The default policy and default values for configured policies do not show up in the configuration when you issue the **show running-config** command. To display the default policy and any default values within configured policies, use the **show crypto isakmp policy** command.

- Any IPsec transforms or IKE encryption methods that the current hardware does not support should be disabled; they are ignored whenever an attempt to negotiate with the peer is made.

If a user enters an IPsec transform or an IKE encryption method that the hardware does not support, a warning message will be generated. These warning messages are also generated at boot time. When an encrypted card is inserted, the current configuration is scanned. If any IPsec transforms or IKE encryption methods are found that are not supported by the hardware, a warning message will be generated.

What to Do Next

Depending on which authentication method you specified in your IKE policies (RSA signatures, RSA encrypted nonces, or preshared keys), you must do certain additional configuration tasks before IKE and IPsec can successfully use the IKE policies. For information on completing these additional tasks, see [Configuring IKE Authentication, on page 2549](#).

To configure an AES-based transform set, see the module “Configuring Security for VPNs with IPsec.”

Configuring IKE Authentication

After you have created at least one IKE policy in which you specified an authentication method (or accepted the default method), you need to configure an authentication method. IKE policies cannot be used by IPsec until the authentication method is successfully configured.

Note Before configuring IKE authentication, you must have configured at least one IKE policy, which is where the authentication method was specified (or RSA signatures was accepted by default).

To configure IKE authentication, you should perform one of the following tasks, as appropriate:

Prerequisites

You must have configured at least one IKE policy, which is where the authentication method was specified (or RSA signatures was accepted by default).

Configuring RSA Keys Manually for RSA Encrypted Nonces

Note This task can be performed only if a CA is not in use.

To manually configure RSA keys, perform this task for each IPsec peer that uses RSA encrypted nonces in an IKE policy.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto key generate rsa {general-keys} | usage-keys} [label *key-label*] [exportable] [modulus *modulus-size*]**

4. **crypto key generate ec keysize** [256 | 384] [label *label-string*]
5. **exit**
6. **show crypto key mypubkey rsa**
7. **configure terminal**
8. **crypto key pubkey-chain rsa**
9. Do one of the following:
 - **named-key** *key-name* [encryption | signature]
 - **addressed-key** *key-address* [encryption | signature]
10. **address** *ip-address*
11. **key-string** *key-string*
12. **quit**
13. Repeat these steps at each peer that uses RSA encrypted nonces in an IKE policy.
14. **exit**
15. **exit**
16. **show crypto key pubkey-chain rsa** [name *key-name* | address *key-address*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto key generate rsa {general-keys} usage-keys} [label <i>key-label</i>] [exportable] [modulus <i>modulus-size</i>] Example: Router(config)# crypto key generate rsa general-keys modulus 360	Generates the RSA keys. <ul style="list-style-type: none"> • If a <i>key-label</i> argument is not specified, the default value, which is the fully qualified domain name (FQDN) of the router, is used.
Step 4	crypto key generate ec keysize [256 384] [label <i>label-string</i>] Example: Router(config)# crypto key generate ec keysize 256 label Router_1_Key	Generates the EC keys. <ul style="list-style-type: none"> • The 256 keyword specifies a 256-bit keysize. • The 384 keyword specifies a 384-bit keysize. • A label can be specified for the EC key by using the label keyword and <i>label-string</i> argument. <p>Note If a label is not specified, then FQDN value is used.</p>
Step 5	exit Example:	(Optional) Exits global configuration mode.

	Command or Action	Purpose
	Router(config)# exit	
Step 6	show crypto key mypubkey rsa Example: Router# show crypto key mypubkey rsa	(Optional) Displays the generated RSA public keys.
Step 7	configure terminal Example: Router# configure terminal	Returns to global configuration mode.
Step 8	crypto key pubkey-chain rsa Example: Router(config)# crypto key pubkey-chain rsa	Enters public key chain configuration mode (so you can manually specify the RSA public keys of other devices).
Step 9	Do one of the following: <ul style="list-style-type: none"> • named-key <i>key-name</i> [encryption signature] • addressed-key <i>key-address</i> [encryption signature] Example: Router(config-pubkey-chain)# named-key otherpeer.example.com Example: Router(config-pubkey-chain)# addressed-key 10.1.1.2 encryption	Indicates which remote peer's RSA public key you will specify and enters public key configuration mode. <ul style="list-style-type: none"> • If the remote peer uses its hostname as its ISAKMP identity, use the named-key command and specify the remote peer's FQDN, such as somerouter.example.com, as the <i>key-name</i>. • If the remote peer uses its IP address as its ISAKMP identity, use the addressed-key command and specify the remote peer's IP address as the <i>key-address</i>.
Step 10	address ip-address Example: Router(config-pubkey-key)# address 10.5.5.1	Specifies the IP address of the remote peer. <ul style="list-style-type: none"> • If you use the named-key command, you need to use this command to specify the IP address of the peer.
Step 11	key-string key-string Example: Router(config-pubkey-key)# key-string Example: Router(config-pubkey)# 00302017 4A7D385B 1234EF29 335FC973 Example: Router(config-pubkey)# 2DD50A37 C4F4B0FD 9DADE748 429618D5 Example: Router(config-pubkey)# 18242BA3 2EDFBDD3 4296142A DDF7D3D8 Example: Router(config-pubkey)# 08407685 2F2190A0 0B43F1BD 9A8A26DB Example:	Specifies the RSA public key of the remote peer. <ul style="list-style-type: none"> • (This key was previously viewed by the administrator of the remote peer when the RSA keys of the remote router were generated.)

	Command or Action	Purpose
	<pre>Router(config-pubkey)# 07953829 791FCDE9 A98420F0 6A82045B</pre> <p>Example:</p> <pre>Router(config-pubkey)# 90288A26 DBC64468 7789F76E EE21</pre>	
Step 12	<p>quit</p> <p>Example:</p> <pre>Router(config-pubkey-key)# quit</pre>	Returns to public key chain configuration mode.
Step 13	Repeat these steps at each peer that uses RSA encrypted nonces in an IKE policy.	—
Step 14	<p>exit</p> <p>Example:</p> <pre>Router(config-pubkey-key)# exit</pre>	Returns to global configuration mode.
Step 15	<p>exit</p> <p>Example:</p> <pre>Router(config)# exit</pre>	Returns to privileged EXEC mode.
Step 16	<p>show crypto key pubkey-chain rsa [<i>name key-name</i> <i>address key-address</i>]</p> <p>Example:</p> <pre>Router# show crypto key pubkey-chain rsa</pre>	(Optional) Displays either a list of all RSA public keys that are stored on your router or details of a particular RSA key that is stored on your router.

Configuring Preshared Keys

To configure preshared keys, perform these steps for each peer that uses preshared keys in an IKE policy.

- Note** Preshared keys do not scale well with a growing network. Mask preshared keys have the following restrictions:
- The SA cannot be established between the IPsec peers until all IPsec peers are configured for the same preshared key.
 - The mask preshared key must be distinctly different for remote users requiring varying levels of authorization. You must configure a new preshared key for each level of trust and assign the correct keys to the correct parties. Otherwise, an untrusted party may obtain access to protected data.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp identity** {*address* | *dn* | *hostname*}
4. **ip host** *hostname address1* [*address2...address8*]
5. Do one of the following:

- **crypto isakmp key** *keystring* **address** *peer-address* [**mask**] [**no-xauth**]
- **crypto isakmp key** *keystring* **hostname** *hostname* [**no-xauth**]

6. Do one of the following:

- **crypto isakmp key** *keystring* **address** *peer-address* [**mask**] [**no-xauth**]
- **crypto isakmp key** *keystring* **hostname** *hostname* [**no-xauth**]

7. Repeat these steps at each peer that uses preshared keys in an IKE policy.

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp identity { address dn hostname } Example: Router(config)# crypto isakmp identity address	Specifies the peer's ISAKMP identity by IP address, by distinguished name (DN) hostname at the local peer. <ul style="list-style-type: none"> • address--Typically used when only one interface (and therefore only one IP address) will be used by the peer for IKE negotiations, and the IP address is known. • dn--Typically used if the DN of a router certificate is to be specified and chosen as the ISAKMP identity during IKE processing. The dn keyword is used only for certificate-based authentication. • hostname--Should be used if more than one interface on the peer might be used for IKE negotiations, or if the interface's IP address is unknown (such as with dynamically assigned IP addresses).
Step 4	ip host <i>hostname</i> <i>address1</i> [<i>address2...address8</i>] Example: Router(config)# ip host RemoteRouter.example.com 192.168.0.1	If the local peer's ISAKMP identity was specified using a hostname, maps the peer's host name to its IP address(es) at all the remote peers. (This step might be unnecessary if the hostname or address is already mapped in a DNS server.)
Step 5	Do one of the following: <ul style="list-style-type: none"> • crypto isakmp key <i>keystring</i> address <i>peer-address</i> [mask] [no-xauth] 	Specifies at the local peer the shared key to be used with a particular remote peer. <ul style="list-style-type: none"> • If the remote peer specified its ISAKMP identity with an address, use the address keyword in this step; otherwise use the hostname keyword in this step.

	Command or Action	Purpose
	<ul style="list-style-type: none"> • crypto isakmp key <i>keystring</i> hostname <i>hostname</i> [no-xauth] <p>Example:</p> <pre>Router(config)# crypto isakmp key sharedkeystring address 192.168.1.33 no-xauth</pre> <p>Example:</p> <pre>Router(config) crypto isakmp key sharedkeystring hostname RemoteRouter.example.com</pre>	<ul style="list-style-type: none"> • no-xauth--Prevents the router from prompting the peer for Xauth information. <p>Note According to the design of preshared key authentication in IKE main mode, preshared keys must be based on the IP address of the peers. Although you can send a hostname as the identity of a preshared key authentication, the key is searched on the IP address of the peer; if the key is not found (based on the IP address) the negotiation will fail.</p>
Step 6	<p>Do one of the following:</p> <ul style="list-style-type: none"> • crypto isakmp key <i>keystring</i> address <i>peer-address</i> [mask] [no-xauth] • crypto isakmp key <i>keystring</i> hostname <i>hostname</i> [no-xauth] <p>Example:</p> <pre>Router(config) crypto isakmp key sharedkeystring address 10.0.0.1</pre> <p>Example:</p> <pre>Router(config) crypto isakmp key sharedkeystring hostname LocalRouter.example.com</pre>	<p>Specifies at the remote peer the shared key to be used with the local peer.</p> <ul style="list-style-type: none"> • This is the same key you just specified at the local peer. • If the local peer specified its ISAKMP identity with an address, use the address keyword in this step; otherwise use the hostname keyword in this step.
Step 7	Repeat these steps at each peer that uses preshared keys in an IKE policy.	--

Configuring IKE Mode Configuration

Note IKE mode configuration has the following restrictions:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip local pool** *pool-name* *start-addr* *end-addr*
4. **crypto isakmp client configuration address-pool local** *pool-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
	Router> enable	
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip local pool pool-name start-addr end-addr Example: Router(config)# ip local pool pool1 172.16.23.0 172.16.23.255	Defines an existing local address pool that defines a set of addresses.
Step 4	crypto isakmp client configuration address-pool local pool-name Example: Router(config)# crypto isakmp client configuration address-pool local pool1	References the local address pool in the IKE configuration.

Configuring an IKE Crypto Map for IPsec SA Negotiation

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto map tag sequence ipsec-isakmp
4. set pfs {group1 | group2 | group5 | group14 | group15 | group16}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto map tag sequence ipsec-isakmp Example: <pre>Router(config)# crypto map example 1 ipsec-ipsec-isakmp</pre>	Specifies the crypto map and enters crypto map configuration mode. <ul style="list-style-type: none"> • The <i>tag</i> argument specifies the crypto map. • The <i>sequence</i> argument specifies the sequence to insert into the crypto map entry. • The ipsec-isakmp keyword specifies IPsec with IKEv1 (ISAKMP).
Step 4	set pfs {group1 group2 group5 group14 group15 group16} Example: <pre>Router(config-isakmp)# set pfs 14</pre>	Specifies the DH group identifier for IPsec SA negotiation. <ul style="list-style-type: none"> • By default, DH group 1 is used. • group1—768-bit DH (No longer recommended) • group2—1024-bit DH (No longer recommended) • group5—1536-bit DH (No longer recommended) • group14—Specifies the 2048-bit DH group. • group15—Specifies the 3072-bit DH group. • group16—Specifies the 4096-bit DH group. <p>The group chosen must be strong enough (have enough bits) to protect the IPsec keys during negotiation. A generally accepted guideline recommends the use of a 2048-bit group after 2013 (until 2030). Either group 14 can be selected to meet this guideline. Even if a longer-lived security method is needed, the use of Elliptic Curve Cryptography is recommended, but group 15 and group 16 can also be considered.</p>

Configuration Examples for an IKE Configuration

Example: Creating IKE Policies

This section contains the following examples, which show how to configure an AES IKE policy and a 3DES IKE policy.

Note Cisco no longer recommends using 3DES; instead, you should use AES. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

Example: Creating 3DES IKE Policies

This example creates two IKE policies, with policy 15 as the highest priority, policy 20 as the next priority, and the existing default priority as the lowest priority. It also creates a preshared key to be used with policy 20 with the remote peer whose IP address is 192.168.224.33.

```
crypto isakmp policy 15
  encryption 3des
  hash md5
  authentication rsa-sig
  group 2
  lifetime 5000
!
crypto isakmp policy 20
  authentication pre-share
  lifetime 10000
!
crypto isakmp key 1234567890 address 192.168.224.33
```

In the example, the encryption DES of policy default would not appear in the written configuration because this is the default value for the encryption algorithm parameter.

If the **show crypto isakmp policy** command is issued with this configuration, the output is as follows:

```
Protection suite priority 15
encryption algorithm:3DES - Triple Data Encryption Standard (168 bit keys)
hash algorithm:Message Digest 5
authentication method:Rivest-Shamir-Adleman Signature
Diffie-Hellman group:#2 (1024 bit)
lifetime:5000 seconds, no volume limit
Protection suite priority 20
encryption algorithm:DES - Data Encryption Standard (56 bit keys)
hash algorithm:Secure Hash Standard
authentication method:preshared Key
Diffie-Hellman group:#1 (768 bit)
lifetime:10000 seconds, no volume limit
Default protection suite
encryption algorithm:DES - Data Encryption Standard (56 bit keys)
hash algorithm:Secure Hash Standard
authentication method:Rivest-Shamir-Adleman Signature
Diffie-Hellman group:#1 (768 bit)
lifetime:86400 seconds, no volume limit
```

Note that although the output shows “no volume limit” for the lifetimes, you can configure only a time lifetime (such as 86,400 seconds); volume-limit lifetimes are not configurable.

Example: Creating an AES IKE Policy

The following example is sample output from the **show running-config** command. In this example, the AES 256-bit key is enabled.

```
Current configuration : 1665 bytes
!
version 12.2
service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname "Router1"
!
```

```

!
ip subnet-zero
!
!
no ip domain lookup
!
ip audit notify log
ip audit po max-events 100
!
crypto isakmp policy 10
  encryption aes 256
  authentication pre-share
  lifetime 180
crypto isakmp key cisco123 address 10.0.110.1
!
!
crypto ipsec transform-set aasset esp-aes 256 esp-sha-hmac
mode transport

.
.
.

```

Example: Configuring IKE Authentication

The following example shows how to manually specify the RSA public keys of two IPsec peer-- the peer at 10.5.5.1 uses general-purpose keys, and the other peer uses special-usage keys:

```

crypto key pubkey-chain rsa
  named-key otherpeer.example.com
  address 10.5.5.1
  key-string
005C300D 06092A86 4886F70D 01010105
00034B00 30480241 00C5E23B 55D6AB22
04AEF1BA A54028A6 9ACC01C5 129D99E4

quit
exit
exit

```

Where to Go Next

After you have successfully configured IKE negotiation, you can begin configuring IPsec. For information on completing these tasks, see the module “Configuring Security for VPNs With IPsec.”

Feature Information for Configuring IKE for IPsec VPNs

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 264: Feature Information for Configuring IKE for IPsec VPNs

Feature Name	Releases	Feature Information
Ability to Disable Extended Authentication for Static IPsec Peers	12.2(4)T	<p>This feature allows a user to disable Xauth while configuring the preshared key for router-to-router IPsec. Thus, the router will not prompt the peer for a username and password, which are transmitted when Xauth occurs for VPN-client-to-Cisco-IOS IPsec.</p> <p>The following command was modified by this feature: crypto isakmp key.</p>
Advanced Encryption Standard (AES)	12.2(8)T	<p>This feature adds support for the new encryption standard AES, which is a privacy transform for IPsec and IKE and has been developed to replace DES.</p> <p>The following commands were modified by this feature: crypto ipsec transform-set, encryption (IKE policy), show crypto ipsec transform-set, crypto ipsec transform-set, show crypto isakmp policy.</p>
SEAL Encryption	12.3(7)T	<p>This feature adds support for SEAL encryption in IPsec.</p> <p>The following command was modified by this feature: crypto ipsec transform-set.</p>
Suite-B support in IOS SW crypto	15.1(2)T	<p>Suite-B adds support in the Cisco IOS for the SHA-2 family (HMAC variant) hash algorithm used to authenticate packet data and verify the integrity verification mechanisms for the IKE protocol. HMAC is a variant that provides an additional level of hashing. This feature also adds elliptic curve Diffie-Hellman (ECDH) support for IPsec SA negotiation.</p> <p>See the Configuring Security for VPNs with IPsec feature module for more detailed information about Cisco IOS Suite-B support.</p> <p>The following command was modified by this feature: authentication, crypto key generate ec keysize, crypto map, group, hash, set pfs.</p>

CHAPTER 197

Call Admission Control for IKE

The Call Admission Control for IKE feature describes the application of Call Admission Control (CAC) to the Internet Key Exchange (IKE) protocol in Cisco IOS software. CAC limits the number of simultaneous IKE and IPsec security associations (SAs) that is, calls to CAC that a router can establish.

- [Prerequisites for Call Admission Control for IKE, on page 2563](#)
- [Information About Call Admission Control for IKE, on page 2563](#)
- [How to Configure Call Admission Control for IKE, on page 2565](#)
- [Configuration Examples for Call Admission Control for IKE, on page 2568](#)
- [Additional References, on page 2568](#)
- [Feature Information for Call Admission Control for IKE, on page 2569](#)

Prerequisites for Call Admission Control for IKE

- Configure IKE on the device.

Information About Call Admission Control for IKE

IKE Session

There are two ways to limit the number of Internet Key Exchange (IKE) security associations (SAs) that a device can establish to or from another device:

- Configure the absolute IKE SA limit by entering the **crypto call admission limit** command. The device drops new IKE SA requests when the configured limit is reached.
- Configure the system resource limit by entering the **call admission limit** command. The device drops new IKE SA requests when the level of system resources that are configured in the unit of charge is being used.

Call Admission Control (CAC) is applied only to new SAs (that is, when an SA does not already exist between peers). Every effort is made to preserve existing SAs. New SA requests are denied due to a lack of system resources or because the configured IKE SA limit is reached.

Security Association Limit

An SA is a description of how two or more entities will utilize security services to communicate securely on behalf of a particular data flow. IKE requires and uses SAs to identify the parameters of its connections. IKE can negotiate and establish its own SA. An IKE SA is used by IKE only, and it is bidirectional. An IKE SA cannot limit IPsec.

IKE drops SA requests based on a user-configured SA limit. To configure an IKE SA limit, enter the **crypto call admission limit** command. When there is a new SA request from a peer router, IKE determines whether the number of active IKE SAs plus the number of SAs being negotiated meets or exceeds the configured SA limit. If the number is greater than or equal to the limit, the new SA request is rejected and a syslog is generated. This log contains the source destination IP address of the SA request.

The **ipsec sa number** and **ike sa number** keyword and argument pairs in the **crypto call admission limit** command set the limit for the number of established IPsec SAs and IKE SAs.

Limit on Number of In-Negotiation IKE Connections

You can limit the number of in-negotiation IKE connections that can be configured on a device based on your Cisco release. This type of IKE connection represents either an aggressive mode IKE SA or a main mode IKE SA prior to its authentication and actual establishment. The default value for maximum in-negotiation CAC for IKEv2 is 40.

You can use the **crypto call admission limit ike in-negotiation-sa number** command to specify the maximum number of Internet Key Exchange (IKE) and IPsec security associations (SAs) that the device can establish before IKE begins rejecting the new SA requests.

The **all in-negotiation-sa number** and **ike in-negotiation-sa number** keyword and argument pairs in the **crypto call admission limit** command limit all SAs in negotiation and IKE SAs in negotiation.

System Resource Usage

CAC polls a global resource monitor so that IKE knows when the router is running short of CPU cycles or memory buffers. You can configure a limit, in the range 1 to 100000, that represents the level of system resource usage in system resource usage units. When that level of resources is being used, IKE drops (will not accept new) SA requests. To configure the system resource usage limit, enter the **call admission limit** command.

For each incoming new SA request, the current load on the router is converted into a numerical value, representing the system resource usage level, and is compared to the resource limit set by the **call admission limit** command. If the current load is more than the configured resource limit, IKE drops the new SA request. Load on the router includes active SAs, CPU usage, and SA requests being considered.

The **call admission load** command configures a multiplier value from 0 to 1000 that represents a scaling factor for current system resource usage and a load metric poll rate of 1 to 32 seconds. The numerical value for the system resource usage level is calculated by the formula (scaling factor * current system resource usage) / 100. It is recommended that the **call admission load** command not be used unless advised by a Cisco Technical Assistance Center (TAC) engineer.

How to Configure Call Admission Control for IKE

Configuring the IKE Security Association Limit

Perform this task to configure the absolute IKE SA limit. The router drops new IKE SA requests when the limit has been reached.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto call admission limit** {all in-negotiation-sa *number* | ipsec sa *number* | ike {in-negotiation-sa *number* | sa *number*}}
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto call admission limit {all in-negotiation-sa <i>number</i> ipsec sa <i>number</i> ike {in-negotiation-sa <i>number</i> sa <i>number</i> }} Example: Router(config)# crypto call admission limit ike sa 25	Specifies the maximum number of IKE SAs or total SAs in negotiation or the maximum IKE SAs or IPsec SAs that can be established before IKE begins rejecting new SA requests. The recommended CAC value for IKEv1 is 40.
Step 4	exit Example: Router(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.

Configuring the IKEv2 Security Association Limit

Perform this task to configure the absolute IKEv2 SA limit. The router drops new IKE SA requests when the limit has been reached.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 limit** {**max-in-negotiation-sa limit** *number* | **max-sa limit** *number*}
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto ikev2 limit { max-in-negotiation-sa limit <i>number</i> max-sa limit <i>number</i> } Example: <pre>Router(config)# crypto ikev2 limit max-in-negotiation-sa 5000</pre>	Enables call admission control as follows: <ul style="list-style-type: none"> • max-in-negotiation-sa limit: Limits the total number of in-negotiation IKEv2 SAs on the node. • max-sa limit: Limits the total number of IKEv2 SAs on the node.
Step 4	exit Example: <pre>Router(config)# exit</pre>	Exits global configuration mode and returns to privileged EXEC mode.

Configuring the System Resource Limit

Perform this task to configure the system resource limit. The router drops new IKE SA requests when the level of system resources that are configured in the unit of charge is being used.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **call admission limit** *charge*
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	call admission limit <i>charge</i> Example: <pre>Router(config)# call admission limit 1000</pre>	Sets the level of the system resources that, when used, causes IKE to stop accepting new SA requests. <ul style="list-style-type: none"> • <i>charge</i> --Valid values are 1 to 100000.
Step 4	exit Example: <pre>Router(config)# exit</pre>	Exits global configuration mode and returns to privileged EXEC mode.

Verifying the Call Admission Control for IKE Configuration

To verify the CAC for IKE configuration, perform the following steps.

SUMMARY STEPS

1. **show call admission statistics**
2. **show crypto call admission statistics**

DETAILED STEPS

Step 1 **show call admission statistics**

Use this command to monitor the global CAC configuration parameters and the behavior of CAC.

Example:

```
Router# show call admission statistics
Total Call admission charges: 82, limit 1000
Total calls rejected 1430, accepted 0
Load metric: charge 82, unscaled 82%
```

Step 2 **show crypto call admission statistics**

Use this command to monitor crypto CAC statistics.

Example:

```

Router# show crypto call admission statistics
-----
                Crypto Call Admission Control Statistics
-----
System Resource Limit:      111 Max IKE SAs:      0 Max in nego:  1000
Total IKE SA Count:        0 active:          0 negotiating:  0
Incoming IKE Requests:    0 accepted:      0 rejected:    0
Outgoing IKE Requests:    0 accepted:      0 rejected:    0
Rejected IKE Requests:    0 rsrc low:      0 Active SA limit: 0
                                           In-neg SA limit: 0

IKE packets dropped at dispatch:      0
Max IPSEC SAs:      111
Total IPSEC SA Count:      0 active:      0 negotiating:      0
Incoming IPSEC Requests:  0 accepted:  0 rejected:      0
Outgoing IPSEC Requests:  0 accepted:  0 rejected:      0
Phase1.5 SAs under negotiation:      0

```

Configuration Examples for Call Admission Control for IKE

Example Configuring the IKE Security Association Limit

The following example shows how to specify a maximum limit of 25 SAs before IKE starts rejecting new SA requests:

```
Router(config)# crypto call admission limit ike sa 25
```

Example Configuring the System Resource Limit

The following example shows how to specify that IKE should drop SA requests when the level of system resources that are configured in the unit of charge reaches 9000:

```
Router(config)# call admission limit 9000
```

CHAPTER 198

Certificate to ISAKMP Profile Mapping

The Certificate to ISAKMP Profile Mapping feature enables you to assign an Internet Security Association and Key Management Protocol (ISAKMP) profile to a peer on the basis of the contents of arbitrary fields in the certificate. In addition, this feature allows you to assign a group name to those peers that are assigned an ISAKMP profile.

- [Prerequisites for Certificate to ISAKMP Profile Mapping, on page 2571](#)
- [Restrictions for Certificate to ISAKMP Profile Mapping, on page 2571](#)
- [Information About Certificate to ISAKMP Profile Mapping, on page 2572](#)
- [How to Configure Certificate to ISAKMP Profile Mapping, on page 2573](#)
- [Configuration Examples for Certificate to ISAKMP Profile Mapping, on page 2576](#)
- [Additional References, on page 2579](#)
- [Feature Information for Certificate to ISAKMP Profile Mapping, on page 2580](#)

Prerequisites for Certificate to ISAKMP Profile Mapping

- You should be familiar with configuring certificate maps.
- You should be familiar with configuring ISAKMP profiles.

Restrictions for Certificate to ISAKMP Profile Mapping

This feature is not applicable if you use Rivest, Shamir, and Adelman (RSA)-signature or RSA-encryption authentication without certificate exchange. ISAKMP peers must be configured for RSA-signature or RSA-encryption authentication using certificates.

From Cisco IOS XE Dublin 17.11.x onwards, support for IPsec with two trustpoints enrolled in the same Certificate Authority (CA) server is added. When there are two or more ISAKMP profiles, each having a different trustpoint enrolled in the same CA server, the responder selects the last global trustpoint. (Trustpoints are selected in the reverse order in which they are defined globally). For the IPsec tunnel establishment to be successful for peers, the trustpoint selected by the initiator should match the trustpoint selected by the responder. All other IPsec tunnels will fail to establish connection if the trustpoints do not match.

Information About Certificate to ISAKMP Profile Mapping

Certificate to ISAKMP Profile Mapping Overview

Prior to Cisco IOS Release 12.3(8)T, the only way to map a peer to an ISAKMP profile was as follows. The ISAKMP identity field in the ISAKMP exchange was used for mapping a peer to an ISAKMP profile. When certificates were used for authentication, the ISAKMP identity payload contained the subject name from the certificate. If a CA did not provide the required group value in the first Organizational Unit (OU) field of a certificate, an ISAKMP profile could not be assigned to a peer.

Effective with Cisco IOS Release 12.3(8)T, a peer can still be mapped as explained above. However, the Certificate to ISAKMP Profile Mapping feature enables you to assign an ISAKMP profile to a peer on the basis of the contents of arbitrary fields in the certificate. You are no longer limited to assigning an ISAKMP profile on the basis of the subject name of the certificate. In addition, this feature allows you to assign a group to a peer to which an ISAKMP profile has been assigned.

How Certificate to ISAKMP Profile Mapping Works

The figure below illustrates how certificate maps may be attached to ISAKMP profiles and assigned group names.

Figure 101: Certificate Maps Mapped for Profile Group Assignment

A certificate map can be attached to only one ISAKMP profile although an ISAKMP profile can have several certificate maps attached to it.

Certificate maps provide the ability for a certificate to be matched with a given set of criteria. ISAKMP profiles can bind themselves to certificate maps, and if the presented certificate matches the certificate map present in an ISAKMP profile, the peer will be assigned the ISAKMP profile. If the ISAKMP profile contains a client configuration group name, the same group name will be assigned to the peer. This ISAKMP profile information will override the information in the ID_KEY_ID identity or in the first OU field of the certificate.

Assigning an ISAKMP Profile and Group Name to a Peer

To assign an ISAKMP profile to a peer on the basis of arbitrary fields in the certificate, use the **match certificate** command after the ISAKMP profile has been defined.

To associate a group name with an ISAKMP profile that will be assigned to a peer, use the **client configuration group** command, also after the ISAKMP profile has been defined.

How to Configure Certificate to ISAKMP Profile Mapping

Mapping the Certificate to the ISAKMP Profile

To map the certificate to the ISAKMP profile, perform the following steps. This configuration will enable you to assign the ISAKMP profile to a peer on the basis of the contents of arbitrary fields in the certificate.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp profile** *profile-name*
4. **match certificate** *certificate-map*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp profile <i>profile-name</i> Example: Router (config)# crypto isakmp profile vpnprofile	Defines an ISAKMP profile and enters into crypto ISAKMP profile configuration mode.
Step 4	match certificate <i>certificate-map</i> Example: Router (conf-isa-prof)# match certificate map1	Accepts the name of a certificate map.

Verifying That the Certificate Has Been Mapped

The following **show** command may be used to verify that the subject name of the certificate map has been properly configured.

SUMMARY STEPS

1. **enable**
2. **show crypto ca certificates**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto ca certificates Example: Router# show crypto ca certificates	Displays information about your certificate.

Assigning the Group Name to the Peer

To associate a group name with a peer when the peer is mapped to an ISAKMP profile, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp profile** *profile-name*
4. **client configuration group** *group-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto isakmp profile <i>profile-name</i> Example: Router (config)# crypto isakmp profile vpnprofile	Defines an ISAKMP profile and enters into isakmp profile configuration mode.
Step 4	client configuration group <i>group-name</i> Example: Router (conf-isa-prof)# client configuration group group1	Accepts the name of a group that will be assigned to a peer when the peer is assigned this crypto ISAKMP profile.

Monitoring and Maintaining Your Certificate to ISAKMP Profile Mapping

To monitor and maintain your certificate to ISAKMP profile mapping, you may use the following **debug** command.

SUMMARY STEPS

1. **enable**
2. **debug crypto isakmp**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	debug crypto isakmp Example: Router# debug crypto isakmp	Displays output showing that the certificate has gone through certificate map matching and that the certificate matches the ISAKMP profile. The command may also be used to verify that the peer has been assigned a group.

Configuration Examples for Certificate to ISAKMP Profile Mapping

Certificates Mapped to the ISAKMP Profile on the Basis of Arbitrary Fields Example

The following configuration example shows that whenever a certificate contains “ou = green,” the ISAKMP profile “cert_pro” will be assigned to the peer:

```
crypto pki certificate map cert_map 10
  subject-name co ou = green
  !
  !
crypto isakmp identity dn
crypto isakmp profile cert_pro
  ca trust-point 2315
  ca trust-point LaBcA
  initiate mode aggressive
  match certificate cert_map
```

Group Name Assigned to a Peer That Is Associated with an ISAKMP Profile Example

The following example shows that the group “some_group” is to be associated with a peer that has been assigned an ISAKMP profile:

```
crypto isakmp profile id_profile
  ca trust-point 2315
  match identity host domain cisco.com
  client configuration group some_group
```

Mapping a Certificate to an ISAKMP Profile Verification Example

The following examples show that a certificate has been mapped to an ISAKMP profile. The examples include the configurations for the responder and initiator, **show command** output verifying that the subject name of the certificate map has been configured, and **debug** command output showing that the certificate has gone through certificate map matching and been matched to the ISAKMP profile.

Responder Configuration

```
crypto pki certificate map cert_map 10
! The above line is the certificate map definition.
  subject-name co ou = green
! The above line shows that the subject name must have "ou = green."
  !
crypto isakmp profile certpro
! The above line shows that this is the ISAKMP profile that will match if the certificate
of the peer matches cert_map (shown on third line below).
```

```

ca trust-point 2315
ca trust-point LaBCA
match certificate cert_map
initiate mode aggressive

```

Initiator Configuration

```

crypto ca trustpoint LaBCA
  enrollment url http://10.76.82.20:80/cgi-bin/openscep
  subject-name ou=green,c=IN
! The above line ensures that the subject name "ou = green" is set.
  revocation-check none

```

show crypto ca certificates Command Output for the Initiator

```

Router# show crypto ca certificates
Certificate
  Status: Available
  Certificate Serial Number: 21
  Certificate Usage: General Purpose
  Issuer:
    cn=blue-lab CA
    o=CISCO
    c=IN
  Subject:
    Name: Router1.cisco.com
    c=IN
    ou=green
! The above line is a double check that "ou = green" has been set as the subject name.
  hostname=Router1.cisco.com
  Validity Date:
    start date: 14:34:30 UTC Mar 31 2004
    end   date: 14:34:30 UTC Apr 1 2009
    renew date: 00:00:00 UTC Jan 1 1970
  Associated Trustpoints: LaBCA

```

debug crypto isakmp Command Output for the Responder

```

Router# debug crypto isakmp
6d23h: ISAKMP (0:268435460): received packet from 192.0.0.2 dport 500 sport 500 Global (R)
  MM_KEY_EXCH
6d23h: ISAKMP: Main Mode packet contents (flags 1, len 892):
6d23h:      ID payload
6d23h:      FQDN <Router1.cisco.com> port 500 protocol 17
6d23h:      CERT payload
6d23h:      SIG payload
6d23h:      KEEPALIVE payload
6d23h:      NOTIFY payload
6d23h: ISAKMP:(0:4:HW:2):Input = IKE_MSG_FROM_PEER, IKE_MM_EXCH
6d23h: ISAKMP:(0:4:HW:2):Old State = IKE_R_MM4 New State = IKE_R_MM5
6d23h: ISAKMP:(0:4:HW:2): processing ID payload. message ID = 0
6d23h: ISAKMP (0:268435460): ID payload
  next-payload : 6
  type         : 2
  FQDN name    : Router1.cisco.com
  protocol     : 17
  port        : 500
  length      : 28
6d23h: ISAKMP:(0:4:HW:2):: peer matches *none* of the profiles
6d23h: ISAKMP:(0:4:HW:2): processing CERT payload. message ID = 0

```

```

6d23h: ISAKMP:(0:4:HW:2): processing a CT_X509_SIGNATURE cert
6d23h: ISAKMP:(0:4:HW:2): peer's pubkey isn't cached
6d23h: ISAKMP:(0:4:HW:2): OU = green
6d23h: ISAKMP:(0:4:HW:2): certificate map matches certpro profile
! The above line shows that the certificate has gone through certificate map matching and
that it matches the "certpro" profile.
6d23h: ISAKMP:(0:4:HW:2): Trying to re-validate CERT using new profile
6d23h: ISAKMP:(0:4:HW:2): Creating CERT validation list: 2315, LaBcA,
6d23h: ISAKMP:(0:4:HW:2): CERT validity confirmed.

```

Group Name Assigned to a Peer Verification Example

The following configuration and debug output show that a group has been assigned to a peer.

Initiator Configuration

```

crypto isakmp profile certpro
  ca trust-point 2315
  ca trust-point LaBcA
  match certificate cert_map
  client configuration group new_group
! The statement on the above line will assign the group "new_group" to any peer that matches
the ISAKMP profile "certpro."
  initiate mode aggressive
!

```

debug crypto isakmp profile Command Output for the Responder

The following debug output example shows that the peer has been matched to the ISAKMP profile named "certpro" and that it has been assigned a group named "new_group."

```

Router# debug crypto isakmp profile
6d23h: ISAKMP (0:268435461): received packet from 192.0.0.2 dport 500 sport 500 Global (R)
MM_KEY_EXCH
6d23h: ISAKMP: Main Mode packet contents (flags 1, len 892):
6d23h:      ID payload
6d23h:      FQDN <Router1.cisco.com> port 500 protocol 17
6d23h:      CERT payload
6d23h:      SIG payload
6d23h:      KEEPALIVE payload
6d23h:      NOTIFY payload
6d23h: ISAKMP:(0:5:HW:2):Input = IKE_MESG_FROM_PEER, IKE_MM_EXCH
6d23h: ISAKMP:(0:5:HW:2):Old State = IKE_R_MM4 New State = IKE_R_MM5
6d23h: ISAKMP:(0:5:HW:2): processing ID payload. message ID = 0
6d23h: ISAKMP (0:268435461): ID payload
      next-payload : 6
      type          : 2
      FQDN name     : Router1.cisco.com
      protocol      : 17
      port          : 500
      length        : 28
6d23h: ISAKMP:(0:5:HW:2):: peer matches *none* of the profiles
6d23h: ISAKMP:(0:5:HW:2): processing CERT payload. message ID = 0
6d23h: ISAKMP:(0:5:HW:2): processing a CT_X509_SIGNATURE cert
6d23h: ISAKMP:(0:5:HW:2): peer's pubkey isn't cached
6d23h: ISAKMP:(0:5:HW:2): OU = green
6d23h: ISAKMP:(0:5:HW:2): certificate map matches certpro profile
6d23h: ISAKMP:(0:5:HW:2): Trying to re-validate CERT using new profile
6d23h: ISAKMP:(0:5:HW:2): Creating CERT validation list: 2315, LaBcA,

```

```

6d23h: ISAKMP:(0:5:HW:2): CERT validity confirmed.
6d23h: ISAKMP:(0:5:HW:2):Profile has no keyring, aborting key search
6d23h: ISAKMP:(0:5:HW:2): Profile certpro assigned peer the group named new_group

```

<p>The Cisco Support website provides extensive online resources, including documentation and tools for troubleshooting and resolving technical issues with Cisco products and technologies.</p> <p>To receive security and technical information about your products, you can subscribe to various services, such as the Product Alert Tool (accessed from Field Notices), the Cisco Technical Services Newsletter, and Really Simple Syndication (RSS) Feeds.</p> <p>Access to most tools on the Cisco Support website requires a Cisco.com user ID and password.</p>	<p>http://www.cisco.com/cisco/web/support/index.html</p>

Feature Information for Certificate to ISAKMP Profile Mapping

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 266: Feature Information for Certificate to ISAKMP Profile Mapping

Feature Name	Releases	Feature Information
Certificate to ISAKMP Profile Mapping	12.3(8)T 12.2(33)SRA 12.2(33)SXH	<p>The Certificate to ISAKMP Profile Mapping feature enables you to assign an Internet Security Association and Key Management Protocol (ISAKMP) profile to a peer on the basis of the contents of arbitrary fields in the certificate. In addition, this feature allows you to assign a group name to those peers that are assigned an ISAKMP profile.</p> <p>This feature was introduced in the Cisco IOS Release 12.3(8)T</p> <p>This feature was integrated into Cisco IOS Release 12.2(33)SRA.</p> <p>This feature was integrated into Cisco IOS Release 12.2(33)SXH.</p>

CHAPTER 199

Encrypted Preshared Key

The Encrypted Preshared Key feature allows you to securely store plain text passwords in type 6 (encrypted) format in NVRAM.

- [Restrictions for Encrypted Preshared Key, on page 2581](#)
- [Information About Encrypted Preshared Key, on page 2581](#)
- [How to Configure an Encrypted Preshared Key, on page 2583](#)
- [Configuration Examples for Encrypted Preshared Key, on page 2591](#)
- [Where to Go Next, on page 2592](#)
- [Additional References, on page 2592](#)

Restrictions for Encrypted Preshared Key

- Old ROM monitors (ROMMONs) and boot images cannot recognize the new type 6 passwords. Therefore, errors are expected if you boot from an old ROMMON.
- For Cisco 836 routers, please note that support for Advanced Encryption Standard (AES) is available only on IP plus images.

Information About Encrypted Preshared Key

Using the Encrypted Preshared Key Feature to Securely Store Passwords

Using the Encrypted Preshared Key feature, you can securely store plain text passwords in type 6 format in NVRAM using a command-line interface (CLI). Type 6 passwords are encrypted. Although the encrypted passwords can be seen or retrieved, it is difficult to decrypt them to find out the actual password. Use the **key config-key** command with the **password encryption aes** command to configure and enable the password (symmetric cipher AES is used to encrypt the keys). The password (key) configured using the **config-key password-encryption** command is the master encryption key that is used to encrypt all other keys in the router.

If you configure the **password encryption aes** command without configuring the **key config-key** command, the following message is printed at startup or during any nonvolatile generation (NVGEN) process, such as when the **show running-config** or **copy running-config startup-config** commands have been configured:

```
"Can not encrypt password. Please configure a configuration-key with 'key config-key'"
```

Changing a Password

If the password (master key) is changed, or reencrypted, using the **key config-key password-encryption** command, the list registry passes the old key and the new key to the application modules that are using type 6 encryption.

Deleting a Password

If the master key that was configured using the **key config-key password-encryption** command is deleted from the system, a warning is printed (and a confirm prompt is issued) that states that all type 6 passwords will become useless. As a security measure, after the passwords have been encrypted, they will never be decrypted in the software. However, passwords can be reencrypted as explained in the previous paragraph.

Caution If the password configured using the **key config-key password-encryption** command is lost, it cannot be recovered. The password should be stored in a safe location.

Unconfiguring Password Encryption

If you later unconfigure password encryption using the **no password encryption aes** command, all existing type 6 passwords are left unchanged, and as long as the password (master key) that was configured using the **key config-key password-encryption** command exists, the type 6 passwords will be decrypted as and when required by the application.

Storing Passwords

Because no one can “read” the password (configured using the **key config-key password-encryption** command), there is no way that the password can be retrieved from the router. Existing management stations cannot “know” what it is unless the stations are enhanced to include this key somewhere, in which case the password needs to be stored securely within the management system. If configurations are stored using TFTP, the configurations are not standalone, meaning that they cannot be loaded onto a router. Before or after the configurations are loaded onto a router, the password must be manually added (using the **key config-key password-encryption** command). The password can be manually added to the stored configuration but is not recommended because adding the password manually allows anyone to decrypt all passwords in that configuration.

Configuring New or Unknown Passwords

If you enter or cut and paste cipher text that does not match the master key, or if there is no master key, the cipher text is accepted or saved, but an alert message is printed. The alert message is as follows:

```
"ciphertext>[for username bar>] is incompatible with the configured master key."
```

If a new master key is configured, all the plain keys are encrypted and made type 6 keys. The existing type 6 keys are not encrypted. The existing type 6 keys are left as is.

If the old master key is lost or unknown, you have the option of deleting the master key using the **no key config-key password-encryption** command. Deleting the master key using the **no key config-key**

password-encryption command causes the existing encrypted passwords to remain encrypted in the router configuration. The passwords will not be decrypted.

Enabling the Encrypted Preshared Key

The **password encryption aes** command is used to enable the encrypted password.

How to Configure an Encrypted Preshared Key

Configuring an Encrypted Preshared Key

To configure an encrypted preshared key, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **key config-key password-encryption** *[text]*
4. **password encryption aes**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	key config-key password-encryption <i>[text]</i> Example: <pre>Router (config)# key config-key password-encryption</pre>	Stores a type 6 encryption key in private NVRAM. <ul style="list-style-type: none"> • If you want to key in interactively (using the enter key) and an encrypted key already exists, you will be prompted for the following: Old key, New key, and Confirm key. • If you want to key in interactively but an encryption key is not present, you will be prompted for the following: New key and Confirm key. • If you want to remove the password that is already encrypted, you will see the following prompt: “WARNING: All type 6 encrypted keys will become

	Command or Action	Purpose
		unusable. Continue with master key deletion? [yes/no]:”.
Step 4	password encryption aes Example: Router (config)# password-encryption aes	Enables the encrypted preshared key.

Troubleshooting Tips

If you see the warning message “ciphertext >[for username bar>] is incompatible with the configured master key,” you have entered or cut and pasted cipher text that does not match the master key or there is no master key. (The cipher text will be accepted or saved.) The warning message will allow you to locate the broken configuration line or lines.

Monitoring Encrypted Preshared Keys

To get logging output for encrypted preshared keys, perform the following steps.

1. **enable**
2. **password logging**

SUMMARY STEPS

1. **enable**
2. **password logging**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	password logging Example: Router# password logging	Provides a log of debugging output for a type 6 password operation.

Examples

The following **password logging** debug output shows that a new master key has been configured and that the keys have been encrypted with the new master key:

```

Router (config)# key config-key password-encrypt
New key:
Confirm key:
Router (config)#
01:40:57: TYPE6_PASS: New Master key configured, encrypting the keys with
the new master keypas
Router (config)# key config-key password-encrypt
Old key:
New key:
Confirm key:
Router (config)#
01:42:11: TYPE6_PASS: Master key change heralded, re-encrypting the keys
with the new master key
01:42:11: TYPE6_PASS: Mac verification successful
01:42:11: TYPE6_PASS: Mac verification successful
01:42:11: TYPE6_PASS: Mac verification successful

```

What To Do Next

You can perform any of the following procedures. Each procedure is independent of the others.

Configuring an ISAKMP Preshared Key

To configure an ISAKMP preshared key, perform the following procedure.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp key** *keystring* **address** *peer-address*
4. **crypto isakmp key** *keystring* **hostname** *hostname*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp key <i>keystring</i> address <i>peer-address</i> Example: Router (config)# crypto isakmp key cisco address 10.2.3.4	Configures a preshared authentication key. <ul style="list-style-type: none"> • The <i>peer-address</i> argument specifies the IP address of the remote peer.

	Command or Action	Purpose
Step 4	crypto isakmp key <i>keystring</i> hostname <i>hostname</i> Example: <pre>Router (config)# crypto isakmp key mykey hostname mydomain.com</pre>	Configures a preshared authentication key. <ul style="list-style-type: none"> The <i>hostname</i> argument specifies the fully qualified domain name (FQDN) of the peer.

Example

The following sample output shows that an encrypted preshared key has been configured:

```
crypto isakmp key 6 _Hg[^^ECgLGgPF^RXTQfDDWQ][YAAB address 10.2.3.4
crypto isakmp key 6 `eR\eTRaKCUZPYyQfDgXRwi_AAB hostname mydomain.com
```

Configuring an ISAKMP Preshared Key in ISAKMP Keyrings

To configure an ISAKMP preshared key in ISAKMP keyrings, which are used in IPsec Virtual Route Forwarding (VRF) configurations, perform the following procedure.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto keyring** *keyring-name*
4. **pre-shared-key address** *address* **key** *key*
5. **pre-shared-key hostname** *hostname* **key** *key*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router# enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto keyring <i>keyring-name</i> Example: <pre>Router (config)# crypto keyring mykeyring</pre>	Defines a crypto keyring to be used during Internet Key Exchange (IKE) authentication and enters keyring configuration mode.
Step 4	pre-shared-key address <i>address</i> key <i>key</i>	Defines a preshared key to be used for IKE authentication.

	Command or Action	Purpose
	Example: Router (config-keyring)# pre-shared-key address 10.2.3.5 key cisco	<ul style="list-style-type: none"> The <i>address</i> argument specifies the IP address of the remote peer.
Step 5	pre-shared-key hostname <i>hostname</i> key <i>key</i> Example: Router (config-keyring)# pre-shared-key hostname mydomain.com key cisco	Defines a preshared key to be used for IKE authentication. <ul style="list-style-type: none"> The <i>hostname</i> argument specifies the FQDN of the peer.

Example

The following **show-running-config** sample output shows that an encrypted preshared key in ISAKMP keyrings has been configured.

```
crypto keyring mykeyring
pre-shared-key address 10.2.3.5 key 6 `WHCJYR_Z]GRPF^RXTQfDcfZ]GPAAB
pre-shared-key hostname mydomain.com key 6 aE_REHDcOfYCPf^RXTQfDJYVVNSAAB
```

Configuring ISAKMP Aggressive Mode

To configure ISAKMP aggressive mode, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp peer ip-address** *ip-address*
4. **set aggressive-mode client-endpoint** *client-endpoint*
5. **set aggressive-mode password** *password*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto isakmp peer <i>ip-address ip-address</i> Example: <pre>Router (config)# crypto isakmp peer ip-address 10.2.3.4</pre>	To enable an IP Security (IPSec) peer for IKE querying of authentication, authorization, and accounting (AAA) for tunnel attributes in aggressive mode and to enter ISAKMP peer configuration mode.
Step 4	set aggressive-mode client-endpoint <i>client-endpoint</i> Example: <pre>Router (config-isakmp-peer)# set aggressive-mode client-endpoint fqdn cisco.com</pre>	Specifies the Tunnel-Client-Endpoint attribute within an ISAKMP peer configuration.
Step 5	set aggressive-mode password <i>password</i> Example: <pre>Router (config-isakmp-peer)# set aggressive-mode password cisco</pre>	Specifies the Tunnel-Password attribute within an ISAKMP peer configuration.

Example

The following **show-running-config** sample output shows that an encrypted preshared key in ISAKMP aggressive mode has been configured.

```
crypto isakmp peer address 10.2.3.4
 set aggressive-mode password 6 ^aKPIQ_KJE_PPF^RXTQfDTIaLNeAAB
 set aggressive-mode client-endpoint fqdn cisco.com
```

Configuring a Unity Server Group Policy

To configure a unity server group policy, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp client configuration group** *group-name*
4. **pool** *name*
5. **domain name**
6. **key** *name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
	Router# enable	
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp client configuration group <i>group-name</i> Example: Router (config)# crypto isakmp client configuration group mygroup	Specifies the policy profile of the group that will be defined and enters ISAKMP group configuration mode.
Step 4	pool <i>name</i> Example: Router (config-isakmp-group)# pool mypool	Defines a local pool address.
Step 5	domain name Example: Router (config-isakmp-group)# domain cisco.com	Specifies the Domain Name Service (DNS) domain to which a group belongs.
Step 6	key <i>name</i> Example: Router (config-isakmp-group)# key cisco	Specifies the IKE preshared key for group policy attribute definition.

Example

The following **show-running-config** sample output shows that an encrypted key has been configured for a unity server group policy:

```
crypto isakmp client configuration group mygroup
key 6 cZZgDZPOE\gDPF^RXTQfDTIaLNeAAB
domain cisco.com
pool mypool
```

Configuring an Easy VPN Client

To configure an Easy VPN client, perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal

3. **crypto ipsec client ezvpn** *name*
4. **peer** *ipaddress*
5. **mode client**
6. **group** *group-name* **key** *group-key*
7. **connect manual**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto ipsec client ezvpn <i>name</i> Example: Router (config)# crypto ipsec client ezvpn myclient	Creates a Cisco Easy VPN remote configuration and enters Cisco Easy VPN remote configuration mode.
Step 4	peer <i>ipaddress</i> Example: Router (config-isakmp-peer)# peer 10.2.3.4	Sets the peer IP address for the VPN connection.
Step 5	mode client Example: Router (config-isakmp-ezpvpy)# mode client	Automatically configures the router for Cisco Easy VPN Client mode operation, which uses Network Address Translation (NAT) or Peer Address Translation (PAT) address translations.
Step 6	group <i>group-name</i> key <i>group-key</i> Example: Router (config-isakmp-ezvpn)# group mygroup key cisco	Specifies the group name and key value for the VPN connection.
Step 7	connect manual Example: Router (config-isakmp-ezvpn)# connect manual	Specifies the manual setting for directing the Cisco Easy VPN remote client to wait for a command or application program interface (API) call before attempting to establish the Cisco Easy VPN remote connection.

Example

The following **show-running-config** sample output shows that an Easy VPN client has been configured. The key has been encrypted.

```
crypto ipsec client ezvpn myclient
connect manual

Configuration Examples for Encrypted Preshared Key

Encrypted Preshared Key Example

The following is an example of a configuration for which a type 6 preshared key has been encrypted. It includes the prompts and messages that a user might see.

```
Router (config)# crypto isakmp key cisco address 10.0.0.2
Router (config)# exit
Router# show running-config | include crypto isakmp key
crypto isakmp key cisco address 10.0.0.2
Router#
Router# configure terminal
Enter configuration commands, one per line. End with CNTL/Z.
Router (config)# password encryption aes

Router (config)# key config-key password-encrypt

New key:
Confirm key:
Router (config)#
01:46:40: TYPE6_PASS: New Master key configured, encrypting the keys with
the new master key
Router (config)# exit
Router # show running-config | include crypto isakmp key
crypto isakmp key 6 CXWdhVTZYB_Vcd^`cIHD0ahiFTa address 10.0.0.2
```

No Previous Key Present Example

In the following configuration example, no previous key is present:

```
Router (config)#
```

Key Already Exists Example

In the following configuration example, a key already exists:

```
Router (config)#
```

```
Old key:
Router (config)#
```

Key Already Exists But the User Wants to Key In Interactively Example

In the following configuration example, the user wants to key in interactively, but a key already exists. The Old key, New key, and Confirm key prompts will show on your screen if you enter the **key config-key** command and press the enter key to get into interactive mode.

```
Router (config)#
Old key:
New key:
Confirm key:
```

No Key Present But the User Wants to Key In Interactively Example

In the following example, the user wants to key in interactively, but no key is present. The New key and Confirm key prompts will show on your screen if you are in interactive mode.

```
Router (config)#

New key:
Confirm key:
```

Removal of the Password Encryption Example

In the following configuration example, the user wants to remove the encrypted password. The “WARNING: All type 6 encrypted keys will become unusable. Continue with master key deletion? [yes/no]:” prompt will show on your screen if you are in interactive mode.

```
Router (config)#
WARNING: All type 6 encrypted keys will become unusable. Continue with master key deletion
? [yes/no]: y
```

Where to Go Next

Configure any other preshared keys.

CHAPTER 200

Distinguished Name Based Crypto Maps

Feature History

Release	Modification
12.2(4)T	This feature was introduced.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

This feature module describes the Distinguished Name Based Crypto Map feature in Cisco IOS Release 12.2(4)T. It includes the following sections:

- [Feature Overview](#), on page 2595
- [Supported Platforms](#), on page 2596
- [Supported Standards MIBs and RFCs](#), on page 2597
- [Prerequisites](#), on page 2597
- [Configuration Tasks](#), on page 2597
- [Configuration Examples](#), on page 2600

Feature Overview

The Distinguished Name Based Crypto Maps feature allows you to configure the router to restrict access to selected encrypted interfaces for those peers with specific certificates, especially certificates with particular Distinguished Names (DNs).

Previously, if the router accepted a certificate or a shared secret from the encrypting peer, Cisco IOS did not have a method of preventing the peer from communicating with any encrypted interface other than the restrictions on the IP address of the encrypting peer. This feature allows you to configure which crypto maps are usable to a peer based on the DN that a peer used to authenticate itself, thereby, enabling you to control which encrypted interfaces a peer with a specified DN can access.

Benefits

The Distinguished Name Based Crypto Maps feature allows you to set restrictions in the router configuration that prevent peers with specific certificates--especially certificates with particular DNSs-- from having access to selected encrypted interfaces.

Restrictions

System Requirements

To configure this feature, your router must support IP Security.

Performance Impact

If you restrict access to a large number of DNSs, it is recommended that you specify a few number of crypto maps referring to large identity sections instead of specifying a large number of crypto maps referring to small identity sections.

Related Documents

The following documents provide information related to the Distinguished Name Based Crypto Maps feature:

- Cisco IOS Security Command Reference
- Cisco IOS Security Configuration Guide: Secure Connectivity, Release 12.4T
- [Next Generation Encryption](#) (NGE) white paper.

Supported Platforms

This feature is supported on the following platforms:

- Cisco 1700 series
- Cisco 2600 series
- Cisco 3620
- Cisco 3640
- Cisco 3660
- Cisco 7100 series
- Cisco 7200 series
- Cisco uBR905 Cable Access Router
- Cisco uBR925 Cable Access Router

Determining Platform Support Through Feature Navigator

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Prerequisites

Before configuring a DN based crypto map, you must perform the following tasks:

- Create an Internet Key Exchange (IKE) policy at each peer.

For more information on creating IKE policies, refer to the “Configuring Internet Key Exchange for IPsec VPNs” chapter in the *Cisco IOS Security Configuration Guide: Secure Connectivity* ..

- Create crypto map entries for IPsec.

For more information on creating crypto map entries, refer to the “Configuring Security for VPNs with IPsec” chapter in the *Cisco IOS Security Configuration Guide: Secure Connectivity*

Configuration Tasks

See the following sections for configuration tasks for the Distinguished Name Based Crypto Maps feature. Each task in the list is identified as either required or optional.

- [Configuring DN Based Crypto Maps \(authenticated by DN\), on page 2598](#) (required)
- [Configuring DN Based Crypto Maps \(authenticated by hostname\), on page 2598](#) (required)
- [Applying Identity to DN Based Crypto Maps, on page 2599](#) (required)
- [Verifying DN Based Crypto Maps, on page 2599](#) (optional)

Configuring DN Based Crypto Maps (authenticated by DN)

To configure a DN based crypto map that can be used only by peers that have been authenticated by a DN, use the following commands beginning in global configuration mode:

SUMMARY STEPS

1. Router(config)# **crypto identity** *name*
2. Router(crypto-identity)# **dn** *name=string* [*,name=string*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	Router(config)# crypto identity <i>name</i>	Configures the identity of a router with the given list of DNs in the certificate of the router and enters crypto identity configuration mode.
Step 2	Router(crypto-identity)# dn <i>name=string</i> [<i>,name=string</i>]	Associates the identity of the router with the DN in the certificate of the router. Note The identity of the peer must match the identity in the exchanged certificate.

Configuring DN Based Crypto Maps (authenticated by hostname)

To configure a DN based crypto map that can be used only by peers that have been authenticated by a hostname, use the following commands beginning in global configuration mode:

SUMMARY STEPS

1. Router(config)# **crypto identity** *name*
2. Router(crypto-identity)# **fqdn** *name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	Router(config)# crypto identity <i>name</i>	Configures the identity of a router with the given list of DNs in the certificate of the router and enters crypto identity configuration mode.
Step 2	Router(crypto-identity)# fqdn <i>name</i>	Associates the identity of the router with the hostname that the peer used to authenticate itself. Note The identity of the peer must match the identity in the exchanged certificate.

Applying Identity to DN Based Crypto Maps

To apply the identity (within the crypto map context), use the following commands beginning in global configuration mode:

SUMMARY STEPS

1. Router(config)# **crypto map** *map-name seq-num ipsec-isakmp*
2. Router(config-crypto-map)# **identity** *name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	Router(config)# crypto map <i>map-name seq-num ipsec-isakmp</i>	Creates or modifies a crypto map entry and enters the crypto map configuration mode.
Step 2	Router(config-crypto-map)# identity <i>name</i>	<p>Applies the identity to the crypto map.</p> <p>When this command is applied, only the hosts that match a configuration listed within the identity <i>name</i> can use the specified crypto map.</p> <p>Note If the identity command does not appear within the crypto map, the encrypted connection does not have any restrictions other than the IP address of the encrypting peer.</p>

Verifying DN Based Crypto Maps

To verify that this functionality is properly configured, use the following command in EXEC mode:

Command	Purpose
Router# show crypto identity	Displays the configured identities.

Troubleshooting Tips

If an encrypting peer attempts to establish a connection that is blocked by the DN based crypto map configuration, the following error message will be logged:

```
<time>: %CRYPTO-4-IKE_QUICKMODE_BAD_CERT: encrypted connection attempted with a peer without the configured certificate attributes.
```

Configuration Examples

DN Based Crypto Map Configuration Example

The following example shows how to configure DN based crypto maps that have been authenticated by DN and hostname. Comments are included inline to explain various commands.

```
! DN based crypto maps require you to configure an IKE policy at each peer.
crypto isakmp policy 15
  encryption aes
  hash sha
  authentication rsa-sig
  group 14
  lifetime 5000
crypto isakmp policy 20
  encryption aes
  hash sha
  authentication pre-share
  group 14
  lifetime 10000
crypto isakmp key 1234567890 address 171.69.224.33
!
! The following is an IPsec crypto map (part of IPsec configuration). It can be used only
! by peers that have been authenticated by DN and if the certificate belongs to BigBiz.
crypto map map-to-bigbiz 10 ipsec-isakmp
  set peer 172.21.114.196

  match address 124
  identity to-bigbiz
!
crypto identity to-bigbiz
  dn ou=BigBiz
!
!
! This crypto map can be used only by peers that have been authenticated by hostname
! and if the certificate belongs to little.com.
crypto map map-to-little-com 10 ipsec-isakmp
  set peer 172.21.115.119
  set transform-set my-transformset
  match address 125
  identity to-little-com
!
crypto identity to-little-com
  fqdn little.com
!
```

CHAPTER 201

IPsec and Quality of Service

The IPsec and Quality of Service feature allows Cisco IOS quality of service (QoS) policies to be applied to IP Security (IPsec) packet flows on the basis of a QoS group that can be added to the current Internet Security Association and Key Management Protocol (ISAKMP) profile.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

Finding Support Information for Platforms and Cisco IOS Software Images

Use Cisco Feature Navigator to find information about platform support and Cisco IOS software image support. Access Cisco Feature Navigator at <http://tools.cisco.com/ITDIT/CFN/jsp/index.jsp>. You must have an account on Cisco.com. If you do not have an account or have forgotten your username or password, click **Cancel** at the login dialog box and follow the instructions that appear.

- [Prerequisites for IPsec and Quality of Service, on page 2601](#)
- [Restrictions for IPsec and Quality of Service, on page 2602](#)
- [Information About IPsec and Quality of Service, on page 2602](#)
- [How to Configure IPsec and Quality of Service, on page 2602](#)
- [Configuration Examples for IPsec and Quality of Service, on page 2604](#)
- [Additional References, on page 2606](#)
- [Feature Information for IPsec and Quality of Service, on page 2608](#)

Prerequisites for IPsec and Quality of Service

- You should be familiar with IPsec and the concept of ISAKMP profiles.
- You should be familiar with Cisco IOS QoS.

Restrictions for IPsec and Quality of Service

- This feature can be applied only via the ISAKMP profile. The limit of 128 QoS groups that exists for QoS applications applies to this feature as well.
- You can apply an IPsec QoS group only to outbound service policies.
- QoS is not supported for software encryption.

Information About IPsec and Quality of Service

IPsec and Quality of Service Overview

The IPsec and Quality of Service feature allows you to apply QoS policies, such as traffic policing and shaping, to IPsec-protected packets by adding a QoS group to ISAKMP profiles. After the QoS group has been added, this group value will be mapped to the same QoS group as defined in QoS class maps. Any current QoS method that makes use of this QoS group tag can be applied to IPsec packet flows. Common groupings of packet flows can have specific policy classes applied by having the IPsec QoS group made available to the QoS mechanism. Marking IPsec flows allows QoS mechanisms to be applied to classes of traffic that could provide support for such things as restricting the amount of bandwidth that is available to specific groups or devices or marking the type of service (ToS) bits on certain flows.

The application of the QoS group is applied at the ISAKMP profile level because it is the profile that can uniquely identify devices through its concept of match identity criteria. These criteria are on the basis of the Internet Key Exchange (IKE) identity that is presented by incoming IKE connections and includes such things as IP address, fully qualified domain name (FQDN), and group (that is, the virtual private network [VPN] remote client grouping). The granularity of the match identity criteria will impose the granularity of the specified QoS policy, for example, to mark all traffic belonging to the VPN client group named “Engineering” as “TOS 5”. Another example of having the granularity of a specified QoS policy imposed would be to allocate 30 percent of the bandwidth on an outbound WAN link to a specific group of remote VPN devices.

How to Configure IPsec and Quality of Service

Configuring IPsec and Quality of Service

To apply QoS policies to an ISAKMP profile, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp-profile** *profile-number*
4. **qos-group** *group-number*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto isakmp-profile <i>profile-number</i> Example: Router (config)# crypto isakmp-profile vpnprofile	Defines an ISAKMP profile, audits IPsec user sessions, and enters ISAKMP profile configuration mode.
Step 4	qos-group <i>group-number</i> Example: Router(config-isa-prof)# qos-group 1	Applies a QoS group value to an ISAKMP profile.

Verifying IPsec and Quality of Service Sessions

To verify your IPsec and QoS sessions, perform the following steps. The **show** commands can be used in any order or independent of each other.

SUMMARY STEPS

1. **enable**
2. **show crypto isakmp profile**
3. **show crypto ipsec sa**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto isakmp profile Example: Router# show crypto isakmp profile	Shows that the QoS group is applied to the profile.

	Command or Action	Purpose
Step 3	show crypto ipsec sa Example: Router# show crypto ipsec sa	Shows that the QoS group is applied to a particular pair of IPsec security associations (SAs).

Troubleshooting Tips

If you have a problem with your IPsec and QoS sessions, ensure that you have done the following:

- Validated the application of QoS by the QoS service using the QoS-specific commands in the *Cisco IOS Quality of Service Solutions Command Reference*.
- Configured a QoS policy on the router that matches the same QoS group as that specified for the class map match criterion.
- Applied the service policy to the same interface to which a crypto map is applied.

Configuration Examples for IPsec and Quality of Service

QoS Policy Applied to Two Groups of Remote Users Example

In the following example, a specific QoS policy is applied to two groups of remote users. Two ISAKMP profiles are configured so that upon initial connection via IKE, remote users are mapped to a specific profile. From that profile, all IPsec SAs that have been created for that remote will be marked with the specific QoS group. As traffic leaves the outbound interface, the QoS service will map the IPsec set QoS group with the QoS group that is specified in the class maps that comprise the service policy that is applied on that outbound interface.

CHAPTER 202

VRF-Aware IPsec

The VRF-Aware IPsec feature introduces IP Security (IPsec) tunnel mapping to Multiprotocol Label Switching (MPLS) Virtual Private Networks (VPNs).

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

- [Restrictions for VRF-Aware IPsec, on page 2609](#)
- [Information About VRF-Aware IPsec, on page 2610](#)
- [How to Configure VRF-Aware IPsec, on page 2612](#)
- [Configuration Examples for VRF-Aware IPsec, on page 2629](#)
- [Additional References, on page 2641](#)
- [Feature Information for VRF-Aware IPsec, on page 2642](#)
- [Glossary, on page 2642](#)

Restrictions for VRF-Aware IPsec

- If you are configuring the VRF-Aware IPsec feature using a crypto map configuration and the Inside VRF (IVRF) is not the same as the Front Door VRF (FVRF), this feature is not interoperable with unicast reverse path forwarding (uRPF) if uRPF is enabled on the crypto map interface. If your network requires uRPF, it is recommended that you use Virtual Tunnel Interface (VTI) for IPsec instead of crypto maps.
- The VRF-Aware IPsec feature does not allow IPsec tunnel mapping between VRFs. For example, it does not allow IPsec tunnel mapping from VRF vpn1 to VRF vpn2.
- When the VRF-Aware IPsec feature is used with a crypto map, this crypto map cannot use the global VRF as the IVRF and a non-global VRF as the FVRF. However, configurations based on virtual tunnel interfaces do not have that limitation. When VTIs or Dynamic VTIs (DVTIs) are used, the global VRF can be used as the IVRF together with a non-global VRF used as the FVRF.
- You must include the VRF in the **local-address** command when using the local address with VRF in the ISAKMP profile and keyring.

- When configuring IPsec with tunnel protection for VTI, GRE/IPsec, or DMVPN, define the IVRF under the tunnel interface and not under ISAKMP or IKEv2 profile for the peer device. Defining an IVRF under the ISAKMP or IKEv2 profile can lead to IPsec negotiation failures.

Information About VRF-Aware IPsec

VRF Instance

A VRF instance is a per-VPN routing information repository that defines the VPN membership of a customer site attached to the Provider Edge (PE) router. A VRF comprises an IP routing table, a derived Cisco Express Forwarding (CEF) table, a set of interfaces that use the forwarding table, and a set of rules and routing protocol parameters that control the information that is included in the routing table. A separate set of routing and Cisco Express Forwarding (CEF) tables is maintained for each VPN customer.

MPLS Distribution Protocol

The MPLS distribution protocol is a high-performance packet-forwarding technology that integrates the performance and traffic management capabilities of data link layer switching with the scalability, flexibility, and performance of network-layer routing.

VRF-Aware IPsec Functional Overview

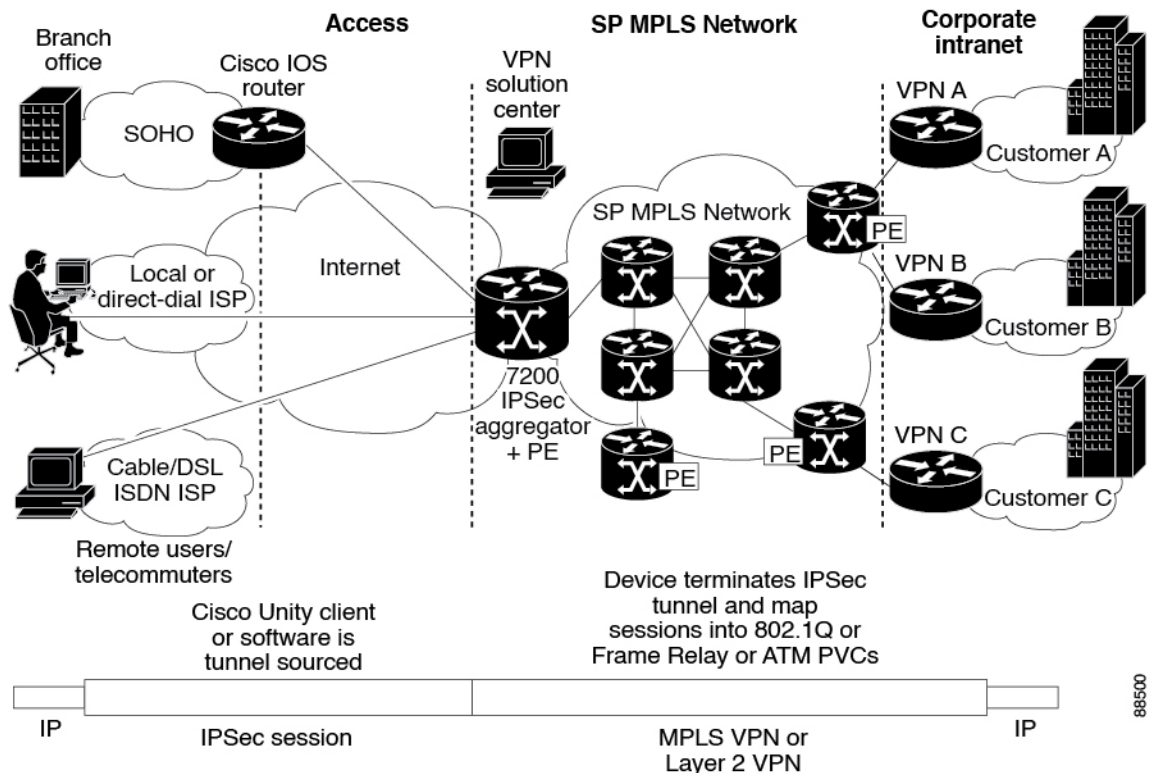

Front Door VRF (FVRF) and Inside VRF (IVRF) are central to understanding the feature.

Each IPsec tunnel is associated with two VRF domains. The outer encapsulated packet belongs to one VRF domain, which we shall call the FVRF, while the inner, protected IP packet belongs to another domain called the IVRF. Another way of stating the same thing is that the local endpoint of the IPsec tunnel belongs to the FVRF while the source and destination addresses of the inside packet belong to the IVRF.

One or more IPsec tunnels can terminate on a single interface. The FVRF of all these tunnels is the same and is set to the VRF that is configured on that interface. The IVRF of these tunnels can be different and depends on the VRF that is defined in the Internet Security Association and Key Management Protocol (ISAKMP) profile that is attached to a crypto map entry.

The diagram below is an illustration of a scenario showing IPsec to MPLS and Layer 2 VPNs.

Figure 102: IPsec to MPLS and Layer 2 VPNs

88500

Packet Flow into the IPsec Tunnel

- A VPN packet arrives from the Service Provider MPLS backbone network to the PE and is routed through an interface facing the Internet.
- The packet is matched against the Security Policy Database (SPD), and the packet is IPsec encapsulated. The SPD includes the IVRF and the access control list (ACL).
- The IPsec encapsulated packet is then forwarded using the FVRF routing table.

Packet Flow from the IPsec Tunnel

- An IPsec-encapsulated packet arrives at the PE router from the remote IPsec endpoint.
- IPsec performs the Security Association (SA) lookup for the Security Parameter Index (SPI), destination, and protocol.
- The packet is decapsulated using the SA and is associated with IVRF.
- The packet is further forwarded using the IVRF routing table.

How to Configure VRF-Aware IPsec

Configuring Crypto Keyrings

A crypto keyring is a repository of preshared and Rivest, Shamir, and Adelman (RSA) public keys. There can be zero or more keyrings on the Cisco IOS router.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto keyring** *keyring-name* [**vrf** *fvrf-name*]
4. **description** *string*
5. **pre-shared-key** {**address** *address* [*mask*] | **hostname** *hostname*} **key** *key*
6. **rsa-pubkey** {**address** *address* | **name** *fqdn*} [**encryption** | **signature**]

8. **serial-number** *serial-number*
9. **key-string**
10. **text**
11. **quit**
12. **exit**
13. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto keyring <i>keyring-name</i> [vrf <i>fvrf-name</i>] Example: Router (config)# crypto keyring VPN1	Defines a keyring with <i>keyring-name</i> as the name of the keyring and enters keyring configuration mode. • (Optional) The vrf keyword and <i>fvrf-name</i> argument imply that the keyring is bound to Front Door Virtual Routing and Forwarding (FVRF). The key in the keyring is searched if the local endpoint is in FVRF. If vrf is not specified, the keyring is bound to the global.

	Command or Action	Purpose
Step 4	<p>description <i>string</i></p> <p>Example:</p> <p>Example:</p> <pre>Router (config-keyring)# description The keys for VPN1</pre>	(Optional) Specifies a one-line description of the keyring.
Step 5	<p>pre-shared-key {address <i>address</i> [<i>mask</i>] hostname <i>hostname</i>} key <i>key</i></p> <p>Example:</p> <pre>Router (config-keyring)# pre-shared-key address 10.72.23.11 key VPN1</pre>	(Optional) Defines a preshared key by address or host name.
Step 6	<p>rsa-pubkey {address <i>address</i> name <i>fqdn</i>} [encryption signature]</p> <p>Example:</p> <pre>Router(config-keyring)# rsa-pubkey name host.vpn.com</pre>	<p>(Optional) Defines an RSA public key by address or host name and enters rsa-pubkey configuration mode.</p> <ul style="list-style-type: none"> • The optional encryption keyword specifies that the key should be used for encryption. • The optional signature keyword specifies that the key should be used for signature. By default, the key is used for signature.
Step 7	<p>address <i>ip-address</i></p> <p>Example:</p> <pre>Router(config-pubkey-key)# address 10.5.5.1</pre>	(Optional) Defines the RSA public key IP address.
Step 8	<p>serial-number <i>serial-number</i></p> <p>Example:</p> <pre>Router(config-pubkey-key)# serial-number 1000000</pre>	(Optional) Specifies the serial number of the public key. The value is from 0 through infinity.
Step 9	<p>key-string</p> <p>Example:</p> <pre>Router (config-pubkey-key)# key-string</pre>	Enters into the text mode in which you define the public key.
Step 10	<p>text</p> <p>Example:</p> <pre>Router (config-pubkey)# 00302017 4A7D385B 1234EF29 335FC973</pre>	<p>Specifies the public key.</p> <p>Note Only one public key may be added in this step.</p>
Step 11	<p>quit</p> <p>Example:</p>	Quits to the public key configuration mode.

	Command or Action	Purpose
	Router (config-pubkey)# quit	
Step 12	exit Example: Router (config-pubkey)# exit	Exits to the keyring configuration mode.
Step 13	exit Example: Router (config-keyring)# exit#	Exits to global configuration mode.

Configuring ISAKMP Profiles

An ISAKMP profile is a repository for Internet Key Exchange (IKE) Phase 1 and IKE Phase 1.5 configuration for a set of peers. An ISAKMP profile defines items such as keepalive, trustpoints, peer identities, and XAUTH AAA list during the IKE Phase 1 and Phase 1.5 exchange. There can be zero or more ISAKMP profiles on the Cisco IOS router.

Note If traffic from the router to a certification authority (CA) (for authentication, enrollment, or for obtaining a certificate revocation list [CRL]) or to an Lightweight Directory Access Protocol (LDAP) server (for obtaining a CRL) needs to be routed via a VRF, the **vrf** command must be added to the trustpoint. Otherwise, the traffic uses the default routing table.

- If a profile does not specify one or more trustpoints, all trustpoints in the router will be used to attempt to validate the certificate of the peer (IKE main mode or signature authentication). If one or more trustpoints are specified, only those trustpoints will be used.

Note A router initiating IKE and a router responding to the IKE request should have symmetrical trustpoint configurations. For example, a responding router (in IKE Main Mode) performing RSA signature encryption and authentication might use trustpoints that were defined in the global configuration when sending the CERT-REQ payloads. However, the router might use a restricted list of trustpoints that were defined in the ISAKMP profile for the certificate verification. If the peer (the IKE initiator) is configured to use a certificate whose trustpoint is in the global list of the responding router but not in ISAKMP profile of the responding router, the certificate will be rejected. (However, if the initiating router does not know about the trustpoints in the global configuration of the responding router, the certificate can still be authenticated.)

>

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **crypto isakmp profile** *profile-name*
4. **description** *string*
5. **vrf** *ivrf-name*
6. **keepalive** *seconds* **retry** *retry-seconds*
7. **self-identity** {*address* | *fqdn* | **user-fqdn** *user-fqdn*}
8. **keyring** *keyring-name*
9. **ca trust-point** {*trustpoint-name*}
10. **match identity** {**group** *group-name* | **address** *address* [*mask*] [*fvr*] | **host** *host-name* | **host domain** *domain-name* | **user** *user-fqdn* | **user domain** *domain-name*}
11. **client configuration address** {**initiate** | **respond**}
12. **client authentication list** *list-name*
13. **isakmp authorization list** *list-name*
14. **initiate mode aggressive**
15. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto isakmp profile <i>profile-name</i> Example: <pre>Router (config)# crypto isakmp profile vpnprofile</pre>	Defines an Internet Security Association and Key Management Protocol (ISAKMP) profile and enters into isakmp profile configuration mode.
Step 4	description <i>string</i> Example: <pre>Router (conf-isa-prof)# description configuration for VPN profile</pre>	(Optional) Specifies a one-line description of an ISAKMP profile.
Step 5	vrf <i>ivrf-name</i> Example: <pre>Router (conf-isa-prof)# vrf VPN1</pre>	(Optional) Maps the IPsec tunnel to a Virtual Routing and Forwarding (VRF) instance. Note The VRF also serves as a selector for matching the Security Policy Database (SPD). If the VRF is not specified in the ISAKMP profile, the IVRF of the IPsec tunnel will be the same as its FVRF.

	Command or Action	Purpose
Step 6	<p>keepalive <i>seconds</i> retry <i>retry-seconds</i></p> <p>Example:</p> <pre>Router (conf-isa-prof)# keepalive 60 retry 5</pre>	<p>(Optional) Allows the gateway to send dead peer detection (DPD) messages to the peer.</p> <ul style="list-style-type: none"> • If not defined, the gateway uses the global configured value. • <i>seconds</i> --Number of seconds between DPD messages. The range is 10 to 3600 seconds. • retry <i>retry-seconds</i> --Number of seconds between retries if the DPD message fails. The range is 2 to 60 seconds.
Step 7	<p>self-identity {<i>address</i> <i>fqdn</i> <i>user-fqdn</i> <i>user-fqdn</i>}</p> <p>Example:</p> <pre>Router (conf-isa-prof)# self-identity address</pre>	<p>(Optional) Specifies the identity that the local Internet Key Exchange (IKE) should use to identify itself to the remote peer.</p> <ul style="list-style-type: none"> • If not defined, IKE uses the global configured value. • address --Uses the IP address of the egress interface. • fqdn-- Uses the fully qualified domain name (FQDN) of the router. • user-fqdn --Uses the specified value.
Step 8	<p>keyring <i>keyring-name</i></p> <p>Example:</p> <pre>Router (conf-isa-prof)# keyring VPN1</pre>	<p>(Optional) Specifies the keyring to use for Phase 1 authentication.</p> <ul style="list-style-type: none"> • If the keyring is not specified, the global key definitions are used.
Step 9	<p>ca trust-point {<i>trustpoint-name</i>}</p> <p>Example:</p> <pre>Router (conf-isa-prof)# ca trustpoint VPN1-trustpoint</pre>	<p>(Optional) Specifies a trustpoint to validate a Rivest, Shamir, and Adelman (RSA) certificate.</p> <ul style="list-style-type: none"> • If no trustpoint is specified in the ISAKMP profile, all the trustpoints that are configured on the Cisco IOS router are used to validate the certificate.
Step 10	<p>match identity {group <i>group-name</i> address <i>address</i> [<i>mask</i>] [<i>fvr</i>] host <i>host-name</i> host domain <i>domain-name</i> user <i>user-fqdn</i> user domain <i>domain-name</i>}</p> <p>Example:</p> <pre>Router (conf-isa-prof)# match identity address 10.1.1.1</pre>	<p>Specifies the client IKE Identity (ID) that is to be matched.</p> <ul style="list-style-type: none"> • group <i>group-name</i> --Matches the <i>group-name</i> with the ID type ID_KEY_ID. It also matches the <i>group-name</i> with the Organizational Unit (OU) field of the Distinguished Name (DN). • address <i>address</i> [<i>mask</i>] <i>fvr</i> --Matches the <i>address</i> with the ID type ID_IPV4_ADDR. The <i>mask</i> argument can be used to specify a range of addresses. The <i>fvr</i> argument specifies that the address is in Front Door Virtual Routing and Forwarding (FVRF)

	Command or Action	Purpose
		<ul style="list-style-type: none"> • host <i>hostname</i> --Matches the <i>hostname</i> with the ID type ID_FQDN. • host domain <i>domain-name</i> --Matches the <i>domain-name</i> to the ID type ID_FQDN whose domain name is the same as the <i>domain-name</i>. Use this command to match all the hosts in the domain. • user <i>username</i> --Matches the <i>username</i> with the ID type ID_USER_FQDN. • user domain <i>domainname</i> --Matches the ID type ID_USER_FQDN whose domain name matches the <i>domainname</i>.
Step 11	client configuration address { initiate respond } Example: <pre>Router (conf-isa-prof)# client configuration address initiate</pre>	(Optional) Specifies whether to initiate the mode configuration exchange or responds to mode configuration requests.
Step 12	client authentication list <i>list-name</i> Example: <pre>Router (conf-isa-prof)# client authentication list xauthlist</pre>	(Optional) AAA (authentication, authorization, and accounting) to use for authenticating the remote client during the extended authentication (XAUTH) exchange.
Step 13	isakmp authorization list <i>list-name</i> Example: <pre>Router (conf-isa-prof)# isakmp authorization list ikessaaalist</pre>	(Optional) Network authorization server for receiving the Phase 1 preshared key and other attribute-value (AV) pairs.
Step 14	initiate mode aggressive Example: <pre>Router (conf-isa-prof)# initiate mode aggressive</pre>	(Optional) Initiates aggressive mode exchange. <ul style="list-style-type: none"> • If not specified, IKE always initiates main mode exchange.
Step 15	exit Example: <pre>Router (conf-isa-prof)# exit</pre>	Exits to global configuration mode.

What to Do Next

Go to [Configuring an ISAKMP Profile on a Crypto Map, on page 2618](#).

Configuring an ISAKMP Profile on a Crypto Map

An ISAKMP profile must be applied to the crypto map. The IVRF on the ISAKMP profile is used as a selector when matching the VPN traffic. If there is no IVRF on the ISAKMP profile, the IVRF will be equal to the FVRF. Perform this task to configure an ISAKMP profile on a crypto map.

Before you begin

Before configuring an ISAKMP profile on a crypto map, you must first configure your router for basic IPsec.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name* **isakmp-profile** *isakmp-profile-name*
4. **set isakmp-profile** *profile-name*
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto map <i>map-name</i> isakmp-profile <i>isakmp-profile-name</i> Example: Router (config)# crypto map vpnmap isakmp-profile vpnprofile	(Optional) Specifies the Internet Key Exchange and Key Management Protocol (ISAKMP) profile for the crypto map set and enters crypto map configuration mode. • The ISAKMP profile will be used during IKE exchange.
Step 4	set isakmp-profile <i>profile-name</i> Example: Router (config-crypto-map)# set isakmp-profile vpnprofile	(Optional) Specifies the ISAKMP profile to use when the traffic matches the crypto map entry.
Step 5	exit Example: Router (config-crypto-map)# exit	Exits to global configuration mode.

Configuring to Ignore Extended Authentication During IKE Phase 1 Negotiation

To ignore XAUTH during an IKE Phase 1 negotiation, use the **no crypto xauth** command. Use the **no crypto xauth** command if you do not require extended authentication for the Unity clients.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **no crypto xauth** *interface*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	no crypto xauth <i>interface</i> Example: Router(config)# no crypto xauth ethernet0	Ignores XAUTH proposals for requests that are destined to the IP address of the interface. By default, Internet Key Exchange (IKE) processes XAUTH proposals.

Verifying VRF-Aware IPsec

To verify your VRF-Aware IPsec configurations, use the following **show** commands. These **show** commands allow you to list configuration information and security associations (SAs):

SUMMARY STEPS

1. **enable**
2. **show crypto ipsec sa** [**map** *map-name*] **address** | **identity** | **interface** *interface* | **peer** [**vrf** *vrf-name*] **address** | **vrf** *vrf-name*] [**detail**]
3. **show crypto isakmp key**
4. **show crypto isakmp profile**
5. **show crypto key pubkey-chain rsa**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable	Enables privileged EXEC mode.

	Command or Action	Purpose
	Example: Router> enable	<ul style="list-style-type: none"> Enter your password if prompted.
Step 2	show crypto ipsec sa [map <i>map-name</i>] address identity interface <i>interface</i> / peer [vrf <i>fvr-f-name</i>] address vrf <i>ivr-f-name</i>] [detail] Example: Router# show crypto ipsec sa vrf vpn1	Allows you to view the settings used by current security associations (SAs).
Step 3	show crypto isakmp key Example: Router# show crypto isakmp key	Lists all the keyrings and their preshared keys. <ul style="list-style-type: none"> Use this command to verify your crypto keyring configuration.
Step 4	show crypto isakmp profile Example: Router# show crypto isakmp profile	Lists all ISAKMP profiles and their configurations.
Step 5	show crypto key pubkey-chain rsa Example: Router# show crypto key pubkey-chain rsa	Views the RSA public keys of the peer that are stored on your router. <ul style="list-style-type: none"> The output is extended to show the keyring to which the public key belongs.

Clearing Security Associations

The following **clear** commands allow you to clear SAs.

SUMMARY STEPS

- enable
- clear crypto sa** [counters | map *map-name* | peer[**vrf** *fvr-f-name*] *address* | spi *address* {**ah** | **esp**} spi | **vrf** *ivr-f-name*]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.

	Command or Action	Purpose
Step 2	<pre>clear crypto sa [counters map map-name peer[vrf fvrf-name] address spi address {ah esp} spi vrf ivrf-name]</pre> <p>Example:</p> <pre>Router# clear crypto sa vrf VPN1</pre>	Clears the IPsec security associations (SAs).

Troubleshooting VRF-Aware IPsec

To troubleshoot VRF-Aware IPsec, use the following **debug** commands:

SUMMARY STEPS

1. **enable**
2. **debug crypto ipsec**
3. **debug crypto isakmp**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<pre>enable</pre> <p>Example:</p> <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<pre>debug crypto ipsec</pre> <p>Example:</p> <pre>Router# debug crypto ipsec</pre>	Displays IP security (IPsec) events.
Step 3	<pre>debug crypto isakmp</pre> <p>Example:</p> <pre>Router(config)# debug crypto isakmp</pre>	Displays messages about Internet Key Exchange (IKE) events.

Debug Examples for VRF-Aware IPsec

The following sample debug outputs are for a VRF-aware IPsec configuration:

IPsec PE

```
Router# debug crypto ipsec

Configuration Examples for VRF-Aware IPsec

Example Static IPsec-to-MPLS VPN

The following sample shows a static configuration that maps IPsec tunnels to MPLS VPNs. The configurations map IPsec tunnels to MPLS VPNs “VPN1” and “VPN2.” Both of the IPsec tunnels terminate on a single public-facing interface.

IPsec PE Configuration

```

ip vrf vpn1
 rd 100:1
 route-target export 100:1
 route-target import 100:1
!
ip vrf vpn2
 rd 101:1
 route-target export 101:1
 route-target import 101:1
!
crypto keyring vpn1
 pre-shared-key address 172.16.1.1 key vpn1
crypto keyring vpn2
 pre-shared-key address 10.1.1.1 key vpn2

Upgrade from Previous Versions of the Cisco Network-Based IPsec VPN Solution

The VRF-Aware IPsec feature in the Cisco network-based IPsec VPN solution release 1.5 requires that you change your existing configurations. The following sample configurations indicate the changes you must make to your existing configurations.

Site-to-Site Configuration Upgrade

The following configurations show the changes that are necessary for a site-to-site configuration upgrade from a previous version of the network-based IPsec VPN solution to the Cisco network-based IPsec VPN solution release 1.5:

Previous Version Site-to-Site Configuration

```

crypto isakmp key VPN1 address 172.21.25.74
crypto isakmp key VPN2 address 172.21.21.74
!
crypto ipsec transform-set VPN1 esp-aes esp-sha-hmac
crypto ipsec transform-set VPN2 esp-aes esp-sha-hmac
!
crypto map VPN1 10 ipsec-isakmp
set peer 172.21.25.74
set transform-set VPN1
match address 101
!
crypto map VPN2 10 ipsec-isakmp
set peer 172.21.21.74
set transform-set VPN2
match address 102
!
interface FastEthernet0/0.1
encapsulation dot1Q 1 native
ip vrf forwarding VPN1
ip address 172.21.25.73 255.255.255.0

```

```

crypto map VPN1
!
interface FastEthernet0/0.2
 encapsulation dot1Q 2 native
 ip vrf forwarding VPN2
 ip address 172.21.21.74 255.255.255.0
 crypto map VPN2

```

New Version Site-to-Site Configuration

The following is an upgraded version of the same site-to-site configuration to the Cisco network-based IPsec VPN solution release 1.5 solution:

Note You must change two keyrings. The VRF-Aware Upset feature requires that keys be associated with a VRF if the IKE local endpoint is in the VRF.

```

crypto keyring VPN1-KEYS vrf VPN1
pre-shared-key address 172.21.25.74 key VPN1
!
crypto keyring VPN2-KEYS vrf VPN2

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for VRF-Aware IPsec

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 268: Feature Information for VRF-Aware IPsec

Feature Name	Releases	Feature Information
VRF-Aware IPsec	12.2(15)T	<p>The VRF-Aware IPsec feature introduces IP Security (IPsec) tunnel mapping to Multiprotocol Label Switching (MPLS) Virtual Private Networks (VPNs). Using the VRF-Aware IPsec feature, you can map IPsec tunnels to Virtual Routing and Forwarding (VRF) instances using a single public-facing address.</p> <p>This feature was introduced in Cisco IOS Release 12.2(15)T.</p> <p>The following sections provide information about this feature:</p> <p>The following commands were introduced or modified: address, ca trust-point, client authentication list, client configuration address, crypto isakmp profile, crypto keyring, crypto map isakmp-profile, initiate-mode, isakmp authorization list, keepalive (isakmp profile), keyring, key-string, match identity, no crypto xauth, pre-shared-key, quit, rsa-pubkey, self-identity, serial-number, set isakmp-profile, show crypto isakmp key, show crypto isakmp profile, vrf, clear crypto sa, crypto isakmp peer, crypto map isakmp-profile, show crypto dynamic-map, show crypto ipsec sa, show crypto isakmp sa, show crypto map (IPsec).</p>
	15.1(1)S	This feature was integrated into Cisco IOS Release 15.1(1)S.

Glossary

CA --certification authority. CA is an entity that issues digital certificates (especially X.509 certificates) and vouches for the binding between the data items in a certificate.

CLI --command-line-interface. CLI is an interface that allows the user to interact with the operating system by entering commands and optional arguments. The UNIX operating system and DOS provide CLIs.

client --Corresponding IPsec IOS peer of the UUT in the Multi Protocol Label Switching (MPLS) network.

dead peer --IKE peer that is no longer reachable.

DN --Distinguished Name. A DN is the global, authoritative name of an entry in the Open System Interconnection (OSI Directory [X.500]).

FQDN --fully qualified domain name. A FQDN is the full name of a system rather than just its host name. For example, aldebaran is a host name, and aldebaran.interop.com is an FQDN.

FR --Frame Relay. FR is an industry-standard, switch-data-link-layer protocol that handles multiple virtual circuits using high-level data link (HDLC) encapsulation between connected devices. Frame Relay is more efficient than X.25, the protocol for which it generally is considered a replacement.

FVRF --Front Door Virtual Routing and Forwarding (VRF) repository. FVRF is the VRF used to route the encrypted packets to the peer.

IDB --Interface descriptor block. An IDB subblock is an area of memory that is private to an application. This area stores private information and states variables that an application wants to associate with an IDB or an interface. The application uses the IDB to register a pointer to its subblock, not to the contents of the subblock itself.

IKE --Internet Key Exchange. IKE establishes a shared security policy and authenticates keys for services (such as IPsec) that require keys. Before any IPsec traffic can be passed, each router, firewall, and host must verify the identity of its peer. This can be done by manually entering preshared keys into both hosts or by a CA service.

IKE keepalive --Bidirectional mechanism for determining the liveness of an IKE peer.

IPsec --Security protocol for IP.

IVRF --Inside Virtual Routing and Forwarding. IVRF is the VRF of the plaintext packets.

MPLS --Multiprotocol Label Switching. MPLS is a switching method that forwards IP traffic using a label. This label instructs the routers and the switches in the network where to forward the packets based on preestablished IP routing information.

RSA --Rivest, Shamir, and Adelman are the inventors of the RSA technique. The RSA technique is a public-key cryptographic system that can be used for encryption and authentication.

SA --Security Association. SA is an instance of security policy and keying material applied to a data flow.

VPN --Virtual Private Network. A VPN enables IP traffic to travel securely over a public TCP or IP network by encrypting all traffic from one network to another. A VPN uses “tunneling” to encrypt all information at the IP level.

VRF --Virtual Route Forwarding. VRF is A VPN routing and forwarding instance. A VRF consists of an IP routing table, a derived forwarding table, a set of interfaces that use the forwarding table, and a set of rules and routing protocols that determine what goes into the forwarding table. In general, a VRF includes the routing information that defines a customer VPN site that is attached to a PE router.

XAUTH --Extended authentication. XAUTH is an optional exchange between IKE Phase 1 and IKE Phase 2, in which the router demands additional authentication information in an attempt to authenticate the actual user (as opposed to authenticating the peer).

CHAPTER 203

IKE Initiate Aggressive Mode

The IKE: Initiate Aggressive Mode feature allows you to specify RADIUS tunnel attributes for an IP security (IPsec) peer and to initiate an Internet Key Exchange (IKE) aggressive mode negotiation with the tunnel attributes. This feature is best implemented in a crypto hub-and-spoke scenario, by which the spokes initiate IKE aggressive mode negotiation with the hub by using the preshared keys that are specified as tunnel attributes and stored on the AAA server. This scenario is scalable because the preshared keys are kept at a central repository (the AAA server) and more than one hub router and one application can use the information.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

- [Prerequisites for IKE Initiate Aggressive Mode, on page 2645](#)
- [Restrictions for IKE Initiate Aggressive Mode, on page 2646](#)
- [Information About IKE Initiate Aggressive Mode, on page 2646](#)
- [How to Configure IKE Initiate Aggressive Mode, on page 2647](#)
- [Configuration Examples for IKE Initiate Aggressive Mode, on page 2649](#)
- [Additional References, on page 2650](#)
- [Feature Information for IKE Initiate Aggressive Mode, on page 2651](#)

Prerequisites for IKE Initiate Aggressive Mode

Before configuring the Initiate Aggressive Mode IKE feature, you must perform the following tasks:

- Configure AAA
- Configure an IPsec Transform
- Configure a static crypto map
- Configure an Internet Security Association and Key Management Protocol (ISAKMP) policy
- Configure a dynamic crypto map

Restrictions for IKE Initiate Aggressive Mode

TED Restriction

This feature is not intended to be used with a dynamic crypto map that uses Tunnel Endpoint Discovery (TED) to initiate tunnel setup. TED is useful in configuring a full mesh setup, which requires an AAA server at each site to store the preshared keys for the peers; this configuration is not practical for use with this feature.

Tunnel-Client-Endpoint ID Types

Only the following ID types can be used in this feature:

- ID_IPV4 (IPV4 address)
- ID_FQDN (fully qualified domain name, for example “foo.cisco.com”)
- ID_USER_FQDN (e-mail address)

Information About IKE Initiate Aggressive Mode

Overview

The IKE: Initiate Aggressive Mode feature allows you to configure IKE preshared keys as RADIUS tunnel attributes for IPsec peers. Thus, you can scale your IKE preshared keys in a hub-and-spoke topology.

Although IKE preshared keys are simple to understand and easy to deploy, they do not scale well with an increasing number of users and are therefore prone to security threats. Instead of keeping your preshared keys on the hub router, this feature allows you to scale your preshared keys by storing and retrieving them from an authentication, authorization, and accounting (AAA) server. The preshared keys are stored in the AAA server as Internet Engineering Task Force (IETF) RADIUS tunnel attributes and are retrieved when a user tries to “speak” to the hub router. The hub router retrieves the preshared key from the AAA server and the spokes (the users) initiate aggressive mode to the hub by using the preshared key that is specified in the Internet Security Association Key Management Policy (ISAKMP) peer policy as a RADIUS tunnel attribute.

RADIUS Tunnel Attributes

To initiate an IKE aggressive mode negotiation, the Tunnel-Client-Endpoint (66) and Tunnel-Password (69) attributes must be configured in the ISAKMP peer policy. The Tunnel-Client-Endpoint attribute will be communicated to the server by encoding it in the appropriate IKE identity payload; the Tunnel-Password attribute will be used as the IKE preshared key for the aggressive mode negotiation.

How to Configure IKE Initiate Aggressive Mode

Configuring RADIUS Tunnel Attributes

To configure the Tunnel-Client-Endpoint and Tunnel-Password attributes within the ISAKMP peer configuration, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name* **isakmp authorization list** *list-name*
4. **crypto isakmp peer** {*ip-address ip-address* | *fqdn fqdn*}
5. **set aggressive-mode client-endpoint** *client-endpoint*
6. **set aggressive-mode password** *password*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto map <i>map-name</i> isakmp authorization list <i>list-name</i> Example: <pre>Router (config)# crypto map testmap10 isakmp authorization list list ike</pre>	Enables IKE querying of AAA for tunnel attributes in aggressive mode.
Step 4	crypto isakmp peer { <i>ip-address ip-address</i> <i>fqdn fqdn</i> } Example: <pre>Router (config)# crypto isakmp peer ip address 10.10.10.1</pre>	Enables an IPsec peer for IKE querying of AAA for tunnel attributes in aggressive mode and enters ISAKMP policy configuration mode.
Step 5	set aggressive-mode client-endpoint <i>client-endpoint</i> Example: <pre>Router (config-isakmp)# set aggressive-mode client-endpoint user-fqdn user@cisco.com</pre>	Specifies the Tunnel-Client-Endpoint attribute within an ISAKMP peer configuration.

	Command or Action	Purpose
Step 6	set aggressive-mode password <i>password</i> Example: <pre>Router (config-isakmp)#set aggressive-mode password cisco123</pre>	Specifies the Tunnel-Password attribute within an ISAKMP peer configuration.

Verifying RADIUS Tunnel Attribute Configurations

To verify that the Tunnel-Client-Endpoint and Tunnel-Password attributes have been configured within the ISAKMP peer policy, use the **show running-config** global configuration command.

Troubleshooting Tips

To troubleshoot the IKE: Initiate Aggressive Mode feature, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **debug aaa authorization**
3. **debug crypto isakmp**
4. **debug radius**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	debug aaa authorization Example: <pre>Router# debug aaa authorization</pre>	Displays information about AAA authorization.
Step 3	debug crypto isakmp Example: <pre>Router# debug crypto isakmp</pre>	Displays messages about IKE events.
Step 4	debug radius Example: <pre>Router# debug radius</pre>	Displays information associated with RADIUS.

Configuration Examples for IKE Initiate Aggressive Mode

Hub Configuration Example

The following example shows how to configure a hub for a hub-and-spoke topology that supports aggressive mode using RADIUS tunnel attributes:

```
!The AAA configurations are as follows:
aaa new-model
aaa authorization network ike group radius
aaa authentication login default group radius
!
! The Radius configurations are as follows:
radius-server host 10.1.1.1 auth-port 1645 acct-port 1646
radius-server key rad123
!
! The IKE configurations are as follows:
crypto isakmp policy 1
 authentication pre-share
!
! The IPsec configurations are as follows:
crypto ipsec transform-set trans1 esp-aes esp-sha-hmac
!
crypto dynamic-map Dmap 10
 set transform-set trans1
!
crypto map Testtag isakmp authorization list ike
crypto map Testtag 10 ipsec-isakmp dynamic Dmap
!
interface FastEthernet0
 ip address 10.4.4.1 255.255.255.0
 crypto map Testtag
!
interface FastEthernet1
 ip address 10.2.2.1 255.255.255.0
```

Spoke Configuration Example

The following example shows how to configure a spoke for a hub-and-spoke topology that supports aggressive mode using RADIUS tunnel attributes:

```
!The IKE configurations are as follows:
crypto isakmp policy 1
 authentication pre-share
!
! The IPsec configurations are as follows:
crypto ipsec transform-set trans1 esp-aes esp-sha-hmac
 access-list 101 permit ip 10.3.3.0 0.0.0.255 10.2.2.0 0.0.0.255
!
! Initiate aggressive mode using Radius tunnel attributes
crypto isakmp peer address 10.4.4.1
 set aggressive-mode client-endpoint user-fqdn user@cisco.com
 set aggressive-mode password cisco123
!

RADIUS User Profile Example

The following is an example of a user profile on a RADIUS server that supports the Tunnel-Client-Endpoint and Tunnel-Password attributes:

```

user@cisco.com Password = "cisco", Service-Type = Outbound
Tunnel-Medium-Type = :1:IP,
Tunnel-Type = :1:ESP,
Cisco:Avpair = "ipsec:tunnel-password=cisco123",
Cisco:Avpair = "ipsec:key-exchange=ike"

```

CHAPTER 204

Dynamic Multipoint VPN

The Dynamic Multipoint VPN feature allows users to better scale large and small IP Security (IPsec) Virtual Private Networks (VPNs) by combining generic routing encapsulation (GRE) tunnels, IPsec encryption, and Next Hop Resolution Protocol (NHRP).

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

- [Glossary, on page 2698](#)

Prerequisites for Dynamic Multipoint VPN

- Before a multipoint GRE (mGRE) and IPsec tunnel can be established, you must define an Internet Key Exchange (IKE) policy by using the **crypto isakmp policy** command.
- To use the 2547oDMPVN--Traffic Segmentation Within DMVPN feature you must configure Multiprotocol Label Switching (MPLS) by using the **mpls ip** command.

Guidelines and Restrictions for Dynamic Multipoint VPN

- Bidirectional protocol-independent multicast (PIM) is not supported over DMVPN. Therefore, you must use PIM Sparse mode (ASM) over DMVPN.
- Protocol-independent multicast (PIM) dense mode is not supported over DMVPN on IOS-XE devices.

- From Cisco IOS XE Release 17.5.1, you can use the following DMVPN commands without a security license because DMVPN can be configured without using encryption:
 - **show dmvpn**
 - **show dmvpn detail**
 - **debug dmvpn**
 - **logging dmvpn**
- If you use the benefit of this feature, you must use IKE certificates or wildcard preshared keys for Internet Security Association Key Management Protocol (ISAKMP) authentication.

Note It is highly recommended that you do not use wildcard preshared keys because an attacker will have access to the VPN if one spoke router is compromised.

- GRE tunnel keepalives (that is, the **keepalive** command under a GRE interface) are not supported on point-to-point or multipoint GRE tunnels in a DMVPN network.
- The device running Cisco IOS XE 16.12.4 or 17.3.1a image is unable to establish CDP neighborhood with peers through a mGRE tunnel.
- If one spoke is behind one Network Address Translation (NAT) device and a different spoke is behind another NAT device, and Port Address Translation (PAT) is the type of NAT used on both NAT devices, then a session initiated between the two spokes cannot be established.

One example of a PAT configuration on a NAT interface is:

```
ip nat inside source list nat_acl interface FastEthernet0/0/1 overload
```

- When using OSPF point-to-multipoint, you must block the OSPF /32 routes. Add the following on all hub and spoke routers to block these host routes:

```
router ospf <#>
...
distribute-list prefix-list Block-32 out //block OSPF/32 connected routes//
ip prefix-list Block-32 deny <tunnel-subnet> <mask> ge 32
ip prefix-list Block-32 permit any le 32
```

- When a CA has a duplicate DN, the router checks all the certificate and stops the check on finding a match. In this scenario, the other certificates on the device are not checked. To overcome this issue, configure the IKEv2 profile with one trust point only.
- **SSO Restrictions**
 - For an ESP reload (no standby ESP), the SA sequence number restarts from 0. The peer router drops packets that do not have the expected sequence number. You may need to explicitly reestablish IPsec sessions to work around this issue for systems that have a single ESP after an ESP reload. Traffic disruption might happen over the IPsec sessions in such cases for the duration of the reload.

Information About Dynamic Multipoint VPN

Benefits of Dynamic Multipoint VPN

Hub Router Configuration Reduction

- For each spoke router, there is a separate block of configuration lines on the hub router that define the crypto map characteristics, the crypto access list, and the GRE tunnel interface. This feature allows users to configure a single mGRE tunnel interface, a single IPsec profile, and no crypto access lists on the hub router to handle all spoke routers. Thus, the size of the configuration on the hub router remains constant even if spoke routers are added to the network.
- DMVPN architecture can group many spokes into a single multipoint GRE interface, removing the need for a distinct physical or logical interface for each spoke in a native IPsec installation.

Automatic IPsec Encryption Initiation

- GRE has the peer source and destination address configured or resolved with NHRP. Thus, this feature allows IPsec to be immediately triggered for the point-to-point GRE tunneling or when the GRE peer address is resolved via NHRP for the multipoint GRE tunnel.

Support for Dynamically Addressed Spoke Routers

- When using point-to-point GRE and IPsec hub-and-spoke VPN networks, the physical interface IP address of the spoke routers must be known when configuring the hub router because the IP address must be configured as the GRE tunnel destination address. This feature allows spoke routers to have dynamic physical interface IP addresses (common for cable and DSL connections). When the spoke router comes online, it will send registration packets to the hub router: within these registration packets is the current physical interface IP address of this spoke.

Dynamic Creation for Spoke-to-Spoke Tunnels

- This feature eliminates the need for spoke-to-spoke configuration for direct tunnels. When a spoke router wants to transmit a packet to another spoke router, it can now use NHRP to dynamically determine the required destination address of the target spoke router. (The hub router acts as the NHRP server, handling the request for the source spoke router.) The two spoke routers dynamically create an IPsec tunnel between them so data can be directly transferred.

Feature Design of Dynamic Multipoint VPN

The Dynamic Multipoint VPN feature combines GRE tunnels, IPsec encryption, and NHRP routing to provide users an ease of configuration via crypto profiles--which override the requirement for defining static crypto maps--and dynamic discovery of tunnel endpoints.

This feature relies on the following two Cisco enhanced standard technologies:

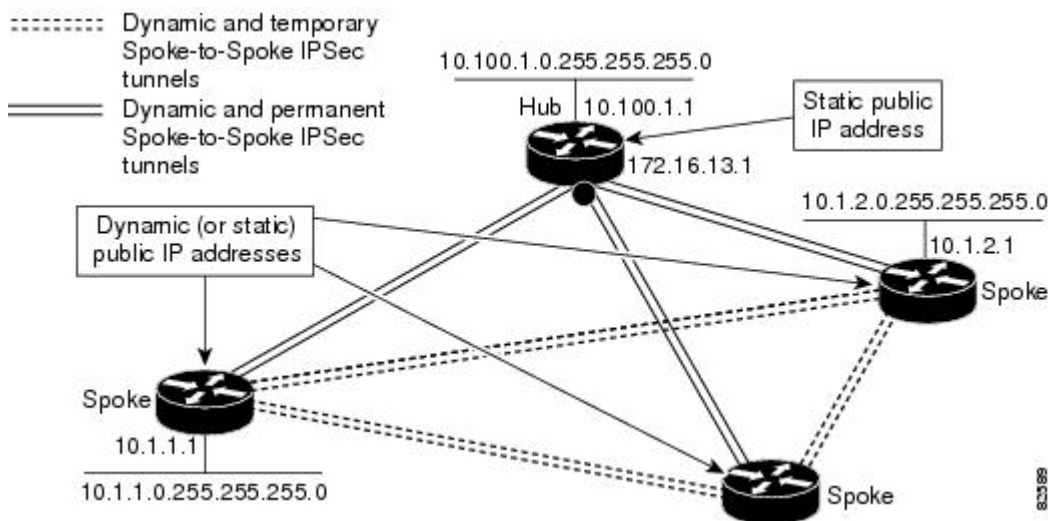

- NHRP--A client and server protocol where the hub is the server and the spokes are the clients. The hub maintains an NHRP database of the public interface addresses of each spoke. Each spoke registers its

real address when it boots and queries the NHRP database for real addresses of the destination spokes to build direct tunnels.

- mGRE tunnel interface --Allows a single GRE interface to support multiple IPsec tunnels and simplifies the size and complexity of the configuration.

The topology shown in the figure below and the corresponding bullets explain how this feature works.

Figure 103: Sample mGRE and IPsec Integration Topology

- Each spoke has a permanent IPsec tunnel to the hub, not to the other spokes within the network. Each spoke registers as clients of the NHRP server.
- When a spoke needs to send a packet to a destination (private) subnet on another spoke, it queries the NHRP server for the real (outside) address of the destination (target) spoke.
- After the originating spoke “learns” the peer address of the target spoke, it can initiate a dynamic IPsec tunnel to the target spoke.
- The spoke-to-spoke tunnel is built over the multipoint GRE interface.
- The spoke-to-spoke links are established on demand whenever there is traffic between the spokes. Thereafter, packets can bypass the hub and use the spoke-to-spoke tunnel.

Note After a preconfigured amount of inactivity on the spoke-to-spoke tunnels, the router will tear down those tunnels to save resources (IPsec security associations [SAs]).

IPsec Profiles

IPsec profiles abstract IPsec policy information into a single configuration entity, which can be referenced by name from other parts of the configuration. Therefore, users can configure functionality such as GRE tunnel protection with a single line of configuration. By referencing an IPsec profile, the user need not configure

an entire crypto map configuration. An IPsec profile contains only IPsec information; that is, it does not contain any access list information or peering information.

Enabling Traffic Segmentation Within DMVPN

Cisco IOS XE Release 2.5 provides an enhancement that allows you to segment VPN traffic within a DMVPN tunnel by using a PE-PE mGRE tunnel. This secured mGRE tunnel can be used to transport all (or a set of) VPN traffic.

The diagram below and the corresponding bullets explain how traffic segmentation within DMVPN works.

Figure 104: Traffic Segmentation with DMVPN

- The hub shown in the diagram is a WAN-PE and a Route Reflector, and the spokes (PE routers) are clients.
- There are three VRFs, designated “red,” “green,” and “blue.”
- Each spoke has both a neighbor relationship with the hub (multiprotocol internal Border Gateway Protocol [MP-iBGP] peering) and a GRE tunnel to the hub.

- Each spoke advertises its routes and VPN-IPv4 (VPNv4) prefixes to the hub.
- The hub sets its own IP address as the next-hop route for all the VPNv4 addresses it learns from the spokes and assigns a local MPLS label for each VPN when it advertises routes back to the spokes. As a result, traffic from Spoke A to Spoke B is routed via the hub.

An example illustrates the process:

1. Spoke A advertises a VPNv4 route to the hub, and applies the label *x* to the VPN.
2. The hub changes the label to *y* when the hub advertises the route to Spoke B.
3. When Spoke B has traffic to send to Spoke A, it applies the *y* label, and the traffic goes to the hub.
4. The hub swaps the VPN label, by removing the *y* label and applying an *x* label, and sends the traffic to Spoke A.

NAT-Transparency Aware DMVPN

DMVPN spokes are often situated behind a NAT router (which is often controlled by the Internet Service Provider [ISP] for the spoke site) with the outside interface address of the spoke router being dynamically assigned by the ISP using a private IP address (per Internet Engineering Task Force [IETF] RFC 1918).

With the NAT-Transparency Aware DMVPN enhancement, NHRP can learn and use the NAT public address for its mappings as long as IPsec transport mode is used (which is the recommended IPsec mode for DMVPN networks). It is recommended that all DMVPN routers be upgraded to the new code before you try to use the NAT-Transparency Aware DMVPN functionality even though spoke routers that are not behind NAT need not be upgraded. In addition, you cannot convert upgraded spoke routers that are behind NAT to the new configuration (IPsec transport mode) until the hub routers have been upgraded.

With this NAT Transparency enhancement, the hub DMVPN router can be behind the static NAT. For this functionality to be used, all the DMVPN spoke routers and hub routers must be upgraded, and IPsec must use transport mode.

For these NAT-Transparency Aware enhancements to work, you must use IPsec transport mode on the transform set. Also, even though NAT-Transparency (IKE and IPsec) can support two peers (IKE and IPsec) being translated to the same IP address (using the UDP ports to differentiate them), this functionality is not supported for DMVPN. All DMVPN spokes must have a unique IP address after they have been NAT translated. They can have the same IP address before they are NAT translated.

The figure below illustrates a NAT-Transparency Aware DMVPN scenario.

Note DMVPN spokes behind NAT will participate in dynamic direct spoke-to-spoke tunnels. The spokes must be behind NAT boxes that are performing NAT, not PAT. The NAT box must translate the spoke to the same outside NAT IP address for the spoke-to-spoke connections as the NAT box does for the spoke-to-hub connection. If there is more than one DMVPN spoke behind the same NAT box, the NAT box must translate the DMVPN spokes to different outside NAT IP addresses. It is also likely that you may not be able to build a direct spoke-to-spoke tunnel between these spokes. If a spoke-to-spoke tunnel fails to form, the spoke-to-spoke packets will continue to be forwarded via the spoke-to-hub-spoke path.

Figure 105: NAT-Transparency Aware DMVPN

Call Admission Control with DMVPN

In a DMVPN network, it is easy for a DMVPN router to become “overwhelmed” with the number of tunnels it is trying to build. Call Admission Control can be used to limit the number of tunnels that can be built at any one time, thus protecting the memory of the router and CPU resources.

It is most likely that Call Admission Control will be used on a DMVPN spoke to limit the total number of ISAKMP sessions (DMVPN tunnels) that a spoke router will attempt to initiate or accept. This limiting is accomplished by configuring an IKE SA limit under Call Admission Control, which configures the router to drop new ISAKMP session requests (inbound and outbound) if the current number of ISAKMP SAs exceeds the limit.

It is most likely that Call Admission Control will be used on a DMVPN hub to rate limit the number of DMVPN tunnels that are attempting to be built at the same time. The rate limiting is accomplished by configuring a system resource limit under Call Admission Control, which configures the router to drop new ISAKMP session requests (new DMVPN tunnels) when the system utilization is above a specified percentage. The dropped session requests allow the DMVPN hub router to complete the current ISAKMP session requests, and when the system utilization drops, it can process the previously dropped sessions when they are reattempted.

No special configuration is required to use Call Admission Control with DMVPN. For information about configuring Call Admission Control, see the “Call Admission Control for IKE” module in the *Cisco IOS XE Security Configuration Guide: Secure Connectivity*.

NHRP Rate-Limiting Mechanism

NHRP has a rate-limiting mechanism that restricts the total number of NHRP packets from any given interface. The default values, which are set using the `ip nhrp max-send` command, are 10,000 packets every 10 seconds per interface. If the limit is exceeded, you will get the following system message:

```
%NHRP-4-QUOTA: Max-send quota of [int]pkts/[int]Sec. exceeded on [chars]
```

For more information about this system message, see the document [System Messages for Cisco IOS XE Software](#).

How to Configure Dynamic Multipoint VPN

To enable mGRE and IPsec tunneling for hub and spoke routers, you must configure an IPsec profile that uses a global IPsec policy template and configure your mGRE tunnel for IPsec encryption. This section contains the following procedures:

Configuring an IPsec Profile

The IPsec profile shares most of the same commands with the crypto map configuration, but only a subset of the commands are valid in an IPsec profile. Only commands that pertain to an IPsec policy can be issued under an IPsec profile; you cannot specify the IPsec peer address or the Access Control List (ACL) to match the packets that are to be encrypted.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

Before you begin

Before configuring an IPsec profile, you must define a transform set by using the **crypto ipsec transform-set** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec profile** *name*
4. **set transform-set** *transform-set-name*
5. **set identity**
6. **set security association lifetime** {seconds *seconds* | kilobytes *kilobytes*}
7. **set pfs** [**group1** | **group2**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto ipsec profile <i>name</i> Example: <pre>Router(config)# crypto ipsec profile vpnprof</pre>	Defines the IPsec parameters that are to be used for IPsec encryption between “spoke and hub” and “spoke and spoke” routers. <ul style="list-style-type: none"> • This command enters crypto map configuration mode. • The <i>name</i> argument specifies the name of the IPsec profile.
Step 4	set transform-set <i>transform-set-name</i> Example: <pre>Router(config-crypto-map)# set transform-set trans2</pre>	Specifies which transform sets can be used with the IPsec profile. <ul style="list-style-type: none"> • The <i>transform-set-name</i> argument specifies the name of the transform set.
Step 5	set identity Example: <pre>Router(config-crypto-map)# set identity</pre>	(Optional) Specifies identity restrictions to be used with the IPsec profile.
Step 6	set security association lifetime { seconds <i>seconds</i> kilobytes <i>kilobytes</i> } Example: <pre>Router(config-crypto-map)# set security association lifetime seconds 1800</pre>	(Optional) Overrides the global lifetime value for the IPsec profile. <ul style="list-style-type: none"> • The seconds <i>seconds</i> option specifies the number of seconds a security association will live before expiring; the kilobytes <i>kilobytes</i> option specifies the volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before that security association expires. • The default for the <i>seconds</i> argument is 3600 seconds.
Step 7	set pfs [group1 group2] Example: <pre>Router(config-crypto-map)# set pfs group2</pre>	(Optional) Specifies that IPsec should ask for perfect forward secrecy (PFS) when requesting new security associations for this IPsec profile. <ul style="list-style-type: none"> • If this command is not specified, the default (group1) is enabled. • The group1 keyword specifies that IPsec should use the 768-bit Diffie-Hellman (DH) prime modulus group when performing the new DH exchange; the group2 keyword specifies the 1024-bit DH prime modulus group.

Configuring the Hub for DMVPN

To configure the hub router for mGRE and IPsec integration (that is, associate the tunnel with the IPsec profile configured in the previous procedure), use the following commands.

Note NHRP network IDs are locally significant and can be different. It makes sense from a deployment and maintenance perspective to use unique **network ID** numbers (using the **ip nhrp network-id** command) across all routers in a DMVPN network, but it is not necessary that they be the same.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel number**
4. **ip address ip-address mask secondary**
5. **ip mtu bytes**
6. **ip nhrp authentication string**
7. **ip nhrp map multicast dynamic**
8. **ip nhrp network-id number**
9. **tunnel source {ip-address | type number}**
10. **tunnel key key-number**
11. **tunnel mode gre multipoint**
12. Do one of the following:
 - **tunnel protection ipsec profile name**
 - **tunnel protection psk key**
13. **bandwidth kbps**
14. **ip tcp adjust-mss max-segment-size**
15. **ip nhrp holdtime seconds**
16. **delay number**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface tunnel number Example: Router(config)# interface tunnel 5	Configures a tunnel interface and enters interface configuration mode <ul style="list-style-type: none"> • The <i>number</i> argument specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.

	Command or Action	Purpose
Step 4	<p>ip address <i>ip-address mask secondary</i></p> <p>Example:</p> <pre>Router(config-if)# ip address 10.0.0.1 255.255.255.0</pre>	<p>Sets a primary or secondary IP address for the tunnel interface.</p> <p>Note All hubs and spokes that are in the same DMVPN network must be addressed in the same IP subnet.</p>
Step 5	<p>ip mtu <i>bytes</i></p> <p>Example:</p> <pre>Router(config-if)# ip mtu 1400</pre>	<p>Sets the maximum transmission unit (MTU) size, in bytes, of IP packets sent on an interface.</p>
Step 6	<p>ip nhrp authentication <i>string</i></p> <p>Example:</p> <pre>Router(config-if)# ip nhrp authentication donttell</pre>	<p>Configures the authentication string for an interface using NHRP.</p> <p>Note The NHRP authentication string must be set to the same value on all hubs and spokes that are in the same DMVPN network.</p>
Step 7	<p>ip nhrp map multicast dynamic</p> <p>Example:</p> <pre>Router(config-if)# ip nhrp map multicast dynamic</pre>	<p>Allows NHRP to automatically add spoke routers to the multicast NHRP mappings.</p> <p>Note Effective with Cisco IOS XE Denali 16.3 ip nhrp map multicast dynamic is enabled by default.</p>
Step 8	<p>ip nhrp network-id <i>number</i></p> <p>Example:</p> <pre>Router(config-if)# ip nhrp network-id 99</pre>	<p>Enables NHRP on an interface.</p> <ul style="list-style-type: none"> The <i>number</i> argument specifies a globally unique 32-bit network identifier from a nonbroadcast multiaccess (NBMA) network. The range is from 1 to 4294967295. <p>Note Effective with Cisco IOS XE Denali 16.3 ip nhrp network-id is enabled by default.</p>
Step 9	<p>tunnel source <i>{ip-address type number}</i></p> <p>Example:</p> <pre>Router(config-if)# tunnel source Gigabitethernet 0/0/0</pre>	<p>Sets the source address for a tunnel interface.</p>
Step 10	<p>tunnel key <i>key-number</i></p> <p>Example:</p> <pre>Router(config-if)# tunnel key 100000</pre>	<p>(Optional) Enables an ID key for a tunnel interface.</p> <ul style="list-style-type: none"> The <i>key-number</i> argument specifies a number from 0 to 4,294,967,295 that identifies the tunnel key. <p>Note The key number must be set to the same value on all hubs and spokes that are in the same DMVPN network.</p>

	Command or Action	Purpose
Step 11	<p>tunnel mode gre multipoint</p> <p>Example:</p> <pre>Router(config-if)# tunnel mode gre multipoint</pre>	Sets the encapsulation mode to mGRE for the tunnel interface.
Step 12	<p>Do one of the following:</p> <ul style="list-style-type: none"> • tunnel protection ipsec profile <i>name</i> • tunnel protection psk <i>key</i> <p>Example:</p> <pre>Router(config-if)# tunnel protection ipsec profile vpnprof</pre> <p>Example:</p> <pre>Router(config-if)# tunnel protection psk test1</pre>	<p>Associates a tunnel interface with an IPsec profile.</p> <ul style="list-style-type: none"> • The <i>name</i> argument specifies the name of the IPsec profile; this value must match the <i>name</i> specified in the crypto ipsec profile <i>name</i> command. <p>or</p> <p>Simplifies the tunnel protection configuration for pre-shared key (PSK) by creating a default IPsec profile.</p>
Step 13	<p>bandwidth <i>kbps</i></p> <p>Example:</p> <pre>Router(config-if)# bandwidth 1000</pre>	<p>Sets the current bandwidth value for an interface to higher-level protocols.</p> <ul style="list-style-type: none"> • The <i>kbps</i> argument specifies the bandwidth in kilobits per second. The default value is 9. The recommended bandwidth value is 1000 or greater. • Setting the bandwidth value to at least 1000 is critical if EIGRP is used over the tunnel interface. Higher bandwidth values may be necessary depending on the number of spokes supported by a hub.
Step 14	<p>ip tcp adjust-mss <i>max-segment-size</i></p> <p>Example:</p> <pre>Router(config-if)# ip tcp adjust-mss 1360</pre>	<p>Adjusts the maximum segment size (MSS) value of TCP packets going through a router.</p> <ul style="list-style-type: none"> • The <i>max-segment-size</i> argument specifies the maximum segment size, in bytes. The range is from 500 to 1460. • The recommended value is 1360 when the number of IP MTU bytes is set to 1400. With these recommended settings, TCP sessions quickly scale back to 1400-byte IP packets so the packets will “fit” in the tunnel.
Step 15	<p>ip nhrp holdtime <i>seconds</i></p> <p>Example:</p> <pre>Router(config-if)# ip nhrp holdtime 450</pre>	<p>Changes the number of seconds that NHRP NBMA addresses are advertised as valid in authoritative NHRP responses.</p> <ul style="list-style-type: none"> • The <i>seconds</i> argument specifies the time in seconds that NBMA addresses are advertised as valid in positive authoritative NHRP responses. The

	Command or Action	Purpose
		recommended value ranges from 300 seconds to 600 seconds.
Step 16	delay <i>number</i> Example: Router(config-if)# delay 1000	(Optional) Changes the EIGRP routing metric for routes learned over the tunnel interface. <ul style="list-style-type: none"> The <i>number</i> argument specifies the delay time in seconds. The recommended value is 1000.

Configuring the Spoke for DMVPN

To configure spoke routers for mGRE and IPsec integration, use the following commands.

Note NHRP network IDs are locally significant and can be different. It makes sense from a deployment and maintenance perspective to use unique **network ID** numbers (using the **ip nhrp network-id** command) across all routers in a DMVPN network, but it is not necessary that they be the same.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** **tunnel** *number*
4. **ip address** *ip-address mask secondary*
5. **ip mtu** *bytes*
6. **ip nhrp authentication** *string*
7. **ip nhrp map** *hub-tunnel-ip-address hub-physical-ip-address*
8. **ip nhrp map multicast** *hub-physical-ip-address*
9. **ip nhrp nhs** *hub-tunnel-ip-address*
10. **ip nhrp network-id** *number*
11. **tunnel source** *{ip-address | type number}*
12. **tunnel key** *key-number*
13. Do one of the following:
 - **tunnel mode gre multipoint**
 - **tunnel destination** *hub-physical-ip-address*
14. Do one of the following:
 - **tunnel protection ipsec profile** *name*
 - **tunnel protection psk** *key*
15. **bandwidth** *kbps*
16. **ip tcp adjust-mss** *max-segment-size*
17. **ip nhrp holdtime** *seconds*
18. **delay** *number*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	interface tunnel number Example: <pre>Router(config)# interface tunnel 5</pre>	Configures a tunnel interface and enters interface configuration mode. <ul style="list-style-type: none"> • The <i>number</i> argument specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ip address ip-address mask secondary Example: <pre>Router(config-if)# ip address 10.0.0.2 255.255.255.0</pre>	Sets a primary or secondary IP address for the tunnel interface. <p>Note All hubs and spokes that are in the same DMVPN network must be addressed in the same IP subnet.</p>
Step 5	ip mtu bytes Example: <pre>Router(config-if)# ip mtu 1400</pre>	Sets the MTU size, in bytes, of IP packets sent on an interface.
Step 6	ip nhrp authentication string Example: <pre>Router(config-if)# ip nhrp authentication donttell</pre>	Configures the authentication string for an interface using NHRP. <p>Note The NHRP authentication string must be set to the same value on all hubs and spokes that are in the same DMVPN network.</p>
Step 7	ip nhrp map hub-tunnel-ip-address hub-physical-ip-address Example: <pre>Router(config-if)# ip nhrp map 10.0.0.1 172.17.0.1</pre>	Statically configures the IP-to-NBMA address mapping of IP destinations connected to an NBMA network. <ul style="list-style-type: none"> • <i>hub-tunnel-ip-address</i> --Defines the NHRP server at the hub, which is permanently mapped to the static public IP address of the hub. • <i>hub-physical-ip-address</i> --Defines the static public IP address of the hub.

	Command or Action	Purpose
Step 8	<p>ip nhrp map multicast <i>hub-physical-ip-address</i></p> <p>Example:</p> <pre>Router(config-if)# ip nhrp map multicast 172.17.0.1</pre>	Enables the use of a dynamic routing protocol between the spoke and hub, and sends multicast packets to the hub router.
Step 9	<p>ip nhrp nhs <i>hub-tunnel-ip-address</i></p> <p>Example:</p> <pre>Router(config-if)# ip nhrp nhs 10.0.0.1</pre>	Configures the hub router as the NHRP next-hop server.
Step 10	<p>ip nhrp network-id <i>number</i></p> <p>Example:</p> <pre>Router(config-if)# ip nhrp network-id 99</pre>	<p>Enables NHRP on an interface.</p> <ul style="list-style-type: none"> The <i>number</i> argument specifies a globally unique 32-bit network identifier from a NBMA network. The range is from 1 to 4294967295. <p>Note Effective with Cisco IOS XE Denali 16.3 ip nhrp network-id is enabled by default.</p>
Step 11	<p>tunnel source <i>{ip-address type number}</i></p> <p>Example:</p> <pre>Router(config-if)# tunnel source GigabitEthernet 0/0/0</pre>	Sets the source address for a tunnel interface.
Step 12	<p>tunnel key <i>key-number</i></p> <p>Example:</p> <pre>Router(config-if)# tunnel key 100000</pre>	<p>(Optional) Enables an ID key for a tunnel interface.</p> <ul style="list-style-type: none"> The <i>key-number</i> argument specifies a number from 0 to 4,294,967,295 that identifies the tunnel key. The key number must be set to the same value on all hubs and spokes that are in the same DMVPN network.
Step 13	<p>Do one of the following:</p> <ul style="list-style-type: none"> tunnel mode gre multipoint tunnel destination <i>hub-physical-ip-address</i> <p>Example:</p> <pre>Router(config-if)# tunnel mode gre multipoint</pre> <p>Example:</p> <pre>Router(config-if)# tunnel destination 172.17.0.1</pre>	<p>Sets the encapsulation mode to mGRE for the tunnel interface.</p> <ul style="list-style-type: none"> Use this command if data traffic can use dynamic spoke-to-spoke traffic. <p>Specifies the destination for a tunnel interface.</p> <ul style="list-style-type: none"> Use this command if data traffic can use hub-and-spoke tunnels.
Step 14	Do one of the following:	Associates a tunnel interface with an IPsec profile.

	Command or Action	Purpose
	<ul style="list-style-type: none"> • tunnel protection ipsec profile <i>name</i> • tunnel protection psk <i>key</i> <p>Example:</p> <pre>Router(config-if)# tunnel protection ipsec profile vpnprof</pre> <p>Example:</p> <pre>Router(config-if)# tunnel protection psk test1</pre>	<ul style="list-style-type: none"> • The <i>name</i> argument specifies the name of the IPsec profile; this value must match the <i>name</i> specified in the crypto ipsec profile <i>name</i> command. <p>or</p> <p>Simplifies the tunnel protection configuration for pre-shared key (PSK) by creating a default IPsec profile.</p>
Step 15	<p>bandwidth <i>kbps</i></p> <p>Example:</p> <pre>Router(config-if)# bandwidth 1000</pre>	<p>Sets the current bandwidth value for an interface to higher-level protocols.</p> <ul style="list-style-type: none"> • The <i>kbps</i> argument specifies the bandwidth in kilobits per second. The default value is 9. The recommended bandwidth value is 1000 or greater. • The bandwidth setting for the spoke need not equal the bandwidth setting for the DMVPN hub. It is usually easier if all of the spokes use the same or similar value.
Step 16	<p>ip tcp adjust-mss <i>max-segment-size</i></p> <p>Example:</p> <pre>Router(config-if)# ip tcp adjust-mss 1360</pre>	<p>Adjusts the MSS value of TCP packets going through a router.</p> <ul style="list-style-type: none"> • The <i>max-segment-size</i> argument specifies the maximum segment size, in bytes. The range is from 500 to 1460. • The recommended number value is 1360 when the number of IP MTU bytes is set to 1400. With these recommended settings, TCP sessions quickly scale back to 1400-byte IP packets so the packets will “fit” in the tunnel.
Step 17	<p>ip nhrp holdtime <i>seconds</i></p> <p>Example:</p> <pre>Router(config-if)# ip nhrp holdtime 450</pre>	<p>Changes the number of seconds that NHRP NBMA addresses are advertised as valid in authoritative NHRP responses.</p> <ul style="list-style-type: none"> • The <i>seconds</i> argument specifies the time in seconds that NBMA addresses are advertised as valid in positive authoritative NHRP responses. The recommended value ranges from 300 seconds to 600 seconds.
Step 18	<p>delay <i>number</i></p> <p>Example:</p> <pre>Router(config-if)# delay 1000</pre>	<p>(Optional) Changes the EIGRP routing metric for routes learned over the tunnel interface.</p> <ul style="list-style-type: none"> • The <i>number</i> argument specifies the delay time in seconds. The recommended value is 1000.

Configuring the Forwarding of Clear-Text Data IP Packets into a VRF

To configure the forwarding of clear-text data IP packets into a VRF, perform the following steps. This configuration assumes that the VRF Blue has already been configured.

Note To configure VRF Blue, use the **ip vrf vrf-name** command in global configuration mode.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip vrf forwarding** *vrf-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: Router(config)# interface tunnel 0	Configures an interface type and enters interface configuration mode.
Step 4	ip vrf forwarding <i>vrf-name</i> Example: Router(config-if)# ip vrf forwarding Blue	Allows the forwarding of clear-text data IP packets into a VRF.

Configuring the Forwarding of Encrypted Tunnel Packets into a VRF

To configure the forwarding of encrypted tunnel packets into a VRF, perform the following steps. This configuration assumes that the VRF Red has already been configured.

Note To configure VRF Red, use the **ip vrf vrf-name** command in global configuration mode.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **tunnel vrf** *vrf-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: <pre>Router(config)# interface tunnel 0</pre>	Configures an interface type and enters interface configuration mode.
Step 4	tunnel vrf <i>vrf-name</i> Example: <pre>Router(config-if)# tunnel vrf RED</pre>	Associates a VPN VRF instance with a specific tunnel destination, interface, or subinterface and allows the forwarding of encrypted tunnel packets into a VRF.

Configuring Traffic Segmentation Within DMVPN

Cisco IOS XE Release 2.5 introduces no new commands to use when configuring traffic segmentation, but you must complete the tasks described in the following sections in order to segment traffic within a DMVPN tunnel:

Prerequisites ofr Traffic Segmentation Within DMVPN

The tasks that follow assume that the DMVPN tunnel and the VRFs Red and Blue have already been configured.

To configure VRF Red or Blue, use the **ip vrf** *vrf-name* command in global configuration mode.

For information on configuring a DMVPN tunnel, see the [Configuring the Spoke for DMVPN, on page 2667](#). For details about VRF configuration, see the [Configuring the Forwarding of Clear-Text Data IP Packets into a VRF, on page 2671](#) and the [Configuring the Forwarding of Encrypted Tunnel Packets into a VRF, on page 2671](#).

Enabling MPLS on the VPN Tunnel

Because traffic segmentation within a DMVPN tunnel depends upon MPLS, you must configure MPLS for each VRF instance in which traffic will be segmented.

Note On the Cisco ASR 1000 Series Aggregation Services Routers, only distributed switching is supported. Use the following commands for distributed switching: **ip multicast-routing** [*vrf vrf-name*] [**distributed**], **debug ip bgp vpnv4 unicast**, and **ip cef distributed**.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **mpls ip**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: Router(config)# interface tunnel 0	Configures an interface type and enters interface configuration mode.
Step 4	mpls ip Example: Router(config-if)# mpls ip	Enables MPLS tagging of packets on the specified tunnel interface.

Configuring Multiprotocol BGP on the Hub Router

You must configure multiprotocol iBGP (MP-iBGP) to enable advertisement of VPNv4 prefixes and labels to be applied to the VPN traffic. Use BGP to configure the hub as a Route Reflector. To force all traffic to be routed via the hub, configure the BGP Route Reflector to change the next hop to itself when it advertises VPNv4 prefixes to the route reflector clients (spokes).

For more information about the BGP routing protocol, see the “Cisco BGP Overview” module in the *Cisco IOS XE IP Routing: BGP Configuration Guide*.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **router bgp** *autonomous-system-number*
4. **neighbor** *ipaddress* **remote-as** *as - number*
5. **neighbor** *ipaddress* **update-source** *interface*
6. **address-family vpv4**
7. **neighbor** *ipaddress* **activate**
8. **neighbor** *ipaddress* **send-community** **extended**
9. **neighbor** *ipaddress* **route-reflector-client**
10. **neighbor** *ipaddress* **route-map** **nexthop** **out**
11. **exit**
12. **address-family ipv4** *vrf-name*
13. **redistribute** **connected**
14. **route-map** *map-tag* [**permit**|**deny**] [*sequence-number*]
15. **set ip next-hop** *ipaddress*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	router bgp <i>autonomous-system-number</i> Example: Router(config)# router bgp 1	Enables configuration of the BGP routing process.
Step 4	neighbor <i>ipaddress</i> remote-as <i>as - number</i> Example: Router(config-router)# neighbor 10.0.0.11 remote-as 1	Adds an entry to the BGP or multiprotocol BGP neighbor table.

	Command or Action	Purpose
Step 5	neighbor <i>ipaddress</i> update-source <i>interface</i> Example: <pre>Router(config-router)# neighbor 10.10.10.11 update-source Tunnel1</pre>	Configures the Cisco IOS XE software to allow BGP sessions to use any operational interface for TCP connections.
Step 6	address-family <i>vpn4</i> Example: <pre>Router(config)# address-family vpn4</pre>	Enters address family configuration mode to configure a routing session using VPNv4 address prefixes.
Step 7	neighbor <i>ipaddress</i> activate Example: <pre>Router(config-router-af)# neighbor 10.0.0.11 activate</pre>	Enables the exchange of information with a BGP neighbor.
Step 8	neighbor <i>ipaddress</i> send-community extended Example: <pre>Router(config-router-af)# neighbor 10.0.0.11 send-community extended</pre>	Specifies that extended community attributes should be sent to a BGP neighbor.
Step 9	neighbor <i>ipaddress</i> route-reflector-client Example: <pre>Router(config-router-af)# neighbor 10.0.0.11 route-reflector-client</pre>	Configures the router as a BGP Route Reflector and configures the specified neighbor as its client.
Step 10	neighbor <i>ipaddress</i> route-map <i>nexthop out</i> Example: <pre>Router(config-router-af)# neighbor 10.0.0.11 route-map nexthop out</pre>	Forces all traffic to be routed via the hub.
Step 11	exit Example: <pre>Router(config-router-af)# exit</pre>	Exits the address family configuration mode for VPNv4.
Step 12	address-family <i>ipv4 vrf-name</i> Example: <pre>Router(config)# address-family ipv4 red</pre>	Enters address family configuration mode to configure a routing session using standard IPv4 address prefixes.

	Command or Action	Purpose
Step 13	redistribute connected Example: <pre>Router(config-router-af)# redistribute connected</pre>	Redistributes routes that are established automatically by virtue of having enabled IP on an interface from one routing domain into another routing domain.
Step 14	route-map map-tag [permit deny] [sequence-number] Example: <pre>Router(config-router-af)# route-map cisco permit 10</pre>	Enters route map configuration mode to configure the next-hop that will be advertised to the spokes.
Step 15	set ip next-hop ipaddress Example: <pre>Router(config-route-map)# set ip next-hop 10.0.0.1</pre>	Sets the next hop to be the hub.

Configuring Multiprotocol BGP on the Spoke Routers

In order to segment traffic within a DMVPN tunnel, Multiprotocol-iBGP (MP-iBGP) must be configured on both the spoke routers and the hub. Perform the following task for each spoke router in the DMVPN.

SUMMARY STEPS

1. **enable**
2. configure terminal
3. **router bgp autonomous-system-number**
4. **neighbor ipaddress remote-as as - number**
5. **neighbor ipaddress update-source interface**
6. **address-family vpnv4**
7. **neighbor ipaddress activate**
8. **neighbor ipaddress send-community extended**
9. **exit**
10. **address-family ipv4 vrf-name**
11. **redistribute connected**
12. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Router# configure terminal	
Step 3	router bgp <i>autonomous-system-number</i> Example: Router(config)# router bgp 1	Enters BGP configuration mode.
Step 4	neighbor <i>ipaddress</i> remote-as <i>as - number</i> Example: Router(config-router)# neighbor 10.0.0.1 remote-as 1	Adds an entry to the BGP or multiprotocol BGP neighbor table.
Step 5	neighbor <i>ipaddress</i> update-source <i>interface</i> Example: Router(config-router)# neighbor 10.10.10.1 update-source Tunnell	Configures the Cisco IOS XE software to allow BGP sessions to use any operational interface for TCP connections.
Step 6	address-family vpnv4 Example: Router(config)# address-family vpnv4	Enters address family configuration mode to configure a routing session using VPNv4 address prefixes.
Step 7	neighbor <i>ipaddress</i> activate Example: Router(config-router-af)# neighbor 10.0.0.1 activate	Enables the exchange of information with a BGP neighbor.
Step 8	neighbor <i>ipaddress</i> send-community extended Example: Router(config-router-af)# neighbor 10.0.0.1 send-community extended	Specifies that extended community attributes should be sent to a BGP neighbor.
Step 9	exit Example: Router(config-router-af)# exit	Exits address family configuration mode.
Step 10	address-family ipv4 <i>vrf-name</i> Example: Router(config)# address-family ipv4 red	Enters address family configuration mode to configure a routing session using standard IPv4 address prefixes.

	Command or Action	Purpose
Step 11	redistribute connected Example: <pre>Router(config-router-af)# redistribute connected</pre>	Redistributes routes that are established automatically by virtue of having enabled IP on an interface from one routing domain into another routing domain.
Step 12	exit Example: <pre>Router(config-router-af)# exit</pre>	Exits address family configuration mode. Note Repeat Steps 10 through 12 for each VRF.

Troubleshooting Dynamic Multipoint VPN

After configuring DMVPN, perform the following optional steps in this task to verify that DMVPN is operating correctly, to clear DMVPN statistics or sessions, or to debug DMVPN. These commands may be used in any order.

From Cisco IOS XE 17.11.1a, a new command **nhrp debug-trace** is introduced to enable or disable btrace logs. This command provides improved debugging capability, by logging NHRP logs as files. This command is enabled by default, and only debugs with level NOTICE and higher are logged in btrace.

This command can be disabled by using the no form of the command:

no nhrp debug-trace

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

SUMMARY STEPS

1. **clear dmvpn session**
2. **clear dmvpn statistics**
3. **debug dmvpn**
4. **debug dmvpn condition**
5. **debug nhrp condition**
6. **debug nhrp error**
7. **nhrp debug-trace**
8. **logging dmvpn**
9. **show crypto ipsec sa**
10. **show crypto isakmp sa**
11. **show crypto map**
12. **show dmvpn**
13. **show ip nhrp traffic**

DETAILED STEPS

Step 1 **clear dmvpn session**

This command clears DMVPN sessions. The following example clears only dynamic DMVPN sessions, for the specified tunnel:

Example:

```
Router# clear dmvpn session interface tunnel 5
```

The following example clears all DMVPN sessions, both static and dynamic, for the specified tunnel:

Example:

```
Router# clear dmvpn session interface tunnel 5 static
```

Step 2 **clear dmvpn statistics**

This command is used to clear DMVPN-related counters. The following example shows how to clear DMVPN-related session counters for the specified tunnel interface:

Example:

```
Router#  
clear dmvpn statistics interface tunnel 5
```

Step 3 **debug dmvpn**

This command is used to debug DMVPN sessions. You can enable or disable DMVPN debugging based on a specific condition. There are three levels of DMVPN debugging, listed in the order of details from lowest to highest:

- Error level
- Detail level
- Packet level

The following example shows how to enable conditional DMVPN debugging that displays all error debugs for NHRP, sockets, tunnel protection, and crypto information:

Example:

```
Router# debug dmvpn error all
```

Step 4 **debug dmvpn condition**

This command displays conditional debug DMVPN session information. The following example shows how to enable conditional debugging for a specific tunnel interface:

Example:

```
Router# debug dmvpn condition interface tunnel 5
```

Step 5 **debug nhrp condition**

This command enables or disables debugging based on a specific condition. The following example shows how to enable conditional NHRP debugging:

Example:

```
Router#
debug nhrp condition
```

Step 6 **debug nhrp error**

This command displays information about NHRP error activity. The following example shows how to enable debugging for NHRP error messages:

Example:

```
Router#
debug nhrp error
```

Step 7 **nhrp debug-trace**

This command is used to enable or disable NHRP btrace logs. The following example shows how to enable btrace logging:

Example:

```
Router(config)#nhrp debug-trace
  G-ACh          Generic Associated Channel
  cache          NHRP cache global commands
  debug-trace    NHRP trace log
  limit          NHRP limiting parameters
  multicast      NHRP multicast related commands
```

Step 8 **logging dmvpn**

This command is used to enable DMVPN system logging. The following example shows how to enable DMVPN system logging at the rate of 1 message every 20 seconds:

Example:

```
Router(config)#
logging dmvpn rate-limit 20
```

The following example shows a sample system log with DMVPN messages:

Example:

```
%DMVPN-7-CRYPTO_SS: Tunnel101-192.0.2.1 socket is UP
%DMVPN-5-NHRP_NHS: Tunnel101 192.0.2.251 is UP
%DMVPN-5-NHRP_CACHE: Client 192.0.2.2 on Tunnel1 Registered.
%DMVPN-5-NHRP_CACHE: Client 192.0.2.2 on Tunnel101 came UP.
%DMVPN-3-NHRP_ERROR: Registration Request failed for 192.0.2.251 on Tunnel101
```

Step 9 **show crypto ipsec sa**

This command displays the settings used by the current SAs. The following example output shows the IPsec SA status of only the active device:

Example:

```
Router#
show crypto ipsec sa active
interface: gigabitethernet0/0/0
  Crypto map tag: to-peer-outside, local addr 209.165.201.3
  protected vrf: (none)
  local ident (addr/mask/prot/port): (192.168.0.1/255.255.255.255/0/0)
```

```

remote ident (addr/mask/prot/port): (172.16.0.1/255.255.255.255/0/0)
current_peer 209.165.200.225 port 500
  PERMIT, flags={origin_is_acl,}
  #pkts encaps: 3, #pkts encrypt: 3, #pkts digest: 3
  #pkts decaps: 4, #pkts decrypt: 4, #pkts verify: 4
  #pkts compressed: 0, #pkts decompressed: 0
  #pkts not compressed: 0, #pkts compr. failed: 0
  #pkts not decompressed: 0, #pkts decompress failed: 0
  #send errors 0, #recv errors 0
  local crypto endpt.: 209.165.201.3, remote crypto endpt.: 209.165.200.225
  path mtu 1500, media mtu 1500
  current outbound spi: 0xD42904F0(3559458032)
  inbound esp sas:
    spi: 0xD3E9ABD0(3555306448)
      transform: esp-3des ,
      in use settings ={Tunnel, }
      conn id: 2006, flow_id: 6, crypto map: to-peer-outside
      sa timing: remaining key lifetime (k/sec): (4586265/3542)
      HA last key lifetime sent(k): (4586267)
      ike_cookies: 9263635C CA4B4E99 C14E908E 8EE2D79C
      IV size: 8 bytes
      replay detection support: Y
      Status: ACTIVE

```

Step 10 **show crypto isakmp sa**

This command displays all current IKE SAs at a peer. For example, the following sample output is displayed after IKE negotiations have successfully completed between two peers:

Example:

```

Router# show crypto isakmp sa
dst          src          state          conn-id      slot
172.17.63.19 172.16.175.76 QM_IDLE        2            0
172.17.63.19 172.17.63.20 QM_IDLE        1            0
172.16.175.75 172.17.63.19 QM_IDLE        3            0

```

Step 11 **show crypto map**

This command displays the crypto map configuration. The following sample output is displayed after a crypto map has been configured:

Example:

```

Router# show crypto map
Crypto Map "Tunnel5-head-0" 10 ipsec-isakmp
  Profile name: vpnprof
  Security association lifetime: 4608000 kilobytes/3600 seconds
  PFS (Y/N): N
  Transform sets={trans2, }
Crypto Map "Tunnel5-head-0" 20 ipsec-isakmp
  Map is a PROFILE INSTANCE.
  Peer = 172.16.175.75
  Extended IP access list
    access-list permit gre host 172.17.63.19 host 172.16.175.75
  Current peer: 172.16.175.75
  Security association lifetime: 4608000 kilobytes/3600 seconds
  PFS (Y/N): N
  Transform sets={trans2, }
Crypto Map "Tunnel5-head-0" 30 ipsec-isakmp
  Map is a PROFILE INSTANCE.
  Peer = 172.17.63.20
  Extended IP access list

```

```

        access-list permit gre host 172.17.63.19 host 172.17.63.20
Current peer: 172.17.63.20
Security association lifetime: 4608000 kilobytes/3600 seconds
PFS (Y/N): N
Transform sets={trans2, }
Crypto Map "Tunnel5-head-0" 40 ipsec-isakmp
Map is a PROFILE INSTANCE.
Peer = 172.16.175.76
Extended IP access list
    access-list permit gre host 172.17.63.19 host 172.16.175.76
Current peer: 172.16.175.76
Security association lifetime: 4608000 kilobytes/3600 seconds
PFS (Y/N): N
Transform sets={trans2, }
Interfaces using crypto map Tunnel5-head-0:

```

Tunnel5

Step 12 show dmvpn

This command displays DMVPN-specific session information. The following sample shows example summary output:

Example:

```

Router# show dmvpn
Legend: Attrb --> S - Static, D - Dynamic, I - Incomplete
        N - NATed, L - Local, X - No Socket
        # Ent --> Number of NHRP entries with same NBMA peer
! The line below indicates that the sessions are being displayed for Tunnel1.
! Tunnel1 is acting as a spoke and is a peer with three other NBMA peers.
Tunnel1, Type: Spoke, NBMA Peers: 3,
# Ent Peer NBMA Addr Peer Tunnel Add State UpDn Tm Attrb
-----
  2    192.0.2.21    192.0.2.116    IKE    3w0d D

```

Step 13 show ip nhrp traffic

This command displays NHRP statistics. The following example shows output for a specific tunnel (tunnel7):

Example:

```

Router# s
how ip nhrp traffic interface tunnel7
Tunnel7: Max-send limit:10000Pkts/10Sec, Usage:0%
Sent: Total 79
    18 Resolution Request    10 Resolution Reply    42 Registration Request
    0 Registration Reply     3 Purge Request       6 Purge Reply
    0 Error Indication       0 Traffic Indication
Rcvd: Total 69
    10 Resolution Request    15 Resolution Reply    0 Registration Request
    36 Registration Reply    6 Purge Request       2 Purge Reply
    0 Error Indication       0 Traffic Indication

```

What to Do Next

Proceed to the following sections [Configuring the Hub for DMVPN](#) and [Configuring the Spoke for DMVPN](#).

Configuration Examples for Dynamic Multipoint VPN

Example: Hub Configuration for DMVPN

In the following example, which configures the hub router for multipoint GRE and IPsec integration, no explicit configuration lines are needed for each spoke; that is, the hub is configured with a global IPsec policy template that all spoke routers can talk to. In this example, EIGRP is configured to run over the private physical interface and the tunnel interface.

```
crypto isakmp policy 1
  authentication pre-share
crypto isakmp key cisco47 address 0.0.0.0
!
crypto ipsec transform-set trans2 esp-des esp-md5-hmac
mode transport
!
crypto ipsec profile vpnprof
  set transform-set trans2
!
interface Tunnel0
  bandwidth 1000
  ip address 10.0.0.1 255.255.255.0
! Ensures longer packets are fragmented before they are encrypted; otherwise, the receiving
  router would have to do the reassembly.
  ip mtu 1400
! The following line must match on all nodes that "want to use" this mGRE tunnel:
  ip nhrp authentication donttell
! Note that the next line is required only on the hub.
  ip nhrp map multicast dynamic
! The following line must match on all nodes that want to use this mGRE tunnel:
  ip nhrp network-id 99
  ip nhrp holdtime 300
! Turns off split horizon on the mGRE tunnel interface; otherwise, EIGRP will not advertise
  routes that are learned via the mGRE interface back out that interface.
  no ip split-horizon eigrp 1
! Enables dynamic, direct spoke-to-spoke tunnels when using EIGRP.
  no ip next-hop-self eigrp 1
  ip tcp adjust-mss 1360
  delay 1000
! Sets IPsec peer address to Ethernet interface's public address.
  tunnel source GigabitEthernet 0/0/0
  tunnel mode gre multipoint
! The following line must match on all nodes that want to use this mGRE tunnel.
  tunnel key 100000
  tunnel protection ipsec profile vpnprof
!
interface FastEthernet0/0/0
  ip address 172.17.0.1 255.255.255.0
!
interface FastEthernet0/0/1
  ip address 192.168.0.1 255.255.255.0
!
router eigrp 1
  network 10.0.0.0 0.0.0.255
```

```
network 192.168.0.0 0.0.0.255
!
```

For information about defining and configuring ISAKMP profiles, see the “Certificate to ISAKMP Profile Mapping” module in the *Cisco IOS XE Security Configuration Guide: Secure Connectivity*.

Example: Spoke Configuration for DMVPN

In the following example, all spokes are configured the same except for tunnel and local interface address, thereby reducing necessary configurations for the user:

```
crypto isakmp policy 1
 authentication pre-share
crypto isakmp key cisco47 address 0.0.0.0
!
crypto ipsec transform-set trans2 esp-des esp-md5-hmac
 mode transport
!
crypto ipsec profile vpnprof
 set transform-set trans2
!
interface Tunnel0
 bandwidth 1000
 ip address 10.0.0.2 255.255.255.0
 ip mtu 1400
! The following line must match on all nodes that want to use this mGRE tunnel:
 ip nhrp authentication donttell
! Definition of NHRP server at the hub (10.0.0.1), which is permanently mapped to the static
public address of the hub (172.17.0.1).
 ip nhrp map 10.0.0.1 172.17.0.1
! Sends multicast packets to the hub router, and enables the use of a dynamic routing
protocol between the spoke and the hub.
 ip nhrp map multicast 172.17.0.1
! The following line must match on all nodes that want to use this mGRE tunnel:
 ip nhrp network-id 99
 ip nhrp holdtime 300
! Configures the hub router as the NHRP next-hop server.
 ip nhrp nhs 10.0.0.1
 ip tcp adjust-mss 1360
 delay 1000
 tunnel source GigabitEthernet 0/0/0
 tunnel mode gre multipoint
! The following line must match on all nodes that want to use this mGRE tunnel:
 tunnel key 100000
 tunnel protection ipsec profile vpnprof
!
! This is a spoke, so the public address might be dynamically assigned via DHCP.
interface FastEthernet0/0/0
 ip address dhcp hostname Spoke1
!
interface FastEthernet0/0/1
 ip address 192.168.1.1 255.255.255.0
!
! EIGRP is configured to run over the inside physical interface and the tunnel.
router eigrp 1
 network 10.0.0.0 0.0.0.255
 network 192.168.1.0 0.0.0.255
```

Example: 2547oDMVPN with BGP Only Traffic Segmentation

The following example show a traffic segmentation configuration in which traffic is segmented between two spokes that serve as PE devices:

Hub Configuration

```

hostname hub-pe1
boot-start-marker

Feature Information for Dynamic Multipoint VPN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 270: Feature Information for Dynamic Multipoint VPN

Feature Name	Releases	Feature Information
Dynamic Multipoint VPN (DMVPN) Phase 1	Cisco IOS XE Release 2.1	The Dynamic Multipoint VPN (DMVPN) feature allows users to better scale large and small IPsec Virtual Private Networks (VPNs) by combining generic routing encapsulation (GRE) tunnels, IP security (IPsec) encryption, and Next Hop Resolution Protocol (NHRP).
DMVPN Phase 2	Cisco IOS XE Release 2.1	DMVPN Spoke-to-Spoke functionality was made more production ready.
NAT-Transparency Aware DMVPN	Cisco IOS XE Release 2.1	The Network Address Translation-Transparency (NAT-T) Aware DMVPN enhancement was added. In addition, DMVPN hub-to-spoke functionality was made more production ready.
Manageability Enhancements for DMVPN	Cisco IOS XE Release 2.5	DMVPN session manageability was expanded with DMVPN-specific commands for debugging, show output, session and counter control, and system log information. The following section provides information about this feature: <ul style="list-style-type: none"> • Troubleshooting Dynamic Multipoint VPN The following commands were introduced or modified by this feature: clear dmvpn session , clear dmvpn statistics , debug dmvpn , debug dmvpn condition , debug nhrp condition , debug nhrp error , logging dmvpn , show dmvpn , show ip nhrp traffic
DMVPN--Enabling Traffic Segmentation Within DMVPN	Cisco IOS XE Release 2.5	The 2547oDMVPN feature allows users to segment VPN traffic within a DMVPN tunnel by applying MPLS labels to VRF instances to indicate the source and destination of each VRF.

Glossary

AM --aggressive mode. A mode during IKE negotiation. Compared to MM, AM eliminates several steps, making it faster but less secure than MM. Cisco IOS XE software will respond in aggressive mode to an IKE peer that initiates aggressive mode.

GRE --generic routing encapsulation. Tunnels that provide a specific pathway across the shared WAN and encapsulate traffic with new packet headers to ensure delivery to specific destinations. The network is private because traffic can enter a tunnel only at an endpoint. Tunnels do not provide true confidentiality (encryption does) but can carry encrypted traffic.

GRE tunneling can also be used to encapsulate non-IP traffic into IP and send it over the Internet or IP network. The Internet Package Exchange (IPX) and AppleTalk protocols are examples of non-IP traffic.

IKE --Internet Key Exchange. A hybrid protocol that implements Oakley key exchange and Skeme key exchange inside the ISAKMP framework. Although IKE can be used with other protocols, its initial implementation is with IPsec. IKE provides authentication of the IPsec peers, negotiates IPsec keys, and negotiates IPsec security associations.

IPsec --IP security. A framework of open standards developed by the Internet Engineering Task Force (IETF). IPsec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPsec acts at the network layer, protecting and authenticating IP packets between participating IPsec devices ("peers"), such as Cisco routers.

ISAKMP--Internet Security Association Key Management Protocol. A protocol framework that defines payload formats, the mechanics of implementing a key exchange protocol, and the negotiation of a security association.

MM--main mode. Mode that is slower than aggressive mode but more secure and more flexible than aggressive mode because it can offer an IKE peer more security proposals. The default action for IKE authentication (rsa-sig, rsa-encr, or preshared) is to initiate main mode.

NHRP --Next Hop Resolution Protocol. Routers, access servers, and hosts can use NHRP to discover the addresses of other routers and hosts connected to an NBMA network.

The Cisco implementation of NHRP supports the IETF draft version 11 of NBMA Next Hop Resolution Protocol (NHRP).

The Cisco implementation of NHRP supports IP Version 4, Internet Packet Exchange (IPX) network layers, and, at the link layer, ATM, FastEthernet, SMDS, and multipoint tunnel networks. Although NHRP is available on FastEthernet, NHRP need not be implemented over FastEthernet media because FastEthernet is capable of broadcasting. FastEthernet support is unnecessary (and not provided) for IPX.

PFS--perfect forward secrecy. A cryptographic characteristic associated with a derived shared secret value. With PFS, if one key is compromised, previous and subsequent keys are not compromised, because subsequent keys are not derived from previous keys.

SA--security association. Describes how two or more entities will utilize security services to communicate securely. For example, an IPsec SA defines the encryption algorithm (if used), the authentication algorithm, and the shared session key to be used during the IPsec connection.

Both IPsec and IKE require and use SAs to identify the parameters of their connections. IKE can negotiate and establish its own SA. The IPsec SA is established either by IKE or by manual user configuration.

transform--The list of operations done on a data flow to provide data authentication, data confidentiality, and data compression. For example, one transform is the ESP protocol with the HMAC-MD5 authentication

algorithm; another transform is the AH protocol with the 56-bit DES encryption algorithm and the ESP protocol with the HMAC-SHA authentication algorithm.

VPN--Virtual Private Network. A framework that consists of multiple peers transmitting private data securely to one another over an otherwise public infrastructure. In this framework, inbound and outbound network traffic is protected using protocols that tunnel and encrypt all data. This framework permits networks to extend beyond their local topology, while remote users are provided with the appearance and functionality of a direct network connection.

CHAPTER 205

IPv6 over DMVPN

This document describes how to implement the Dynamic Multipoint VPN for IPv6 feature, which allows users to better scale large and small IPsec Virtual Private Networks (VPNs) by combining generic routing encapsulation (GRE) tunnels, IP security (IPsec) encryption, and the Next Hop Resolution Protocol (NHRP). In Dynamic Multipoint Virtual Private Network (DMVPN) for IPv6, the public network (the Internet) is a pure IPv4 network, and the private network (the intranet) is IPv6 capable.

IPv6 support on DMVPN was extended to the public network (the Internet) facing the Internet service provider (ISP). The IPv6 transport for DMVPN feature builds IPv6 WAN-side capability into NHRP tunnels and the underlying IPsec encryption, and enables IPv6 to transport payloads on the Internet.

The IPv6 transport for DMVPN feature is enabled by default. You need not upgrade your private internal network to IPv6 for the IPv6 transport for DMVPN feature to function. You can have either IPv4 or IPv6 addresses on your local networks.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

Prerequisites for IPv6 over DMVPN

- One of the following protocols must be enabled for DMVPN for IPv6 to work: Border Gateway Protocol (BGP), Enhanced Interior Gateway Routing Protocol (EIGRP), On-Demand Routing (ODR), Open Shortest Path First (OSPF), and Routing Information Protocol (RIP).
- Every IPv6 NHRP interface is configured with one IPv6 unicast address. This address can be a globally reachable or unique local address.

- Every IPv6 NHRP interface is configured with one IPv6 link-local address that is unique across all DMVPN hosts in the DMVPN cloud (that is, the hubs and spokes).

Information About IPv6 over DMVPN

DMVPN for IPv6 Overview

The DMVPN feature combines NHRP routing, multipoint generic routing encapsulation (mGRE) tunnels, and IPsec encryption to provide users ease of configuration via crypto profiles--which override the requirement for defining static crypto maps--and dynamic discovery of tunnel endpoints.

This feature relies on the following Cisco enhanced standard technologies:

- NHRP--A client and server protocol where the hub is the server and the spokes are the clients. The hub maintains an NHRP database of the public interface addresses of each spoke. Each spoke registers its real address when it boots and queries the NHRP database for real addresses of the destination spokes to build direct tunnels.
- mGRE tunnel interface--An mGRE tunnel interface allows a single GRE interface to support multiple IPsec tunnels and simplifies the size and complexity of the configuration.
- IPsec encryption--An IPsec tunnel interface facilitates for the protection of site-to-site IPv6 traffic with native encapsulation.

In DMVPN for IPv6, the public network (the Internet) is a pure IPv4 network, and the private network (the intranet) is IPv6 capable. The intranets could be a mix of IPv4 or IPv6 clouds connected to each other using DMVPN technologies, with the underlying carrier being a traditional IPv4 network.

NHRP Routing

The NHRP protocol resolves a given intranet address (IPv4 or IPv6) to an Internet address (IPv4 nonbroadcast multiaccess [NBMA] address).

In the figure below, the intranets that are connected over the DMVPN network are IPv6 clouds, and the Internet is a pure IPv4 cloud. Spokes S1 and S2 are connected to Hub H over the Internet using a statically configured tunnel. The address of the tunnel itself is the IPv6 domain, because it is another node on the intranet. The source and destinations address of the tunnel (the mGRE endpoints), however, are always in IPv4, in the Internet domain. The mGRE tunnel is aware of the IPv6 network because the GRE passenger protocol is an IPv6 packet, and the GRE transport (or carrier) protocol is an IPv4 packet.

Figure 106: IPv6 Topology That Triggers NHRP

When an IPv6 host in LAN L1 sends a packet destined to an IPv6 host in LAN L2, the packet is first routed to the gateway (which is Spoke S1) in LAN L1. Spoke S1 is a dual-stack device, which means both IPv4 and IPv6 are configured on it. The IPv6 routing table in S1 points to a next hop, which is the IPv6 address of the tunnel on Spoke S2. This is a VPN address that must be mapped to an NBMA address, triggering NHRP.

IPv6 NHRP Redirect and Shortcut Features

When IPv6 NHRP redirect is enabled, NHRP examines every data packet in the output feature path. If the data packet enters and leaves on the same logical network, NHRP sends an NHRP traffic indication message to the source of the data packet. In NHRP, a logical network is identified by the NHRP network ID, which groups multiple physical interfaces into a single logical network.

When IPv6 NHRP shortcut is enabled, NHRP intercepts every data packet in the output feature path. It checks to see if there is an NHRP cache entry to the destination of the data packet and, if yes, it replaces the current output adjacency with the one present in the NHRP cache. The data packet is therefore switched out using the new adjacency provided by NHRP.

IPv6 Routing

NHRP is automatically invoked for mGRE tunnels carrying the IPv6 passenger protocol. When a packet is routed and sent to the switching path, NHRP looks up the given next hop and, if required, initiates an NHRP resolution query. If the resolution is successful, NHRP populates the tunnel endpoint database, which in turn populates the Cisco Express Forwarding adjacency table. The subsequent packets are Cisco Express Forwarding switched if Cisco Express Forwarding is enabled.

IPv6 Addressing and Restrictions

IPv6 allows multiple unicast addresses on a given IPv6 interface. IPv6 also allows special address types, such as anycast, multicast, link-local addresses, and unicast addresses.

DMVPN for IPv6 has the following addressing restrictions:

- Every IPv6 NHRP interface is configured with one IPv6 unicast address. This address can be a globally reachable or unique local address.
- Every IPv6 NHRP interface is configured with one IPv6 link-local address that is unique across all DMVPN hosts in the DMVPN cloud (that is, the hubs and spokes).
 - If no other tunnels on the device are using the same tunnel source, then the tunnel source address can be embedded into an IPv6 address.
 - If the device has only one DMVPN IPv6 tunnel, then manual configuration of the IPv6 link-local address is not required. Instead, use the **ipv6 enable** command to autogenerate a link-local address.
 - If the device has more than one DMVPN IPv6 tunnel, then the link-local address must be manually configured using the **ipv6 address fe80::2001 link-local** command.

-
- Note** From Cisco IOS XE 17.9.1a, a new attribute **scope** is introduced for the **ipv6 nhrp nhs** command. This attribute defines the scope of IPv6 address that is used while registering with the NHS and allows you to control the scope of creating cache entries between peers.
- If scope is set to **global**, then the spoke registers only with the global unicast IPv6 address during the registration (link-local IPv6 address is not used).
 - (Optional) Scope can be defined for static and dynamic NHS.
-

How to Configure IPv6 over DMVPN

Configuring an IPsec Profile in DMVPN for IPv6

-
- Note** Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.
-

The IPsec profile shares most commands with the crypto map configuration, but only a subset of the commands are valid in an IPsec profile. Only commands that pertain to an IPsec policy can be issued under an IPsec profile; you cannot specify the IPsec peer address or the access control list (ACL) to match the packets that are to be encrypted.

Before you begin

Before configuring an IPsec profile, you must do the following:

- Define a transform set by using the **crypto ipsec transform-set** command.
- Make sure that the Internet Security Association Key Management Protocol (ISAKMP) profile is configured with default ISAKMP settings.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto identity** *name*
4. **exit**
5. **crypto ipsec profile** *name*
6. **set transform-set** *transform-set-name*
7. **set identity**
8. **set security-association lifetime** *seconds seconds* | *kilobytes kilobytes*
9. **set pfs** [*group1* | *group14* | *group15* | *group16* | *group19* | *group2* | *group20* | *group24* | *group5*]
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto identity <i>name</i> Example: Device(config)# crypto identity device1	Configures the identity of the device with a given list of distinguished names (DNs) in the certificate of the device.
Step 4	exit Example: Device(config-crypto-identity)# exit	Exits crypto identity configuration mode and enters global configuration mode.
Step 5	crypto ipsec profile <i>name</i> Example: Device(config)# crypto ipsec profile example1	Defines the IPsec parameters that are to be used for IPsec encryption between "spoke and hub" and "spoke and spoke" routers.

	Command or Action	Purpose
		This command places the device in crypto map configuration mode.
Step 6	set transform-set <i>transform-set-name</i> Example: Device(config-crypto-map)# set transform-set example-set	Specifies which transform sets can be used with the IPsec profile.
Step 7	set identity Example: Device(config-crypto-map)# set identity router1	(Optional) Specifies identity restrictions to be used with the IPsec profile.
Step 8	set security-association lifetime seconds seconds kilobytes kilobytes Example: Device(config-crypto-map)# set security-association lifetime seconds 1800	(Optional) Overrides the global lifetime value for the IPsec profile.
Step 9	set pfs [group1 group14 group15 group16 group19 group2 group20 group24 group5] Example: Device(config-crypto-map)# set pfs group14	(Optional) Specifies that IPsec should ask for perfect forward secrecy (PFS) when requesting new security associations for this IPsec profile. If this command is not specified, the default Diffie-Hellman (DH) group, group1 will be enabled. <ul style="list-style-type: none"> • 1—768-bit DH (No longer recommended.) • 2—1024-bit DH (No longer recommended) • 5—1536-bit DH (No longer recommended) • 14—Specifies the 2048-bit DH group. • 15—Specifies the 3072-bit DH group. • 16—Specifies the 4096-bit DH group. • 19—Specifies the 256-bit elliptic curve DH (ECDH) group. • 20—Specifies the 384-bit ECDH group. • 24—Specifies the 2048-bit DH/DSA group.
Step 10	end Example: Device(config-crypto-map)# end	Exits crypto map configuration mode and returns to privileged EXEC mode.

Configuring the Hub for IPv6 over DMVPN

Perform this task to configure the hub device for IPv6 over DMVPN for mGRE and IPsec integration (that is, associate the tunnel with the IPsec profile configured in the previous procedure).

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **ipv6 address** *{ipv6-address / prefix-length | prefix-name sub-bits / prefix-length}*
5. **ipv6 address** *ipv6-address / prefix-length* **link-local**
6. **ipv6 mtu** *bytes*
7. **ipv6 nhrp authentication** *string*
8. **ipv6 nhrp map multicast dynamic**
9. **ipv6 nhrp network-id** *network-id*
10. **tunnel source** *ip-address | ipv6-address | interface-type interface-number*
11. **tunnel mode** *{aurp | cayman | dvmrp | eon | gre | gre multipoint[ipv6] | gre ipv6 | ipip decapsulate-any} | ipsec ipv4 | iptalk | ipv6 | ipsec ipv6 | mpls | nos | rbscp*
12. Do one of the following:
 - **tunnel protection ipsec profile** *name* [**shared**]
 - **tunnel protection psk** *key*
13. **bandwidth** *{kbps | inherit [kbps] | receive [kbps]}*
14. **ipv6 nhrp holdtime** *seconds*
15. **ipv6 nhrp max-send** *pkt-count every seconds*
16. **ip nhrp registration** [*timeout seconds* | **no-unique**]
17. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 5	Configures a tunnel interface and enters interface configuration mode. <ul style="list-style-type: none"> • The number argument specifies the number of the tunnel interfaces that you want to create or configure.

	Command or Action	Purpose
		There is no limit on the number of tunnel interfaces you can create.
Step 4	ipv6 address <i>{ipv6-address / prefix-length prefix-name sub-bits / prefix-length}</i> Example: <pre>Device(config-if)# ipv6 address 2001:DB8:1:1::72/64</pre>	Configures an IPv6 address based on an IPv6 general prefix and enables IPv6 processing on an interface.
Step 5	ipv6 address <i>ipv6-address / prefix-length</i> link-local Example: <pre>Device(config-if)# ipv6 address fe80::2001 link-local</pre>	Configures an IPv6 link-local address for an interface and enables IPv6 processing on the interface. <ul style="list-style-type: none"> A unique IPv6 link-local address (across all DMVPN nodes in a DMVPN network) must be configured.
Step 6	ipv6 mtu <i>bytes</i> Example: <pre>Device(config-if)# ipv6 mtu 1400</pre>	Sets the maximum transmission unit (MTU) size of IPv6 packets sent on an interface.
Step 7	ipv6 nhrp authentication <i>string</i> Example: <pre>Device(config-if)# ipv6 nhrp authentication examplexx</pre>	Configures the authentication string for an interface using the NHRP. <p>Note The NHRP authentication string must be set to the same value on all hubs and spokes that are in the same DMVPN network.</p>
Step 8	ipv6 nhrp map multicast dynamic Example: <pre>Device(config-if)# ipv6 nhrp map multicast dynamic</pre>	Allows NHRP to automatically add routers to the multicast NHRP mappings. <p>Note Effective with Cisco IOS XE Denali 16.3 ipv6 nhrp map multicast dynamic is enabled by default.</p>
Step 9	ipv6 nhrp network-id <i>network-id</i> Example: <pre>Device(config-if)# ipv6 nhrp network-id 99</pre>	Enables the NHRP on an interface. <p>Effective with Cisco IOS XE Denali 16.3 ipv6 nhrp network-id is enabled by default.</p>
Step 10	tunnel source <i>ip-address ipv6-address interface-type interface-number</i> Example: <pre>Device(config-if)# tunnel source ethernet 0</pre>	Sets the source address for a tunnel interface.
Step 11	tunnel mode <i>{aurp cayman dvmrp eon gre gre multipoint[ipv6] gre ipv6 ipip decapsulate-any} ipsec ipv4 iptalk ipv6 ipsec ipv6 mpls nos rbscp</i>	Sets the encapsulation mode to mGRE for the tunnel interface.

	Command or Action	Purpose
	<p>Example:</p> <pre>Device(config-if)# tunnel mode gre multipoint</pre>	
Step 12	<p>Do one of the following:</p> <ul style="list-style-type: none"> • tunnel protection ipsec profile <i>name</i> [shared] • tunnel protection psk <i>key</i> <p>Example:</p> <pre>Router(config-if)# tunnel protection ipsec profile vpnprof</pre> <p>Example:</p> <pre>Router(config-if)# tunnel protection psk test1</pre>	<p>Associates a tunnel interface with an IPsec profile.</p> <ul style="list-style-type: none"> • The <i>name</i> argument specifies the name of the IPsec profile; this value must match the <i>name</i> specified in the crypto ipsec profile <i>name</i> command. <p>or</p> <p>Simplifies the tunnel protection configuration for pre-shared key (PSK) by creating a default IPsec profile.</p>
Step 13	<p>bandwidth {<i>kbps</i> inherit [<i>kbps</i>] receive [<i>kbps</i>]}</p> <p>Example:</p> <pre>Device(config-if)# bandwidth 1200</pre>	<p>Sets the current bandwidth value for an interface to higher-level protocols.</p> <ul style="list-style-type: none"> • The <i>bandwidth-size</i> argument specifies the bandwidth in kilobits per second. The default value is 9. The recommended bandwidth value is 1000 or greater.
Step 14	<p>ipv6 nhrp holdtime <i>seconds</i></p> <p>Example:</p> <pre>Device(config-if)# ipv6 nhrp holdtime 600</pre>	<p>Changes the number of seconds that NHRP NBMA addresses are advertised as valid in authoritative NHRP responses. The default time is 600 seconds.</p>
Step 15	<p>ipv6 nhrp max-send <i>pkt-count</i> every <i>seconds</i></p> <p>Example:</p> <pre>Device(config-if)# ipv6 nhrp max-send 10000 every 10</pre>	<p>Changes the maximum frequency at which NHRP packets can be sent. Number of packets that can be sent in the range from 1 to 65535. Default is 100 packets.</p>
Step 16	<p>ip nhrp registration [<i>timeout seconds</i> no-unique]</p> <p>Example:</p> <pre>Device(config-if)# ip nhrp registration no-unique</pre>	<p>Enables the client to not set the unique flag in the NHRP request and reply packets. The default is no-unique.</p>
Step 17	<p>end</p> <p>Example:</p> <pre>Device(config-if)# end</pre>	<p>Exits interface configuration mode and returns to privileged EXEC mode.</p>

Configuring the NHRP Redirect and Shortcut Features on the Hub

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel number**
4. **ipv6 address** {*ipv6-address / prefix-length* | *prefix-name sub-bits / prefix-length*}
5. Do one of the following:
 - **ipv6 nhrp redirect** [*timeout seconds*]
 - **ipv6 nhrp redirect** [*interest acl*]
6. **ipv6 nhrp shortcut**
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel number Example: Device(config)# interface tunnel 5	Configures a tunnel interface and enters interface configuration mode. <ul style="list-style-type: none"> • The number argument specifies the number of the tunnel interfaces that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ipv6 address { <i>ipv6-address / prefix-length</i> <i>prefix-name sub-bits / prefix-length</i> } Example: Device(config-if)# ipv6 address 2001:DB8:1:1::72/64	Configures an IPv6 address based on an IPv6 general prefix and enables IPv6 processing on an interface.
Step 5	Do one of the following: <ul style="list-style-type: none"> • ipv6 nhrp redirect [<i>timeout seconds</i>] • ipv6 nhrp redirect [<i>interest acl</i>] Example: Device(config-if)# ipv6 nhrp redirect	Enables NHRP redirect. or Enables the user to specify an ACL. Note You must configure the ipv6 nhrp redirect command on a hub.

	Command or Action	Purpose
	Example: Device(config-if)# ipv6 nhrp redirect interest	
Step 6	ipv6 nhrp shortcut Example: Device(config-if)# ipv6 nhrp shortcut	Enables NHRP shortcut switching. <ul style="list-style-type: none"> You must configure the ipv6 nhrp shortcut command on a spoke. Note Effective with Cisco IOS XE Denali 16.3 ipv6 nhrp shortcut is enabled by default.
Step 7	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring the Spoke for IPv6 over DMVPN

Perform this task to configure the spoke for IPv6 over DMVPN.

SUMMARY STEPS

- enable**
- configure terminal**
- interface tunnel** *number*
- ipv6 address** *{ipv6-address / prefix-length | prefix-name sub-bits / prefix-length}*
- ipv6 address** *ipv6-address / prefix-length* **link-local**
- ipv6 mtu** *bytes*
- ipv6 nhrp authentication** *string*
- ipv6 nhrp map** *ipv6-address nbma-address*
- ipv6 nhrp map multicast** *ipv4-nbma-address*
- ipv6 nhrp nhs** *ipv6- nhs-address scope {global}*
- ipv6 nhrp network-id** *network-id*
- tunnel source** *ip-address | ipv6-address | interface-type interface-number*
- Do one of the following:
 - tunnel mode** *{aurp | cayman | dvmrp | eon | gre| gre multipoint [ipv6] | gre ipv6 | ipip decapsulate-any} | ipsec ipv4 | iptalk | ipv6| ipsec ipv6 | mpls | nos | rbscp*
 - tunnel destination** *{host-name | ip-address | ipv6-address}*
- Do one of the following:
 - tunnel protection ipsec profile** *name [shared]*
 - tunnel protection psk** *key*
- bandwidth** *{interzone | total | session} {default | zone zone-name} bandwidth-size*
- ipv6 nhrp holdtime** *seconds*

17. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 5	Configures a tunnel interface and enters interface configuration mode. <ul style="list-style-type: none"> • The <i>number</i> argument specifies the number of the tunnel interfaces that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ipv6 address { <i>ipv6-address / prefix-length</i> <i>prefix-name sub-bits / prefix-length</i> } Example: Device(config-if) ipv6 address 2001:DB8:1:1::72/64	Configures an IPv6 address based on an IPv6 general prefix and enables IPv6 processing on an interface.
Step 5	ipv6 address <i>ipv6-address / prefix-length</i> link-local Example: Device(config-if)# ipv6 address fe80::2001 link-local	Configures an IPv6 link-local address for an interface and enables IPv6 processing on the interface. <ul style="list-style-type: none"> • A unique IPv6 link-local address (across all DMVPN nodes in a DMVPN network) must be configured.
Step 6	ipv6 mtu <i>bytes</i> Example: Device(config-if)# ipv6 mtu 1400	Sets the MTU size of IPv6 packets sent on an interface.
Step 7	ipv6 nhrp authentication <i>string</i> Example: Device(config-if)# ipv6 nhrp authentication examplexx	Configures the authentication string for an interface using the NHRP. <p>Note The NHRP authentication string must be set to the same value on all hubs and spokes that are in the same DMVPN network.</p>
Step 8	ipv6 nhrp map <i>ipv6-address nbma-address</i> Example:	Statically configures the IPv6-to-NBMA address mapping of IPv6 destinations connected to an NBMA network.

	Command or Action	Purpose
	Device(config-if)# ipv6 nhrp map 2001:DB8:3333:4::5 10.1.1.1	Note Only IPv4 NBMA addresses are supported, not ATM or Ethernet addresses.
Step 9	ipv6 nhrp map multicast <i>ipv4-nbma-address</i> Example: Device(config-if)# ipv6 nhrp map multicast 10.11.11.99	Maps destination IPv6 addresses to IPv4 NBMA addresses.
Step 10	ipv6 nhrp nhs <i>ipv6- nhs-address scope {global}</i> Example: Device(config-if)# ipv6 nhrp nhs 2001:0DB8:3333:4::5 2001:0DB8::/64 scope global	Specifies the address of one or more IPv6 NHRP servers.
Step 11	ipv6 nhrp network-id <i>network-id</i> Example: Device(config-if)# ipv6 nhrp network-id 99	Enables the NHRP on an interface. Note Effective with Cisco IOS XE Denali 16.3 ipv6 nhrp network-id is enabled by default.
Step 12	tunnel source <i>ip-address ipv6-address interface-type interface-number</i> Example: Device(config-if)# tunnel source ethernet 0	Sets the source address for a tunnel interface.
Step 13	Do one of the following: <ul style="list-style-type: none">• tunnel mode {aurp cayman dvmrp eon gre gre multipoint [ipv6] gre ipv6 ipip decapsulate-any} ipsec ipv4 iptalk ipv6 ipsec ipv6 mpls nos rbscp• tunnel destination {host-name ip-address ipv6-address} Example: Device(config-if)# tunnel mode gre multipoint Example: Device(config-if)# tunnel destination 10.1.1.1	Sets the encapsulation mode to mGRE for the tunnel interface. <ul style="list-style-type: none">• Use the tunnel mode command if data traffic can use dynamic spoke-to-spoke traffic. or Specifies the destination for a tunnel interface. <ul style="list-style-type: none">• Use the tunnel destination command if data traffic can use hub-and-spoke tunnels.
Step 14	Do one of the following: <ul style="list-style-type: none">• tunnel protection ipsec profile <i>name</i> [shared]• tunnel protection psk <i>key</i> Example: Router(config-if)# tunnel protection ipsec profile vpnprof	Associates a tunnel interface with an IPsec profile. <ul style="list-style-type: none">• The <i>name</i> argument specifies the name of the IPsec profile; this value must match the <i>name</i> specified in the crypto ipsec profile name command. or

	Command or Action	Purpose
	Example: <pre>Router(config-if)# tunnel protection psk test1</pre>	Simplifies the tunnel protection configuration for pre-shared key (PSK) by creating a default IPsec profile.
Step 15	bandwidth {interzone total session} {default zone zone-name} bandwidth-size Example: <pre>Device(config-if)# bandwidth total 1200</pre>	Sets the current bandwidth value for an interface to higher-level protocols. <ul style="list-style-type: none"> • The <i>bandwidth-size</i> argument specifies the bandwidth in kilobits per second. The default value is 9. The recommended bandwidth value is 1000 or greater. • The bandwidth setting for the spoke need not equal the bandwidth setting for the DMVPN hub. It is usually easier if all of the spokes use the same or similar value.
Step 16	ipv6 nhrp holdtime seconds Example: <pre>Device(config-if)# ipv6 nhrp holdtime 3600</pre>	Changes the number of seconds that NHRP NBMA addresses are advertised as valid in authoritative NHRP responses.
Step 17	end Example: <pre>Device(config-if)# end</pre>	Exits interface configuration mode and returns to privileged EXEC mode.

Verifying DMVPN for IPv6 Configuration

SUMMARY STEPS

1. **enable**
2. **show dmvpn** [ipv4 [vrf vrf-name] | ipv6 [vrf vrf-name]] [debug-condition | [interface tunnel number | peer {nbma ip-address | network network-mask | tunnel ip-address}] [static] [detail]]
3. **show ipv6 nhrp** [dynamic [ipv6-address] | incomplete | static] [address | interface] [brief | detail] [purge]
4. **show ipv6 nhrp multicast** [ipv4-address | interface | ipv6-address]
5. **show ip nhrp multicast** [nbma-address | interface]
6. **show ipv6 nhrp summary**
7. **show ipv6 nhrp traffic** [interfacetunnel number
8. **show ip nhrp shortcut**
9. **show ip route**
10. **show ipv6 route**
11. **show nhrp debug-condition**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show dmvpn [ipv4 [vrf vrf-name] ipv6 [vrf vrf-name]] [debug-condition [interface tunnel number peer {nbma ip-address network network-mask tunnel ip-address}]] [static] [detail]] Example: Device# show dmvpn 2001:0db8:1:1::72/64	Displays DMVPN-specific session information.
Step 3	show ipv6 nhrp [dynamic [ipv6-address] incomplete static] [address interface] [brief detail] [purge] Example: Device# show ipv6 nhrp	Displays NHRP mapping information.
Step 4	show ipv6 nhrp multicast [ipv4-address interface ipv6-address] Example: Device# show ipv6 nhrp multicast	Displays NHRP multicast mapping information.
Step 5	show ip nhrp multicast [nbma-address interface] Example: Device# show ip nhrp multicast	Displays NHRP multicast mapping information.
Step 6	show ipv6 nhrp summary Example: Device# show ipv6 nhrp summary	Displays NHRP mapping summary information.
Step 7	show ipv6 nhrp traffic [interface tunnel number] Example: Device# show ipv6 nhrp traffic	Displays NHRP traffic statistics information.
Step 8	show ip nhrp shortcut Example: Device# show ip nhrp shortcut	Displays NHRP shortcut information.

	Command or Action	Purpose
Step 9	show ip route Example: Device# show ip route	Displays the current state of the IPv4 routing table.
Step 10	show ipv6 route Example: Device# show ipv6 route	Displays the current contents of the IPv6 routing table.
Step 11	show nhrp debug-condition Example: Device# show nhrp debug-condition	Displays the NHRP conditional debugging information.

Monitoring and Maintaining DMVPN for IPv6 Configuration and Operation

SUMMARY STEPS

1. **enable**
2. **clear dmvpn session** [**interface tunnel** *number* | **peer** {*ipv4-address* | *fqdn-string* | *ipv6-address*} | **vrf** *vrf-name*] [**static**]
3. **clear ipv6 nhrp** [*ipv6-address* | **counters**]
4. **debug dmvpn** {**all** | **error** | **detail** | **packet**} {**all** | *debug-type*}
5. **debug nhrp** [**cache** | **extension** | **packet** | **rate**]
6. **debug nhrp condition** [**interface tunnel** *number* | **peer** {**nbma** {*ipv4-address* | *fqdn-string* | *ipv6-address*} | **tunnel** {*ip-address* | *ipv6-address*}} | **vrf** *vrf-name*]
7. **debug nhrp error**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	clear dmvpn session [interface tunnel <i>number</i> peer { <i>ipv4-address</i> <i>fqdn-string</i> <i>ipv6-address</i> } vrf <i>vrf-name</i>] [static] Example: Device# clear dmvpn session	Clears DMVPN sessions.

	Command or Action	Purpose
Step 3	clear ipv6 nhrp [<i>ipv6-address</i> counters Example: Device# clear ipv6 nhrp	Clears all dynamic entries from the NHRP cache.
Step 4	debug dmvpn { all error detail packet } { all <i>debug-type</i> } Example: Device# debug dmvpn	Displays debug DMVPN session information.
Step 5	debug nhrp [cache extension packet rate] Example: Device# debug nhrp ipv6	Enables NHRP debugging.
Step 6	debug nhrp condition [interface tunnel number peer { nbma { <i>ipv4-address</i> <i>fqdn-string</i> <i>ipv6-address</i> } tunnel { <i>ip-address</i> <i>ipv6-address</i> }} vrf vrf-name] Example: Device# debug nhrp condition	Enables NHRP conditional debugging.
Step 7	debug nhrp error Example: Device# debug nhrp ipv6 error	Displays NHRP error-level debugging information.

Examples

Sample Output for the debug nhrp Command

The following sample output is from the **debug nhrp** command with the **ipv6** keyword:

```
Device# debug nhrp ipv6
Aug 9 13:13:41.486: NHRP: Attempting to send packet via DEST
- 2001:DB8:3c4d:0015:0000:0000:1a2f:3d2c/32
Aug 9 13:13:41.486: NHRP: Encapsulation succeeded.
Aug 9 13:13:41.486: NHRP: Tunnel NBMA addr 11.11.11.99
Aug 9 13:13:41.486: NHRP: Send Registration Request via Tunnel0 vrf 0, packet size: 105
Aug 9 13:13:41.486: src: 2001:DB8:3c4d:0015:0000:0000:1a2f:3d2c/32,
dst: 2001:DB8:3c4d:0015:0000:0000:1a2f:3d2c/32
Aug 9 13:13:41.486: NHRP: 105 bytes out Tunnel0
Aug 9 13:13:41.486: NHRP: Receive Registration Reply via Tunnel0 vrf 0, packet size: 125
```

Configuration Examples for IPv6 over DMVPN

Example: Configuring an IPsec Profile

```

Device(config)# crypto identity router1

Device(config)# crypto ipsec profile example1
Device(config-crypto-map)# set transform-set example-set
Device(config-crypto-map)# set identity router1

Device(config-crypto-map)# set security-association lifetime seconds 1800

Device(config-crypto-map)# set pfs group14

```

Example: Configuring the Hub for DMVPN

```

Device# configure terminal
Device(config)# interface tunnel 5

Device(config-if)# ipv6 address 2001:DB8:1:1::72/64
Device(config-if)# ipv6 address fe80::2001 link-local
Device(config-if)# ipv6 mtu 1400
Device(config-if)# ipv6 nhrp authentication examplexx
Device(config-if)# ipv6 nhrp map multicast dynamic
Device(config-if)# ipv6 nhrp network-id 99
Device(config-if)# tunnel source ethernet 0
Device(config-if)# tunnel mode gre multipoint
Device(config-if)# tunnel protection ipsec profile example_profile
Device(config-if)# bandwidth 1200
Device(config-if)# ipv6 nhrp holdtime 3600

```

The following sample output is from the **show dmvpn** command, with the **ipv6** and **detail** keywords, for the hub:

```

Device# show dmvpn ipv6 detail

Legend: Attrb --> S - Static, D - Dynamic, I - Incomplete

Feature Information for IPv6 over DMVPN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 271: Feature Information for IPv6 over DMVPN

Feature Name	Releases	Feature Information
IPv6 over DMVPN		<p>The DMVPN feature allows users to better scale large and small IPsec Virtual Private Networks (VPNs) by combining generic routing encapsulation (GRE) tunnels, IP security (IPsec) encryption, and the Next Hop Resolution Protocol (NHRP). In Dynamic Multipoint Virtual Private Network (DMVPN) for IPv6, the public network (the Internet) is a pure IPv4 network, and the private network (the intranet) is IPv6 capable.</p> <p>The following commands were introduced or modified: clear dmvpn session, clear ipv6 nhrp, crypto ipsec profile, debug dmvpn, debug dmvpn condition, debug nhrp condition, debug nhrp error, ipv6 nhrp authentication, ipv6 nhrp holdtime, ipv6 nhrp interest, ipv6 nhrp map, ipv6 nhrp map multicast, ipv6 nhrp map multicast dynamic, ipv6 nhrp max-send, ipv6 nhrp network-id, ipv6 nhrp nhs, ipv6 nhrp record, ipv6 nhrp redirect, ipv6 nhrp registration, ipv6 nhrp responder, ipv6 nhrp server-only, ipv6 nhrp shortcut, ipv6 nhrp trigger-svc, ipv6 nhrp use, set pfs, set security-association lifetime, set transform-set, show dmvpn, show ipv6 nhrp, show ipv6 nhrp multicast, show ipv6 nhrp nhs, show ipv6 nhrp summary, show ipv6 nhrp traffic.</p>
IPv6 Transport for DMVPN		<p>The IPv6 transport for DMVPN feature builds IPv6 WAN-side capability into NHRP tunnels and the underlying IPsec encryption, and enables IPv6 to transport payloads on the Internet.</p> <p>The IPv6 transport for DMVPN feature is enabled by default.</p>

CHAPTER 206

DMVPN Configuration Using FQDN

The DMVPN Configuration Using FQDN feature enables next hop clients (NHCs) to register with the next hop server (NHS).

This feature allows you to configure a fully qualified domain name (FQDN) for the nonbroadcast multiple access network (NBMA) address of the hub (NHS) on the spokes (NHCs). The spokes resolve the FQDN to IP address using the DNS service and get registered with the hub using the newly resolved address. This allows spokes to dynamically locate the IP address of the hub using FQDN.

With this feature, spokes need not configure the protocol address of the hub. Spokes learn the protocol address of the hub dynamically from the NHRP registration reply of the hub. According to RFC 2332, the hub to which the NHRP registration was sent responds with its own protocol address in the NHRP registration reply and hence the spokes learn the protocol address of the hub from the NHRP registration reply packet.

In Cisco IOS Release 15.1(2)T and earlier releases, in Dynamic Multipoint VPN (DMVPN), NHS NBMA addresses were configured with either IPv4 or IPv6 addresses. Because NHS was configured to receive a dynamic NBMA address, it was difficult for NHCs to get the updated NBMA address and register with the NHS. This limitation is addressed with the DMVPN Configuration Using FQDN feature. This feature allows NHC to use an FQDN instead of an IP address to configure NBMA and register with the NHS dynamically.

Prerequisites for DMVPN Configuration Using FQDN

Cisco IOS Domain Name System (DNS) client must be available on the spoke.

Restrictions for DMVPN Configuration Using FQDN

If the NBMA IP address resolved from the FQDN is not mapped to an NHS configured with the protocol address, the spoke cannot register with the hub.

Information About DMVPN Configuration Using FQDN

DNS Functionality

A Domain Name System (DNS) client communicates with a DNS server to translate a hostname to an IP address.

The intermediate DNS server or the DNS client on the route enters the FQDN DNS reply from the DNS server into the cache for a lifetime. If the DNS client receives another query before the lifetime expires, the DNS client uses the entry information from the cache. If the cache expires, the DNS client queries the DNS server. If the NBMA address of the NHS changes frequently, the DNS entry lifetime must be short, otherwise the spokes may take some time before they start using the new NBMA address for the NHS.

DNS Server Deployment Scenarios

A DNS server can be located either in a hub network or outside a hub and spoke network.

Following are the four DNS server load balancing models:

- Round robin--Each DNS request is assigned an IP address sequentially from the list of IP addresses configured for an FQDN.
- Weighted round robin--This is similar to round-robin load balancing except that the IP addresses are assigned weights and nodes, where higher weights can take more load or traffic.
- Geography or network--Geography-based load balancing allows the requests to be directed to the optimal node that is geographically the nearest or the most efficient to the requester.
- Failover--Failover load balancing sends all requests to a single host until the load balancer determines a particular node to be no longer available. It then directs traffic to the next node available in the list.

How to Configure DMVPN Configuration Using FQDN

Configuring a DNS Server on a Spoke

Perform this task to configure a DNS server on a spoke. You must perform this task only if you want to resolve FQDN using an external DNS server.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip name-server** *ip-address*
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip name-server <i>ip-address</i> Example: Router(config)# ip name-server 192.0.2.1	Configures a DNS server on a spoke.
Step 4	exit Example: Router(config)# exit	Exits global configuration mode.

Configuring a DNS Server

Perform this task to configure a DNS server. You must perform the configuration on a DNS server.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip dns server**
4. **ip host** *hostname* *ip-address*
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	ip dns server Example: Router(config)# ip dns server	Enables a DNS server.
Step 4	ip host <i>hostname ip-address</i> Example: Router(config)# ip host host1.example.com 192.0.2.2	Maps a FQDN (<i>hostname</i>) with the IP address in the DNS hostname cache for a DNS view. Note Configure the ip host command on a DNS server if you have configured a DNS server on the spoke and configure the command on the spoke if you have not configured a DNS server on the spoke. See the Configuring a DNS Server on a Spoke task.
Step 5	exit Example: Router(config)# exit	Exits global configuration mode.

Configuring an FQDN with a Protocol Address

Perform this task to configure an FQDN with a protocol address. You must know the protocol address of the NHS while you are configuring the FQDN. This configuration registers spoke to a hub using NBMA.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel *number***
4. **ip nhrp nhs *nhs-address* [nbma {*nbma-address* | *FQDN-string*}] [multicast] [priority *value*] [cluster *number*]**
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	interface tunnel <i>number</i> Example: <pre>Router(config)# interface tunnel 1</pre>	Enters interface configuration mode.
Step 4	ip nhrp nhs <i>nhs-address</i> [nbma { <i>nbma-address</i> <i>FQDN-string</i> }] [multicast] [priority value] [cluster number] Example: <pre>Router(config-if)# ip nhrp nhs 192.0.2.1 nbma examplehub.example1.com multicast</pre>	Registers a spoke to a hub. <ul style="list-style-type: none"> You can configure the command in the following two ways: <ul style="list-style-type: none"> ip nhrp nhs protocol-ipaddress nbma FQDN-string--Use this command to register spoke to a hub using the FQDN string. ip nhrp nhs protocol-ipaddress nbma nbma-ipaddress--Use this command to register spoke to a hub using the NHS NBMA IP address. <p>Note You can use the ipv6 nhrp nhs protocol-ipaddress [nbma {nhs-ipaddress FQDN-string}] [multicast] [priority value] [cluster number] command for registering IPv6 address.</p>
Step 5	end Example: <pre>Router(config-if)# end</pre>	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring a FQDN Without an NHS Protocol Address

Perform this task to configure an FQDN without an NHS protocol address.

SUMMARY STEPS

- enable
- configure terminal
- interface tunnel *number*
- ip nhrp nhs dynamic nbma {*nbma-address* | *FQDN-string*} [multicast] [priority value] [cluster value]
- end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: <pre>Router(config)# interface tunnel 1</pre>	Enters interface configuration mode.
Step 4	ip nhrp nhs dynamic nbma {<i>nbma-address</i> <i>FQDN-string</i>} [multicast] [priority value] [cluster value] Example: <pre>Router(config-if)# ip nhrp nhs dynamic nbma examplehub.example1.com</pre>	Registers a spoke to a hub. <ul style="list-style-type: none"> The NHS protocol address is dynamically fetched by the spoke. You can configure the command in the following two ways: <ul style="list-style-type: none"> ip nhrp nhs dynamic nbma <i>FQDN-string</i>--Use this command to register a spoke to a hub using the FQDN string. ip nhrp nhs dynamic nbma <i>nbma-address</i>--Use this command to register a spoke to a hub using the NHS NBMA IP address. <p>Note You can use the ipv6 nhrp nhs dynamic nbma {<i>nbma-address</i> <i>FQDN-string</i>} [multicast] [priority value] [cluster value] command for registering IPv6 address.</p>
Step 5	end Example: <pre>Router(config-if)# end</pre>	Exits interface configuration mode and returns to privileged EXEC mode.

Verifying DMVPN FQDN Configuration

This task shows how to display information to verify DMVPN FQDN configuration. The following **show** commands can be entered in any order.

SUMMARY STEPS

1. **enable**
2. **show dmvpn**
3. **show ip nhrp nhs**
4. **show running-config interface tunnel *tunnel-number***
5. **show ip nhrp multicast**

DETAILED STEPS

Step 1 enable

Enables privileged EXEC mode. Enter your password if prompted.

Example:

```
Router# enable
```

Step 2 show dmvpn

Displays DMVPN-specific session information.

Example:

```
Router# show dmvpn
Legend: Attrb --> S - Static, D - Dynamic, I - Incomplete
        N - NATed, L - Local, X - No Socket
        # Ent --> Number of NHRP entries with same NBMA peer
        NHS Status: E --> Expecting Replies, R --> Responding, W --> Waiting
        UpDn Time --> Up or Down Time for a Tunnel
=====
Interface: Tunnell1, IPv4 NHRP Details
Type:Spoke, NHRP Peers:1,
# Ent Peer NBMA Addr Peer Tunnel Add State UpDn Tm Attrb
-----
      1      192.0.2.1      192.0.2.2 UP 00:00:12      S
      (h1.cisco.com)
```

Step 3 show ip nhrp nhs

Displays the status of the NHS.

Example:

```
Router# show ip nhrp nhs
IPv4 Registration Timer: 10 seconds
Legend: E=Expecting replies, R=Responding, W=Waiting
Tunnell:
192.0.2.1 RE NBMA Address: 192.0.2.2 (h1.cisco.com) priority = 0 cluster = 0
```

Step 4 show running-config interface tunnel *tunnel-number*

Displays the contents of the current running configuration file or the tunnel interface configuration.

Example:

```
Router# show running-config interface tunnel 1
Building configuration...
Current configuration : 462 bytes
!
interface Tunnell1
 ip address 192.0.2.1 255.255.255.0
 no ip redirects
 ip mtu 1440
 ip nhrp authentication testing
 ip nhrp group spoke_group2
 ip nhrp network-id 123
 ip nhrp holdtime 150
 ip nhrp nhs dynamic nbma h1.cisco.com multicast
```

```

ip nhrp registration unique
ip nhrp registration timeout 10
ip nhrp shortcut
no ip route-cache cef
tunnel source Ethernet0/0
tunnel mode gre multipoint
tunnel key 1001
tunnel protection ipsec profile DMVPN
end

```

Step 5 show ip nhrp multicast

Displays NHRP multicast mapping information.

Example:

```

Route# show ip nhrp multicast
I/F      NBMA address
Tunnel1  192.0.2.1  Flags: nhs

```

Configuration Examples for DMVPN Configuration Using FQDN

Example: Configuring a Local DNS Server

The following example shows how to configure a local DNS server:

```

enable
configure terminal
ip host host1.example.com 192.0.2.2

```

Example: Configuring an External DNS Server

The following example shows how to configure an external DNS server:

On a spoke

```

enable
configure terminal
ip name-server 192.0.2.1

```

On a DNS Server

```

enable
configure terminal
ip dns server
ip host host1.example.com 192.0.2.2

```

Example: Configuring NHS with a Protocol Address and an NBMA Address

The following example shows how to configure NHS with a protocol address and an NBMA address:

```
enable
configure terminal
interface tunnel 1
ip nhrp nhs 192.0.2.1 nbma 209.165.200.225
```

Example: Configuring NHS with a Protocol Address and an FQDN

The following example shows how to configure NHS with a protocol address and an FQDN:

```
enable
configure terminal
interface tunnel 1
ip nhrp nhs 192.0.2.1 nbma examplehub.example1.com
```

Example: Configuring NHS Without a Protocol Address and with an NBMA Address

The following example shows how to configure NHS without a protocol address and with an NBMA address:

```
enable
configure terminal
interface tunnel 1
ip nhrp nhs dynamic nbma 192.0.2.1
```

Example: Configuring NHS Without a Protocol Address and with an FQDN

The following example shows how to configure NHS without a protocol address and with an FQDN:

```
enable
configure terminal
interface tunnel 1
ip nhrp nhs dynamic nbma examplehub.example1.com
```

Feature Information for DMVPN Configuration Using FQDN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 272: Feature Information for DMVPN Configuration Using FQDN

Feature Name	Releases	Feature Information
DMVPN Configuration Using FQDN		The DMVPN Configuration Using FQDN feature enables the NHC to register with the NHS. It uses the NHRP without using the protocol address of the NHS. The following commands were introduced or modified: clear dmvpn session , debug nhrp condition , ip nhrp nhs , and ipv6 nhrp nhs .

CHAPTER 207

DMVPN-Tunnel Health Monitoring and Recovery Backup NHS

The DMVPN-Tunnel Health Monitoring and Recovery (Backup NHS) feature allows you to control the number of connections to the Dynamic Multipoint Virtual Private Network (DMVPN) hub and allows you to switch to alternate hubs in case of a connection failure to the primary hubs.

The recovery mechanism provided by the DMVPN-Tunnel Health Monitoring and Recovery (Backup NHS) feature allows spokes to recover from a failed spoke-to-hub tunnel path by replacing the tunnel by another active spoke-to-hub tunnel. Spokes can select the next hop server (NHS) [hub] from a list of NHSs configured on the spoke. You can configure priority values to the NHSs that control the order in which spokes select the NHS.

Information About DMVPN-Tunnel Health Monitoring and Recovery Backup NHS

NHS States

An NHS attains different states while associating with the hubs to form a spoke-to-hub tunnel. The table below describes different NHS states.

Table 273: NHS States

State	Description
DOWN	NHS is waiting to get scheduled.
PROBE	NHS is declared as “DOWN” but it is still actively probed by the spoke to bring it “UP”.

State	Description
UP	NHS is associated with a spoke to establish a tunnel.

NHS Priorities

NHS priority is a numerical value assigned to a hub that controls the order in which spokes select hubs to establish a spoke-to-hub tunnel. The priority value ranges from 0 to 255, where 0 is the highest and 255 is the lowest priority.

You can assign hub priorities in the following ways:

- Unique priorities to all NHS.
- Same priority level to a group of NHS.
- Unspecified priority (value 0) for an NHS, a group of NHSs, or all NHSs.

NHS Clusterless Model

NHS clusterless model is a model where you assign the priority values to the NHSs and do not place the NHSs into any group. NHS clusterless model groups all NHSs to a default group and maintains redundant connections based on the maximum NHS connections configured. Maximum NHS connections is the number of NHS connections in a cluster that must be active at any point in time. The valid range for maximum NHS connections is from 0 to 255.

Priority values are assigned to the hubs to control the order in which the spokes select hubs to establish the spoke-to-hub tunnel. However, assigning these priorities in a clusterless model has certain limitations.

The table below provides an example of limitations for assigning priorities in a clusterless model.

Table 274: Limitations of Clusterless Mode

Maximum Number of Connections = 3			
NHS	NHS Priority	Scenario 1	Scenario 2
NHS A1	1	UP	UP
NHS B1	1	UP	PROBE
NHS C1	1	UP	UP
NHS A2	2	DOWN	UP
NHS B2	2	DOWN	DOWN
NHS C2	2	DOWN	DOWN

Consider a scenario with three data centers A, B, and C. Each data center consists of two NHSs: NHSs A1 and A2 comprise one data center, NHS B1 and B2 another, and C1 and C3 another.

Although two NHSs are available for each data center, the spoke is connected to only one NHS of each data center at any point in time. Hence, the maximum connection value is set to 3. That is, three spoke-to-hub

tunnels are established. If any one NHS, for example, NHS B1, becomes inactive, the spoke-to-hub tunnel associated with NHS B1 goes down. Based on the priority model, NHS A2 has the next priority value and the next available NHS in the queue, so it forms the spoke-to-hub tunnel and goes up. However, this does not meet the requirement that a hub from data center B be associated with the spoke to form a tunnel. Hence, no connection is made to data center B.

This problem can be addressed by placing NHSs into different groups. Each group can be configured with a group specific maximum connection value. NHSs that are not assigned to any groups belong to the default group.

NHS Clusters

The table below presents an example of cluster functionality. NHSs corresponding to different data centers are grouped to form clusters. NHS A1 and NHS A2 with priority 1 and 2, respectively, are grouped as cluster1, NHS B1 and NHS B2 with priority 1 and 2, respectively, are grouped as cluster2, and NHS C1 and NHS C2 with priority 1 and 2, respectively, are grouped as cluster3. NHS 7, NHS 8, and NHS 9 are part of the default cluster. The maximum cluster value is set to 1 for each cluster so that at least one spoke-to-hub tunnel is continuously established with all the four clusters.

In scenario 1, NHS A1, NHS B1, and NHS C1 with the highest priority in each cluster are in the UP state. In scenario 2, the connection between the spoke and NHS A1 breaks, and a connection is established between the spoke and NHS A2 (hub from the same cluster). NHS A1 with the highest priority attains the PROBE state. In this way, at any point in time a connection is established to all the three data centers.

Table 275: Cluster Functionality

NHS	NHS Priority	Cluster	Maximum Number of Connections	Scenario	Scenario
				1	2
NHS A1	1	1	1	UP	PROBE
NHS A2	2			DOWN	UP
NHS B1	1	2	1	UP	UP
NHS B2	2			DOWN	DOWN
NHS C1	1	3	1	UP	UP
NHS C2	2			DOWN	DOWN
NHS 7	1	Default	2	UP	DOWN
NHS 8	2			UP	UP
NHS 9	0			PROBE	UP

NHS Fallback Time

Fallback time is the time that the spoke waits for the NHS to become active before detaching itself from an NHS with a lower priority and connecting to the NHS with the highest priority to form a spoke-to-hub tunnel. Fallback time helps in avoiding excessive flaps.

The table below shows how the spoke flaps from one NHS to another excessively when the fallback time is not configured on the spoke. Five NHSs having different priorities are available to connect to the spoke to form a spoke-to-hub tunnel. All these NHSs belong to the default cluster. The maximum number of connection is one.

Table 276: NHS Behavior when Fallback Time is not Configured

NHS	NHS Priority	Cluster	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5
NHS 1	1	Default	PROBE	PROBE	PROBE	PROBE	UP
NHS 2	2	Default	PROBE	PROBE	PROBE	UP	DOWN
NHS 3	3	Default	PROBE	PROBE	UP	DOWN	DOWN
NHS 4	4	Default	PROBE	UP	DOWN	DOWN	DOWN
NHS 5	5	Default	UP	DOWN	DOWN	DOWN	DOWN

In scenario 1, NHS 5 with the lowest priority value is connected to the spoke to form a tunnel. All the other NHSs having higher priorities than NHS 5 are in the PROBE state.

In scenario 2, when NHS 4 becomes active, the spoke breaks connection with the existing tunnel and establishes a new connection with NHS 4. In scenario 3 and scenario 4, the spoke breaks the existing connections as soon as an NHS with a higher priority becomes active and establishes a new tunnel. In scenario 5, as the NHS with the highest priority (NHS 1) becomes active, the spoke connects to it to form a tunnel and continues with it until the NHS becomes inactive. Because NHS 1 is having the highest priority, no other NHS is in the PROBE state.

The table below shows how to avoid the excessive flapping by configuring the fallback time. The maximum number of connection is one. A fallback time period of 30 seconds is configured on the spoke. In scenario 2, when an NHS with a higher priority than the NHS associated with the spoke becomes active, the spoke does not break the existing tunnel connection until the fallback time. Hence, although NHS 4 becomes active, it does not form a tunnel and attain the UP state. NHS 4 remains active but does not form a tunnel until the fallback time elapses. Once the fallback time elapses, the spoke connects to the NHS having the highest priority among the active NHSs.

This way, the flaps that occur as soon as an NHS of higher priority becomes active are avoided.

Table 277: NHS Behavior when Fallback Time is Configured

NHS	NHS Priority	Cluster	Scenario 1	Scenario 2	Scenario 3	Scenario 4	Scenario 5
NHS 1	1	Default	PROBE	PROBE	PROBE	UP-hold	UP
NHS 2	2	Default	PROBE	PROBE	UP-hold	UP-hold	DOWN
NHS 3	3	Default	PROBE	UP-hold	UP-hold	UP-hold	DOWN
NHS 4	4	Default	UP-hold	UP-hold	UP-hold	UP-hold	DOWN
NHS 5	5	Default	UP	UP	UP	UP	DOWN

NHS Recovery Process

NHS recovery is a process of establishing an alternative spoke-to-hub tunnel when the existing tunnel becomes inactive, and connecting to the preferred hub upon recovery.

The following sections explain NHS recovery:

Alternative Spoke to Hub NHS Tunnel

When a spoke-to-hub tunnel fails it must be backed up with a new spoke-to-hub tunnel. The new NHS is picked from the same cluster to which the failed hub belonged. This ensures that the required number of spoke-to-hub tunnels are always present although one or more tunnel paths are unavailable.

The table below presents an example of NHS backup functionality.

Table 278: NHS Backup Functionality

NHS	NHS Priority	Cluster	Maximum Number of Connections	Scenario 1	Scenario 2	Scenario 3
NHS A1	1	1	1	UP	PROBE	PROBE
NHS A2	2			DOWN	UP	DOWN
NHS A3	2			DOWN	DOWN	UP
NHS A4	2			DOWN	DOWN	DOWN
NHS B1	1	3	1	UP	PROBE	PROBE
NHS B2	2			DOWN	UP	DOWN
NHS B3	2			DOWN	DOWN	UP
NHS B4	2			DOWN	DOWN	DOWN
NHS 9	Default	Default	1	UP	UP	DOWN
NHS 10				DOWN	DOWN	UP

Four NHSs belonging to cluster 1 and cluster 3 and two NHSs belonging to the default cluster are available for setting up spoke-to-hub tunnels. All NHSs have different priorities. The maximum number of connections is set to 1 for all the three clusters. That is, at any point in time, at least one NHS from each cluster must be connected to the spoke to form a tunnel.

In scenario 1, NHS A1 from cluster 1, NHS B1 from cluster 3, and NHS 9 from the default cluster are UP. They establish a contact with the spoke to form different spoke-to-hub tunnels. In scenario 2, NHS A1 and NHS B1 with the highest priority in their respective clusters become inactive. Hence a tunnel is established from the spoke to NHS A2 and NHS B2, which have the next highest priority values. However, the spoke continues to probe NHS A1 and NHS B1 because they have the highest priority. Hence, NHS A1 and NHS B1 remain in the PROBE state.

In scenario 3, NHS A2, NHS B2, and NHS 9 become inactive. The spoke checks if the NHSs in PROBE state have turned active. If yes, then the spoke establishes a connection to the NHS that has turned active. However, as shown in scenario 3, because none of the NHSs in the PROBE state is active, the spoke connects to NHS

A3 of cluster 1 and NHS B3 of cluster 2. NHS A1 and NHS B1 continue to be in the PROBE state until they associate themselves with the spoke to form a tunnel and attain the UP state.

Returning to Preferred NHS Tunnel upon Recovery

When a spoke-to-hub tunnel fails, a backup tunnel is established using an NHS having the next higher priority value. Even though the tunnel is established with an NHS of lower priority, the spoke continuously probes the NHS having the highest priority value. Once the NHS having the highest priority value becomes active, the spoke establishes a tunnel with the NHS and hence the NHS attains the UP state.

The table below presents NHS recovery functionality. Four NHSs belonging to cluster 1 and cluster 3 and two NHSs belonging to the default cluster are available for setting up spoke-to-hub tunnels. All NHSes have different priorities. The maximum connection value is set to 1. In scenario 1, NHS A4, NHS B4, and NHS 10 with the least priority in their respective clusters associate with the spoke in establishing a tunnel. The spoke continues to probe NHSs of higher priority to establish a connection with the NHS having the highest priority value. Hence, in scenario 1, NHSs having the highest priority value in their respective clusters are in the PROBE state. In scenario 2, NHS A1 is ACTIVE, forms a tunnel with the spoke, and attains the UP state. Because NHS A1 has the highest priority, the spoke does not probe any other NHS in the cluster. Hence, all the other NHSs in cluster1 are in the DOWN state.

When the connection with NHS B4 breaks, the spoke connects to NHS B3, which has the next higher priority value, because NHS B1 of cluster 3 is not active. In scenario 3, NHS A1 continues to be in the UP state and NHS B1 with the highest priority in cluster 2 becomes active, forms a tunnel, and attains the UP state. Hence, no other NHSs in cluster 2 are in the PROBE state. However, because NHS 10 having the lowest priority value in the default cluster is in the UP state, the spoke continues to probe NHS 9 having the highest priority in the cluster.

In scenario 4, NHS A1 and NHS B1 continue to be in the UP state and NHS 9 having the highest priority in the default cluster attains the UP state. Hence, because the spoke is associated with the NHSs having the highest priority in all the clusters, none of the NHSs are in the PROBE state.

Table 279: NHS Recovery Functionality

NHS	NHS Priority	Cluster	Maximum Number of Connections	Scenario 1	Scenario 2	Scenario 3	Scenario 4
NHS A1	1	1	1	PROBE	UP	UP	UP
NHS A2	2			DOWN	DOWN	DOWN	DOWN
NHS A3	2			DOWN	DOWN	DOWN	DOWN
NHS A4	2			UP	DOWN	DOWN	DOWN
NHS B1	1	3	1	PROBE	PROBE	UP	UP
NHS B2	10			PROBE	DOWN	DOWN	DOWN
NHS B3	10			PROBE	UP	DOWN	DOWN
NHS B4	30			UP	DOWN	DOWN	DOWN

NHS	NHS Priority	Cluster	Maximum Number of Connections	Scenario 1	Scenario 2	Scenario 3	Scenario 4
NHS 9	Default	Default	1	PROBE	PROBE	PROBE	UP
NHS 10	100			UP	UP	UP	DOWN

How to Configure DMVPN-Tunnel Health Monitoring and Recovery Backup NHS

Configuring the Maximum Number of Connections for an NHS Cluster

Perform this task to configure the desired maximum number of connections for an NHS cluster.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **ip nhrp nhs cluster** *cluster-number* **max-connections** *value*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: <pre>Router(config)# interface tunnel 1</pre>	Enters interface configuration mode.
Step 4	ip nhrp nhs cluster <i>cluster-number</i> max-connections <i>value</i> Example:	Configures the desired maximum number of connections. Note Use the ipv6 nhrp nhs cluster <i>cluster-number</i> max-connections <i>value</i> command for IPv6 configuration.

	Command or Action	Purpose
	Router(config-if)# ip nhrp nhs cluster 5 max-connections 100	

Configuring NHS Fallback Time

Perform this task to configure NHS fallback time.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **ip nhrp nhs fallback** *fallback-time*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Router(config)# interface tunnel 1	Enters interface configuration mode.
Step 4	ip nhrp nhs fallback <i>fallback-time</i> Example: Router(config-if)# ip nhrp nhs fallback 25	Configures NHS fallback time. Note Use the ipv6 nhrp nhs fallback <i>fallback-time</i> command for IPv6 configuration.

Configuring NHS Priority and Group Values

Perform this task to configure NHS priority and group values.

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **interface tunnel** *number*
4. **ip nhrp nhs** *nhs-address* **priority** *nhs-priority* **cluster** *cluster-number*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: <pre>Router(config)# interface tunnel 1</pre>	Enters interface configuration mode.
Step 4	ip nhrp nhs <i>nhs-address</i> priority <i>nhs-priority</i> cluster <i>cluster-number</i> Example: <pre>Router(config-if)# ip nhrp nhs 172.0.2.1 priority 1 cluster 2</pre>	Configures the desired priority and cluster values. Note Use the ipv6 nhrp nhs <i>nhs-address</i> priority <i>nhs-priority</i> cluster <i>cluster-number</i> command for IPv6 configuration.

Verifying the DMVPN-Tunnel Health Monitoring and Recovery Backup NHS Feature

Perform this task to display information and verify DMVPN-Tunnel Health Monitoring and Recovery (Backup NHS) feature configuration. You can enter these **show** commands in any order.

SUMMARY STEPS

1. **enable**
2. **show ip nhrp nhs**
3. **show ip nhrp nhs redundancy**
4. **show ipv6 nhrp nhs**
5. **show ipv6 nhrp nhs redundancy**

DETAILED STEPS

-
- Step 1** **enable**
- Enables privileged EXEC mode. Enter your password if prompted.

Example:

```
Router# enable
```

Step 2 **show ip nhrp nhs**

Displays NHRP NHS information.

Example:

```
Router# show ip nhrp nhs
Legend: E=Expecting replies, R=Responding, W=Waiting
Tunnel0:
10.0.0.1 RE priority = 0 cluster = 0
```

Step 3 **show ip nhrp nhs redundancy**

Displays NHRP NHS recovery information.

Example:

```
Router# show ip nhrp nhs redundancy
Legend: E=Expecting replies, R=Responding, W=Waiting
No.  Interface  Cluster  NHS           Priority  Cur-State  Cur-Queue  Prev-State  Prev-Queue
1    Tunnel0     0        10.0.0.253   3         RE         Running    E           Running
2    Tunnel0     0        10.0.0.252   2         RE         Running    E           Running
3    Tunnel0     0        10.0.0.251   1         RE         Running    E           Running
No.  Interface  Cluster  Status  Max-Con  Total-NHS  Responding  Expecting  Waiting  Fallback
1    Tunnel0     0        Enable  3        3          3           0          0        0
```

Step 4 **show ipv6 nhrp nhs**

Displays IPv6, specific NHRP NHS information.

Example:

```
Router# show ipv6 nhrp nhs
Legend: E=Expecting replies, R=Responding, W=Waiting
Tunnel0:
2001::101 RE priority = 1 cluster = 5
```

Step 5 **show ipv6 nhrp nhs redundancy**

Displays IPv6, specific NHRP NHS recovery information.

Example:

```
Router# show ipv6 nhrp nhs redundancy
Legend: E=Expecting replies, R=Responding, W=Waiting
No.  Interface  Cluster  NHS           Priority  Cur-State  Cur-Queue  Prev-State  Prev-Queue
1    Tunnel0     5        2001::101    1         E          Running    RE          Running
No.  Interface  Cluster  Status  Max-Con  Total-NHS  Responding  Expecting  Waiting  Fallback
1    Tunnel0     5        Disable Not Set  1         0           1           0          0
```

Configuration Examples for DMVPN-Tunnel Health Monitoring and Recovery Backup NHS

Example: Configuring Maximum Connections for an NHS Cluster

The following example shows how to configure a “max-connections” value of 3 for three NHSs that belong to cluster 0:

```
interface tunnel 0
 bandwidth 1000
 ip address 10.0.0.1 255.0.0.0
 no ip redirects
 ip mtu 1400
 ip nhrp authentication test
 ip nhrp map multicast 172.0.2.1
 ip nhrp map 10.0.0.253 172.0.2.1
 ip nhrp map multicast 172.0.2.2
 ip nhrp map 10.0.0.251 172.0.2.2
 ip nhrp map multicast 172.0.2.3
 ip nhrp map 10.0.0.252 172.0.2.3
 ip nhrp network-id 100000
 ip nhrp holdtime 300
 ip nhrp nhs 10.0.0.252 priority 2
 ip nhrp nhs 10.0.0.251 priority 1
 ip nhrp nhs 10.0.0.253 priority 3
 ip nhrp nhs cluster 0 max-connections 3

ip nhrp shortcut
 delay 100
 tunnel source Ethernet0/0
 tunnel mode gre multipoint
 tunnel key 100000
 tunnel protection ipsec profile vpnprof
!
```

Example: Configuring NHS Fallback Time

The following example shows how to configure NHS fallback time to 25 seconds:

```
configure terminal
 interface tunnel 1
 ip nhrp nhs fallback 25
```

Example: Configuring NHS Priority and Group Value

The following example shows how to group NHSs under different clusters and then assign different maximum connection values to the clusters:

```
Configure terminal
 interface tunnel 0
 ip nhrp nhs 10.0.0.251 priority 1 cluster 1
```

```

ip nhrp map 10.0.0.251 192.0.2.4
ip nhrp map multicast 192.0.2.4
end
configure terminal
interface tunnel 0
ip nhrp nhs 10.0.0.252 priority 2 cluster 2
ip nhrp map 10.0.0.252 192.0.2.5
ip nhrp map multicast 192.0.2.5
end
configure terminal
interface tunnel 0
ip nhrp nhs 10.0.0.253 priority 3 cluster 3
ip nhrp map 10.0.0.253 192.0.2.6
ip nhrp map multicast 192.0.2.6
end
configure terminal
interface tunnel 0
ip nhrp nhs cluster 1 max 1
ip nhrp nhs cluster 2 max 1
ip nhrp nhs cluster 3 max 1
end

```

Feature Information for DMVPN-Tunnel Health Monitoring and Recovery Backup NHS

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 280: Feature Information for DMVPN-Tunnel Health Monitoring and Recovery Backup NHS

Feature Name	Releases	Feature Information
DMVPN-Tunnel Health Monitoring and Recovery (Backup NHS)		<p>The DMVPN-Tunnel Health Monitoring and Recovery (Backup NHS) feature allows you to control the number of connections to the DMVPN hub and allows you to switch to alternate hubs in case of connection failure to primary hubs.</p> <p>The following commands were introduced or modified: ip nhrp nhs, ipv6 nhrp nhs, show ip nhrp nhs, show ipv6 nhrp nhs.</p>

CHAPTER 208

DMVPN Tunnel Health Monitoring and Recovery

The Dynamic Multipoint VPN Tunnel Health Monitoring and Recovery feature enhances the ability of the system to monitor and report Dynamic Multipoint VPN (DMVPN) events. It includes support for Simple Network Management Protocol (SNMP) Next Hop Resolution Protocol (NHRP) notifications for critical DMVPN events and support for DMVPN syslog messages. It also enables the system to control the state of the tunnel interface based on the health of the DMVPN tunnels.

- [Prerequisites for DMVPN Tunnel Health Monitoring and Recovery, on page 2749](#)
- [Restrictions for DMVPN Tunnel Health Monitoring and Recovery, on page 2749](#)

- [Additional References for DMVPN Tunnel Health Monitoring and Recovery, on page 2756](#)
- [Feature Information for DMVPN Tunnel Health Monitoring and Recovery, on page 2757](#)

Prerequisites for DMVPN Tunnel Health Monitoring and Recovery

SNMP NHRP notifications

- SNMP is enabled in the system.
- Generic SNMP configurations for Get and Set operations and for notifications are implemented in the system.
- All relevant NHRP traps are enabled.

Restrictions for DMVPN Tunnel Health Monitoring and Recovery

MIB SNMP

- SNMP SET UNDO is not supported.

- The MIB Persistence feature that enables the MIB-SNMP data to persist across reloads is not supported. However, a virtual persistence for the MIB notification control object happens, because that information is also captured via the configuration command line interface (CLI).
- Notifications and syslogs are not virtual routing and forwarding (VRF)-aware.
- The Rate Limit Exceeded notification does not differentiate between the IPv4 or IPv6 protocol type.

Interface State Control

- Interface state control can be configured on leaf spoke nodes only.
- Interface state control supports IPv4 only.

Information About DMVPN Tunnel Health Monitoring and Recovery

NHRP Extension MIB

The NHRP Extension MIB module comprises objects that maintain redirect-related statistics for both clients and servers, and for the following SNMP notifications for critical DMVPN events:

- A spoke perceives that a hub has gone down. This can occur even if the spoke was not previously registered with the hub.
- A spoke successfully registers with a hub.
- A hub perceives that a spoke has gone down.
- A hub perceives that a spoke has come up.
- A spoke or hub perceives that another NHRP peer, not related by an NHRP registration, has gone down. For example, a spoke-spoke tunnel goes down.
- A spoke or hub perceives that another NHRP peer, not related by an NHRP registration, has come up. For example, a spoke-spoke tunnel comes up.
- The rate limit set for NHRP packets on the interface is exceeded.

The agent implementation of the MIB provides a means to enable and disable specific traps, from either the network management system or the CLI.

DMVPN Syslog Messages

The DMVPN syslog feature provides syslog messages for the following events:

- All next-hop state change events. For example, when the system declares that a Next Hop Server (NHS), Next Hop Client (NHC), or a Next Hop Peer (NHP) is up or down. The severity level for these messages is set to critical.

- NHRP resolution events. For example, when a spoke sends a resolution to a remote spoke, or when an NHRP resolution times out without receiving a response. The severity level for these messages is set to informational.
- DMVPN cryptography events. For example, when a DMVPN socket entry changes from open to closed, or from closed to open. The severity level for these messages is set to notification.
- NHRP error notifications. For example, when an NHRP registration or resolution event fails, when a system check event fails, or when an NHRP encapsulation error occurs, an NHRP error notification is displayed. The severity level for these messages is set to errors.

A sample NHRP error message is given below:

```
Received Error Indication from 209.165.200.226, code: administratively prohibited(4), (trigger src:
209.165.200.228 (nbma: 209.165.200.230) dst: 209.165.202.140), offset: 0, data: 00 01 08 00 00 00 00
00 00 FE 00 68 F4 03 00 34
```

The error message includes the IP address of the node where the error originates, the source nonbroadcast multiaccess (NBMA), and the destination address.

- DMVPN error notifications. For example, when the NET_ID value is not configured, or when an NHRP multicast replication failure occurs. The severity level is set to notification for the unconfigured NET_ID value message, and set to errors if an NHRP multicast replication failure occurs.
- The rate limit set for NHRP packets on the interface is exceeded. This event occurs when the NHRP packets handled by the NHRP process exceeds the rate limit set on the interface. The severity level for this message is set to warning.

Note From Cisco IOS XE 17.8.1, the **logging dmvpn rate-limit** command is enabled by default, with a rate-limit of 600 messages per minute. To disable, use the **no** form of the command. For more details, see section [Troubleshooting Dynamic Multipoint VPN, on page 2678](#).

Interface State Control

The Interface State Control feature allows NHRP to control the state of the interface based on whether the tunnels on the interface are live. If NHRP detects that all NHSS configured on the interface are in the down state, NHRP can change the interface state to down. However, if NHRP detects that any one of the NHSS configured on the interface is up, then it can change the state of the interface to up.

When the NHRP changes the interface state, other Cisco services can react to the state change, for example:

- If the interface state changes, the generic routing and encapsulation (GRE) interface generates IF-MIB notifications (traps) that report a LinkUp or LinkDown message. The system uses these traps to monitor the connectivity to the DMVPN cloud.
- If the interface state changes to down, the Cisco IOS backup interface feature can be initiated to allow the system to use another interface to provide an alternative path to the failed primary path.
- If the interface state changes to down, the system generates an update that is sent to all dynamic routing protocols. The Interface State Control feature a failover mechanism for dynamic routing when the multipoint GRE (mGRE) interface is down.

- If the interface state changes to down, the system clears any static routes that use the mGRE interface as the next hop. The Interface State Control feature provides a failover mechanism for routing when the mGRE interface is down.

The interface state control feature works on both point-to-point and mGRE interfaces.

Interface State Control Configuration Workflow

The diagram below illustrates how the system behaves when the Interface State Control feature is initialized.

Figure 107: Interface State Control Configuration Initialization Workflow

The Interface State Control initialization works as follows:

1. The Interface State Control feature is enabled on the GRE interface with NHRP configured.
2. The system reevaluates the protocol state and changes the state to line up and protocol down if none of the configured NHSs is responding.
3. The line up state change initiates the NHRP registration process.
4. The NHRP registration process initiates the IPsec tunnel.
5. The IPsec tunnel initiation starts the IPsec and IKE tunnel negotiation process.
6. On successful completion of the tunnel negotiation process, the system sends an IPsec Session Up message.
7. The NHRP registration process receives the IPsec Session Up message.
8. The NHRP registration process reports the line up and protocol up state to the GRE interface.
9. The GRE interface state changes to line up and protocol up.
10. The system reports the GRE interface state change to Cisco software.
11. The state change triggers Cisco services, such as interface event notifications, syslog events, DHCP renew, IP route refresh, and SNMP traps.

How to Configure DMVPN Tunnel Health Monitoring and Recovery

The DMVPN Tunnel Health Monitoring and Recovery feature allows you to configure SNMP NHRP notifications and interface states.

Configuring Interfaces to Generate SNMP NHRP Notifications

You can configure an interface so that SNMP NHRP traps are generated for NHRP events. In addition, you can configure the system to send the traps to particular trap receivers. To configure SNMP NHRP notifications on an interface, perform the steps in this section.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server community *string* rw**
4. **snmp-server enable traps nhrp nhs**
5. **snmp-server enable traps nhrp nhc**
6. **snmp-server enable traps nhrp nhp**
7. **snmp-server enable traps nhrp quota-exceeded**
8. **snmp-server host *ip-address* version *snmpversion* community-string**
9. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	snmp-server community <i>string</i> rw Example: Device(config)# snmp-server community public rw	Configures the community access string to permit access to the SNMP.
Step 4	snmp-server enable traps nhrp nhs Example:	Enables NHRP NHS notifications.

	Command or Action	Purpose
	Device(config)# snmp-server enable traps nhrp nhc	
Step 5	snmp-server enable traps nhrp nhc Example: Device(config)# snmp-server enable traps nhrp nhc	Enables NHRP NHC notifications.
Step 6	snmp-server enable traps nhrp nhp Example: Device(config)# snmp-server enable traps nhrp nhp	Enables NHRP NHP notifications.
Step 7	snmp-server enable traps nhrp quota-exceeded Example: Device(config)# snmp-server enable traps nhrp quota-exceeded	Enables notifications for when the rate limit set on the NHRP packets is exceeded on the interface.
Step 8	snmp-server host ip-address version snmpversion community-string Example: Device(config)# snmp-server host 192.40.3.130 version 2c public	Specifies the recipient of an SNMP notification operation. <ul style="list-style-type: none"> • By default, SNMP notifications are sent as traps. • All NHRP traps are sent to the notification receiver with the IP address 192.40.3.130 using the community string public.
Step 9	end Example: Device(config)# end	Exits the current configuration mode and returns to privileged EXEC mode.

Troubleshooting Tips

Use the `debug snmp mib nhrp` command to troubleshoot SNMP NHRP notifications.

Configuring Interface State Control on an Interface

The Interface State Control feature enables the system to control the state of an interface based on whether the DMVPN tunnels connected to the interface are live or not. To configure interface state control on an interface, perform the steps in this section.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface type number`
4. `if-state nhrp`
5. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>type</i> <i>number</i> Example: Device(config)# interface tunnel 1	Configures an interface type and enters interface configuration mode.
Step 4	if-state nhrp Example: Device(config-if)# if-state nhrp	Enables NHRP to control the state of the tunnel interface.
Step 5	end Example: Device(config-if)# end	Exits the current configuration mode and returns to privileged EXEC mode.

Configuration Examples for DMVPN Tunnel Health Monitoring and Recovery

Example: Configuring SNMP NHRP Notifications

The following example shows how to configure SNMP NHRP notifications on a hub or spoke:

```
Device(config)# snmp-server community public rw
Device(config)# snmp-server enable traps nhrp nhs
Device(config)# snmp-server enable traps nhrp nhc
Device(config)# snmp-server enable traps nhrp nhp
Device(config)# snmp-server enable traps nhrp quota-exceeded
Device(config)# snmp-server host 209.165.200.226 version 2c public
```

Example: Configuring Interface State Control

The following example shows how to configure the Interface State Control feature for a spoke:

```

interface Tunnel 1
 ip address 209.165.200.228 255.255.255.0
 no ip redirects
 ip nhrp authentication cisco
 ip nhrp map 209.165.201.2 209.165.201.10
 ip nhrp map 209.165.201.3 209.165.201.11
 ip nhrp map multicast 209.165.201.10
 ip nhrp map multicast 209.165.201.11
 ip nhrp network-id 1
 ip nhrp holdtime 90
 ip nhrp nhs 209.165.201.3
 ip nhrp nhs 209.165.201.2
 ip nhrp shortcut
 if-state nhrp
 tunnel source Ethernet0/0
 tunnel mode gre multipoint
 !
end

```

Feature Information for DMVPN Tunnel Health Monitoring and Recovery

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 281: Feature Information for Tunnel Health Monitoring and Recovery

Feature Name	Releases	Feature Information
DMVPN—Tunnel Health Monitoring and Recovery (Interface Line Control)		The DMVPN—Tunnel Health Monitoring and Recovery (Interface Line Control) feature enables NHRP to control the state of the tunnel interface based on the health of the DMVPN tunnels. The following command was introduced: if-state nhrp .

CHAPTER 209

DMVPN Event Tracing

The DMVPN Event Tracing feature provides a trace facility for troubleshooting Cisco IOS Dynamic Multipoint VPN (DMVPN). This feature enables you to monitor DMVPN events, errors, and exceptions. During runtime, the event trace mechanism logs trace information in a buffer space. A display mechanism extracts and decodes the debug data.

You can use the DMVPN Event Tracing feature to analyze the cause of a device failure. When you configure the DMVPN Event Tracing feature, the router logs messages from specific DMVPN subsystem components into the device memory. You can view trace messages stored in the memory or save them to a file.

- [Information About DMVPN Event Tracing, on page 2759](#)
- [How to Configure DMVPN Event Tracing, on page 2760](#)
- [Configuration Examples for DMVPN Event Tracing, on page 2761](#)
- [Additional References, on page 2762](#)
- [Feature Information for DMVPN Event Tracing, on page 2763](#)

Information About DMVPN Event Tracing

Benefits of DMVPN Event Tracing

- Displays debug information on the console during runtime.
- Avoids multiple debug calls, and hence improves device performance.
- Saves memory space.

DMVPN Event Tracing Options

The DMVPN Event Tracing feature defines the event data type, provides functionalities to capture the event, and prints the events and the CLI extensions required to access and modify the log. The table below lists different options that can be monitored using the DMVPN Event Tracing feature.

Table 282: DMVPN Event Trace Options

Event Type	Description
NHRP Event Trace	General Next Hop Resolution Protocol (NHRP) events, such as NHRP protocol, NHRP messages, changes in NHRP data structure, NHRP NBMA or protocol address change, and NHRP traps.
NHRP Error Trace	All NHRP error events.
NHRP Exception Trace	All NHRP exception events.
Tunnel Event Trace	All tunnel events.

How to Configure DMVPN Event Tracing

You can configure the DMVPN Event Tracing feature in privileged EXEC mode or global configuration mode based on the desired parameters. See the *Cisco IOS Security Command Reference* for information on different parameters available in privileged EXEC mode or global configuration mode.

Perform one of the following tasks to configure the DMVPN Event Tracing feature:

Configuring DMVPN Event Tracing in Privileged EXEC Mode

Perform this task to configure DMVPN event tracing in privileged EXEC mode.

SUMMARY STEPS

1. **enable**
2. **monitor event-trace dmvpn {nhrp {error | event | exception} | tunnel} {clear | continuous [cancel] | disable | enable | one-shot} | tunnel}**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	monitor event-trace dmvpn {nhrp {error event exception} tunnel} {clear continuous [cancel] disable enable one-shot} tunnel} Example: Router# monitor event-trace dmvpn nhrp error enable	Monitors and controls DMVPM traces.

Configuring DMVPN Event Tracing in Global Configuration Mode

Perform this task to configure DMVPN event tracing in global configuration mode.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **monitor event-trace dmvpn {dump-file url | {nhrp {error | event | exception} | tunnel} {disable | dump-file url | enable | size | stacktrace value}}**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	monitor event-trace dmvpn {dump-file url {nhrp {error event exception} tunnel} {disable dump-file url enable size stacktrace value}} Example: <pre>Router(config)# monitor event-trace dmvpn nhrp error enable</pre>	Monitors and controls DMVPM traces.
Step 4	exit Example: <pre>Router(config)# exit</pre>	Exits global configuration mode.

Configuration Examples for DMVPN Event Tracing

Example: Configuring DMVPN Event Tracing in Privileged EXEC Mode

The following example shows how to monitor NHRP error traces in privileged EXEC mode:

```
Router> enable
Router# monitor event-trace dmvpn nhrp error enable
```

Example: Configuring DMVPN Event Tracing in Global Configuration Mode

The following example shows how to monitor NHRP error traces in global configuration mode:

```
Router> enable
Router# configure terminal
Router(config)# monitor event-trace dmvpn nhrp error enable
```

CHAPTER 210

NHRP MIB

The Cisco NHRP MIB feature introduces support for the NHRP MIB, which helps to manage and monitor the Next Hop Resolution Protocol (NHRP) via Simple Network Management Protocol (SNMP). Statistics can be collected and monitored via standards-based SNMP techniques (get operations) to query objects defined in the NHRP MIB. The NHRP MIB is VPN Routing and Forwarding (VRF) aware and supports VRF-aware queries.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

- [Prerequisites for NHRP MIB, on page 2765](#)
- [Restrictions for NHRP MIB, on page 2765](#)
- [Information About NHRP MIB, on page 2766](#)
- [How to Use NHRP MIB, on page 2766](#)
- [Configuration Examples for NHRP MIB, on page 2767](#)
- [Additional References, on page 2769](#)
- [Feature Information for NHRP MIB, on page 2770](#)

Prerequisites for NHRP MIB

- You should be familiar with configuring SNMP.

Restrictions for NHRP MIB

- Cisco does not support all the MIB variables defined in RFC 2677, Definitions of Managed Objects for the NBMA Next Hop Resolution Protocol (NHRP). For a list of variables supported and other caveats of this feature, see the Agent Capabilities file. Cisco does not support the set operations defined in RFC 2677.

Information About NHRP MIB

CISCO-NHRP-MIB

CISCO-NHRP-MIB provides NHRP MIB information on managed objects relating to clients only, servers only, and clients and servers.

The NHRP MIB module contains ten tables of objects as follows:

- NHRP Cache Table
- NHRP Purge Request Table
- NHRP Client Table
- NHRP Client Registration Table
- NHRP Client NHS Table
- NHRP Client Statistics Table
- NHRP Server Table
- NHRP Server Cache Table
- NHRP Server NHC Table
- NHRP Server Statistics Table

The Cisco implementation supports all of the tables except the NHRP Purge Request Table.

RFC-2677

RFC-2677 - Definitions of Managed Objects for the NBMA Next Hop Resolution Protocol (NHRP), describes managed objects that can be used to remotely monitor NHRP using SNMP and provide management information on the performance of NHRP.

How to Use NHRP MIB

No special configuration is needed to implement the NHRP MIB feature. The SNMP framework can be used to manage NHRP MIB. See the section “Configuration Examples for NHRP MIB” for an example of how to manage a VRF-aware NHRP MIB.

This section contains the following task:

Verifying NHRP MIB Status

Use this task to verify the NHRP MIB status.

SUMMARY STEPS

1. **enable**
2. **show snmp mib nhrp status**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show snmp mib nhrp status Example: Router# show snmp mib nhrp status	Displays the status of the NHRP MIB.

Configuration Examples for NHRP MIB

Example Verifying NHRP MIB Status

The following output is from the show snmp mib nhrp status command:

```
Router# show snmp mib nhrp status
NHRP-SNMP Agent Feature: Enabled
NHRP-SNMP Tree State: Good
ListEnqueue Count = 0 Node Malloc Counts = 1
Spoke_103#
```

The “Enabled” status of “NHRP-SNMP Agent Feature:” indicates that the NHRP MIB is enabled. If the NHRP MIB was disabled, it would display “Disabled.” “ListEnqueue Count” and “Node Malloc Counts” counts are internal counts. “ListEnqueue Count” indicates how many nodes are queued for freeing. “Node Malloc Counts” displays how many nodes are allocated.

Example VRF-Aware NHRP MIB Configuration

The following is an example of how to configure a VRF table with the name Vrf1, for monitoring by SNMP:

```
ip vrf Vrf1
 rd 198102
 ! Name of the SNMP VPN context

CHAPTER 211

DMVPN Dynamic Tunnels Between Spokes Behind a NAT Device

The DMVPN Dynamic Tunnels Between Spokes Behind a NAT Device feature allows Next Hop Resolution Protocol (NHRP) spoke-to-spoke tunnels to be built in Dynamic Multipoint Virtual Private Networks (DMVPNs), even if one or more spokes is behind a Network Address Translation (NAT) device.

- [Feature Information for DMVPN Dynamic Tunnels Between Spokes Behind a NAT Device, on page 2771](#)
- [Restrictions for DMVPN Dynamic Tunnels Between Spokes Behind a NAT Device, on page 2771](#)
- [Information About DMVPN Dynamic Tunnels Between Spokes Behind a NAT Device, on page 2772](#)
- [Additional References, on page 2776](#)

Feature Information for DMVPN Dynamic Tunnels Between Spokes Behind a NAT Device

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Restrictions for DMVPN Dynamic Tunnels Between Spokes Behind a NAT Device

In order for two spokes to build tunnels between them, they need to know the post-NAT address of the other spoke.

Consider the following restrictions when using spoke-to-spoke tunneling in NAT environments:

- **Multiple NAT translations** --A packet can go across multiple NAT devices in a nonbroadcast multiaccess (NBMA) DMVPN cloud and make several (unimportant) translations before it reaches its destination. The last translation is the important translation because it is used to create the NAT translation for all devices that reach a spoke through the last NAT device.

- **Hub or spoke can be reached through pre-NAT addresses** --It is possible for two or more spokes to be behind the same NAT device, which can be reached through a pre-NAT IP address. Only the post-NAT IP address is relied on even if it means that a tunnel may take a less desirable path. If both spokes use NAT through the same device, then a packet may not travel inside-out or outside-in as expected by the NAT device and translations may not occur correctly.
- **Interoperability between NAT and non-NAT capable devices** --In networks that are deployed with DMVPN, it is important that a device with NHRP NAT functionality operate together with non-NAT supported devices. A capability bit in the NHRP packet header indicates to any receiver whether a sending device understands a NAT extension.
- **Same NAT translation** --A spoke's post-NAT IP address must be the same when the spoke is communicating with its hubs and when it is communicating with other spokes. For example, a spoke must have the same post-NAT IP address no matter where it is sending tunnel packets within the DMVPN network.
- If one spoke is behind one NAT device and another different spoke is behind another NAT device, and Port Address Translation (PAT) is the type of NAT used on both NAT devices, then a session initiated between the two spokes cannot be established.

One example of a PAT configuration on a NAT interface is:

```
ip nat inside source list nat_acl interface FastEthernet0/1 overload
```

Information About DMVPN Dynamic Tunnels Between Spokes Behind a NAT Device

The following sections describe how the DMVPN Dynamic Tunnels Between Spokes Behind a NAT Device feature allows spoke-to-spoke tunnels to be built even if one or both spoke devices are behind a NAT device:

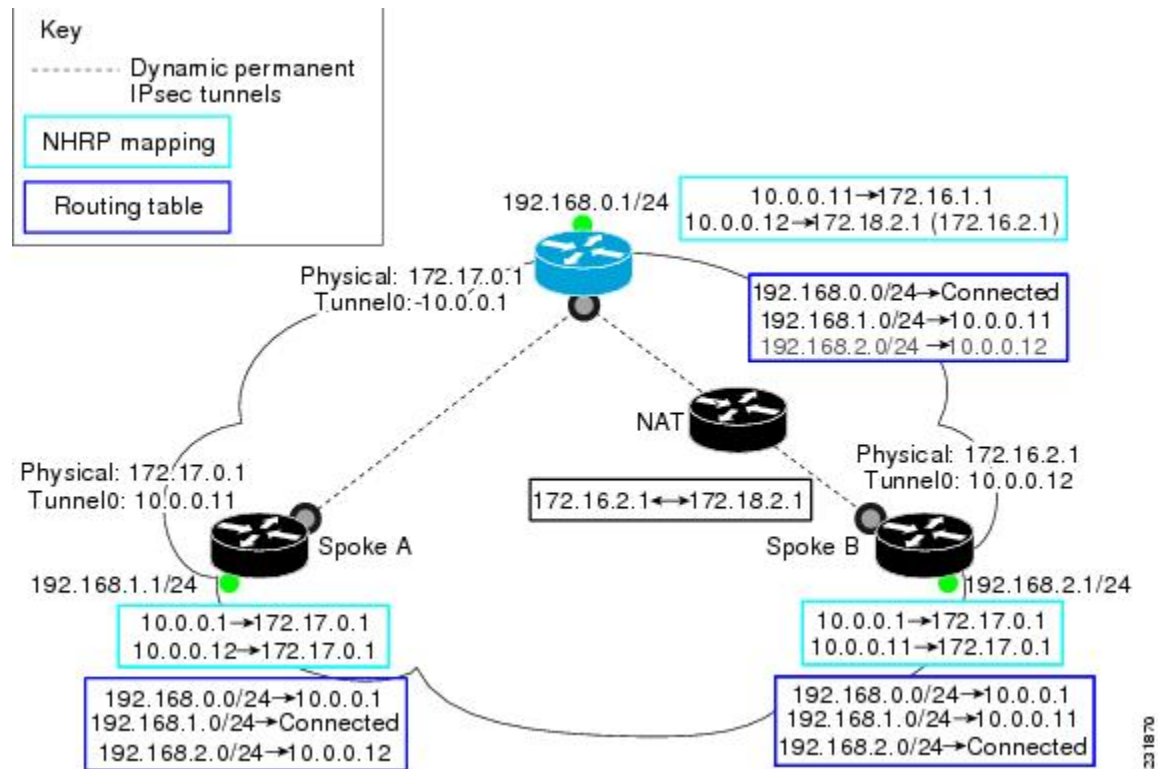

DMVPN Spoke-to-Spoke Tunneling Limited to Spokes Not Behind a NAT Device

NAT allows a single device, such as a router, to act as agent between the Internet (or “public network”) and a local (or “private”) network, and is often used because of the scarcity of available IP addresses. A single unique IP address is required to represent an entire group of devices to anything outside the NAT device. NAT is also deployed for security and administration purposes.

In DMVPN networks, spoke-to-spoke tunneling is limited to spokes that are not behind the NAT device. If one or both spokes are behind a NAT device, a spoke-to-spoke tunnel cannot be built to or from the NAT device because it is possible for the spoke-to-spoke tunnel traffic to fail or be lost for an extended period.

The figure below and the following sections describe how DMVPN works when spoke-to-spoke tunneling is limited to spokes that are not behind a NAT device.

Figure 108: Implementation of DMVPN Spoke-to-Spoke Tunneling Limited to Spokes Not Behind a NAT Device

NHRP Registration

When an NHRP registration is received, the hub checks the source IP address on the encapsulating GRE/IP header of the NHRP packet with the source NBMA IP address, which is contained in the NHRP registration packet. If these IP addresses are different, then NHRP knows that NAT is changing the outer IP header source address. The hub preserves both the pre- and post-NAT address of the registered spoke.

Note If encryption is used, then IPsec transport mode must be used to enable NHRP.

The following **show ip nhrp** command output example shows the source IP address of the NHRP packet and tunnel information for Spoke B in the figure above:

Note The NBMA (post-NAT) address for Spoke B is 172.18.2.1 (the claimed NBMA (pre-NAT) source address is 172.16.2.1).

```
Router# show ip nhrp
10.0.0.11/32 via 10.0.0.11, Tunnel0 created 00:00:21, expire 00:05:38
  Type: dynamic, Flags: authoritative unique registered used
  NBMA address: 172.18.2.1
    (Claimed NBMA address: 172.16.2.1)
```

NHRP Resolution

The following describes the NHRP resolution process between Spoke A and Spoke B shown in the figure above, where Spoke B is behind a NAT device with pre-NAT address of 172.16.2.1 and a post-NAT address of 172.18.2.1:

- The NHRP table entry for Spoke B on the hub contains both the post-NAT and pre-NAT addresses. When the hub receives an NHRP resolution request for the VPN address (tunnel address) of Spoke B, it answers with its own NBMA address instead of Spoke B's NBMA address.
- When the hub receives an NHRP resolution request sourced from Spoke B for any other spoke, the hub also answers with its own NBMA address. This ensures that any attempt to build a spoke-to-spoke tunnel with Spoke B results in the data packets being sent through the hub rather than through a spoke-to-spoke tunnel.

For example:

- Data traffic from source IP address 192.168.1.1 (behind Spoke A) to destination IP address 192.168.2.1 (behind Spoke B) triggers Spoke A to send a resolution request for Spoke B (10.0.0.12) to the next hop router (hub).
- The hub receives the resolution request and finds a mapping entry for Spoke B (10.0.0.12). Because Spoke B is behind a NAT device, it acts as a proxy and replies with its own NBMA address (172.17.0.1).
- The hub also receives a resolution request from Spoke B for Spoke A (10.0.0.11). Because Spoke B is behind a NAT device, it acts as a proxy and replies with its own NBMA address (172.17.0.1). This restricts any spoke-to-spoke traffic to or from Spoke B to travel through the hub router, which is done rather than having a tunnel between the spokes.

NHRP Spoke-to-Spoke Tunnel with a NAT Device

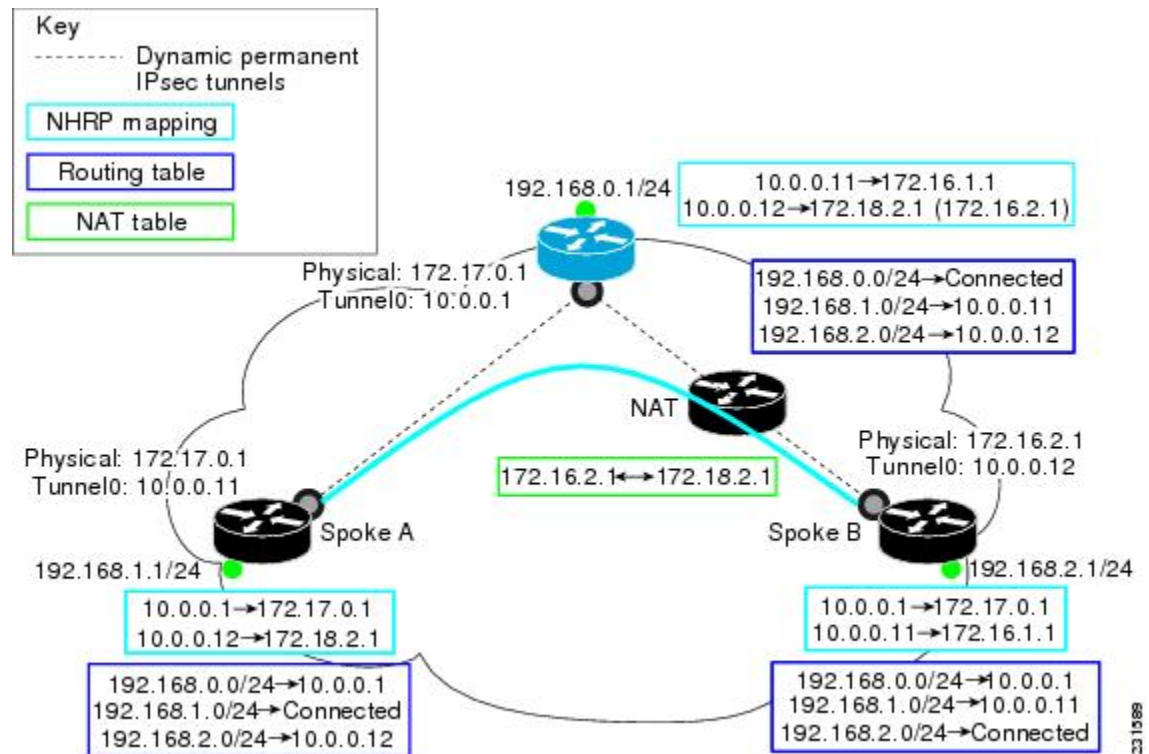

The NHRP Spoke-to-Spoke Tunnel with NAT feature introduces NAT extension in the NHRP protocol and is enabled automatically. The NHRP NAT extension is a Client Information Entry (CIE) entry with information about the protocol and post-NAT NBMA address. This additional information allows the support of spoke-to-spoke tunnels between spokes where one or both are behind a NAT device without the problem of losing traffic for an extended period.

Note The spoke-to-spoke tunnel may fail to come up, but it is detected and the data traffic flows through the hub, rather than being lost.

The figure below shows how the NHRP spoke-to-spoke tunnel works with NAT.

Figure 109: NHRP Between Spoke-to-Spoke Tunnels

NHRP Registration Process

The following steps describe the NHRP registration process:

1. A spoke sends a registration request with the NAT-Capability=1 parameter and a NAT NHRP extension of the NBMA address of the hub as configured on the spoke.
2. The hub compares the NHRP (NAT) extension with its configured NBMA address and determines whether it is or is not behind a NAT device. The hub also makes a note of whether the spoke is behind a NAT device by comparing the incoming GRE/IP source address with the spoke's NBMA address in the NHRP packet.
3. The registration reply from the hub to the spoke includes a NAT NHRP extension with the post-NAT address of the spoke, if the hub detects if it is behind a NAT device.
4. If the spokes get a NAT NHRP extension in the NHRP registration reply, it then records its post-NAT IP address for possible use later.

NHRP Resolution and Purge Process

The following steps describe the NHRP resolution and purge process:

1. When a spoke is behind a NAT device, it includes a NAT NHRP extension when it sends NHRP resolution requests.
2. The hub receives the resolution request. If the spoke is behind a NAT device and there is no NAT extension, then the hub adds a NAT extension before forwarding this extension to the next node (spoke or next hop).

server) along the path. However, if the hub is forwarding the request to a non-NAT extension capable node, it rewrites the source-NBMA inside the packet to be the post-NAT IP address for the requesting spoke rather than its pre-NAT IP address.

- The receiver (spoke) uses a NAT NHRP extension record (NAT capable) or the source NBMA address (non-NAT capable information) to build the tunnel. This spoke's reply includes its own NAT extension if it is behind a NAT device.

Note Hubs do not answer NHRP resolution requests on behalf of spokes. Hubs always forward NHRP resolution requests to the end spoke that has the requested tunnel IP address or services the requested data from the host IP address.

The following describes the NHRP resolution process between Spoke A and Spoke B shown in the figure above, where Spoke B is behind a NAT device with pre-NAT address 172.16.2.1 and post-NAT address of 172.18.2.1:

- Data traffic to the 192.168.2.0/24 network from hosts behind Spoke A triggers an NHRP resolution request for Spoke B's tunnel IP address (10.0.0.12) to be sent through the hub. The hub receives a resolution request and forwards it to Spoke B. Spoke B creates a dynamic spoke-to-spoke tunnel using the source NBMA IP address for Spoke A from the NHRP resolution request and sends an NHRP resolution reply directly to Spoke A. It includes its post-NAT address in the NAT NHRP-extension header.
- Alternatively, traffic to the 192.168.1.0/24 network from hosts behind the NAT device on Spoke B triggers an NHRP resolution request for Spoke A's tunnel IP address (10.0.0.11). Spoke B adds its own post-NAT IP address in the NHRP NAT-extension in the resolution request. The hub receives a resolution request and forwards it to Spoke A. Spoke A parses the NHRP NAT-extension and builds a tunnel using Spoke B's post-NAT address and replies directly to Spoke B.

CHAPTER 212

Sharing IPsec with Tunnel Protection

The Sharing IPsec with Tunnel Protection feature allows an IP Security (IPsec) Security Association Database (SADB) to be shared between two or more generic routing encapsulation (GRE) tunnel interfaces when tunnel protection is used. These tunnel interfaces share a single underlying cryptographic SADB, cryptographic map, and IPsec profile in the Dynamic Multipoint Virtual Private Network (DMVPN) configuration.

If IPsec security association (SA) sessions are not shared in the same IPsec SADB, then an IPsec SA may get associated with an undesired IPsec SADB, and may also get associated with a wrong tunnel interface, causing duplication of IPsec SAs and flapping of tunnel interfaces. If the tunnel interfaces flap (change rapidly and repeatedly between online and offline states), then network connectivity problems occur.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

Prerequisites for Sharing IPsec with Tunnel Protection

- Before a multipoint GRE (mGRE) and IPsec tunnel can be established, you must define an Internet Key Exchange (IKE) policy by using the **crypto isakmp policy** command.

Restrictions for Sharing IPsec with Tunnel Protection

- The **tunnel source** command on all the tunnel interfaces that use the same tunnel source must be configured using interface type and number, not the tunnel's IP address.

- All tunnels with the same tunnel source interface must use the same IPsec profile and must have the **tunnel protection shared** command configured. The only exception is a scenario when there are only peer-to-peer (P2P) GRE tunnel interfaces configured with the same tunnel source in the system, all with unique tunnel destination IP addresses.

- Different IPsec profile names must be used for shared and unshared tunnels.

For example, if “tunnel 1” is configured with the **tunnel source loopback0** command, and “tunnel 2” and “tunnel 3” are shared using the **tunnel source loopback1** command, use **ipsec-profile-1** for tunnel 1 and **ipsec-profile-2** for tunnels 2 and 3.

- A different IPsec profile must be used for each set of shared tunnels.

For example, if tunnels 1 through 5 use **loopback0** as their tunnel source and tunnels 6 through 10 use **loopback1**, then define the profile **ipsec-profile-1** for tunnels 1 through 5 and **ipsec-profile-2** for tunnels 6 through 10.

- It may be desirable to not share an IPsec session between two or more tunnel interfaces using the same tunnel source.

For example, in a service provider environment, each DMVPN cloud can represent a different customer. It is desirable to lock the connections from a customer to a tunnel interface and not share or allow IPsec sessions from other customers. For such scenarios, Internet Security Association and Key Management Protocol (ISAKMP) profiles can be used to identify and bind customer connections to an ISAKMP profile and use the ISAKMP profile to connect to an IPsec profile. This ISAKMP profile limits the IPsec profile to accept only those connections that matched the corresponding ISAKMP profile. Separate ISAKMP and IPsec profiles can be obtained for each DMVPN cloud (tunnel interface) without sharing the same IPsec SADB.

- Sharing IPsec is not desired and not supported for a virtual tunnel interface (VTI). A VTI provides a routable interface type for terminating IPsec tunnels and a way to define protection between sites to form an overlay network.
- Sharing IPsec is not supported on Virtual-Template type tunnel interfaces. It cannot be used either in the default **tunnel mode gre ip** mode with IPsec protection, (for example, FlexVPN) or with the **tunnel mode ipsec ipv4** (for example, Dynamic Virtual Tunnel interface - DVTI). Each virtual-template interface must have a separate and unshared IPsec profile. Otherwise, the router might crash after the virtual-access is deleted.

Information About Sharing IPsec with Tunnel Protection

Single IPsec SAs and GRE Tunnel Sessions

In a dual-hub, dual-DMVPN topology, it is possible to have two or more GRE tunnel sessions (same tunnel source and destination, but different tunnel keys) between the two endpoints of the same type. In this case, you should use a single IPsec SA to secure both GRE tunnel sessions. It is not possible to determine the tunnel interface under which an IPsec Quick Mode (QM) request must be processed and bound when two tunnel interfaces use the same tunnel source.

The **tunnel protection ipsec profile shared** command is used to create a single IPsec SADB for all the tunnel interfaces that use the same profile and tunnel source interface. This configuration allows a single IPsec SA to be used for all GRE tunnels (same tunnel source and destination, but different tunnel keys) between two endpoints of the same type. The **tunnel protection ipsec profile shared** command also makes IPsec

QM processing unambiguous because there is one SADB to process the incoming IPsec QM request for all shared tunnel interfaces as opposed to multiple SADBs (one for each tunnel interface when not shared).

The SA of a QM proposal to a tunnel interface is processed by using the shared SADB and cryptographic map parameters. On the cryptodata plane, the decrypted and GRE decapsulated packets are demultiplexed to the appropriate tunnel interface by the GRE module using a local address, a remote address, and optional tunnel key information.

When the IPsec path maximum transmission unit (MTU) changes, the value of SA MTU in the Quantum Flow Processor (QFP) and the hardware cryptographic engine gets updated and becomes consistent with the IPsec MTU. While the MTU changes, the system may drop some packets and transient %ATTN-3-SYNC_TIMEOUT errors may be displayed on the console.

Note The tunnel source, tunnel destination, and tunnel key (triplet) must be unique for all tunnel interfaces on a router. For a multipoint GRE (mGRE) interface where the tunnel destination is not configured, the pair (tunnel source and tunnel key) must be unique. Incoming GRE packets are also matched to P2P GRE tunnels first; if there is no match, then they are matched to mGRE tunnels.

How to Configure Sharing IPsec with Tunnel Protection

Sharing an IPsec SADB Between Multiple Tunnel Interfaces in a DMVPN

Perform this task to configure a Cisco IOS router to share an IPsec SADB between multiple tunnel interfaces in a DMVPN.

If your configuration requires more spoke routers in a dual-hub, dual DMVPN topology, repeat the steps listed in this task to configure additional spokes.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **tunnel source** {*ip-address* | *interface-type interface-number*}
5. **tunnel protection ipsec profile** *name* [shared]
6. **exit**
7. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: <pre>Router(config)# interface tunnel 5</pre>	Configures a tunnel interface and enters interface configuration mode. <ul style="list-style-type: none"> The <i>number</i> argument specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	tunnel source {<i>ip-address</i> <i>interface-type interface-number</i>} Example: <pre>Router(config-if)# tunnel source GigabitEthernet 0</pre>	Sets the source IP address or source interface type number for a tunnel interface. <ul style="list-style-type: none"> When you are using the tunnel protection ipsec profile command, you must specify an interface, not an IP address for the tunnel source.
Step 5	tunnel protection ipsec profile <i>name</i> [shared] Example: <pre>Router(config-if)# tunnel protection ipsec profile vpnprof shared</pre>	Associates a tunnel interface with an IPsec profile. <ul style="list-style-type: none"> The <i>name</i> argument specifies the name of the IPsec profile; this value must match the <i>name</i> specified in the crypto ipsec profile <i>name</i> command. The shared keyword allows IPsec sessions to be shared between multiple tunnel interfaces configured with the same tunnel source IP.
Step 6	exit Example: <pre>Router(config-if)# exit</pre>	Exits interface configuration mode and enters global configuration mode.
Step 7	exit Example: <pre>Router(config)# exit</pre>	Exits global configuration mode and enters privileged EXEC mode.

Configuration Examples for Sharing IPsec with Tunnel Protection

Example: Dual-Hub Router, Dual-DMVPN Topology

The dual-hub router, dual-DMVPN topology, shown in the following figure, has the following attributes:

- Each hub router is configured with a single mGRE tunnel interface.
- Each hub router is connected to one DMVPN subnet (cloud), and the spokes are connected to both DMVPN-1 and DMVPN-2.
- Each spoke router is configured with two mGRE tunnel interfaces.
- One mGRE tunnel interface belongs to DMVPN-1, and the other mGRE tunnel interface belongs to DMVPN-2.
- Each mGRE tunnel interface is configured with the same tunnel source IP address and uses shared tunnel protection between them.

Figure 110: Dual-Hub Router, Dual-DMVPN Topology

Example: Configuring an IPsec SADB Between Multiple Tunnel Interfaces in a DMVPN

Example: HUB-1 Configuration

HUB-1 and HUB-2 configurations are similar, except that each hub belongs to a different DMVPN.

HUB-1 has the following DMVPN configuration:

- IP subnet: 10.0.0.0/24
- Next Hop Address Resolution Protocol (NHRP) network ID: 100000
- Tunnel key: 100000
- Dynamic routing protocol: Enhanced Interior Gateway Routing Protocol (EIGRP)

Example: Results on SPOKE 1

SPOKE 1 has the following results for its DMVPN configuration:

```
Spoke1# show ip nhrp

10.0.0.1/32 via 10.0.0.1, Tunnel 0 created 00:06:52, never expire
  Type: static, Flags: used
  NBMA address: 172.17.0.1
10.0.0.12/32 via 10.0.0.12, Tunnel 0 created 00:03:17, expire 00:01:52
  Type: dynamic, Flags: router
  NBMA address: 172.17.0.12
10.0.1.1/32 via 10.0.1.1, Tunnel 1 created 00:13:45, never expire
  Type: static, Flags: used
  NBMA address: 172.17.0.5
10.0.1.12/32 via 10.0.1.12, Tunnel 1 created 00:00:02, expire 00:04:57
  Type: dynamic, Flags: router
  NBMA address: 172.17.0.12
Spoke1# show crypto socket
```

Note There are only three crypto connections (172.17.0.12, 172.17.0.5 and 172.17.0.1). The two NHRP sessions (10.0.0.12, Tunnel 0) and (10.0.1.12, Tunnel 1) represent the same IPsec session because they both have the same nonbroadcast multiaccess (NBMA) IPsec peer address.

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for Sharing IPsec with Tunnel Protection

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Glossary

GRE—generic routing encapsulation. Tunnels that provide a specific pathway across the shared WAN and encapsulate traffic with new packet headers to ensure delivery to specific destinations. The network is private because traffic can enter a tunnel only at an endpoint. Tunnels do not provide true confidentiality (encryption does), but can carry encrypted traffic.

GRE tunneling can also be used to encapsulate non-IP traffic into IP and send it over the Internet or IP network. The Internet Package Exchange (IPX) and AppleTalk protocols are examples of non-IP traffic.

IKE—Internet Key Exchange. A hybrid protocol that implements Oakley key exchange and Skeme key exchange inside the ISAKMP framework. Although IKE can be used with other protocols, its initial implementation is with IPsec. IKE provides authentication of the IPsec peers, negotiates IPsec keys, and negotiates IPsec security associations.

IPsec—IP Security. A framework of open standards developed by the IETF. IPsec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPsec acts at the network layer, protecting and authenticating IP packets between participating IPsec peers, such as Cisco routers.

ISAKMP—Internet Security Association Key Management Protocol. A protocol framework that defines payload formats, the mechanics of implementing a key exchange protocol, and the negotiation of a security association.

NHRP—Next Hop Resolution Protocol. Protocol that routers, access servers, and hosts can use to discover the addresses of other routers and hosts connected to an NBMA network.

The Cisco implementation of NHRP supports the IETF draft version 11 of NBMA NHRP.

The Cisco implementation of NHRP supports IP Version 4, IPX network layers, and, at the link layer, ATM, Ethernet, SMDS, and multipoint tunnel networks. Although NHRP is available on Ethernet, NHRP need not be implemented over Ethernet media because Ethernet is capable of broadcasting. Ethernet support is unnecessary (and not provided) for IPX.

SA—security association. Describes how two or more entities use security services to communicate securely. For example, an IPsec SA defines the encryption algorithm (if used), the authentication algorithm, and the shared session key to be used during the IPsec connection.

Both IPsec and IKE require and use SAs to identify the parameters of their connections. IKE can negotiate and establish its own SA. The IPsec SA is established either by IKE or by manual user configuration.

transform—List of operations performed on a data flow to provide data authentication, data confidentiality, and data compression. For example, one transform is the Encapsulating Security Payload (ESP) protocol with the Hash-based Message Authentication Code (HMAC)-Message Digest Algorithm (MD5) authentication algorithm; another transform is the Authentication Header (AH) protocol with the 56-bit DES encryption algorithm and the ESP protocol with the HMAC-Secure Hash Algorithm (SHA) authentication algorithm.

tunnel—A secure communication path between two peers, such as two routers. It does not refer to using IPsec in tunnel mode.

VPN—Virtual Private Network. A framework that consists of multiple peers transmitting private data securely to one another over an otherwise public infrastructure. In this framework, inbound and outbound network traffic is protected using protocols that tunnel and encrypt all data. This framework permits networks to extend beyond their local topology, while remote users are provided with the appearance and functionality of a direct network connection.

CHAPTER 213

Per-Tunnel QoS for DMVPN

The Per-Tunnel QoS for DMVPN feature introduces per-tunnel QoS support for DMVPN and increases per-tunnel QoS performance for IPsec tunnel interfaces.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

- [Additional References for Per-Tunnel QoS for DMVPN, on page 2812](#)
- [Feature Information for Per-Tunnel QoS for DMVPN, on page 2813](#)

Prerequisites for Per-Tunnel QoS for DMVPN

- Before you configure the Per-Tunnel QoS for DMVPN feature, you must configure Cisco Express Forwarding switching.
- Before you can configure an Next Hop Resolution Protocol (NHRP) group on a spoke and map the NHRP group to a QoS policy on a hub, the spoke and the hub must already be configured for DMVPN without the per-tunnel QoS.

Restrictions for Per-Tunnel QoS for DMVPN

- The Per-Tunnel QoS for DMVPN feature only supports the following encapsulation and transport protocol combinations:
 - Per-Tunnel QoS for IPv4 over DMVPN with IPv4 transport (Effective from Cisco IOS XE Release 3.6S).
 - Per-Tunnel QoS for IPv6 over DMVPN with IPv4 transport (Effective from Cisco IOS XE Release 3.8S).

- Per-Tunnel QoS for IPv4 over DMVPN with IPv6 transport (Effective from Cisco IOS XE Release 3.11S).
 - Per-Tunnel QoS for IPv6 over DMVPN with IPv6 transport (Effective from Cisco IOS XE Release 3.11S).
 - Per-Tunnel QoS for MPLS VPN over DMVPN with IPv4 transport (2547oDMVPN) (Effective from Cisco IOS XE Release 3.15S).
 - Per-Tunnel QoS for MPLS VPN over DMVPN with IPv6 transport (2547oDMVPN) (Effective from Cisco IOS XE Release 3.15S).
- For a given DMVPN tunnel interface, one transport protocol, either IPv4 or IPv6, can only be used. However, different DMVPN tunnel interfaces on the same device may use IPv4 or IPv6 transport protocol at the same time. Per-tunnel QoS can be configured for IPv4 and IPv6 DMVPN passenger traffic packets and be associated with an outbound physical interface that is either IPv4, IPv6 or both. This DMVPN tunnel traffic may be mixed with non-DMVPN IPv4 and IPv6 traffic, or both, on the outbound physical interface with its own QoS policy with restrictions.
 - The Per-Tunnel QoS for DMVPN feature does not support the following:
 - Per-Tunnel QoS for IPv4 or IPv6 or Multiprotocol Label Switching (MPLS) VPN over DMVPN with Layer 2 Tunnel Protocol (L2TP) transport.
 - Per-Tunnel QoS for IPv4 or IPv6 or MPLS VPN over DMVPN.
 - Per-Tunnel QoS service policies are only supported in the egress direction.
 - This feature does not support adding the capability of user configurable queuing and schedules before the crypto engine.
 - Fair queuing should not be used in a per-tunnel QoS for DMVPN policy map because the outer header with nonchanging IP addresses is used for individual flow queue selection. This results in the same queue being selected for all traffic flowing through the class with fair queuing.
 - A QoS service policy is supported on the main interface or subinterface that the tunnel is sourced from in conjunction with a per-tunnel QoS service policy on the DMVPN tunnel interface. However, there are certain restrictions for the main or subinterface service policy, which are as follows:
 - A service policy is supported on either the main interface or the subinterface, but not both, in conjunction with the per-tunnel QoS service policy.
 - The main interface or subinterface QoS service policy is limited to only a class-default shaper (it can only contain the **class class-default** and **shape** commands). Additional QoS configurations are not supported on the main interface or subinterface when two different QoS service policies are applied to the main or subinterface and the tunnel interface simultaneously.
 - The main interface or subinterface QoS service policy must be applied before the tunnel interface service policy.
 - The main interface or subinterface QoS service policy is checked for validity only when a QoS service policy is applied on the tunnel interface. The main interface or subinterface service policy is not checked during a tunnel movement or modification.
 - Adding new classes or features to the main interface or subinterface policy map is not supported. The classes or features may not be blocked on CLI and could result in unpredictable behavior.

- The policy-map counters for the main interface or subinterface service policy (from the **show policy-map interface** command) may not account for all packets and therefore should not be used or referenced. However, this does not affect the QoS functionality. The shaper will still limit the traffic on the main interface or subinterface, including all DMVPN tunnel traffic over that interface.

Information About Per-Tunnel QoS for DMVPN

Per-Tunnel QoS for DMVPN Overview

The Per-Tunnel QoS for DMVPN feature lets you apply a quality of service (QoS) policy on a Dynamic Multipoint VPN (DMVPN) hub on a per-tunnel instance (per-spoke basis) in the egress direction for DMVPN hub-to-spoke tunnels. The QoS policy on a DMVPN hub on a per-tunnel instance lets you shape tunnel traffic to individual spokes (a parent policy) and differentiate individual data flows going through the tunnel for policing (a child policy). The QoS policy that the hub uses for a specific spoke is selected according to the specific Next Hop Resolution Protocol (NHRP) group into which that spoke is configured. Although you can configure many spokes into the same NHRP group, the tunnel traffic for each spoke is measured individually for shaping and policing.

You can use this feature with DMVPN with or without Internet Protocol Security (IPsec).

When the Per-Tunnel QoS for DMVPN feature is enabled, queuing and shaping are performed at the outbound physical interface for generic routing encapsulation (GRE)/IPsec tunnel packets. The Per-Tunnel QoS for DMVPN feature ensures that the GRE header, the IPsec header, and the Layer 2 (for the physical interface) header are included in the packet-size calculations for shaping and bandwidth queuing of packets under QoS.

Benefits of Per-Tunnel QoS for DMVPN

Before the introduction of Per-Tunnel QoS for DMVPN feature, quality of service (QoS) on a Dynamic Multipoint VPN (DMVPN) hub could be configured to measure only either the outbound traffic in the aggregate (overall spokes) or outbound traffic on a per-spoke basis (with extensive manual configuration).

The Per-Tunnel QoS for DMVPN feature provides the following benefits:

- The QoS policy is attached to the DMVPN hub, and the criteria for matching the tunnel traffic are set up automatically as each spoke registers with the hub (which means that extensive manual configuration is not needed).
- Traffic can be regulated from the hub to spokes on a per-spoke basis.
- The hub cannot send excessive traffic to (and overrun) a small spoke.
- The amount of outbound hub bandwidth that a “greedy” spoke can consume can be limited; therefore, the traffic cannot monopolize a hub’s resources and starve other spokes.

NHRP QoS Provisioning for DMVPN

Next Hop Resolution Protocol (NHRP) performs the provisioning for the Per-Tunnel QoS for DMVPN feature by using NHRP groups.

An NHRP group, a new functionality introduced by this feature, is the group identity information signaled by a Dynamic Multipoint VPN (DMVPN) node (a spoke) to the DMVPN hub. The hub uses this information to select a locally defined quality of service (QoS) policy instance for the remote node.

You can configure an NHRP group on the spoke router on the DMVPN generic routing encapsulation (GRE) tunnel interface. The NHRP group name is communicated to the hub in each of the periodic NHRP registration requests sent from the spoke to the hub.

NHRP group-to-QoS policy mappings are configured on the hub DMVPN GRE tunnel interface. The NHRP group string received from a spoke is mapped to a QoS policy, which is applied to that hub-to-spoke tunnel in the egress direction.

After an NHRP group is configured on a spoke, the group is not immediately sent to the hub, but is sent in the next periodic registration request. The spoke can belong to only one NHRP group per GRE tunnel interface. If a spoke is configured as part of two or more DMVPN networks (multiple GRE tunnel interfaces), then the spoke can have a different NHRP group name on each of the GRE tunnel interfaces.

If an NHRP group is not received from the spoke, then a QoS policy is not applied to the spoke, and any existing QoS policy applied to that spoke is removed. If an NHRP group is received from the spoke when previous NHRP registrations did not have an NHRP group, then the corresponding QoS policy is applied. If the same NHRP group is received from a spoke similar to the earlier NHRP registration request, then no action is taken because a QoS policy would have already been applied for that spoke. If a different NHRP group is received from the spoke than what was received in the previous NHRP registration request, any applied QoS policy is removed, and the QoS policy corresponding to the new NHRP group is applied.

Per-Tunnel QoS for Spoke to Spoke Connections

The QoS: Spoke to Spoke per tunnel QoS for DMVPN feature enables a DMVPN client to establish a direct crypto tunnel with another DMVPN client leveraging the per-tunnel QoS policy, using Next Hop Resolution Protocol (NHRP) to build spoke-to-spoke connections.

This feature enhances the Adaptive QoS over DMVPN feature, which ensures effective bandwidth management using dynamic shapers based on available bandwidth.

A spoke-to-spoke connection is established when a group identity information, configured on the spokes using the **nhrp attribute group** command, is exchanged between the spokes through the NHRP Vendor Private Extension (VPE). The NHRP Vendor Private Extensions, encapsulated in NHRP control packets—NHRP resolution request and reply packets.

Assume a network with two spokes—Spoke A and Spoke B, connected to hub. If Spoke A is configured with the **nhrp attribute group** command and traffic exists between the Spoke A and Spoke B, a resolution request from the Spoke A carries the group identity information as part of Vendor Private Extension (VPE). On receiving the resolution request, Spoke B extracts the VPE header and checks the extension types received as part of the resolution request packet. If the VPE extension has group type, the NHRP VPE parser extracts the group information and checks if a matching map is present. If a matching map is present, QoS applies the policy on the target interface.

How to Configure Per-Tunnel QoS for DMVPN

To configure the Per-Tunnel QoS for DMVPN feature, you define a Next Hop Resolution Protocol (NHRP) group on the spokes and then map the NHRP group to a quality of service (QoS) policy on the hub.

Configuring an NHRP Group on a Spoke

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **nhrp group** *group-name*
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 1	Configures a tunnel interface and enters interface configuration mode.
Step 4	nhrp group <i>group-name</i> Example: Device(config-if)# nhrp group spoke_group1	Configures a Next Hop Resolution Protocol (NHRP) group on the spoke.
Step 5	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring an NHRP Group Attribute on a Spoke

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **nhrp attribute group** *group-name*
5. **nhrp map group** *group-name* **service-policy output** *qos-policy-map-name*
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 1	Configures a tunnel interface and enters interface configuration mode.
Step 4	nhrp attribute group <i>group-name</i> Example: Device(config-if)# nhrp attribute group spokel	Configures the QoS group identity information on the spoke.
Step 5	nhrp map group <i>group-name</i> service-policy output <i>qos-policy-map-name</i> Example: Device(config-if)# nhrp map group spoke_group1 service-policy output group1_parent	Adds the Next Hop Resolution Protocol (NHRP) group to the quality of service (QoS) policy mapping.
Step 6	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Mapping an NHRP Group to a QoS Policy on the Hub

SUMMARY STEPS

1. enable
2. configure terminal
3. interface tunnel *number*
4. nhrp map group *group-name* service-policy output *qos-policy-map-name*
5. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 1	Configures a tunnel interface and enters interface configuration mode.
Step 4	nhrp map group <i>group-name</i> service-policy output <i>qos-policy-map-name</i> Example: Device(config-if)# nhrp map group spoke_group1 service-policy output group1_parent	Adds the Next Hop Resolution Protocol (NHRP) group to the quality of service (QoS) policy mapping on the hub.
Step 5	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Enabling DMVPN Per-tunnel QoS Sourced from Port Channel

To enable the feature, you must configure the command *platform qos port-channel-aggregate <port-channel number>* before configuring port channel.

The *platform qos port-channel-aggregate <port-channel number>* is required for this feature. The order of the configuration steps are important to enable DMVPN Per-tunnel QoS Sourced from Port-Channel feature. The *platform qos port-channel-aggregate <port-channel number>* command must be configured first. Then, the port-channel interface must be created. Lastly, *channel-group x* command must be applied to member ports.

Both port-channel main-interface and sub-interface are supported in aggregate mode.

Note Before configuring the command, you must remove the 'port channel interface' and 'channel-group' configuration from physical interface.

1. Enable the command *platform qos port-channel-aggregate <port-channel number>* before configuring port channel.
2. Configure per-tunnel QoS.
3. Reset the NHRP registration process to ensure the spokes register now that the new configuration is present on the hub BR. Use the command *show dmvpn detail* to display the NHRP group for each spoke.

Verifying Per-Tunnel QoS for DMVPN

SUMMARY STEPS

1. enable
2. show dmvpn detail
3. show nhrp
4. show nhrp group [group-name]
5. show nhrp group-map [group-name]
6. show policy-map multipoint [tunnel tunnel-interface-number]
7. show tunnel endpoints

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show dmvpn detail Example: Device# show dmvpn detail	Displays detailed Dynamic Multipoint VPN (DMVPN) information for each session, including the Next Hop Server (NHS) and NHS status, crypto session information, and socket details. <ul style="list-style-type: none"> • The output includes the Next Hop Resolution Protocol (NHRP) group received from the spoke and the quality of service (QoS) policy applied to the spoke tunnel.
Step 3	show nhrp Example: Device# show nhrp	Displays the NHRP cache and the NHRP group received from the spoke.
Step 4	show nhrp group [group-name] Example: Device# show nhrp group	Displays NHRP group mapping. <ul style="list-style-type: none"> • The output includes the associated QoS policy name and the list of tunnel endpoints using the QoS policy.
Step 5	show nhrp group-map [group-name] Example: Device# show nhrp group-map group1-parent	Displays the group-to-policy maps configured on the hub and also displays the tunnels on which the QoS policy is applied.
Step 6	show policy-map multipoint [tunnel tunnel-interface-number] Example: Device# show policy-map multipoint tunnel 1	Displays QoS policy details applied to multipoint tunnels.

	Command or Action	Purpose
Step 7	show tunnel endpoints Example: Device# show tunnel endpoints	Displays information about the source and destination endpoints for multipoint tunnels and the QoS policy applied on the spoke tunnel.

Configuration Examples for Per-Tunnel QoS for DMVPN

Example: Configuring an NHRP Group on a Spoke

The following example shows how to configure two Next Hop Resolution Protocol (NHRP) groups on three spokes:

Configuring the First Spoke

```
interface tunnel 1
 ip address 209.165.200.225 255.255.255.224
 no ip redirects
 ip mtu 1400
 ip nhrp authentication testing
 nhrp group spoke_group1
 ip nhrp map 209.165.200.226 203.0.113.1
 ip nhrp map multicast 203.0.113.1
 ip nhrp network-id 172176366
 ip nhrp holdtime 300
 ip tcp adjust-mss 1360
 ip nhrp nhs 209.165.200.226
 tunnel source fastethernet 2/1/1
 tunnel mode gre multipoint
 tunnel protection ipsec profile DMVPN
interface fastethernet 2/1/1
 ip address 203.0.113.2 255.255.255.0
```

Configuring the Second Spoke

```
interface tunnel 1
 ip address 209.165.200.227 255.255.255.224
 no ip redirects
 ip mtu 1400
 ip nhrp authentication testing
 nhrp group spoke_group1
 ip nhrp map 209.165.200.226 203.0.113.1
 ip nhrp map multicast 203.0.113.1
 ip nhrp network-id 172176366
 ip nhrp holdtime 300
 ip tcp adjust-mss 1360
 ip nhrp nhs 209.165.200.226
 tunnel source fastethernet 2/1/1
 tunnel mode gre multipoint
 tunnel protection ipsec profile DMVPN
interface fastethernet 2/1/1
 ip address 203.0.113.3 255.255.255.0
```

Configuring the Third Spoke

```
interface tunnel 1
 ip address 209.165.200.228 255.255.255.224
 no ip redirects
 ip mtu 1400
 ip nhrp authentication testing
 nhrp group spoke_group2
 ip nhrp map 209.165.200.226 203.0.113.1
 ip nhrp map multicast 203.0.113.1
 ip nhrp network-id 172176366
 ip nhrp holdtime 300
 ip tcp adjust-mss 1360
 ip nhrp nhs 209.165.200.226
 tunnel source fastethernet 2/1/1
 tunnel mode gre multipoint
 tunnel protection ipsec profile DMVPN
interface fastethernet 2/1/1
 ip address 203.0.113.4 255.255.255.0
```

Example: Configuring an NHRP Group Attribute on a Spoke

The following example shows how to configure two Next Hop Resolution Protocol (NHRP) groups attributes on two spokes:

Configuring the First Spoke

```
class-map match-any class2
 match ip precedence 5
end
!
policy-map p2
 class class2
  priority percent 60
end
!
interface Tunnel0
 ip address 10.0.0.2 255.255.255.0
 no ip redirects
 ip mtu 1436
 ip nhrp authentication hlthere
 ip nhrp attribute group1
 ip nhrp map group group1 service-policy output p2
 ip nhrp map multicast 172.17.0.1
 ip nhrp map 10.0.0.1 172.17.0.1
 ip nhrp network-id 253
 ip nhrp nhs 10.0.0.1
 ip nhrp registration timeout 600
 ip nhrp cache non-authoritative
 no ip mroute-cache
 tunnel source 172.17.0.2
 tunnel mode gre multipoint
 tunnel key 253
 tunnel protection ipsec profile dmvpn-profile
end
```

Configuring the Second Spoke

```
class-map match-any class1
 match ip precedence 5
```

```

policy-map policy p1
  class class1
    priority 70

interface Tunnel0
  ip address 10.0.0.1 255.255.255.0
  no ip redirects
  ip mtu 1436
  ip nhrp authentication hlthere
  ip nhrp attribute group1
  ip nhrp map group group1 service-policy output p1
  ip nhrp map multicast 172.17.0.2
  ip nhrp map 10.0.0.2 172.17.0.2
  ip nhrp network-id 253
  ip nhrp nhs 10.0.0.2
  ip nhrp registration timeout 600
  ip nhrp cache non-authoritative
  no ip mroute-cache
  tunnel source 172.17.0.1
  tunnel mode gre multipoint
  tunnel key 253
  tunnel protection ipsec profile dmvpn-profile
end

```

Example: Mapping an NHRP Group to a QoS Policy on the Hub

The following example shows how to map Next Hop Resolution Protocol (NHRP) groups to a quality of service (QoS) policy on the hub. The example shows a hierarchical QoS policy (parent: group1_parent/group2_parent; child: group1/group2) that will be used for configuring Per-tunnel QoS for Dynamic Multipoint VPN (DMVPN) feature. The example also shows how to map the NHRP group spoke_group1 to the QoS policy group1_parent and map the NHRP group spoke_group2 to the QoS policy group2_parent on the hub:

```

class-map match-all group1_Routing
  match ip precedence 6
class-map match-all group2_Routing
  match ip precedence 6
class-map match-all group2_voice
  match access-group 100
class-map match-all group1_voice
  match access-group 100
policy-map group1
  class group1_voice
    priority 1000
  class group1_Routing
    bandwidth percent 20
policy-map group1_parent
  class class-default
    shape average 3000000
  service-policy group1
policy-map group2
  class group2_voice
    priority percent 20
  class group2_Routing
    bandwidth percent 10
policy-map group2_parent
  class class-default
    shape average 2000000
  service-policy group2

```

```

interface tunnel 1
 ip address 209.165.200.225 255.255.255.224
 no ip redirects
 ip mtu 1400
 ip nhrp authentication testing
 ip nhrp map multicast dynamic
 ip nhrp map group spoke_group1 service-policy output group1_parent
 ip nhrp map group spoke_group2 service-policy output group2_parent
 ip nhrp network-id 172176366
 ip nhrp holdtime 300
 ip nhrp registration unique
 tunnel source fastethernet 2/1/1
 tunnel mode gre multipoint
 tunnel protection ipsec profile DMVPN
interface fastethernet 2/1/1
 ip address 209.165.200.226 255.255.255.224

```

Example: Enabling DMVPN Per-tunnel QoS Sourced from Port Channel

The following example shows how to enable DMVPN Per-tunnel QoS Sourced from Port Channel.

Example: Configuring on hub

```

platform qos port-channel-aggregate 1
!
class-map match-any class2
match ip precedence 5
!
policy-map p1
class class2
  priority percent 60
!
interface Port-channel1
 ip address 203.0.113.1 255.255.255.0
!
interface GigabitEthernet0/0/0
 channel-group 1
!
interface GigabitEthernet0/0/1
 channel-group 1
!
interface Tunnell
 ip address 10.9.9.1 255.255.255.0
 no ip redirects
 ip nhrp authentication cisco
 nhrp map group group1 service-policy output p1
 ip nhrp map multicast dynamic
 ip nhrp network-id 1
 tunnel source Port-channel 1
 tunnel mode gre multipoint

```

Example: Configuring on spoke

```

platform qos port-channel-aggregate 1
!
interface Port-channel1
 ip address 203.0.113.100 255.255.255.0
!
interface GigabitEthernet0/0/0
 channel-group 1
!
interface GigabitEthernet0/0/1

```

```

channel-group 1
!
interface Tunnel1
ip address 10.9.9.11 255.255.255.0
no ip redirects
ip nhrp authentication cisco
ip nhrp map 10.9.9.1 203.0.113.1
ip nhrp map multicast 203.0.113.1
ip nhrp network-id 1
ip nhrp nhs 10.9.9.1
tunnel source Port-channel 1
nhrp group group1
tunnel mode gre multipoint

```

Example: Verifying Per-Tunnel QoS for DMVPN

The following example shows how to display the information about Next Hop Resolution Protocol (NHRP) groups received from the spokes and display the quality of service (QoS) policy that is applied to each spoke tunnel. You can enter this command on the hub.

```
Device# show dmvpn detail
```

```

Legend: Attrb --> S - Static, D - Dynamic, I - Incomplete
        N - NATed, L - Local, X - No Socket
        # Ent --> Number of NHRP entries with same NBMA peer
        NHS Status: E --> Expecting Replies, R --> Responding
        UpDn Time --> Up or Down Time for a Tunnel

Pending DMVPN Sessions:

```

The following example shows how to display information about the NHRP groups that are received from the spokes. You can enter this command on the hub.

```

Device# show ip nhrp

192.0.2.240/32 via 192.0.2.240
  Tunnel1 created 00:22:49, expire 00:01:40
  Type: dynamic, Flags: registered
  NBMA address: 209.165.200.227
  Group: spoke_group1
192.0.2.241/32 via 192.0.2.241
  Tunnel1 created 00:22:48, expire 00:01:41
  Type: dynamic, Flags: registered
  NBMA address: 209.165.200.228
  Group: spoke_group1
192.0.2.242/32 via 192.0.2.242
  Tunnel1 created 00:22:52, expire 00:03:27
  Type: dynamic, Flags: registered
  NBMA address: 209.165.200.229
  Group: spoke_group2

```

The following example shows how to display the details of NHRP group mappings on a hub and the list of tunnels using each of the NHRP groups defined in the mappings. You can enter this command on the hub.

```

Device# show nhrp group-map

Interface: tunnel1
  NHRP group: spoke_group1
  QoS policy: group1_parent
  Tunnels using the QoS policy:
  Tunnel destination overlay/transport address
  198.51.100.220/203.0.113.240
  198.51.100.221/203.0.113.241
  NHRP group: spoke_group2
  QoS policy: group2_parent
  Tunnels using the QoS policy:
  Tunnel destination overlay/transport address
  198.51.100.222/203.0.113.242

```

The following example shows how to display statistics about a specific QoS policy as it is applied to a tunnel endpoint. You can enter this command on the hub.

```

Device# show policy-map multipoint

Interface tunnel1 <--> 203.0.113.252
  Service-policy output: group1_parent
  Class-map: class-default (match-any)
  29 packets, 4988 bytes
  5 minute offered rate 0 bps, drop rate 0 bps

```

```

Feature Information for Per-Tunnel QoS for DMVPN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 285: Feature Information for Per-Tunnel QoS for DMVPN

Feature Name	Releases	Feature Information
Per-Tunnel QoS	15.4(1)T / 3.11S	<p>In , this feature was enhanced to provide support for IPv6 addresses.</p> <p>The following commands were introduced or modified: ip nhrp map, nhrp group, nhrp map group, show dmvpn, show ip nhrp, show ip nhrp group-map, show nhrp group-map, show policy-map multipoint tunnel.</p> <p>The commands ip nhrp group and ip nhrp map group were deprecated and hidden in the CLI. They are replaced with protocol agnostic nhrp group and nhrp map group. The configuration needs to be manually migrated to the new syntax.</p>
	16.6.5, 16.8.1	The commands ip nhrp group and ip nhrp map group are removed from CLI. Manual migration before or after upgrade is required.
QoS: Spoke to Spoke Per-tunnel QoS for DMVPN		<p>The following commands were introduced or modified: nhrp attribute group, show dmvpn, show ip nhrp.</p> <p>Note The command show ip nhrp group is deprecated and is not in use.</p>
QoS: DMVPN Per-tunnel QoS over Aggregate GEC	Cisco IOS XE Everest 16.4.1	The QoS: DMVPN Per-tunnel QoS over Aggregate GEC feature is supported.

CHAPTER 214

Configuring TrustSec DMVPN Inline Tagging Support

The TrustSec DMVPN Inline Tagging Support feature enables IPsec to carry the Cisco TrustSec (CTS) Security Group Tag (SGT) between IPsec peers.

- [Prerequisites for Configuring TrustSec DMVPN Inline Tagging Support, on page 2815](#)
- [Restrictions for Configuring TrustSec DMVPN Inline Tagging Support, on page 2815](#)
- [Information About Configuring TrustSec DMVPN Inline Tagging Support, on page 2816](#)
- [How to Configure TrustSec DMVPN Inline Tagging Support, on page 2818](#)
- [Configuration Examples for TrustSec DMVPN Inline Tagging Support, on page 2821](#)
- [Additional References for TrustSec DMVPN Inline Tagging Support, on page 2825](#)
- [Feature Information for TrustSec DMVPN Inline Tagging Support, on page 2826](#)

Prerequisites for Configuring TrustSec DMVPN Inline Tagging Support

Internet Key Exchange Version 2 (IKEv2) and IPsec must be configured on the router. For more information, see the “*Configuring Internet Key Exchange Version 2 and FlexVPN Site-to-Site*” and “*Configuring Security for VPNs with IPsec*” modules.

Restrictions for Configuring TrustSec DMVPN Inline Tagging Support

The TrustSec DMVPN Inline Tagging Support feature via IKEv2 supports the following:

- Dynamic Virtual Tunnel Interface (dVTI)
- GRE with Tunnel Protection
- Site-to-site VPNs
- Static crypto maps
- Static Virtual Tunnel Interface (sVTI)

The TrustSec DMVPN Inline Tagging Support feature does not support the following:

- Cisco AnyConnect
- Cisco VPNClient
- DMVPN with IKEv1
- EasyVPN
- FlexVPN
- GetVPN
- IKEv1 IPsec methods
- SSLVPN

crypto ikev2 cts sgt and **cts sgt inline** commands on tunnel are two different features. Do not configure these two features together as it causes the packets getting tagged twice. These commands are also not supported when the DMVPN is configured on MPLS using IKEv2.

cts sgt inline command does not rely on crypto or IKEv2. It can be configured statically or by NHRP. **cts sgt inline** command works with DMVPN IPSEC tunnel and also in transport mode.

The TrustSec DMVPN Inline Tagging Support feature via the **cts sgt inline** command is supported on all combinations of DMVPN (IKEv1, IKEv2, non-crypto, crypto accelerators such as ISM-VPN, point-to-point, multipoint) except when running MPLS (as an MPLS cloud extension or as MPLS L3VPN) over DMVPN.

Information About Configuring TrustSec DMVPN Inline Tagging Support

Cisco TrustSec

The Cisco TrustSec (CTS) architecture helps to build secure networks by establishing a domain of trusted network devices by combining identity, trust, and policy to protect user transactions and enforce role-based policies. CTS uses the user and the device identification information acquired during the authentication phase to classify packets as they enter the network. CTS maintains a classification of each packet by tagging packets on ingress to the CTS network so that they can be properly identified for applying security and other policy criteria along the data path. The packets or frames are tagged using the Security Group Tag (SGT), which allows network intermediaries such as switches and firewalls, to enforce an access control policy based on the classification.

The IPsec Inline Tagging for TrustSec feature is used to propagate the SGT to other network devices.

Note If this feature is not supported, you can use the SGT Exchange Protocol over TCP (SXP) feature.

For more information on CTS and SXP, see the [Cisco TrustSec Switch Configuration Guide](#).

SGT and IPsec

IPsec uses the IKE protocol for negotiating algorithms, keys, and capabilities. IKEv2 is used to negotiate and inform IPsec about the SGT capability. Once the peers acknowledge the SGT tagging capability, an SGT tag number (a 16-bit) is added as the SGT Cisco Meta Data (CMD) payload into IPsec and sent to the receiving peer.

The access layer device authenticates the incoming packets. The access layer device receives an SGT from the authentication server and assigns the SGT along with an IP address to the incoming packets. In other words, an IP address is bound to an SGT. This IP address/SGT binding is propagated to upstream devices to enforce SGT-based policy and inline tagging.

If IKEv2 is configured to negotiate the SGT capability in the initiator, the initiator proposes the SGT capability information in the SA_INIT request. If IKEv2 is configured to negotiate the SGT capability in the responder, the responder acknowledges in the SA_INIT response and the initiator and the responder inform IPsec to use inline tagging for all packets to the peer.

During egress, IPsec adds the SGT capability and prefixes to the IPsec payload if the peer supports inline tagging; otherwise the packet is not tagged.

During ingress, IPsec inspects the packet for the SGT capability. If a tag is available, IPsec extracts the tag information and passes the information to the device only if inline tagging is negotiated. If there is no tag, IPsec processes the packet as a normal packet.

The tables below describe how IPsec behaves during egress and ingress.

Table 286: IPsec Behavior on the Egress Path

Inline Tagging Negotiated	CTS Provides SGT	IPsec Behavior
Yes	Yes	An SGT CMD is added to the packet.
Yes	No	The packet is sent without the SGT CMD.
No	Yes or no	The packet is sent without the SGT CMD.

Table 287: IPsec Behavior on the Ingress Path

Packet Is Tagged	Inline Tagging Negotiated	IPsec Behavior
Yes	Yes	The SGT CMD in the packet is processed.
Yes	No	The SGT CMD in the packet is not processed.
No	Yes or no	The packet is processed as a normal IPsec packet.

SGT on the IKEv2 Initiator and Responder

To enable SGT on an IKEv2 session, the SGT capability support must be sent to the peers using the **crypto ikev2 cts** command. SGT is a Cisco proprietary capability; hence, it is sent as a Vendor ID (VID) payload in the SA_INIT exchange.

The table below explains the scenarios when SGT capability is configured on the initiator and the responder:

Table 288: SGT Capability on IKEv2 Initiator and Responder

SGT Enabled on Initiator	SGT Enabled on Responder	What Happens . . .
Yes	Yes	The VID is exchanged between the initiator and the responder, and IPsec SA is enabled with the SGT inline tagging capability.
Yes	No	The initiator proposes the VID, but the responder ignores the VID. IPsec SA is not enabled with the SGT inline tagging capability.
No	Yes	The initiator does not propose the VID, and the responder does not send the VID payload. IPsec SA is not enabled with the SGT inline tagging capability.
No	No	The initiator does not propose the VID, and responder also does not send the VID payload. IPsec SA is not enabled with the SGT inline tagging capability.

Handling Fragmentation

Fragmentation is handled in the following two ways:

- Fragmentation before IPsec—If IPsec receives fragmented packets, each fragment is tagged.
- Fragmentation after IPsec—If IPsec packets are fragmented after encryption, the first fragment will be tagged.

How to Configure TrustSec DMVPN Inline Tagging Support

Enabling IPsec Inline Tagging

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `interface tunnel tunnel id`
4. `cts sgt inline`
5. `exit`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code> Example: <code>Device> enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>tunnel id</i> Example: Device(config)# interface tunnel 1	Specifies a tunnel interface number, and enters interface configuration mode.
Step 4	cts sgt inline Example: Device(config-if)# cts sgt inline	Enables TrustSec on DMVPN. This command is valid for generic routing encapsulation (GRE) and to tunnel interfaces modes only.
Step 5	exit Example: Device(config)# exit	Exits global configuration mode.

Monitoring and Verifying TrustSec DMVPN Inline Tagging Support

To monitor and verify the TrustSec DMVPN Inline Tagging Support configuration, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **show dmvpn**
3. **show ip nhrp nhs detail**
4. **show tunnel endpoints**
5. **show adjacency *interface-type interface-number detail***

DETAILED STEPS

Step 1 enable

Example:

```
Device> enable
```

Enables privileged EXEC mode.

Step 2 show dmvpn

Example:

```
Device# show dmvpn
```

```
Legend: Attrb --> S - Static, D - Dynamic, I - Incomplete
N - NATed, L - Local, X - No Socket
T1 - Route Installed, T2 - Nexthop-override
C - CTS Capable
# Ent --> Number of NHRP entries with same NBMA peer
```

```
NHS Status: E --> Expecting Replies, R --> Responding, W --> Waiting
UpDn Time --> Up or Down Time for a Tunnel
```

```
Interface: Tunnel0, IPv4 NHRP Details
Type:Spoke, NHRP Peers:1,
```

```
# Ent Peer NBMA Addr Peer Tunnel Add State UpDn Tm Attrb
-----
1 1.1.1.99 10.1.1.99 UP 00:00:01 SC
```

Use this command to display Dynamic Multipoint VPN (DMVPN)-specific session information.

Step 3 show ip nhrp nhs detail

Example:

```
Device# show ip nhrp nhs detail
```

```
Legend: E=Expecting replies, R=Responding, W=Waiting
```

```
Tunnel0:
```

```
10.1.1.99 RE NBMA Address: 1.1.1.99 priority = 0 cluster = 0 req-sent 44 req-failed 0 repl-recv
43 (00:01:37 ago)
TrustSec Enabled
```

Use this command to display Next Hop Resolution Protocol (NHRP) next hop server (NHS) information.

Step 4 show tunnel endpoints

Example:

```
Device# show tunnel endpoints
```

```
Tunnel0 running in multi-GRE/IP mode
```

```
Endpoint transport 1.1.1.99 Refcount 3 Base 0xF3FB79B4 Create Time 00:03:15
overlay 10.1.1.99 Refcount 2 Parent 0xF3FB79B4 Create Time 00:03:15
```

```
Tunnel Subblocks:
```

```
tunnel-nhrp-sb:
```

```
NHRP subblock has 1 entries; TrustSec enabled
```

Use this command to display the contents of the tunnel endpoint database that is used for tunnel endpoint address resolution, when running a tunnel in multipoint generic routing encapsulation (mGRE) mode.

Step 5 show adjacency interface-type interface-number detail

Example:

```
Device# show adjacency tunnel0 detail
```

```
Protocol Interface Address
IP Tunnel0 10.1.1.99(2)
0 packets, 0 bytes
epoch 0
sourced in sev-epoch 1
Encap length 32
4500000000000000FF2FB76901010101
01010163000089090800010100010000
Tun endpt
Next chain element:
.
.
.
```

Use this command to display information about the protocol.

Enabling IPsec Inline Tagging on IKEv2 Networks

Configuring the `cts sgt inline` and `crypto ikev2 cts sgt` commands results in the packets getting tagged twice - once each by each command.

Before you begin

IKEv2 and IPsec must be configured.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto ikev2 cts sgt`
4. `exit`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<code>enable</code> Example: <code>Device> enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	<code>configure terminal</code> Example: <code>Device# configure terminal</code>	Enters global configuration mode.
Step 3	<code>crypto ikev2 cts sgt</code> Example: <code>Device(config)# crypto ikev2 cts sgt</code>	Enables TrustSec on DMVPN on IKEv2 networks. This command is valid for generic routing encapsulation (GRE) and to tunnel interfaces modes only.
Step 4	<code>exit</code> Example: <code>Device(config)# exit</code>	Exits global configuration mode.

Configuration Examples for TrustSec DMVPN Inline Tagging Support

Example: Enabling IPsec Inline Tagging on IKEv2 Networks

Static VTI Initiator Configuration

The following example shows how to enable IPsec inline tagging on a static VTI initiator. You can use this configuration for configuring crypto maps and VTIs.

Feature Information for TrustSec DMVPN Inline Tagging Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Information About Spoke-to-Spoke NHRP Summary Maps

Spoke-to-Spoke NHRP Summary Maps

In DMVPN phase 3, route summarization is performed at a hub. The hub is the next-hop for any spoke to reach any network behind a spoke. On receiving a packet, the hub sends a redirect message to a local spoke and indicates the local spoke to send Next Hop Resolution Protocol (NHRP) resolution request for the destination network. The resolution request is forwarded by the hub to a remote spoke with the destination LAN network. The remote spoke responds to the resolution request and initiates a tunnel with the local spoke.

When a spoke answers an NHRP resolution request for a local host, it uses the explicit IP address network and subnet mask from the Routing Information Base (RIB) in response. Multiple networks behind a local spoke require similar NHRP messages for a host behind remote spoke to exchange packets with the hosts in these networks. It is difficult to handle NHRP messages for a huge number of spokes and large networks behind each spoke.

The number of NHRP messages between spokes can be limited when the first NHRP resolution reply provides information about the network behind a local spoke instead of a specific network. The spoke-to-spoke NHRP summary map uses the configured IP address network and subnet mask in the NHRP resolution response instead of the IP address network and subnet mask from RIB. If RIB has more number of IP address networks (lesser subnet mask length) than the configured IP address network and subnet mask, the spoke still uses the configured IP address network and subnet mask for NHRP resolution response thereby summarizing and

reducing the NHRP resolution traffic on the network. Use the **ip nhrp summary-map** command to configure NHRP summary map on a spoke.

Note In DMVPN, it is recommended to configure a Rendezvous Point (RP) at or behind the hub. If there is an IP multicast source behind a spoke, the **ip pim spt-threshold infinity** command must be configured on spokes to avoid multicast traffic going through spoke-to-spoke tunnels.

How Spoke-to-Spoke NHRP Summary Maps Works

On receiving the resolution request, the spoke

1. Looks into the RIB for the IP address and subnet mask and returns.
2. Checks the IP address and subnet mask against the configured NHRP summary map and verifies if the destination IP address is covered.
3. Sends the summary map in the NHRP resolution reply to the remote spoke and NHRP on the remote spoke adds the IP address and subnet mask with the next-hop of the local spoke to the RIB.

The entire network behind the local spoke is identified to the remote spoke with one NHRP resolution request.

The following figure shows the working of spoke-to-spoke NHRP summary maps.

Figure 111: Spoke-to-Spoke NHRP Summary Maps

A local spoke with the address space 192.0.0.0/19 on its local LAN has all 32-24 RIB entries – 192.0.0.0/24, ..., 192.0.31.0/24. When a routing protocol like EIGRP is used to advertise this local address space, the routing protocol is configured to summarize the networks to 192.0.0.0/19 and advertise that to the hub. The hub summarizes this further, to 192.0.0.0/16, when it advertises it to the other spokes. The other spokes start with only a 192.0.0.0/16 routing table entry with the next-hop of the hub in the RIB.

If a remote host communicates with 192.0.12.1, the local spoke receives the NHRP resolution request for 192.0.12.1/32. It looks into the RIB and returns 192.0.12.0/24 in NHRP resolution reply.

If the local spoke is configured with NHRP summary map for eg. "ip nhrp summary-map 192.0.0.0/19", the local spoke upon receiving the resolution request for 192.0.12.1 checks the RIB which returns 192.0.12.0/24. The local spoke then checks for summary map configuration 192.0.0.0/19 and verifies if the destination 192.0.12.1/32 is covered and returns 192.0.0.0/19 in NHRP resolution reply.

NHRP Summary Map Support for IPv6 Overlay

Spoke-to-spoke NHRP summary maps feature is supported on IPv6 and is configured using **ipv6 nhrp summary-map** command.

Information About NHRP Default Maps

NHRP Default Maps

A default-map specifies the default forwarding and encapsulation that is used in the absence of a better match. When you send a registration request, for easy provisioning, an NHRP default-map is pushed as a special summary map from the hub (NHS) as part of the registration reply. This is specified by configuring the **ip nhrp summary-map <Prefix> <IPv4/IPv6 NBMA Address>** command on the NHS. The prefix is the network for which default-maps have to be pushed to the NHCs and the NBMA address is the address of the data plane hub (same as the control plane hub for collocated case).

Also, as a part of the registration reply, you can configure the NHCs as neighbors (**neighbor nhc Tunnel<number>**). In addition, you can push any network that is configured locally or the networks imported from other protocols as part of redistribution to subscribing spokes. This allows the system to monitor these networks and notify the spokes when there is any change in the NHSs LAN side networks.

When you use NHCs as neighbors instead of summary-map along with redistribution from another routing protocol on the LAN side (OSPF), it is recommended to use route filters while redistributing into NHRP (e.g. from OSPF). NHRP routes use a default tag of the network-id of the interface to learn the route/mapping. You can filter the in-bound route redistribution into NHRP based on these or any other tag that is configured explicitly when the network was originally redistributed from NHRP (e.g. into OSPF). Also, you can use other redistribution filtering mechanisms to avoid a loop where another routing protocol imports routes from NHRP and exports them back to NHRP.

Alternatively, the NHS may choose not to specify any NBMA address for a specific prefix or network. In this case, the NHCs is expected to resolve addresses covered by the prefix. This becomes a hub-less model (no data plane hub) and can be set up by using the **resolve** keyword in the summary-map configuration **ip nhrp summary-map <Prefix> resolve**. An NHS may use a mix of both kinds of summary and default maps to provide a default forwarding path for some subnets (till more specific mapping information is learnt, often through resolution), while forcing a resolution for other subnets.

How to Configure Spoke-to-Spoke NHRP Summary Maps

Configuring Spoke-to-Spoke NHRP Summary Maps on Spoke

Note The following task can be performed to configure the spoke device.

SUMMARY STEPS

1. **enable**

2. **configure terminal**
3. **interface tunnel** *number*
4. **ip address** *ip-address mask secondary ip-address mask*
5. **ip nhrp authentication** *string*
6. **ip nhrp summary-map** {*ip-address* | *mask*}
7. **ip nhrp network-id** *number*
8. **ip nhrp nhs** [*hub-tunnel-ip-address*] **nbma** [*hub-wan--ip*] **multicast**
9. **ip nhrp shortcut**
10. **tunnel source** {*ip-address* | *type number*}
11. **tunnel mode gre multipoint**
12. **tunnel key** *key-number*
13. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 5	Configures a tunnel interface and enters interface configuration mode. <ul style="list-style-type: none"> • <i>number</i>—Specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ip address <i>ip-address mask secondary ip-address mask</i> Example: Device(config-if)# ip address 10.0.0.2 255.255.255.0	Sets a primary or secondary IP address for the tunnel interface. <p>Note All hubs and spokes that are in the same DMVPN network must be addressed in the same IP subnet.</p>
Step 5	ip nhrp authentication <i>string</i> Example: Device(config-if)# ip nhrp authentication donttell	Configures an authentication string for an interface using NHRP.
Step 6	ip nhrp summary-map { <i>ip-address</i> <i>mask</i> } Example:	Summarizes and reduces the NHRP resolution traffic on the network.

	Command or Action	Purpose
	Device(config-if)# ip nhrp summary-map 10.0.0.0/24	
Step 7	ip nhrp network-id <i>number</i> Example: Device(config-if)# ip nhrp network-id 99	Enables NHRP on an interface. <ul style="list-style-type: none"> • <i>number</i>—Specifies a globally unique 32-bit network identifier from a nonbroadcast multiaccess (NBMA) network.
Step 8	ip nhrp nhs [<i>hub-tunnel-ip-address</i>] nbma [<i>hub-wan--ip</i>] multicast Example: Device(config-if)# ip nhrp nhs 10.0.0.1 nbma 172.17.0.1 multicast	Configures the hub router as the NHRP next-hop server.
Step 9	ip nhrp shortcut Example: Device(config-if)# ip nhrp shortcut	Enables NHRP shortcut switching.
Step 10	tunnel source { <i>ip-address</i> <i>type number</i> } Example: Device(config-if)# tunnel source Gigabitethernet 0/0/0	Sets the source address for a tunnel interface.
Step 11	tunnel mode gre multipoint Example: Device(config-if)# tunnel mode gre multipoint	Sets the encapsulation mode to Multiple Generic Routing Encapsulation (mGRE) for the tunnel interface. <ul style="list-style-type: none"> • Use this command if data traffic can use dynamic spoke-to-spoke traffic.
Step 12	tunnel key <i>key-number</i> Example: Device(config-if)# tunnel key 100000	(Optional) Enables an ID key for a tunnel interface. <ul style="list-style-type: none"> • <i>key-number</i>—Specifies a number to identify a tunnel key. This must be set to the same value on all hubs and spokes that are in the same DMVPN network.
Step 13	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Verifying Spoke-to Spoke NHRP Summary Maps

SUMMARY STEPS

1. enable

2. show ip nhrp

DETAILED STEPS

Step 1 enable

Example:

```
Device> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 show ip nhrp

Example:

The following is an example of show command output on spoke.

```
Device# show ip nhrp

15.0.0.1/32 (vrf1) via 15.0.0.1
  Tunnel3 created 09:09:00, never expire
  Type: static, Flags: used
  NBMA address: 123.0.0.1
15.0.0.20/32 (vrf1) via 15.0.0.20
  Tunnel3 created 00:00:54, expire 00:04:05
  Type: dynamic, Flags: router nhop rib
  NBMA address: 42.0.0.1
190.0.0.0/22 (vrf1) via 15.0.0.10
  Tunnel3 created 09:09:00, never expire
  Type: static, Flags: local
  NBMA address: 121.0.0.1
  (no-socket)
201.0.0.0/22 (vrf1) via 15.0.0.20
  Tunnel3 created 00:00:54, expire 00:04:05
  Type: dynamic, Flags: router rib nho
  NBMA address: 42.0.0.1
```

Displays Next Hop Resolution Protocol (NHRP) mapping information.

Troubleshooting Spoke-to-Spoke NHRP Summary Maps

SUMMARY STEPS

1. debug dmvpn all nhrp

DETAILED STEPS

```
debug dmvpn all nhrp
```

Checks the IP address and subnet mask received by the spoke for a resolution request.

Example:

```
Device# debug dmvpn all nhrp

NHRP-RT: Attempting to create instance PDB for vrf global(0x0) (0x0)
NHRP-CACHE: Tunnel0: Cache add for target 67.0.0.1/32 vrf global(0x0) label none next-hop 67.0.0.1

NHRP-CACHE: Tunnel0: Cache add for target 67.0.0.0/24 vrf global(0x0) label none next-hop 15.0.0.30
80.0.0.1
NHRP-CACHE: Inserted subblock node(2 now) for cache: Target 67.0.0.0/24 nhop 15.0.0.30
NHRP-CACHE: Converted internal dynamic cache entry for 67.0.0.0/24 interface Tunnel0 vrf global(0x0)
to external
NHRP-RT: Adding route entry for 67.0.0.0/24 (Tunnel0 vrf:global(0x0)) to RIB
NHRP-RT: Route addition to RIB Successful
NHRP-RT: Route watch started for 67.0.0.0/23
NHRP-CACHE: Updating label on Tunnel0 for 15.0.0.30 vrf global(0x0), old none new none nhop 15.0.0.30

NHRP-CACHE: Deleting incomplete entry for 67.0.0.1/32 interface Tunnel0 vrf global(0x0)
NHRP-CACHE: Still other cache entries with same overlay nhop 67.0.0.1
NHRP-RT: Received route watch notification for 67.0.0.0/24
NHRP-RT: Covering prefix is 67.0.0.0/22
NHRP-RT: Received route watch notification for 67.0.0.0/24
NHRP-RT: (0x0):NHRP RIB entry for 67.0.0.0/24 is unreachable
```

Configuration Examples for Spoke-to-Spoke NHRP Summary Maps

Example: Spoke-to-Spoke NHRP Summary Maps

Example: Spoke-to-Spoke NHRP Summary Maps

The following is an example of configuring DMVPN phase 3 on hub for summary map .

```
interface Tunnel0
 ip address 15.0.0.1 255.255.255.0
 no ip redirects
 no ip split-horizon eigrp 2
 ip nhrp authentication cisco123
 ip nhrp network-id 23
 ip nhrp redirect
 ip summary-address eigrp 2 190.0.0.0 255.255.252.0
 ip summary-address eigrp 2 201.0.0.0 255.255.252.0
 tunnel source GigabitEthernet1/0/0
 tunnel mode gre multipoint
 tunnel key 6
end
```

The following example shows how to configure spoke-to-spoke NHRP summary maps on spoke 1.

```
interface Tunnel0
 vrf forwarding vrf1
 ip address 15.0.0.10 255.255.255.0
 ip nhrp authentication cisco123
 ip nhrp summary-map 190.0.0.0/22
 ip nhrp network-id 5
 ip nhrp nhs 15.0.0.1 nbma 123.0.0.1 multicast
 ip nhrp shortcut
 tunnel source GigabitEthernet0/1/0
 tunnel mode gre multipoint
 tunnel key 6
end
```

The following example shows how to configure spoke-to-spoke NHRP summary maps on spoke 2.

```
interface Tunnel0
 ip address 15.0.0.20 255.255.255.0
 ip nhrp authentication cisco123
 ip nhrp summary-map 201.0.0.0/22
 ip nhrp network-id 5
 ip nhrp nhs 15.0.0.1 nbma 123.0.0.1 multicast
 ip nhrp shortcut
 tunnel source GigabitEthernet0/0/0
 tunnel mode gre multipoint
 tunnel key 6
end
```

The following is a sample output of the show ip nhrp command on the hub.

```
Device# show ip nhrp
15.0.0.10/32 via 15.0.0.10
 Tunnel0 created 00:22:26, expire 00:07:35
 Type: dynamic, Flags: registered used nhop
 NBMA address: 41.0.0.1
15.0.0.20/32 via 15.0.0.20
 Tunnel0 created 00:13:43, expire 00:09:36
 Type: dynamic, Flags: registered used nhop
 NBMA address: 42.0.0.1
```

The following is a sample output of the show ip nhrp command on spoke 1.

```
Device# show ip nhrp
15.0.0.1/32 (vrf1) via 15.0.0.1
 Tunnel3 created 09:09:00, never expire
 Type: static, Flags: used
 NBMA address: 123.0.0.1
15.0.0.20/32 (vrf1) via 15.0.0.20
 Tunnel3 created 00:00:54, expire 00:04:05
 Type: dynamic, Flags: router nhop rib
 NBMA address: 42.0.0.1
190.0.0.0/22 (vrf1) via 15.0.0.10
 Tunnel3 created 09:09:00, never expire
```

```
Type: static, Flags: local
NBMA address: 121.0.0.1
(no-socket)
201.0.0.0/22 (vrf1) via 15.0.0.20
Tunnel3 created 00:00:54, expire 00:04:05
Type: dynamic, Flags: router rib nho
NBMA address: 42.0.0.1
```

The following is a sample output of the show ip nhrp command on spoke 2.

```
Device# show ip nhrp

15.0.0.1/32 via 15.0.0.1
Tunnel0 created 09:08:16, never expire
Type: static, Flags: used
NBMA address: 123.0.0.1
15.0.0.10/32 via 15.0.0.10
Tunnel0 created 00:00:04, expire 01:59:55
Type: dynamic, Flags: router nhop rib
NBMA address: 121.0.0.1
190.0.0.0/22 via 15.0.0.10
Tunnel0 created 00:00:04, expire 01:59:55
Type: dynamic, Flags: router rib nho
NBMA address: 121.0.0.1
201.0.0.0/22 via 15.0.0.20
Tunnel0 created 09:08:16, never expire
Type: static, Flags: local
NBMA address: 42.0.0.1
(no-socket)
```

How to Configure NHRP for Tunnel Setup

Configure NHRP for Tunnel Setup

To set up the tunnel for configuring NHRP:

- [Configuring NHRP for Tunnel on Hub1](#)
- [Configuring NHRP for Tunnel on Hub2](#)
- [Configuring NHRP for Tunnel on a Spoke](#)

Configuring NHRP for Tunnel on Hub1

Note The following task can be performed to configure the NHRP for tunnel on a hub.

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **interface tunnel** *number*
4. **ip address** *ip-address mask secondary ip-address mask*
5. **ip nhrp network-id** *number*
6. **ip nhrp redirect interest** *<acl_num/acl_name>*
7. **tunnel source** *{ip-address | type number}*
8. **tunnel mode gre multipoint**
9. **tunnel key** *key-number*
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 0	Configures a tunnel interface and enters interface configuration mode. • <i>number</i> —Specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ip address <i>ip-address mask secondary ip-address mask</i> Example: Device(config-if)# ip address 10.0.0.99 255.255.255.0	Sets a primary or secondary IP address for the tunnel interface. Note All hubs and spokes that are in the same DMVPN network must be addressed in the same IP subnet.
Step 5	ip nhrp network-id <i>number</i> Example: Device(config-if)# ip nhrp network-id 1	Enables NHRP on an interface. • <i>number</i> —Specifies a globally unique 32-bit network identifier from a nonbroadcast multiaccess (NBMA) network.
Step 6	ip nhrp redirect interest <i><acl_num/acl_name></i> Example: Device(config-if)# ip nhrp redirect	Enables redirect traffic indication if traffic is forwarded with the NHRP network. From Cisco IOS XE 17.11.1a, a new keyword interest is introduced to configure the interest ACL in AF VRF, if the traffic VRF matches the AF VRF.
Step 7	tunnel source <i>{ip-address type number}</i> Example:	Sets the source address for a tunnel interface.

	Command or Action	Purpose
	Device(config-if)# tunnel source Ethernet 0/0	
Step 8	tunnel mode gre multipoint Example: Device(config-if)# tunnel mode gre multipoint	Sets the encapsulation mode to Multiple Generic Routing Encapsulation (mGRE) for the tunnel interface. <ul style="list-style-type: none"> Use this command if data traffic can use dynamic spoke-to-spoke traffic.
Step 9	tunnel key <i>key-number</i> Example: Device(config-if)# tunnel key 1	(Optional) Enables an ID key for a tunnel interface. <ul style="list-style-type: none"> <i>key-number</i>—Specifies a number to identify a tunnel key. This must be set to the same value on all hubs and spokes that are in the same DMVPN network.
Step 10	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring NHRP for Tunnel on Hub2

Note The following task can be performed to configure the NHRP for tunnel on a hub.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel *number***
4. **ip address *ip-address mask secondary ip-address mask***
5. **ip nhrp network-id *number***
6. **ip nhrp redirect interest *<acl_num/acl_name>***
7. **tunnel source *{ip-address | type number}***
8. **tunnel mode gre multipoint**
9. **tunnel key *key-number***
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 1	Configures a tunnel interface and enters interface configuration mode. <ul style="list-style-type: none"> <i>number</i>—Specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ip address <i>ip-address mask secondary ip-address mask</i> Example: Device(config-if)# ip address 10.0.0.98 255.255.255.0	Sets a primary or secondary IP address for the tunnel interface. Note All hubs and spokes that are in the same DMVPN network must be addressed in the same IP subnet.
Step 5	ip nhrp network-id <i>number</i> Example: Device(config-if)# ip nhrp network-id 2	Enables NHRP on an interface. <ul style="list-style-type: none"> <i>number</i>—Specifies a globally unique 32-bit network identifier from a nonbroadcast multiaccess (NBMA) network.
Step 6	ip nhrp redirect interest <<i>acl_num/acl_name</i>> Example: Device(config-if)# ip nhrp redirect	Enables redirect traffic indication if traffic is forwarded with the NHRP network. From Cisco IOS XE 17.11.1a, a new keyword interest is introduced to configure the interest ACL in AF VRF, if the traffic VRF matches the AF VRF.
Step 7	tunnel source {<i>ip-address</i> <i>type number</i>} Example: Device(config-if)# tunnel source Ethernet 0/0	Sets the source address for a tunnel interface.
Step 8	tunnel mode gre multipoint Example: Device(config-if)# tunnel mode gre multipoint	Sets the encapsulation mode to Multiple Generic Routing Encapsulation (mGRE) for the tunnel interface. <ul style="list-style-type: none"> Use this command if data traffic can use dynamic spoke-to-spoke traffic.
Step 9	tunnel key <i>key-number</i> Example: Device(config-if)# tunnel key 2	(Optional) Enables an ID key for a tunnel interface. <ul style="list-style-type: none"> <i>key-number</i>—Specifies a number to identify a tunnel key. This must be set to the same value on all hubs and spokes that are in the same DMVPN network.
Step 10	end Example:	Exits interface configuration mode and returns to privileged EXEC mode.

	Command or Action	Purpose
	Device(config-if)# end	

Configuring NHRP for Tunnel on a Spoke

Note The following task can be performed to configure the NHRP for tunnel on a spoke.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **ip address** *ip-address mask secondary ip-address mask*
5. **ip nhrp network-id** *number*
6. **ip nhrp nhs dynamic nbma** {*nbma-address* | *FQDN-string*} [**multicast**] [**priority value**] [**cluster value**]
7. **ip nhrp path preference** *value*
8. **tunnel source** {*ip-address* | *type number*}
9. **tunnel mode gre multipoint**
10. **tunnel key** *key-number*
11. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 10	Configures a tunnel interface and enters interface configuration mode. <ul style="list-style-type: none"> • <i>number</i>—Specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ip address <i>ip-address mask secondary ip-address mask</i> Example:	Sets a primary or secondary IP address for the tunnel interface.

	Command or Action	Purpose
	Device(config-if)# ip address 10.0.0.n 255.0.0.0	Note All hubs and spokes that are in the same DMVPN network must be addressed in the same IP subnet.
Step 5	ip nhrp network-id <i>number</i> Example: Device(config-if)# ip nhrp network-id 1	Enables NHRP on an interface. <ul style="list-style-type: none"> • <i>number</i>—Specifies a globally unique 32-bit network identifier from a nonbroadcast multiaccess (NBMA) network.
Step 6	ip nhrp nhs dynamic nbma { <i>nbma-address</i> <i>FQDN-string</i> } [multicast] [priority value] [cluster value] Example: Router(config-if)# ip nhrp nhs 10.0.0.99 nbma 1.1.1.99 multicast	Registers a spoke to a hub. <ul style="list-style-type: none"> • The NHS protocol address is dynamically fetched by the spoke. <ul style="list-style-type: none"> • ip nhrp nhs dynamic nbma <i>nbma-address</i>--Use this command to register a spoke to a hub using the NHS NBMA IP address. Note You can use the ipv6 nhrp nhs dynamic nbma { <i>nbma-address</i> <i>FQDN-string</i> } [multicast] [priority value] [cluster value] command for registering IPv6 address.
Step 7	ip nhrp path preference <i>value</i> Example: Device(config-if)# ip nhrp path preference 192	
Step 8	tunnel source { <i>ip-address</i> <i>type number</i> } Example: Device(config-if)# tunnel source Ethernet 0/0	Sets the source address for a tunnel interface.
Step 9	tunnel mode gre multipoint Example: Device(config-if)# tunnel mode gre multipoint	Sets the encapsulation mode to Multiple Generic Routing Encapsulation (mGRE) for the tunnel interface. <ul style="list-style-type: none"> • Use this command if data traffic can use dynamic spoke-to-spoke traffic.
Step 10	tunnel key <i>key-number</i> Example: Device(config-if)# tunnel key 1	(Optional) Enables an ID key for a tunnel interface. <ul style="list-style-type: none"> • <i>key-number</i>—Specifies a number to identify a tunnel key. This must be set to the same value on all hubs and spokes that are in the same DMVPN network.
Step 11	end Example: Device(config-if)# end	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring NHRP for Tunnel on a Spoke2

Note The following task can be performed to configure the NHRP for tunnel on a spoke2.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **ip address** *ip-address mask secondary ip-address mask*
5. **ip nhrp network-id** *number*
6. **ip nhrp nhs dynamic nbma** {*nbma-address* | *FQDN-string*} [**multicast**] [**priority** *value*] [**cluster** *value*]
7. **ip nhrp path preference** *value*
8. **tunnel source** {*ip-address* | *type number*}
9. **tunnel mode gre multipoint**
10. **tunnel key** *key-number*
11. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 11	Configures a tunnel interface and enters interface configuration mode. <ul style="list-style-type: none"> • <i>number</i>—Specifies the number of the tunnel interface that you want to create or configure. There is no limit on the number of tunnel interfaces you can create.
Step 4	ip address <i>ip-address mask secondary ip-address mask</i> Example: Device(config-if)# ip address 11.0.0.n 255.0.0.0	Sets a primary or secondary IP address for the tunnel interface. <p>Note All hubs and spokes that are in the same DMVPN network must be addressed in the same IP subnet.</p>
Step 5	ip nhrp network-id <i>number</i>	Enables NHRP on an interface.

	Command or Action	Purpose
	<p>Example:</p> <pre>Device(config-if)# ip nhrp network-id 1</pre>	<ul style="list-style-type: none"> <i>number</i>—Specifies a globally unique 32-bit network identifier from a nonbroadcast multiaccess (NBMA) network.
Step 6	<p>ip nhrp nhs dynamic nbma {<i>nbma-address</i> <i>FQDN-string</i>} [multicast] [priority value] [cluster value]</p> <p>Example:</p> <pre>Router(config-if)# ip nhrp nhs 11.0.0.98 nbma 1.1.1.98 multicast</pre>	<p>Registers a spoke to a hub.</p> <ul style="list-style-type: none"> The NHS protocol address is dynamically fetched by the spoke. <ul style="list-style-type: none"> ip nhrp nhs dynamic nbma <i>nbma-address</i>--Use this command to register a spoke to a hub using the NHS NBMA IP address. <p>Note You can use the ipv6 nhrp nhs dynamic nbma {<i>nbma-address</i> <i>FQDN-string</i>} [multicast] [priority value] [cluster value] command for registering IPv6 address.</p>
Step 7	<p>ip nhrp path preference <i>value</i></p> <p>Example:</p> <pre>Device(config-if)# ip nhrp path preference 64</pre>	
Step 8	<p>tunnel source {<i>ip-address</i> <i>type number</i>}</p> <p>Example:</p> <pre>Device(config-if)# tunnel source Ethernet 0/0</pre>	Sets the source address for a tunnel interface.
Step 9	<p>tunnel mode gre multipoint</p> <p>Example:</p> <pre>Device(config-if)# tunnel mode gre multipoint</pre>	<p>Sets the encapsulation mode to Multiple Generic Routing Encapsulation (mGRE) for the tunnel interface.</p> <ul style="list-style-type: none"> Use this command if data traffic can use dynamic spoke-to-spoke traffic.
Step 10	<p>tunnel key <i>key-number</i></p> <p>Example:</p> <pre>Device(config-if)# tunnel key 2</pre>	<p>(Optional) Enables an ID key for a tunnel interface.</p> <ul style="list-style-type: none"> <i>key-number</i>—Specifies a number to identify a tunnel key. This must be set to the same value on all hubs and spokes that are in the same DMVPN network.
Step 11	<p>end</p> <p>Example:</p> <pre>Device(config-if)# end</pre>	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring Network Registration and Redistribution

You can configure the networks to be registered as part of the router block (global or address-family). These networks can also be learnt as redistributed from another routing process.

Configuring Spoke for Network Registration and Redistribution

To register and redistribute the spoke network:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **router nhrp number**
4. **neighbor nhs tunnel number**
5. **neighbor nhs tunnel number**
6. (Optional) **router ospf process id**
7. (Optional) **redistribute nhrp number tag number**
8. (Optional) **network ip-address wildcard-mask area area-id**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	router nhrp number Example: Device(config-if)# router nhrp 5	Enables NHRP on an interface.
Step 4	neighbor nhs tunnel number Example: Device(config-if)# neighbor nhs Tunnel0	
Step 5	neighbor nhs tunnel number Example: Device(config-if)# neighbor nhs Tunnell	
Step 6	(Optional) router ospf process id Example: Device(config-if)# router nhrp 5	Enables OSPF routing and enters router configuration mode..
Step 7	(Optional) redistribute nhrp number tag number	

	Command or Action	Purpose
	Example: <pre>Device(config-router)# redistribute nhrp 5 tag 55</pre>	
Step 8	(Optional) network <i>ip-address wildcard-mask area area-id</i> Example: <pre>Device(config-router)# network 192.168.2.0 0.0.0.255 area 0</pre>	Defines an interface on which OSPF runs and defines the area ID for that interface.

Configuring Hub for Network Registration and Redistribution

You can configure the hub with just advertising one or more summary mapping information or instruct the spokes to resolve all networks (in the later case, it degenerates into a hub-less model!) using the standard summary-map command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **IP nhrp summary-map** *ip-address ? preference?*
5. **IP nhrp summary-map** *ip-address ? preference?*
6. **IP nhrp summary-map** *ip-address ? preference?*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: <pre>Device(config-if)# interface Tunnel0</pre>	Configures an interface and enters interface configuration mode.

	Command or Action	Purpose
Step 4	IP nhrp summary-map <i>ip-address ? preference?</i> Example: Device(config-router)# ip nhrp summary-map 192.168.0.0/16 1.1.1.99 preference 1	Summarizes and reduces the NHRP resolution traffic on the network.
Step 5	IP nhrp summary-map <i>ip-address ? preference?</i> Example: Device(config-router)# ip nhrp summary-map 192.168.0.0/20 1.1.1.99 preference 16	Summarizes and reduces the NHRP resolution traffic on the network.
Step 6	IP nhrp summary-map <i>ip-address ? preference?</i> Example: Device(config-router)# ip nhrp summary-map 192.168.128.0/20 1.1.1.99 preference 32	Summarizes and reduces the NHRP resolution traffic on the network.

Verifying NHRP Configuration?

SUMMARY STEPS

1. enable
2. show ip routenhrp | begin Gateway

DETAILED STEPS

Step 1 enable

Example:

```
Device> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 show ip routenhrp | begin Gateway

Example:

The following is an example of show command output on hub.

```
Device# show sh ip route nhrp | begin Gateway
```

```

Configuration Examples for Spoke-to-Spoke NHRP Summary Maps

Example: Dual Hub and Dual DMVPN Design

Deploying Dual Data Centers

In this topology, the tunnel configuration is a standard DMVPN tunnel configuration with the hub Datacenter (DC) tunnel which is a multipoint. This DMVPN tunnel configuration is without a routing protocol. The spoke (branch) tunnel can be either point-to-point or multipoint. The spoke and branch routers register their LAN networks (either configured or redistributed from connected or static or another routing protocol) with the hub DC router. The hub router sends back one or more summary routes (configured using summary-map) as a part of the registration reply. These routes can be active-active (ECMP/UCMP) or active-passive and the ratio of preferences governs the load sharing ratio (flow based). This provides both egress load-balancing and ingress traffic engineering behaviour (if all nodes respect the preference). Also, a router can override to use active-passive even if the source says active-active by using the **traffic-share** command in the router mode. In such a case, egress load distribution is governed by local configuration overriding ingress traffic engineering. The common standard routing operations of redistribution, admin distance, filtering(in/out), tagging(local) and so on are available.

Figure 112: Deploying Dual Datacenter

Topology

This sample configuration example shows how to configure the dual datacenters.

```
Example Datacenter 1
crypto ikev2 profile default
match identity remote any
authentication remote pre-share key CISCO
authentication local pre-share key CISCO
```

357394

```

dpd 10 2 periodic
!
crypto ipsec transform-set default esp-gcm 256
!
crypto ipsec profile default
  set ikev2-profile default
!
interface Tunnel0
  ip address 10.0.0.99 255.0.0.0
  ip nhrp summary-map 192.168.0.0/16 172.16.99.1 preference 96
  ip nhrp summary-map 192.169.0.0/16 172.16.99.1 preference 96
  ip nhrp network-id 1
  tunnel source Ethernet0/0
  tunnel mode gre multipoint
  tunnel key 1
  tunnel protection ipsec profile default
!

```

Example Datacenter 2

```

crypto ikev2 profile default
  match identity remote any
  authentication remote pre-share key CISCO
  authentication local pre-share key CISCO
  dpd 10 2 periodic
!
crypto ipsec transform-set default esp-gcm 256
!
crypto ipsec profile default
  set ikev2-profile default
!
interface Tunnel1
  ip address 11.0.0.98 255.0.0.0
  ip nhrp summary-map 192.168.0.0/16 172.16.98.1 preference 32
  ip nhrp summary-map 192.169.0.0/16 172.16.98.1 preference 32
  ip nhrp network-id 2
  ip nhrp path preference 64
  tunnel source Ethernet0/0
  tunnel mode gre multipoint
  tunnel key 2
  tunnel protection ipsec profile default
!

```

Note Note: The summary-map on the hub is relatively static from hub's LAN perspective. For example, spokes may not learn if the LAN side link is down unless there is an inter-router path at the DC. However, it tracks the hub reachability and can be unreachable (on the spokes) when the hub is unreachable. If it is dynamically tracked similar to regular routing, then redistribution along with neighbour command can be used (newer releases) on the hub router. **router nhrp 5 redistribute bgp 99 <<<<< LAN side protocol at DC neighbor nhr Tunnel0!** However, this is not meant to be used for distributing a large number of subnets to the spokes. Also, like any other protocol, care has to be taken while redistributing routes cyclically NHRP > OSPF > NHRP. For example, tag routes while redistributing from NHRP to OSPF so that we can filter them while redistributing back from OSPF to NHRP. For ease of use, NHRP routes are auto-tagged with a value which is the network-id on the interface on which they are learnt.

CHAPTER 216

BFD Support on DMVPN

Bidirectional Forwarding Detection (BFD) support on DMVPN provides fast peer failure detection by sending rapid failure detection notices to the control protocols and reducing overall network convergence time.

- [Prerequisites for BFD Support on DMVPN, on page 2851](#)
- [Restrictions for BFD Support on DMVPN, on page 2851](#)
- [Information About BFD Support on DMVPN, on page 2852](#)
- [How to Configure BFD Support on DMVPN, on page 2852](#)
- [Example: BFD Support on DMVPN, on page 2853](#)
- [Additional References for BFD Support on DMVPN, on page 2857](#)
- [Feature Information for BFD Support on DMVPN, on page 2858](#)

Prerequisites for BFD Support on DMVPN

BFD for DMVPN supports both IPv4 and IPv6 overlay address and is agnostic to transport address family.

For more BFD prerequisites refer [Prerequisites for Bidirectional Forwarding Detection](#)

Restrictions for BFD Support on DMVPN

- NHRP currently acts only on BFD down events and not on up events.
- Both peers must configure BFD to get BFD support. If one of the peers is not configured with BFD, the other peer creates BFD sessions in down or unknown state.
- Before configuring BFD support on DMVPN, in case of point-to-point (P2P) tunnel, next hop server (NHS) must be configured.
- BFD intervals configured on the peers should be the same in the BFD echo mode for spoke to spoke refresh to work as expected.
- A single DMVPN hub with BFD can be scaled to a maximum of 4095 sessions on a Cisco Aggregation Service Router 1000 Series since the number of BFD sessions on these platforms is limited to 4095 currently. Regular methods of scaling DMVPN like clustering, Server Load Balancing (SLB), hierarchical designs, etc. still apply. This does not impact DMVPN scale without BFD.
- For hierarchical DMVPN deployment, BFD sessions cannot be established between spokes of two different regions if they are in disjoint networks.

Information About BFD Support on DMVPN

BFD Operation

BFD provides a low-overhead, short-duration method of detecting failures in the forwarding path between two adjacent routers, including the interfaces, data links, and forwarding planes.

BFD is a detection protocol that is enabled at the interface and protocol levels. Cisco supports BFD asynchronous mode, which depends on the sending of BFD control packets between two systems to activate and maintain BFD neighbor sessions between routers. Therefore, in order for a BFD session to be created, BFD must be configured on both systems (or BFD peers). Once BFD has been enabled on the interfaces and at the router level for the appropriate protocols (NHRP and the routing protocol on overlay), a BFD session is created, BFD timers are negotiated, and the BFD peers will begin to send BFD control packets to each other at the negotiated interval.

Note To enable BFD, it is recommended to use the BFD template configuration and enable the same BFD template under the interface, instead of directly configuring the BFD parameters under the interface.

Benefits of BFD Support on DMVPN

- Faster detection of link failure.
- In non-crypto deployments, spoke can detect hub failure only after NHRP registration timeout but hub cannot detect a spoke failure until cache on hub expires (even though routing can re-converge much earlier). BFD allows for a very fast detection for such a failure.
- BFD validates the forwarding path between non authoritative sessions, for example, in scenarios where the hub is configured to respond on behalf of the spoke.
- BFD validates end-to-end data path including the tunnel unlike IKE keepalives/DPD that doesn't pass through the tunnel.
- BFD probes can be off-loaded.

There is no special NHRP configuration needed for BFD support on DMVPN, enabling BFD on an NHRP enabled interface suffices. For DMVPN configuration, refer [How to Configure Dynamic Multipoint VPN](#).

How to Configure BFD Support on DMVPN

Configuring BFD Support on DMVPN

BFD intervals can be directly configured on tunnel interface as shown below:

```
enable
```

```
configure terminal
interface tunnel1
bfd interval 1000 min_rx 1000 multiplier 5
no echo
```

BFD intervals can also be configured by defining a template and attaching it to the tunnel interface as shown below

```
enable
configure terminal
bfd-template single-hop sample
interval min-tx 1000 min-rx 1000 multiplier 5
interface tunnel1
bfd template sample
```

Example: BFD Support on DMVPN

Example: BFD Support on DMVPN

The following is an example of configuring BFD support on DMVPN on hub.

```
bfd-template single-hop sample
 interval min-tx 1000 min-rx 1000 multiplier 5
!
interface Tunnel0
 ip address 10.0.0.1 255.255.255.0
 no ip redirects
 ip nhrp authentication cisco123
 ip nhrp network-id 5
 ip nhrp redirect
 ip mtu 1400
 ip tcp adjust-mss 1360
 bfd template sample
 tunnel source GigabitEthernet0/0/0
 tunnel mode gre multipoint
 tunnel key 6
!
interface GigabitEthernet0/0/0
 ip address 10.0.0.1 255.0.0.0
 negotiation auto
!
router eigrp 2
 network 10.0.0.0 0.0.0.255
 bfd all-interfaces
 auto-summary
!
```

The following is an example of configuring BFD support on DMVPN on spoke.

```
bfd-template single-hop sample
 interval min-tx 1000 min-rx 1000 multiplier 5
!
```

```

interface Tunnel1
 ip address 10.0.0.10 255.255.255.0
 no ip redirects
 ip nhrp authentication cisco123
 ip nhrp network-id 5
 ip nhrp nhs 10.0.0.1 nbma 10.0.0.10 multicast
 bfd template sample
 tunnel source GigabitEthernet0/0/0
 tunnel mode gre multipoint
 tunnel key 6
!
interface GigabitEthernet0/0/0
 mtu 4000
 ip address 11.0.0.1 255.0.0.0
 media-type rj45
 negotiation auto
!
interface GigabitEthernet0/0/1
 mtu 6000
 ip address 111.0.0.1 255.255.255.0
 negotiation auto
!
router eigrp 2
 network 11.0.0.0 0.0.0.255
 network 111.0.0.0 0.0.0.255
 network 10.0.0.0 0.0.0.255
 bfd all-interfaces
 auto-summary
!
 ip route 0.0.0.0 0.0.0.0 10.0.0.2

```

The following example outlines how to delete the tunnel entry details when BFD support is down by addition of `ip nhrp bfd` command. By default, the tunnel entry is not immediately deleted and is deleted after expiry of the entry.

```

!
interface Tunnel0
 ip address 10.0.1.100 255.255.255.0
 no ip redirects
 ip nhrp authentication testing
 ip nhrp summary-map 192.168.0.0/16 72.68.100.2
 ip nhrp summary-map 77.77.0.0/16 72.68.100.2
 ip nhrp network-id 100
 ip nhrp bfd delete
 ip nhrp redirect
 bfd interval 1000 min_rx 1000 multiplier 5
 tunnel source Ethernet0/0
 tunnel mode gre multipoint
 tunnel key 100
 tunnel protection ipsec profile default
!

```

Note In this configuration, the tunnel entry is immediately deleted upon receiving a BFD down event. Without this configuration, the cache entry pertaining to the tunnel address of the peer is not deleted and performs its default behaviour.

The following is an example to illustrate faster convergence on spoke.

```

interface Tunnell
ip address 18.0.0.10 255.255.255.0
no ip redirects
ip nhrp authentication cisco123
ip nhrp network-id 12
ip nhrp nhs 10.0.0.1 nbma 10.0.0.10 multicast
bfd template sample
tunnel source GigabitEthernet0/0/0
tunnel mode gre multipoint
tunnel key 18
tunnel protection ipsec profile MY_PROFILE
!
bfd-template single-hop sample
interval min-tx 1000 min-rx 1000 multiplier 3
echo
!
router eigrp 2
bfd interface Tunnell -----> Specify the interface on which the routing
  protocol must act for BFD up/down events
network 11.0.0.0 0.0.0.255
network 111.0.0.0 0.0.0.255

```

With the above configuration, as soon as BFD is reported down (3 seconds to detect), EIGRP will remove the routes installed from RIB.

The following sample output shows a summary output on hub:

```

device#show dmvpn

Legend: Attrb --> S - Static, D - Dynamic, I - Incomplete
        N - NATed, L - Local, X - No Socket
        T1 - Route Installed, T2 - Nexthop-override
        C - CTS Capable
        # Ent --> Number of NHRP entries with same NBMA peer
        NHS Status: E --> Expecting Replies, R --> Responding, W --> Waiting
        UpDn Time --> Up or Down Time for a Tunnel
=====

Interface: Tunnell, IPv4 NHRP Details
Type:Hub, NHRP Peers:2,

# Ent Peer NBMA Addr Peer Tunnel Add State UpDn Tm Attrb
-----
  1 172.17.0.1          10.0.0.1   UP 00:00:14   D
  1 172.17.0.2          10.0.0.2   BFD 00:00:03   D

```

BFD is a new state which implies that while the session is UP as seen by lower layers (IKE, IPsec and NHRP), BFD sees the session as DOWN. As usual, the state is an indication of the lower most layer where the session is not UP. Also, this applies only to the parent cache entry. This could be because it was detected as DOWN by BFD or BFD is not configured on the other side.

The following sample output shows a summary output on spoke:

```

device#show dmvpn

Legend: Attrb --> S - Static, D - Dynamic, I - Incomplete
        N - NATed, L - Local, X - No Socket
        T1 - Route Installed, T2 - Nexthop-override
        C - CTS Capable
        # Ent --> Number of NHRP entries with same NBMA peer

```

```
NHS Status: E --> Expecting Replies, R --> Responding, W --> Waiting
UpDn Time --> Up or Down Time for a Tunnel
```

```
Interface: Tunnel2, IPv4 NHRP Details
Type:Spoke, NHRP Peers:2,
```

```
# Ent Peer NBMA Addr Peer Tunnel Add State UpDn Tm Attrb
-----
  2 172.17.0.2          10.0.0.2   BFD 00:00:02   DT1
    10.0.0.2          10.0.0.2   UP  00:00:02   DT2
  1 172.17.0.11        10.0.0.11   UP  00:05:35    S
```

The following sample shows output for **show ip/ipv6 nhrp** command

```
device#show ip nhrp
10.0.0.2/32 via 10.0.0.2
  Tunnel2 created 00:00:15, expire 00:04:54
  Type: dynamic, Flags: router nhop rib bfd
  NBMA address: 172.17.0.2
10.0.0.11/32 via 10.0.0.11
  Tunnel2 created 00:09:04, never expire
  Type: static, Flags: used bfd
  NBMA address: 172.17.0.11
192.168.1.0/24 via 10.0.0.1
  Tunnel2 created 00:00:05, expire 00:04:54
  Type: dynamic, Flags: router unique local
  NBMA address: 172.17.0.1
  (no-socket)
192.168.2.0/24 via 10.0.0.2
  Tunnel2 created 00:00:05, expire 00:04:54
  Type: dynamic, Flags: router rib nho
  NBMA address: 172.17.0.2
```

BFD flag here implies that there is a BFD session for this peer. This marking is only for parent entries.

The following sample shows output for **show tunnel endpoints** command

```
device#show tunnel endpoints
Tunnel2 running in multi-GRE/IP mode

Endpoint transport 172.17.0.2 Refcount 3 Base 0x2ABF53ED09F0 Create Time 00:00:07
overlay 10.0.0.2 Refcount 2 Parent 0x2ABF53ED09F0 Create Time 00:00:07
Tunnel Subblocks:
  tunnel-nhrp-sb:
    NHRP subblock has 2 entries; BFD(0x2):U
Endpoint transport 172.17.0.11 Refcount 3 Base 0x2ABF53ED0B80 Create Time 00:09:07
overlay 10.0.0.11 Refcount 2 Parent 0x2ABF53ED0B80 Create Time 00:09:07
Tunnel Subblocks:
  tunnel-nhrp-sb:
    NHRP subblock has 1 entries; BFD(0x1):U
```

For every tunnel endpoint, a new text "**BFD(handle):state**" is added. State here is UP(U), DOWN(D), NONE(N) or INVALID(I).

- In case, BFD is not configured on peer or a session is not UP for the first time, then the state will be N.

The following sample shows output for **show nhrp interfaces** command. This shows the configuration (and not operational) states on the interface or globally.

```
device#show nhrp interfaces
NHRP Config State
-----
Global:
  BFD: Registered

Tunnel1:
  BFD: Disabled

Tunnel2:
  BFD: Enabled
```

This is an internal and hidden command. This will currently display if NHRP is client of BFD and if BFD is enabled on the NHRP interface.

CHAPTER 217

DMVPN Support for IWAN

DMVPN supports Cisco Intelligent WAN architecture to provide transport independence through overlay routing. The DMVPN Multiple Tunnel Termination feature enables support for secondary paths for the supported routing protocols in the Routing Information Base (RIB).

- [Prerequisites for DMVPN Support for IWAN, on page 2859](#)
- [Restrictions for DMVPN Support for IWAN, on page 2859](#)
- [Information About DMVPN Support for IWAN, on page 2859](#)
- [How to Configure DMVPN Support for IWAN, on page 2862](#)
- [Configuration Examples for DMVPN Support for IWAN, on page 2863](#)
- [Additional References for DMVPN Support for IWAN, on page 2868](#)
- [Feature Information for DMVPN Support for IWAN, on page 2869](#)

Prerequisites for DMVPN Support for IWAN

For DMVPN Multiple Tunnel Termination feature to work, the following prerequisites must be considered

- DMVPN Multiple Tunnel Termination feature requires support from crypto maps and DMVPN.
- Only BGP and EIGRP routing protocols are supported on this feature. One of the two routing protocols, BGP and EIGRP, must be enabled for this feature to work.

Restrictions for DMVPN Support for IWAN

For DMVPN Multiple Tunnel Termination feature the overlay routing should be active-passive in nature.

Information About DMVPN Support for IWAN

Transport Independence

DMVPN supports Cisco IWAN by providing transport independence through overlay routing. Overlay routing simplifies the WAN transport (dial-up, leased circuits, MPLS, and IPsec VPNs), by deploying and supporting

consistent routing protocol across any transport, controlling traffic and load sharing. Overlay routing provides transport independence so that the user can select any WAN technology.

Transport independence eases change in transport options and service providers. Changing transports does not impact the overlay routing design. This technology supports use of multiple WAN transports, as the transport type is associated to the underlay network and is not relevant to the overlay network which is consistent to the DMVPN tunnel.

Transport independence provides single routing domain, consistent troubleshooting and topology for WAN transports. As long as the transport network delivers the DMVPN packets between the hub and the spoke, the transport device topology is not relevant to the traffic flowing across the DMVPN tunnel.

DMVPN for IWAN

DMVPN uses multipoint generic routing encapsulation (mGRE) tunnels to interconnect the hubs and all of the spokes. For IWAN deployments, DMVPN provides integration with PfR and simplifies route control across any transport. DMVPN supports full mesh connectivity over any carrier transport with a simple hub-and-spoke configuration. DMVPN also supports spoke that have dynamically assigned IP addresses.

The following figure shows IWAN deployments with multiple WAN transports. This design enables convergence across WAN transports when all channels in a given transport fail or reach their maximum bandwidth limits.

Figure 113: DMVPN for IWAN

Secondary Paths

For a single tunnel case, the routing method installs multiple paths in the RIB, one or more leaving each tunnel. Based on the configuration, this includes some or all of the available free paths. The paths can be classified into following classes:

- Regular next-hops/paths are the most common kind of paths. They are also referred to as primary paths; other alternate next-hops are sometimes referred to as secondary paths.
- Repair next-hops/paths forward traffic during a routing transition and are not used as long as one or more regular next hops are active.
- Secondary next-hops/paths are special loop free paths that is used as an alternate to regular and repair paths.

When at least one of the primary paths are in use, the secondary paths are not used for regular forwarding. The secondary paths should be distinguishable from other regular and alternate paths. The secondary paths can still be overridden using next hop overrides. The routing protocol computes "n" secondary paths with the following requirement from RIB:

- Allow the routing protocol to install the "n1" primary paths as a regular path
- Allow the routing protocol to install the "n2" secondary paths as alternate paths.

DMVPN Multiple Tunnel Termination

Network access resiliency at a single hub in Cisco IWAN without having to add any network devices, involves terminating multiple WAN links on the same device. The DMVPN Multiple Tunnel Termination feature provides support for multiple tunnel terminations (interfaces) in the same VRF on the same hub device.

Figure 114: DMVPN Multiple Tunnel Termination

The DMVPN Multiple Tunnel Termination feature also provides transport resiliency to DMVPN. Using one tunnel per-transport provides better visibility to Performance Routing (PfR), about the conditions in the underlying transport and still being transport independent. IWAN as a whole is transport independent along with the services running on the overlay.

DMVPN Multiple Tunnel Termination feature brings in support for secondary paths for the supported routing protocols in the RIB. The routing protocols are configured in such a way that there is only one primary/regular path and one or more secondary paths for a network. When PfR is used in conjunction with this feature, PfR

is used as the primary as well the secondary path so that all paths can be used in an active-active manner. Use the **maximum-secondary-paths** [**eigrp** | **ibgp**] *path* command to configure this feature, where the *path* indicates the number of secondary paths a routing protocol is allowed to install. The range for *path* is from zero to 32.

How to Configure DMVPN Support for IWAN

Configuring DMVPN Support for IWAN

Perform this task to configure IPsec profile on the device.

```
crypto ikev2 keyring keyring1
peer peer1
  address 0.0.0.0 0.0.0.0
  pre-shared-key key1

crypto ikev2 proposal proposal1
  encryption aes-cbc-128
  prf sha256 sha512
  group 14

crypto ikev2 policy proposal1
  match fvrf vrfl
  proposal proposal1

crypto ikev2 profile profile1
  description This is an IKEv2 profile
  match fvrf vrfl
  match identity remote address 10.0.0.1
  identity local address 10.0.0.0
  authentication remote pre-share
  authentication local pre-share
  keyring local key1

crypto ipsec transform-set transform1 esp-gcm 256
  mode transport

crypto ipsec profile profile2
  set transform-set esp-gcm 256
  set ikev2-profile profile1

crypto ipsec security-association replay window-size 15
```

Perform this task to configure the tunnel.

```
interface Tunnel 10
  tunnel source GigabitEthernet0/0/0
  tunnel mode gre multipoint
  tunnel key 10000
  tunnel vrf vrfl
  tunnel protection ipsec profile profile2
```

Perform the following task to configure BGP routing process.

```

router bgp 45000
  bgp router-id 172.17.1.99
  bgp log-neighbor-changes
  timers bgp 70 120
  neighbor 192.168.1.2 remote-as 40000
  neighbor 192.168.3.2 remote-as 50000
  neighbor 192.168.3.2 description finance
  !
  address-family ipv4
    neighbor 192.168.1.2 activate
    neighbor 192.168.3.2 activate
    no auto-summary
    no synchronization
    network 172.17.1.0 mask 255.255.255.0
  exit-address-family
  !

```

Configuring DMVPN Multiple Tunnel Termination

Perform the following task to configure DMVPN Multiple Tunnel Termination

```

router bgp 1
  bgp log-neighbor-changes
  bgp listen range 192.168.0.0/16
  peer-group SPOKES2
  bgp listen range 190.168.0.0/16
  peer-group SPOKES network 192.168.0.0
  aggregate-address 192.168.0.0 255.255.0.0 summary-only
  timers bgp 10 30
  neighbor SPOKES2 peer-group
  neighbor SPOKES2 remote-as 1
  neighbor SPOKES2 next-hop-self
  maximum-secondary-paths eigrp 1

```

Configuration Examples for DMVPN Support for IWAN

Example: DMVPN Support for IWAN

The following is an example for configuring DMVPN on hub.

```

router eigrp DMVPN
  !
  address-family ipv4 unicast autonomous-system 100
  !
  af-interface Tunnel0 \
  summary-address 192.168.0.0 255.255.0.0
  no split-horizon
  exit-af-interface
  !
  af-interface Tunnel1
  summary-address 192.168.0.0 255.255.0.0
  no split-horizon
  exit-af-interface

```

```

!
topology base
maximum-secondary-paths 4
fast-reroute per-prefix all
fast-reroute tie-break interface-disjoint 1
exit-af-topology
network 10.0.0.0
network 20.0.0.0
network 192.168.149.0
exit-address-family
!

```

The following is an example for configuring DMVPN on spoke 1.

```

router bgp 1
bgp log-neighbor-changes
bgp listen range 20.0.0.0/8
peer-group SPOKES2
bgp listen range 10.0.0.0/8
peer-group SPOKES
network 192.168.149.0
aggregate-address 192.168.0.0 255.255.0.0 summary-only
timers bgp 10 30
neighbor SPOKES peer-group
neighbor SPOKES remote-as 1
neighbor SPOKES next-hop-self
neighbor SPOKES2 peer-group
neighbor SPOKES2 remote-as 1
neighbor SPOKES2 next-hop-self
maximum-secondary-paths eigrp 1
!

```

The following is an example for configuring DMVPN on spoke 2.

```

router bgp 1
bgp log-neighbor-changes
bgp listen range 20.0.0.0/8
peer-group SPOKES2
bgp listen range 10.0.0.0/8
peer-group SPOKES
bgp additional-paths install
network 192.168.149.0
aggregate-address 192.168.0.0 255.255.0.0 summary-only
timers bgp 10 30
neighbor SPOKES peer-group
neighbor SPOKES remote-as 1
neighbor SPOKES next-hop-self
neighbor SPOKES2 peer-group
neighbor SPOKES2 remote-as 1
neighbor SPOKES2 next-hop-self
maximum-secondary-paths eigrp 1
!

```

The following is the sample output for the **show ip bgp** command.

```

Device# show ip bgp

Feature Information for DMVPN Support for IWAN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 292: Feature Information for DMVPN Support for IWAN

CHAPTER 218

Configuring MPLS over DMVPN

The MPLS over DMVPN feature implements Multiprotocol Label Switching (MPLS) over a dynamically established IPsec tunnel, thereby enabling communication between overlapping addresses in customer sites.

Prerequisites for Configuring MPLS over DMVPN

- MP-BGP must be configured as MP-BGP allows labels to be distributed for every prefix or per VRF; label assignment per VRF would make it easy to maintain.
- NHRP Redirect feature must be installed as an MPLS output feature. To send the NHRP redirect, NHRP must know the VRF to which the redirect must be sent to.

Information About MPLS over DMVPN

MPLS over DMVPN Networks

Traffic in network domains having overlapping addressing spaces are segregated via VRFs. This is to ensure that traffic intended for one customer does not enter into another customer's domain. To protect data between provider-edge (PE) devices using IPsec, a tunnel interface with IPsec protection can be defined for each VRF, which ensures that traffic from every customer domain passes over the corresponding IPsec tunnel. However, as the number of customer sites and nodes grow in the network, this is not scalable since there is a need for separate IPsec tunnel and an interface for each customer site that must be protected.

MPLS provides the ability to assign labels per-VRF or per-prefix, thereby identifying the correct VRF into which traffic needs to be routed to. This is achieved with an MPLS-aware interface having IPsec protection and an IPsec tunnel built between the PE devices. The basic methodologies in MPLS are as follows:

MPLS forwarding—This is used in the transport networks where a label is pushed at the ingress PE device for a particular prefix and the labels are swapped as the data moves towards the egress PE device. At the egress PE device or a device before the egress PE (penultimate hop pop), the label is popped and data is forwarded based on the Layer 3 protocol. LDP is typically the label distribution protocol run in the transport space along with unicast routing protocol.

MPLS VPNs—This is used to carry data across a transport network between customer sites on VRFs. The overlay prefixes are identified by a VPN overlay label and is used as an inner label in a MPLS data packet. The outer label is the MPLS transport label and is for switching the packet in the core. LDP is used along with a IGP to achieve MPLS unicast IP forwarding in the core network and MP-BGP provides a mechanism to identify the customer VRF network to which a packet is forwarded when a packet arrives at Egress Label Edge Router (E-LER). Each of the protocols – LDP and MP-BGP protocols distribute labels to help in achieving this.

The goal of the MPLS over Dynamic IPsec Tunnels feature is to provide a solution that helps communication between overlapping addresses in customer sites when a remote customer site needs to be discovered dynamically using NHRP and at the same time secure the data traffic between the PE routers using IPsec. This solution can be used to deploy an MPLS network and to extend their MPLS network on a new network (determined dynamically), in a different region, securely over the Internet.

Until this feature was introduced, MPLS support on DMVPN existed in a DMVPN hub and spoke network only. The feature extends support in DMVPN spoke to spoke networks where data packets are tag-switched on the hub and cannot trigger a NHRP redirect thereby addressing a scalable solution using multipoint GRE interface on DMVPN networks and point-to-point interface on FlexVPN networks.

From Cisco IOS XE 17.11.1a, a new keyword **interest** is introduced for the **ip nhrp redirect** command to configure the interest ACL in AF VRF, if the traffic VRF matches the AF VRF. See section [Configure NHRP for Tunnel Setup](#) for details.

How MPLS Works

The basic goal of a Layer 3 VPN network is to allow sites in a customer network to communicate with each other. The following diagram explains the need for MPLS with the help of an example.

Figure 115: Overlapping addresses in Customer Edge (CE) Domain

Per the above diagram, Customer A network behind spoke A/PE1 router needs to communicate with the customer A subnet 10.1.1.0/24. However, because of overlapping address space with customer B, spoke B/PE2

router would learn about two different 10.1.1.0/24 prefixes and if it picks the route to customer B as best route, packets would never reach the customer A network behind spoke B.

MPLS solves this problem by associating labels for each customer prefix present in different VRF tables. These labels are distributed between PEs, used during packet forwarding to determine the correct customer network to which a packet should be forwarded to. MPLS deals with overlapping prefixes by prepending another number to the BGP NLRI (prefix). MP-BGP has the provision of adding a variable-length number called address family in front of the prefix. MPLS VPNs use the address family to carry route distinguishers (RDs). The combined VPNv4 address (64-bit RD + 32-bit prefix) makes the address unique. The steps involved are:

- Provider and provider-edge devices run LDP and IGP to support unicast IP routing. IGP only advertises routes for subnets inside the MPLS network but does not include any customer routes.
- PEs learn customer specific routes using IGP and store the routes in per-customer VRF routing tables.
- PEs use MP-BGP to exchange customer routes with other PEs.

Components of MPLS over Dynamic IPsec Tunnels Feature

The essential components of this solution comprise:

IKEv2 and IPsec—Internet Key Exchange version 2 (IKEv2) and IPsec secure traffic between spoke and the hub and later between the spokes when the remote spoke is discovered dynamically. IKEv2 is used to add static routes to the peer's tunnel overlay address as a directly connected route in FlexVPN. This results in an implicit-NULL label to be added to the LIB for the peer's tunnel overlay address. (IPRM (IP Resource manager) adds the implicit-NULL label and is the common component that is used for implicit-NULL label addition by applications such as LDP and now IKEv2). IKEv2 is used instead of LDP for the following reasons:

If LDP is used for distributing transports labels, it involves establishing TCP channel with every LDP neighbor making it heavy-weight in a scaled scenario.

LDP keepalive will try to keep the spoke-to-spoke tunnel active, even in the absence of traffic, and never bring the spoke-to-spoke tunnel down.

NHRP—Next Hop Resolution Protocol (NHRP) resolves the remote overlay address and dynamically discovers the transport end point needed to establish a secure tunnel. If a multipoint GRE interface is used, the tunnel end point database stores the mapping between the overlay and corresponding nonbroadcast multiaccess (NBMA) address. NHRP control packets that are not specific to a VRF are forwarded to global addresses. Control packets specific to a virtual domain context (for example, resolution request destined for a customer network or host address) are forwarded to a specific VRF.

MPLS—Multiprotocol label switching (MPLS) enables MPLS tag switching for data packets. Label Distribution Protocol (LDP) is not enabled between spokes.

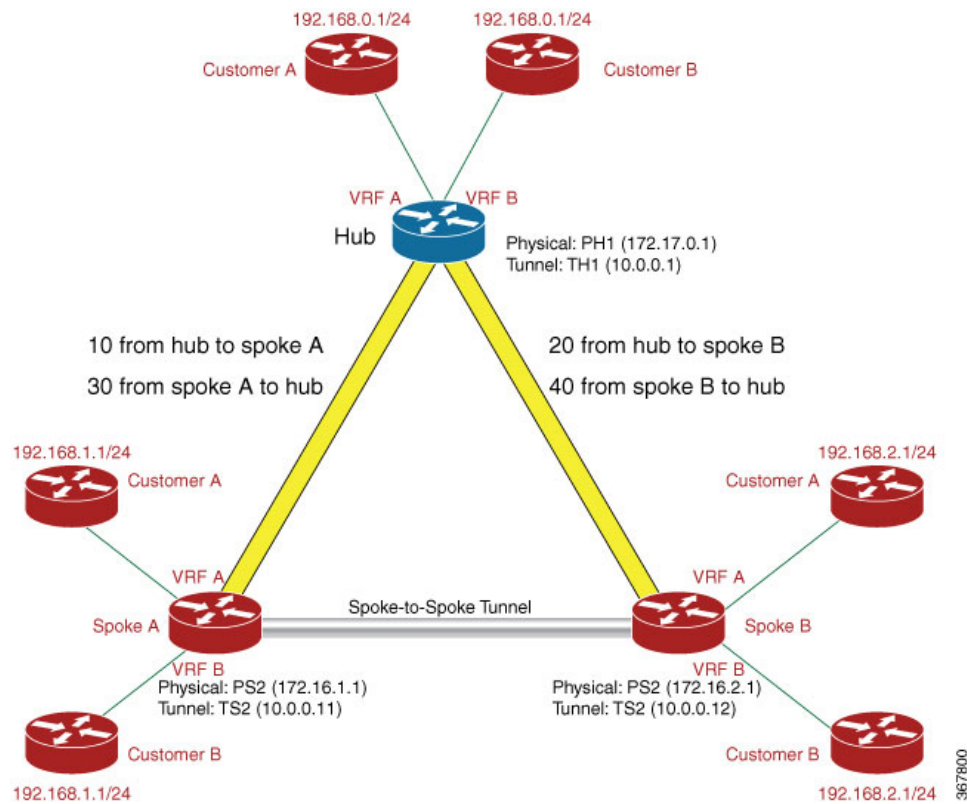

MFI—Multicast Forwarding Information (MFI) allocates and releases labels assigned to tunnels.

MP-BGP—Multiprotocol BGP (MP-BGP) distributes overlay labels for the customer network on different VRFs.

Working of MPLS over Dynamic IPsec Tunnels Feature

This section describes the working of the MPLS over Dynamic IPsec Tunnels feaytre with the help of the following topology as an example, where traffic flows from IP address 192.168.1.1 of Customer A, behind Spoke A to IP address 192.168.2.1 of Customer A, behind Spoke B.

Figure 116: DMVPN Spoke-Hub-Spoke Topology

1. IKEv2 and IPsec security associations (SA) are established from the spoke to the hub. IKEv2 installs the implicit-NULL label values for the peer's overlay address received in the mode config reply and mode config set. Implicit-NULL label is installed because the spoke and hub are always next hop to each other in the overlay space. To enable MPLS tag switching, use the `mpls nhrp` command on the tunnel interface or virtual template interface.

Note Using the `mpls ip` command performs the same function as `mpls nhrp` command but enables LDP also, which is not recommended.

2. After establishing an IPsec session between a spoke and a hub and the implicit-NULL label is installed, MP-BGP exchanges label per-VRF or label per-prefix for all VRFs.
3. Data is forwarded when label and route exchange is complete. When the first packet destined for 192.168.2.1 arrives on spoke A on VRF A, the packet is forwarded to the hub. The packet is label encapsulated (with just the overlay label), GRE encapsulated and encrypted.
4. When the packet reaches the virtual access interface or GRE interface on the hub, the packet is decrypted and GRE decapsulated. The label identifies the VRF on which the packet arrives and the VRF information corresponding to the label is conveyed to NHRP. NHRP constructs the redirect packet and dispatches the packet in the MPLS switching path and sends the packet to MPLS LSP. The packet is label encapsulated, GRE encapsulated, encrypted, and sent to the host behind Spoke A.

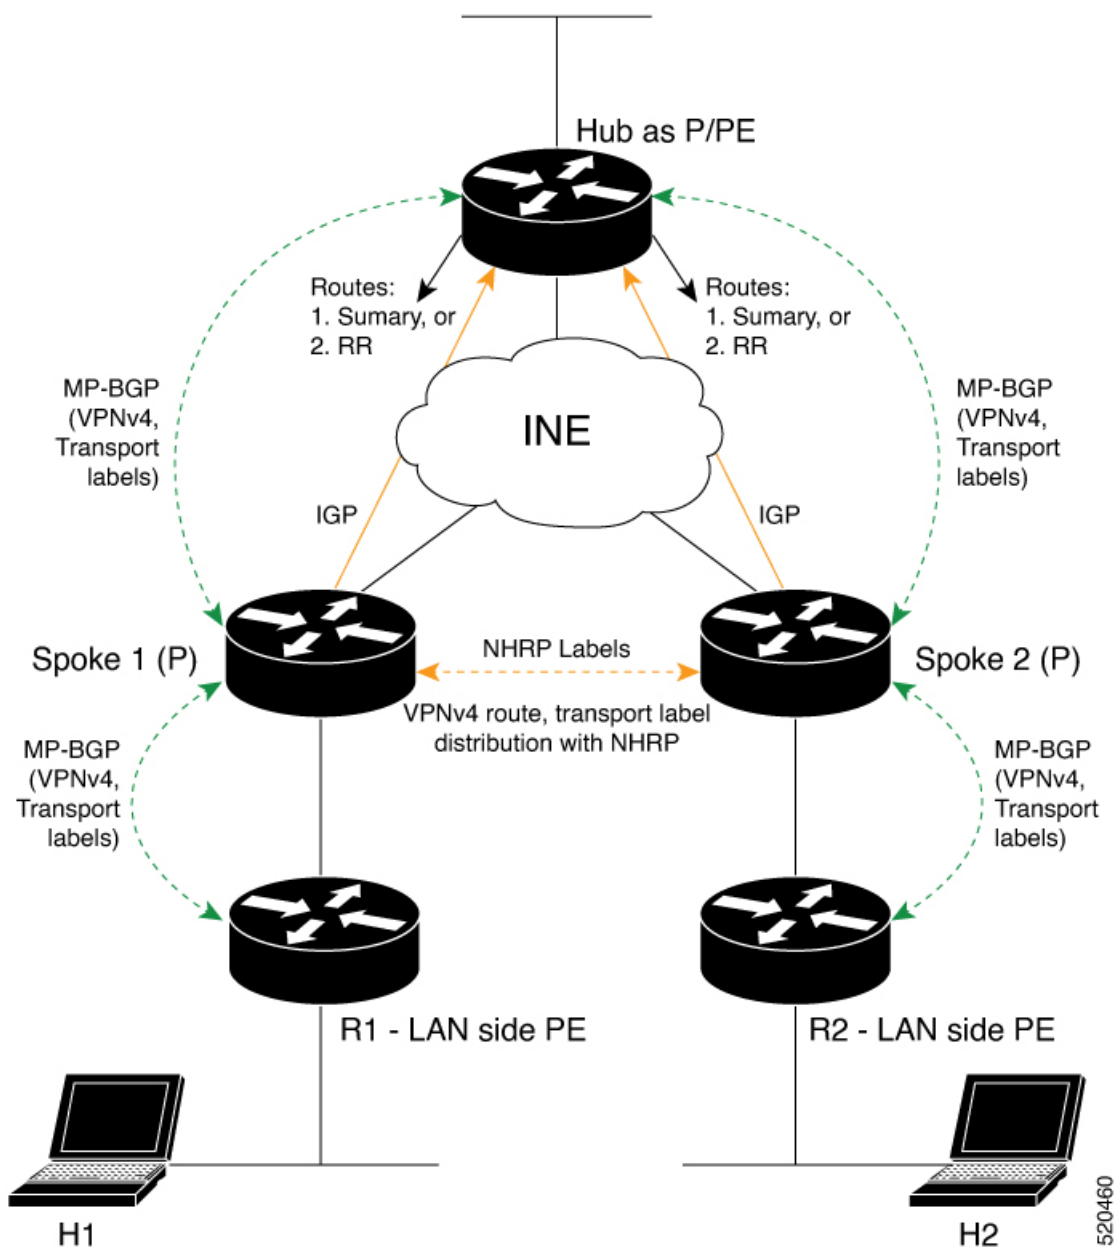

5. The redirect packet (NHRP) arrives at spoke A, is decrypted, and is GRE decapsulated. The redirect packet is processed and a NHRP resolution request is triggered. The request is sent to a specific VRF in a host network behind Spoke B. This is because the host network behind Spoke B needs to be resolved and it is also possible that the network can have overlapping address with another network. MPLS provides the VRF information, which corresponds to the outer VRF label. This resolution packet is label encapsulated, GRE encapsulated, encrypted and sent to the hub. An NHRP mapping entry is created and VRF A is also associated for the prefix that needs to be resolved.
6. NHRP resolution request arrives at the hub and is decrypted and GRE decapsulated. NHRP looks up the route in the VRF table and identifies the outgoing interface. The resolution request is label encapsulated, GRE encapsulated, encrypted and sent to Spoke 2.
7. Spoke B decrypts the resolution request packet gets decrypted on the spoke B and learns the VRF label. A virtual access is created on Spoke B for point-to-point solution and an IKEv2 or IPsec session is initiated from Spoke B to Spoke A. This result in the creation of virtual access on Spoke A also by IKEv2 in a point-to-point solution. NHRP adds the route for Spoke A tunnel IP address via the new virtual access interface.
8. NHRP resolution reply is received at virtual access interface on Spoke A. NHRP request ID in the reply packet is matched with the request ID of the request, which is sent by Spoke A to know the VRF for which the request was sent. NHRP looks up to find the NHRP entry and the entry is said to be “Complete.” NHRP also inserts a route into the VRF routing table with the label information. With the routes and labels setup between Spoke A and Spoke B, traffic is VPN label encapsulated and encrypted over the spoke-spoke dynamically established tunnel between Spoke A to Spoke B.

Support for Spoke Nodes as P Nodes in MPLS over DMVPN Phase 3

In IOS XE Amsterdam 17.1.x and earlier releases, in an MPLS over DMVPN Phase 3 deployment you could configure a spoke node only as a PE node. From IOS XE Amsterdam 17.2.1, you can configure spoke node as either a P or PE node.

Overview of the Support for Spoke Nodes as P Nodes in MPLS over DMVPN Phase 3

Consider the configuration in the following figure, in which Spoke 1 and Spoke 2 are P nodes:

H1 and H2 are hosts connected to the PE nodes R1 and R2, respectively, and part of a customer network. There may be other customer networks connected to R1 and R2. So, VRFs are configured on both R1 and R2 to segregate the traffic of one customer network from another.

Spoke 1 and Spoke 2 are P nodes in the MPLS DMVPN cloud. Spoke 1 learns of the VPNv4 prefixes and overlay labels for each VRF defined on R1 via MP-BGP. The VPNv4 prefixes and labels are also imported, on demand, to and from NHRP as part of NHRP resolution. Similarly, Spoke 2 learns of the VPNv4 prefixes and labels for the VRFs defined on R2.

Spoke 1 and Spoke 2 register with the Hub and exchange routing information (VPNv4 prefixes and labels) through MP-BGP via the Hub.

Suppose that the host H1, connected to the PE node R1, attempts to send some traffic to the host H2, connected to the PE node R2. R1 forwards the packets to Spoke 1 after tagging the packets with the appropriate VRF and outer labels.

When the first packet arrives at Spoke 1, Spoke 1 forwards the packet to the Hub after swapping the outer labels appropriately. The Hub examines the VRF label and sends an NHRP traffic indication to Spoke 1 to indicate the availability of a more optimal route.

On receiving the NHRP traffic indication, Spoke 1 sends an NHRP resolution request for the VPNv4 destination address to Spoke 2 via the Hub.

Spoke 2 sends an NHRP resolution reply to Spoke 1 after an on-demand dynamic tunnel is established between the two spokes. NHRP inserts route and label into the BGP (VPNv4), RIB (Global/Default), and LFIB. MP-BGP imports the route/label and redistributes the information to R1.

Packets from H1 to H2 are tagged with the appropriate VRF label and transport label to be sent over the spoke-to-spoke tunnel.

Restrictions for Support for Spoke Nodes as P Nodes in MPLS over DMVPN Phase 3

- This feature requires BGP VPNv4 peering between the P nodes deployed as spoke nodes and the PE nodes on the LAN side.
- This feature is supported only with IPv4 addressing.
- All nodes must use the same RD for DMVPN Phase 3.

Enhancements to BGP and NHRP

To support a configuration with spoke nodes as P nodes, BGP and NHRP are enhanced to redistribute routes and labels between the P nodes acting as spoke nodes and the PE nodes on the LAN side.

Enhancements to BGP

- BGP receives a notification from NHRP when NHRP learns of a new VPNv4 prefix. In response, BGP imports the prefix information from NHRP and propagates the information to the LAN-side PE node.
- BGP provides a mechanism for NHRP to import information from BGP.
- BGP notifies NHRP when the information redistributed to NHRP must be updated.
- BGP propagates prefix updates or deletes prefix information based on NHRP notifications.

Enhancements to NHRP

- MPLS-labelled packets are inspected and packets that carry a GAL label and an NHRP channel number are punted to control plane for further processing.
- NHRP imports information from BGP. Information imported by NHRP includes route(prefix/mask), RD, RT and other opaque data (needed by BGP to reconstruct the VPNv4 prefix at the other end).
- NHRP adds, updates, and deletes prefix information to the RIB and LFIB on the P nodes acting as spoke nodes.
- NHRP notifies BGP to add, update, or withdraw prefix information.
- In response to resolution request, NHRP provides the forwarding information in an enhanced CIE.

- Between peers, NHRP purges information on a per-prefix basis. Earlier, the purge was based on the peer address and request ID. Now, prefix is also taken into account.

Enhanced NHRP CIE

The NHRP CIE is enhanced to include a TLV block in which NHRP packs the forwarding information. The E flag is set to indicate the presence of this new TLV block. The CIE and TLV block formats are as follows:

CIE Format:

Code	Prefix Length	E	unused
Maximum Transmission Unit	Holding Time		
Cli Addr T/L	Cli SAddr T/L	Cli Proto Len	Preference
Client NBMA Address (variable length)			
Client NBMA Subaddress (variable length)			
Client Protocol Address (variable length)			

To manage a scenario in which one peer node is updated to IOS XE 17.2.1 or a later release, but the other peer node is not, nodes use capability negotiation to check the capability of a peer before sending the enhanced CIE.

NHRP Enhanced CIE TLV structure:

C	Reserved	Type	Reserved	Length
Value ...				

C - Compulsory (CIE can't be interpreted if this extension is not understood)

IVRF Support

If a tunnel interface belongs to an IVRF, routing related operations, such as, route lookup, route addition and deletion, that happen in NHRP are performed in the routing table of IVRF configured on tunnel interface.

How to Configure MPLS over DMVPN

Configuring MPLS over FlexVPN

Perform this task to configure MPLS over DMVPN.

SUMMARY STEPS

1. enable
2. configure terminal
3. interface tunnel *number*

4. Do one of the following: **mpls nhrpor** **mpls bgp forwarding**
5. **end**
6. **show mpls forwarding-table**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 1	Configures the FlexVPN client interface and enters interface configuration mode.
Step 4	Do one of the following: mpls nhrpor mpls bgp forwarding Example: Device(config-if)# mpls nhrp Device(config-if)# mpls bgp forwarding	
Step 5	end Example: Device(config-if)# end	Exits interface configuration mode and returns to global configuration mode.
Step 6	show mpls forwarding-table Example: Device# show mpls forwarding-table	Displays information about the Multiprotocol Label Switching (MPLS) Label Forwarding Information Base (LFIB).

Configuration Examples for MPLS over FlexVPN

Example: MPLS over DMVPN—Using LDP and BGP

This section lists a sample configuration on spokes and the hub using LDP and BGP. The following is the configuration on Spoke A:

```
ip vrf custA
rd 10:100
route-target export 10:1000
route-target import 10:1000
!
ip vrf custB
rd 10:110
route-target export 10:2000
route-target import 10:2000
mpls label mode all-vrfs protocol bgp-vpnv4 per-vrf
```

   network 1.1.1.1 0.0.0.255
   nhrp redirect interest 2
 exit-address-family
!

```

Restrictions for Configuring 6VPE and 6PE Support in MPLS over DMVPN Phase 2

- 6VPE and 6PE in DMVPN Phase 3 behaves like DMVPN Phase 1. All the packets from spoke-to-spoke travel through the hub as no dynamic spoke-to-spoke tunnel is created.
- In DMVPN Phase 2, if the dynamic spoke-to-spoke tunnel is not created for some reason, the packets do not travel through the hub, causing failure in connectivity.
- Initial packets from spoke-to-spoke travel in cleartext and drop by the hub until the dynamic tunnel is established between spokes.

Configuring 6VPE Support in MPLS over DMVPN Phase 2

To configure 6VPE support in MPLS over DMVPN phase 2, you must enable various components such as VRF, Tunnel, IPsec Tunnel Protection, WAN Facing Interface, Transport routing and Overlay Routing for the hub and the spokes.

Enabling Components for the Hub

To configure 6VPE support in MPLS over DMVPN phase 2 for the hub, you must enable the following in the order:

1. VRF
2. Tunnel
3. IPsec Tunnel Protection
4. WAN Facing Interface
5. Transport Routing
6. Overlay Routing

Configuring VRF for the Hub

```
enable
config terminal
vrf definition blue
rd 100:1
address-family ipv6
route-target export 100:1
route-target import 100:1
exit-address-family
vrf definition red
rd 100:2
address-family ipv6
route-target export 100:2
route-target import 100:2
exit-address-family
```

Enabling Tunnel for the Hub

```
interface Tunnel1
ip address 192.168.1.1 255.255.255.0
no ip redirects
ip nhrp authentication cisco123
ip nhrp network-id 101
mpls nhrp
tunnel source GigabitEthernet0/0/1
tunnel mode gre multipoint
tunnel key 101
```

Enabling IPsec Tunnel Protection for the Hub

```
interface Tunnel1
tunnel protection ipsec profile ipsec_ikev2
no shut
end
```

Enabling WAN Interfaces for the Hub

```
interface GigabitEthernet0/0/1
ip address 10.1.1.1 255.255.255.0
negotiation auto
cdp enable
ipv6 address 10::1/64
hold-queue 4096 in
hold-queue 4096 out
```

Enabling Transport Routing for the Hub

```
router eigrp 100
network 10.1.1.0 0.0.0.255
```

Enabling Overlay Routing for the Hub

```
router bgp 1
bgp router-id 192.168.1.1
bgp log-neighbor-changes
neighbor 192.168.1.101 remote-as 1
neighbor 192.168.1.101 update-source Tunnel1
neighbor 192.168.1.102 remote-as 1
neighbor 192.168.1.102 update-source Tunnel1
address-family ipv4
neighbor 192.168.1.101 activate
neighbor 192.168.1.102 activate
exit-address-family
address-family vpnv6
neighbor 192.168.1.101 activate
neighbor 192.168.1.101 send-community extended
neighbor 192.168.1.101 route-reflector-client
no neighbor 192.168.1.101 next-hop-self all
neighbor 192.168.1.102 activate
neighbor 192.168.1.102 send-community extended
neighbor 192.168.1.102 route-reflector-client
no neighbor 192.168.1.102 next-hop-self all
exit-address-family
address-family ipv6 vrf blue
redistribute connected
exit-address-family
address-family ipv6 vrf red
redistribute connected
exit-address-family
```

Enabling the Components for the Spokes

To configure 6VPE support in MPLS over DMVPN phase 2, you must enable the following for the spokes in the order:

1. VRF
2. Tunnel
3. IPsec Tunnel Protection
4. WAN Facing Interface
5. PE-CE Interfaces
6. Transport Routing
7. Overlay Routing

Configuring VRF for the Spokes

```
vrf definition blue
rd 100:1
address-family ipv6
```

```

        route-target export 100:1
        route-target import 100:1
    exit-address-family
vrf definition red
  rd 100:2
  address-family ipv6
    route-target export 100:2
    route-target import 100:2
  exit-address-family

```

Enabling Tunnel for the Spokes

```

interface Tunnell
  ip address 192.168.1.101 255.255.255.0
  no ip redirects
  ip nhrp authentication cisco123
  ip nhrp map multicast 10.1.1.1
  ip nhrp map 192.168.1.1 10.1.1.1
  ip nhrp network-id 101
  ip nhrp nhs 192.168.1.1
  mpls nhrp
  tunnel source GigabitEthernet0/0/1
  tunnel mode gre multipoint
  tunnel key 101

```

Enabling IPsec Tunnel Protection for Spokes

```

interface Tunnell
  tunnel protection ipsec profile ipsec_ikev2
  no shut
end

```

Enabling WAN Facing Interfaces for Spokes

```

interface GigabitEthernet0/0/1
  ip address 40.1.1.6 255.255.255.0
  negotiation auto
  ipv6 address 40::6/64
  ipv6 enable

```

Enabling PE-CE Interfaces for Spokes

```

interface GigabitEthernet0/0/3.1
  vrf forwarding blue
  encapsulation dot1q 1
  ip address 60.1.1.6 255.255.255.0
  negotiation auto
  ipv6 address 60::6/64
  ipv6 enable
interface GigabitEthernet0/0/3.2
  vrf forwarding red
  encapsulation dot1q 2
  ip address 80.1.1.6 255.255.255.0
  negotiation auto
  ipv6 address 80::6/64
  ipv6 enable

```

Enabling Transport Routing for Spokes

```

router eigrp 100
  network 40.1.1.0 0.0.0.255

```

Enabling Overlay Routing for the Spokes

```

router bgp 1
  bgp router-id 192.168.1.101
  bgp log-neighbor-changes
  neighbor 192.168.1.1 remote-as 1
  neighbor 192.168.1.1 update-source Tunnel1
  address-family ipv4
    neighbor 192.168.1.1 activate
  exit-address-family
  address-family vpnv6
    neighbor 192.168.1.1 activate
    neighbor 192.168.1.1 send-community extended
  exit-address-family
  address-family ipv6 vrf blue
    redistribute connected
  exit-address-family
  address-family ipv6 vrf red
    redistribute connected
  exit-address-family

```

Enabling Transport Routing for IPv6

The 6VPE over DMVPN with IPv6 transport feature allows IPv6 LAN prefixes over an IPv4 overlay neighbourhood created over an IPv6 DMVPN transport. Multi-tenant IPv6 LAN extension (L3VPN) over DMVPN supports IPv6 transport. It supports IPv6 transport and Inter-region connectivity with daisy-chained hubs.

```

!
ipv6 router eigrp 1
  eigrp router-id 1.1.1.1
!

```

Enabling WAN Interfaces for IPv6

```

!
interface GigabitEthernet2
  no ip address
  negotiation auto
  ipv6 address 172:16:1::1/64
  ipv6 eigrp 1
  no mop enabled
  no mop sysid
!
interface GigabitEthernet3
  no ip address
  negotiation auto
  ipv6 address 172:16:2::1/64
  ipv6 eigrp 1
  no mop enabled
  no mop sysid
!
interface GigabitEthernet4
  no ip address
  negotiation auto
  ipv6 address 172:16:3::1/64
  ipv6 eigrp 1
  no mop enabled
  no mop sysid

```

Enabling Tunnel for Hubs

The following configuration allows you one of the hubs to get daisy-chained with other hubs.

```
!  
interface Tunnel1  
 ip address 50.0.1.1 255.255.0.0  
 ip nhrp network-id 1  
 ip nhrp nhs 50.0.2.2 nbma 172:16:52::52 multicast  
 ip nhrp nhs 50.0.2.3 nbma 172:16:53::53 multicast  
 ip nhrp nhs 50.0.3.4 nbma 172:16:54::54 multicast  
 load-interval 30  
 ipv6 mtu 1450  
 mpls nhrp  
 if-state nhrp  
 tunnel source Loopback0  
 tunnel mode gre multipoint ipv6  
 tunnel key 1  
 tunnel path-mtu-discovery  
 end
```

Enabling Tunnel for Spokes

```
!  
interface Tunnel1  
 ip address 50.0.1.6 255.255.0.0  
 ip nhrp network-id 1  
 ip nhrp nhs 50.0.1.1 nbma 172:16:51::51 multicast  
 load-interval 30  
 ipv6 mtu 1450  
 mpls nhrp  
 if-state nhrp  
 tunnel source Loopback0  
 tunnel mode gre multipoint ipv6  
 tunnel key 1  
 tunnel path-mtu-discovery  
 end
```

Configuring 6PE Support in MPLS over DMVPN Phase 2

To configure 6PE Support in MPLS over DMVPN Phase 2, you must enable various components such as Tunnel, IPsec Tunnel Protection, WAN Facing Interfaces, Transport Routing, and Overlay Routing for the hub and spokes.

Enabling Components for the Hub

To configure 6PE support in MPLS over DMVPN phase 2, you must enable the following in the order:

1. Tunnel
2. IPsec Tunnel Protection
3. WAN Facing Interfaces
4. PE-CE Interfaces
5. Transport Routing

6. Overlay Routing

Enabling Tunnel for Hub

```
interface Tunnel1
 ip address 192.168.1.1 255.255.255.0
 no ip redirects
 ip nhrp authentication cisco123
 ip nhrp network-id 101
 mpls nhrp
 tunnel source GigabitEthernet0/0/1
 tunnel mode gre multipoint
 tunnel key 101
```

Enabling IPsec Tunnel Protection for the Hub

```
interface Tunnel1
 tunnel protection ipsec profile ipsec_ikev2
 no shut
 end
```

Enabling WAN Facing Interfaces for Hub

```
interface GigabitEthernet0/0/1
 ip address 10.1.1.1 255.255.255.0
 negotiation auto
 cdp enable
 ipv6 address 10::1/64
 hold-queue 4096 in
 hold-queue 4096 out
```

Enabling Transport Routing for Hub

```
router eigrp 100
 network 10.1.1.0 0.0.0.255
```

Enabling Overlay Routing for Hub

```
router bgp 1
 bgp router-id 192.168.1.1
 bgp log-neighbor-changes
 neighbor 192.168.1.101 remote-as 1
 neighbor 192.168.1.101 update-source Tunnel1
 neighbor 192.168.1.102 remote-as 1
 neighbor 192.168.1.102 update-source Tunnel1
 address-family ipv4
   neighbor 192.168.1.101 activate
   neighbor 192.168.1.102 activate
 exit-address-family
 address-family ipv6
   redistribute connected
   neighbor 192.168.1.101 activate
   neighbor 192.168.1.101 send-community extended
   neighbor 192.168.1.101 route-reflector-client
   no neighbor 192.168.1.101 next-hop-self all
   neighbor 192.168.1.102 activate
   neighbor 192.168.1.102 send-community extended
   neighbor 192.168.1.102 route-reflector-client
   no neighbor 192.168.1.102 next-hop-self all
 exit-address-family
```

Enabling Components for the Spokes

To configure 6PE support in MPLS over DMVPN phase 2, you must enable the following for the spokes:

1. Tunnel
2. IPsec Tunnel Protection
3. WAN Facing Interface
4. PE-CE Interfaces
5. Transport Routing
6. Overlay Routing

Enabling Tunnel for Spokes

```
interface Tunnell
 ip address 192.168.1.101 255.255.255.0
 no ip redirects
 ip nhrp authentication cisco123
 ip nhrp map multicast 10.1.1.1
 ip nhrp map 192.168.1.1 10.1.1.1
 ip nhrp network-id 101
 ip nhrp nhs 192.168.1.1
 mpls nhrp
 tunnel source GigabitEthernet0/0/1
 tunnel mode gre multipoint
 tunnel key 101
```

Enabling IPsec Tunnel Protection for Spokes

```
interface Tunnell
 tunnel protection ipsec profile ipsec_ikev2
 no shut
 end
```

Enabling WAN Facing Interfaces for Spokes

```
interface GigabitEthernet0/0/1
 ip address 40.1.1.6 255.255.255.0
 negotiation auto
 ipv6 address 40::6/64
 ipv6 enable
```

Enabling PE-CE Interface for Spokes

```
interface GigabitEthernet0/0/3.1
 encapsulation dot1q 1
 ip address 60.1.1.6 255.255.255.0
 negotiation auto
 ipv6 address 60::6/64
 ipv6 enable
interface GigabitEthernet0/0/3.2
 encapsulation dot1q 2
 ip address 80.1.1.6 255.255.255.0
 negotiation auto
 ipv6 address 80::6/64
 ipv6 enable
```

Enabling Transport Routing for Spokes

```
router eigrp 100
 network 40.1.1.0 0.0.0.255
```

Enabling Overlay Routing for Spokes

```
router bgp 1
 bgp router-id 192.168.1.101
 bgp log-neighbor-changes
 neighbor 192.168.1.1 remote-as 1
 neighbor 192.168.1.1 update-source Tunnell
 address-family ipv4
  neighbor 192.168.1.1 activate
 exit-address-family
 address-family ipv6
  redistribute connected
  neighbor 192.168.1.1 activate
  neighbor 192.168.1.1 send-community extended
 exit-address-family
```

Verifying the 6VPE support in MPLS over DMVPN Phase 2 Configurations

Use the following show commands to verify that the 6VPE support in MPLS over DMVPN phase 2 configurations are enabled on the router:

```
show ipv6 route vrf blue 60::/64
show ipv6 route vrf blue 70::/64
show mpls forwarding-table
show mpls forwarding-table vrf blue 60::/64 detail
show mpls forwarding-table vrf blue 70::/64 detail
show ipv6 cef vrf blue 60::/64
show ipv6 cef vrf blue 70::/64
show ipv6 cef vrf red 61::/64
show ipv6 cef vrf red 71::/64
show bgp vpnv6 unicast all
show dmvpn
show ip nhrp
```

Verifying the 6PE support in MPLS over DMVPN Phase 2 Configurations

Use the following show commands to verify that the 6PE support in MPLS over DMVPN phase 2 configurations are enabled on the router:

```
show ipv6 route vrf blue 60::/64
show ipv6 route vrf blue 70::/64
show mpls forwarding-table
show mpls forwarding-table vrf blue 60::/64 detail
show mpls forwarding-table vrf blue 70::/64 detail
show ipv6 cef vrf blue 60::/64
show ipv6 cef vrf blue 70::/64
show ipv6 cef vrf red 61::/64
show ipv6 cef vrf red 71::/64
```

```
show bgp ipv6 unicast
show dmvpn
show ip nhrp
```

Configure a Spoke Node as a P Node in MPLS over DMVPN Phase 3

To deploy spoke node as a P node, you must configure

- the spoke node as you would configure a P node in an MPLS L3VPN deployment
- the following NHRP and BGP enhancements on the spoke node:
 - Configure inspection of MPLS-labelled packets.
 - Configure BGP to import routes from NHRP.
 - Configure NHRP to import routes from BGP.

Configure Inspection of MPLS-labelled Packets

Configure the inspection of MPLS-labelled packets using the command **mpls nhrp inspect**.

```
interface tunnel-name
 ip address ipv4-address subnet-mask
 ...
 mpls nhrp inspect
 ...
```

Configure BGP to Import Routes from NHRP

Configure BGP to import routes from NHRP using the command **import nhrp**.

```
router bgp autonomous-system-number
 ...
 address-family vpnv4
 import nhrp
 ...
```

Configure NHRP to Import Routes from BGP

Configure NHRP to import routes from BGP using the command **import bgp**.

```
...
 address-family vpnv4
 import bgp autonomous-system-number
 ...
```

Feature Information for MPLS over DMVPN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 293: Feature Information for Configuring MPLS over DMVPN

Feature Name	Releases	Feature Information
6VPE and 6PE Support in MPLS over DMVPN	Cisco IOS XE Gibraltar 16.10.x	The 6VPE and 6PE Support in MPLS over DMVPN feature enables service providers running an MPLS/IPv4 infrastructure to offer IPv6 services without any major changes in the infrastructure. It enables IPv6 sites to communicate with each other over a DMVPN MPLS/IPv4 core network using MPLS label switched paths (LSPs).
Support for Spoke Nodes as P Nodes in MPLS over DMVPN Phase 3	Cisco IOS XE Amsterdam 17.2.1	In IOS XE Amsterdam 17.1.x and earlier releases, in an MPLS over DMVPN Phase 3 deployment you could configure a spoke node only as a PE node. From IOS XE Amsterdam 17.2.1, you can configure spoke node as either a P or PE node.

CHAPTER 219

DHCP Tunnels Support

The DHCP Tunnels Support feature provides the capability to configure the node (or spoke) of the generic routing encapsulation (GRE) tunnel interfaces dynamically using DHCP.

In a Dynamic Multipoint VPN (DMVPN) network, each participating spoke must have a unique IP address belonging to the same IP subnet. It is difficult for a network administrator to configure the spoke addresses manually on a large DMVPN network. Hence, DHCP is used to configure the spoke address dynamically on a DMVPN network.

- [Restrictions for DHCP Tunnels Support, on page 2903](#)
- [Information About DHCP Tunnels Support, on page 2904](#)
- [How to Configure DHCP Tunnels Support, on page 2905](#)
- [Configuration Examples for DHCP Tunnels Support, on page 2907](#)
- [Additional References, on page 2908](#)
- [Feature Information for DHCP Tunnels Support, on page 2909](#)

Restrictions for DHCP Tunnels Support

- The DHCP functionality of address validation is not supported on DMVPN.
- The DHCP IP address is not assigned to the spoke when configured in DMVPN phase 1.
- When you register the spoke to the hub using the `ip nhrp nhs {dynamic nbma nbma-address | FQDN-string} [multicast]` command, the unicast adjacency is only created after the session comes up.
- When using the Dual-hub single-DMVPN topology, Cisco DHCP server automatically changes the unicast flag to broadcast mode. To prevent this automatic change, run the following command on the Cisco DHCP server:

```
no ip dhcp auto-broadcast
```
- When DHCP is configured on an interface, the interface may take more time than usual to shutdown.

Information About DHCP Tunnels Support

DHCP Overview

DHCP is based on the Bootstrap Protocol (BOOTP), which provides the framework for passing configuration information to hosts on a TCP/IP network. DHCP adds the capability to automatically allocate reusable network addresses and configuration options to Internet hosts. DHCP consists of two components: a protocol for delivering host-specific configuration parameters from a DHCP server to a host and a mechanism for allocating network addresses to hosts. DHCP is built on a client/server model, where designated DHCP server hosts allocate network addresses and deliver configuration parameters to dynamically configured hosts. See the “DHCP” section of the *Cisco IOS IP Addressing Configuration Guide* for more information.

DHCP Behavior on a Tunnel Network

DMVPN spoke nodes establish a tunnel with a preconfigured DMVPN next hop server (NHS) (hub node) and exchange IP packets with the NHS before an IP address is configured on the tunnel interface. This allows the DHCP client on the spoke and the DHCP relay agent or the DHCP server on the NHS to send and receive the DHCP messages. A DHCP relay agent is any host that forwards DHCP packets between clients and servers.

When the tunnel on a spoke is in the UP state or becomes active, the spoke establishes a tunnel with the preconfigured hub node. The tunnel formation may include setting up IP Security (IPsec) encryption for the tunnel between the spoke and the hub. DHCP receives the GRE tunnel interface UP notification only after the spoke establishes a tunnel with the hub. The DHCP client configured on the spoke must exchange the DHCP IP packets with the hub (DHCP relay agent or server) to obtain an IP address for the GRE tunnel interface. Therefore, the spoke-to-hub tunnel must be in active state before the GRE tunnel interface UP notification is sent to the DHCP server or the relay agent.

IP packets that are broadcast on the DMVPN spoke reach the DMVPN hub. The spoke broadcasts a DHCPDISCOVER message to the DHCP relay agent on the DMVPN hub, before the spoke has an IP address on the GRE tunnel interface. By using the DHCPDISCOVER message, DHCP unicasts the offer back to the client. The hub cannot send IP packets to the spoke before the hub receives a Next Hop Resolution Protocol (NHRP) registration from the spoke. The DHCP relay agent configured on the DMVPN hub adds mapping information to the DHCP client packets (DHCPDISCOVER and DHCPREQUEST).

Depending on whether the hub is a DHCP server or a DHCP relay agent, the mapping is handled differently.

- If the hub is a DHCP server, the Non-Broadcast Multiple Access (NBMA) address is known and a temporary mapping is created on the hub. The hub then unicasts a reply to the spoke.
- If the hub is a DHCP relay agent, the server behind the relay assigns the address. To preserve the NBMA address of the spoke, the address is attached to the DHCP message. When the reply is received, the NBMA address is fetched from the message. The address is sent to the spoke to create the mapping.

Note The NHRP registration sent by the spoke is suppressed until DHCP obtains an address for the GRE tunnel interface. Hence allows reliable exchange of standard DHCP messages.

DMVPN Hub as a DHCP Relay Agent

Relay agents are not required for DHCP to work. Relay agents are used only when the DHCP client and server are in different subnets. The relay agent acts as a communication channel between the DHCP client and server. The DHCP--Tunnels Support feature requires the DMVPN hub to act as a relay agent to relay the DHCP messages to the DHCP server.

The DHCP server is located outside the DMVPN network and is accessible from the DMVPN hub nodes through a physical path. The spoke nodes reach the DHCP servers through the hub-to-spoke tunnel (GRE tunnel). The DHCP server is not directly reachable from the DMVPN spoke. The DHCP relay agent on the DMVPN hub helps the DHCP protocol message exchange between the DHCP client on the spoke and the DHCP server.

DMVPN Topologies

Dual-Hub Single-DMVPN Topology

In a dual-hub single-DMVPN topology, both the hubs must be connected to the same DHCP server that has the high availability (HA) support to maintain DMVPN redundancy. If the hubs are connected to different DHCP servers, they must be configured with mutually exclusive IP address pools for address allocation.

Dual-Hub Dual-DMVPN Topology

In the dual-hub dual-DMVPN topology, each hub is connected to a separate DHCP server. The DMVPN hubs (DHCP relay agents) include a client-facing tunnel IP address in the relayed DHCP requests. DHCP requests are used by the DHCP server to allocate an IP address from the correct pool.

Hierarchical DMVPN Topology

In a DMVPN hierarchical topology, there are multiple levels of DMVPN hubs. However, all the tunnel interface IP addresses are allocated from the same IP subnet address. The DHCP client broadcast packets are broadcast to the directly connected hubs. Hence, the DMVPN hubs at all levels must either be DHCP servers or DHCP relay agents. If DHCP servers are used then the servers must synchronize their databases. The DMVPN hubs must be configured as DHCP relay agents to forward the DHCP client packets to the central DHCP servers. If the DHCP server is located at the central hub, all DHCP broadcasts are relayed through the relay agents until they reach the DHCP server.

How to Configure DHCP Tunnels Support

Configuring the DHCP Relay Agent to Unicast DHCP Replies

Perform this task to configure the DHCP relay agent (hub) to unicast DHCP replies.

By default, the DHCP replies are broadcast from the DMVPN hub to the spoke. Therefore a bandwidth burst occurs. The DHCP Tunnels Support feature does not function if the DHCP messages are broadcast. Hence, you must configure the DHCP relay agent to unicast the DHCP messages for the DHCP to be functional in a DMVPN environment.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **ip dhcp support tunnel unicast**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	ip dhcp support tunnel unicast Example: Router(config)# ip dhcp support tunnel unicast	Configures a spoke-to-hub tunnel to unicast DHCP replies over the DMVPN network.
Step 4	exit Example: Router(config)# exit	Exits global configuration mode.

Configuring a DMVPN Spoke to Clear the Broadcast Flag

Perform this task to configure a DMVPN spoke to clear the broadcast flag.

By default, DMVPN spokes set the broadcast flag in the DHCP DISCOVER and REQUEST messages. Therefore the DHCP relay agent is forced to broadcast the DHCP replies back to the spokes, even though the relay agent has sufficient information to unicast DHCP replies. Hence, you must clear the broadcast flag from the DMVPN spoke.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel *number***
4. **ip dhcp client broadcast-flag clear**
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Router(config)# interface tunnel 1	Configures a tunnel interface and enters interface configuration mode.
Step 4	ip dhcp client broadcast-flag clear Example: Router(config-if)# ip dhcp client broadcast-flag clear	Configures the DHCP client to clear the broadcast flag.
Step 5	exit Example: Router(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.

Configuration Examples for DHCP Tunnels Support

Example: Configuring a DHCP Relay Agent to Unicast DHCP Replies

The following example shows how to configure a DHCP relay agent to unicast DHCP replies:

```
Device# configure terminal
Device(config)# ip dhcp support tunnel unicast
Device(config)# exit
.
.
.
```

Example: Configuring a DMVPN Spoke to Clear the Broadcast Flag and Set the IP Address to DHCP

The following example shows how to configure a DMVPN spoke to clear the broadcast flag and set the IP address to DHCP:

```
Device# configure terminal
Device(config)# interface tunnel 1
Device(config-if)# ip dhcp client broadcast-flag clear
Device(config-if)# exit
```

Feature Name	Releases	Feature Information
DHCP--Tunnels Support	Cisco IOS XE Release 16.12	<p>The DHCP--Tunnels Support feature provides the capability to configure the node (or spoke) of the GRE tunnel interfaces dynamically using DHCP.</p> <p>The following commands were introduced or modified: ip address dhcp, ip dhcp client broadcast-flag, ip dhcp support tunnel unicast.</p>

CHAPTER 220

Per-Tunnel QoS Support for Multiple Policy Maps (MPOL)

The document explains the support for Per-Tunnel QoS configurations using port-channels (referred to as multiple policy maps (MPOL)) on the Cisco 4000 Series Integrated Services Routers and Cisco ASR 1000 Series Aggregation Routers.

- [Prerequisites Per-Tunnel QoS Support for Multiple Policy Maps \(MPOL\)](#), on page 2911
- [Information About Per-Tunnel QoS Support for Multiple Policy Maps \(MPOL\)](#), on page 2912
- [How to Configure Per-Tunnel QoS Support for Multiple Policy Maps \(MPOL\)](#), on page 2913
- [Additional References for Per-Tunnel QoS Support for Multiple Policy Maps \(MPOL\)](#), on page 2916

Prerequisites Per-Tunnel QoS Support for Multiple Policy Maps (MPOL)

The following command must be configured before Per-Tunnel QoS is applied on a port-channel interface as the tunnel source:

```
platform qos port-channel-aggregate port-channel-interface-number
```

If a port-channel is already configured, the above command will fail. This command must be defined *before* configuring the port-channel, else, the following error occurs:

```
Port-channel 1 has been configured with non-aggregate mode already, please use different interface number that port-channel interface hasn't been configured
```

If you encounter the above error you must delete the port-channel and reconfigure the port-channel by using this command.

Information About Per-Tunnel QoS Support for Multiple Policy Maps (MPOL)

Per-Tunnel QoS and Multiple Policy Maps (MPOL)

Per-Tunnel QoS offers the ability to police traffic in a hub-and-spoke environment on a per-spoke basis. Per-Tunnel QoS is configured on a hub router to ensure that the circuit bandwidth in the download direction at the spoke does not go beyond the circuit bandwidth. This is because the aggregate bandwidth on the hub router is significantly higher than the spoke.

However, there are various network designs or configurations that may be considered in the context of the Per-Tunnel QoS feature. One design, which is becoming more prevalent in today's networks, is sourcing tunnels on these hub routers from port-channel main or subinterfaces.

Supported Configurations

The following table lists MPOL configurations and the releases in which the support is available:

MPOL Configurations	On Cisco ASR 1000 Series	On Cisco 4000 Series
MPOL with tunnel sourced from port-channel main interface	Cisco IOS XE Everest16.5.1	Cisco IOS XE Everest 16.6.1
MPOL with tunnel sourced from port-channel sub-interface	Cisco IOS XE 3.16.4S/Cisco IOS XE Everest16.4.1	Cisco IOS XE Everest16.6.1
MPOL with tunnels sourced from different port-channel sub-interfaces of the same port-channel main interface	Cisco IOS XE Denali 16.3.6/Cisco IOS XE Everest16.6.3/Cisco IOS XE Fuji 16.8.1	Cisco IOS XE Everest16.6.1
MPOL with two tunnels in different VRF's sourced from the same port-channel sub-interface in a third VRF	Cisco IOS XE 3.16.4S/Cisco IOS XE Everest16.4.1	Cisco IOS XE Everest16.6.1

Components in MPOL

Before configuring MPOL, it is important to understand each component in reference to the broader solution thereby helping in understanding the supported and recommended configurations in each component.

Class Maps

Class maps segment traffic to match the Differentiated Services Code Point (DSCP) profile supported by the service provider. You mark traffic on ingress to any number of DSCP that are supported in your enterprise network. Alternatively, these markings could be available from a LAN device, which handles the marking for the site. However, on egress of the tunnel, the markings must be grouped into a set of DSCP supported by the class model defined by the ISP for the customer (4-class, 8-class, etc.).

Policy Maps

Child policy map provide a common queuing policy to each spoke. This policy map groups the DSCP into a smaller subset of classes and provide queuing definition as well as sets the tunnel DSCP for egress marking.

Per-Spoke Policy Maps

Policy maps are applied to each spoke based on NHRP group registration. These policy maps are defined according to the download speeds at the spokes. Typically, the policy maps may be grouped into a select number of values and a policy map exists for each value. It is within these values that a child policy map is nested to provide queuing in the context of the policed rate.

Traffic Shaping

A *Flat* policy map is used for shaping traffic that is applied on the parent WAN interface. This WAN interface acts as the tunnel source (in our case, a port-channel interface of some type). This shaper ensures that the egress shaped rate outbound from the hub router does not exceed the specified upload speed.

How to Configure Per-Tunnel QoS Support for Multiple Policy Maps (MPOL)

Setting Up MPOL Components

Configuring Policy Maps

```
policy-map WAN
  class INTERACTIVE-VIDEO
    bandwidth remaining percent 30
    random-detect dscp-based
    set dscp tunnel af41
  class STREAMING-VIDEO
    bandwidth remaining percent 10
    random-detect dscp-based
    set dscp tunnel af31
  class NET-CTRL
    bandwidth remaining percent 5
    set dscp tunnel cs6
  class CALL-SIGNALING
    bandwidth remaining percent 4
    set dscp tunnel af21
  class CRITICAL-DATA
    bandwidth remaining percent 25
    random-detect dscp-based
    set dscp tunnel af21
  class SCAVENGER
    bandwidth remaining percent 1
    set dscp tunnel af11
  class VOICE
    priority level 1
    police cir percent 10
    set dscp tunnel ef
  class class-default
```

```
bandwidth remaining percent 25
random-detect
```

Applying Policy Maps to Spoke

```
policy-map RS-GROUP-300MBPS-POLICY
class class-default
  shape average 300000000
  bandwidth remaining ratio 300
  service-policy WAN
```

Applying Shaping

```
policy-map TRANSPORT-1-SHAPE-ONLY
class class-default
  shape average 600000000
```

Enabling MPOL

The recommended configuration order for enabling MPOL is as follows:

1. Define the routers to use QoS on the port-channel interface that will be configured
2. Define policy shaper.
3. Define the port-channel interface and subinterface and apply the policy shaper.
4. Define class maps to match the ingress traffic or DSCP for egress marking.
5. Define the child policy map for queuing definition and setting the tunnel DSCP.
6. Define the per-spoke policy maps to shape traffic on each spoke based on NHRP group registration and nest the child policy map in each spoke
7. Apply the per-spoke policy-maps to the tunnel interfaces and define the tunnel source to be the port-channel main or subinterface.

```
platform qos port-channel-aggregate <#>
policy-map TRANSPORT-1-SHAPE-ONLY
  class class-default
    shape average 600000000
interface Port-channel1
!
interface Port-channel1.10
  ...
  service-policy output TRANSPORT-1-SHAPE-ONLY
interface Tunnel100
  nhrp map group SPOKE-10MBPS service-policy output SPOKE-POLICE-10MBPS
  ...
  tunnel source Port-channel1.10
```

Verifying MPOL Configuration

After configuring MPOL, use the following commands to verify that the NHRP group is attached to the respective peer and to display the active policy:

- **show dmvpn detail**
- **show policy-map**

Router# **show dmvpn detail**

```

Legend: Attrb --> S - Static, D - Dynamic, I - Incomplete
N - NATed, L - Local, X - No Socket
T1 - Route Installed, T2 - Nexthop-override
C - CTS Capable, I2 - Temporary
# Ent --> Number of NHRP entries with same NBMA peer
NHS Status: E --> Expecting Replies, R --> Responding, W --> Waiting
UpDn Time --> Up or Down Time for a Tunnel

CHAPTER 221

Introduction to FlexVPN

Internet Key Exchange Version 2 (IKEv2), a next-generation key management protocol based on RFC 4306, is an enhancement of the IKE Protocol. IKEv2 is used for performing mutual authentication and establishing and maintaining security associations (SAs).

FlexVPN is Cisco's implementation of the IKEv2 standard featuring a unified paradigm and CLI that combines site to site, remote access, hub and spoke topologies and partial meshes (spoke to spoke direct). FlexVPN offers a simple but modular framework that extensively uses the tunnel interface paradigm while remaining compatible with legacy VPN implementations using crypto maps.

This guide contains the following modules:

- [Configuring Internet Key Exchange Version 2 \(IKEv2\) and FlexVPN Remote Access, on page 2919](#)
- [Configuring FlexVPN Server, on page 2920](#)
- [Configuring FlexVPN Client, on page 2920](#)
- [Configuring IKEv2 Load Balancer, on page 2920](#)
- [Configuring IKEv2 Fragmentation, on page 2920](#)
- [Configuring IKEv2 Reconnect, on page 2920](#)
- [Configuring IKEv2 Packet of Disconnect, on page 2920](#)
- [Configuring IKEv2 Change of Authorization Support, on page 2920](#)
- [Configuring Aggregate Authentication, on page 2920](#)
- [Appendix: FlexVPN RADIUS Attributes, on page 2921](#)
- [Appendix: IKEv2 and Legacy VPNs, on page 2921](#)

Configuring Internet Key Exchange Version 2 (IKEv2) and FlexVPN Remote Access

This module describes IKEv2 CLI and is divided into basic and advanced sections.

The basic section introduces basic IKEv2 commands and describes IKEv2 smart defaults and the mandatory IKEv2 commands required for FlexVPN remote access. This module is a prerequisite for understanding subsequent chapters.

The advanced section describes global IKEv2 commands and how to override the default IKEv2 commands.

Configuring FlexVPN Server

This module describes FlexVPN server features, IKEv2 commands required to configure FlexVPN server, remote access clients and the supported RADIUS attributes.

Configuring FlexVPN Client

This module describes FlexVPN client features and the IKEv2 commands required for FlexVPN client.

Configuring IKEv2 Load Balancer

This module describes the IKEv2 Load Balancer Support feature and the IKEv2 commands required to configure the IKEv2 Load Balancer.

Configuring IKEv2 Fragmentation

The IKE Fragmentation adhering to RFC feature implements fragmentation of Internet Key Exchange Version 2 (IKEv2) packets as proposed in the IETF [draft-ietf-ipsecme-ikev2-fragmentation-10](#) document.

Configuring IKEv2 Reconnect

The IOS IKEv2 support for AutoReconnect feature of AnyConnect feature helps in reestablishing IKEv2 negotiation without user interaction with the Cisco AnyConnect client.

Configuring IKEv2 Packet of Disconnect

The IKEv2 Remote Access Change of Authorization (CoA)—Packet of Disconnect feature terminates an active crypto IKEv2 session on Cisco supported devices.

Configuring IKEv2 Change of Authorization Support

The FlexVPN - IKEv2 CoA for QoS and ACL feature supports RADIUS Change of Authorization (CoA) on an active IKEv2 crypto session.

Configuring Aggregate Authentication

The FlexVPN RA - Aggregate Auth Support for AnyConnect feature implements aggregate authentication method by extending support for Cisco AnyConnect client that uses the proprietary AnyConnect EAP

authentication method to establish a secure tunnel over the Internet between Cisco AnyConnect client and FlexVPN server.

Appendix: FlexVPN RADIUS Attributes

This module describes the RADIUS attributes supported by FlexVPN server.

Appendix: IKEv2 and Legacy VPNs

This module contains configuration examples on how to configure legacy VPNs such as crypto maps and DMVPN with Internet Key Exchange Version 2 (IKEv2).

CHAPTER 222

Configuring Internet Key Exchange Version 2

This module contains information about and instructions for configuring basic and advanced Internet Key Exchange Version 2 (IKEv2). The tasks and configuration examples for IKEv2 in this module are divided as follows:

- Basic IKEv2—Provides information about basic IKEv2 commands, IKEv2 smart defaults, basic IKEv2 profile, and IKEv2 key ring.
- Advanced IKEv2—Provides information about global IKEv2 commands and how to override IKEv2 smart defaults.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

- [Prerequisites for Configuring Internet Key Exchange Version 2](#), on page 2923
- [Restrictions for Configuring Internet Key Exchange Version 2](#), on page 2923
- [Information About Internet Key Exchange Version 2](#), on page 2924
- [How to Configure Internet Key Exchange Version 2](#), on page 2929
- [Configuration Examples for Internet Key Exchange Version 2](#), on page 2943
- [Where to Go Next](#), on page 2950
- [Additional References for Configuring Internet Key Exchange Version 2 \(IKEv2\)](#), on page 2950
- [Feature Information for Configuring Internet Key Exchange Version 2 \(IKEv2\)](#), on page 2951

Prerequisites for Configuring Internet Key Exchange Version 2

You should be familiar with the concepts and tasks described in the “Configuring Security for VPNs with IPsec” module.

Restrictions for Configuring Internet Key Exchange Version 2

You cannot configure an option that is not supported on a specific platform. For example, in a security protocol, the capability of the hardware-crypto engine is important, and you cannot specify the Triple Data Encryption

Standard (3DES) or the Advanced Encryption Standard (AES) type of encryption transform in a nonexportable image, or specify an encryption algorithm that a crypto engine does not support.

Information About Internet Key Exchange Version 2

IKEv2 Supported Standards

Cisco implements the IP Security (IPsec) Protocol standard for use in Internet Key Exchange Version 2 (IKEv2).

Note Cisco no longer recommends using DES or MD5 (including HMAC variant); instead, you should use AES and SHA-256. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

The component technologies implemented in IKEv2 are as follows:

- AES-CBC—Advanced Encryption Standard-Cipher Block Chaining
- SHA (HMAC variant)—Secure Hash Algorithm
- Diffie-Hellman—A public-key cryptography protocol
- DES—Data Encryption Standard (No longer recommended)
- MD5 (HMAC [Hash-based Message Authentication Code] variant)—Message digest algorithm 5 (No longer recommended)

For more information about supported standards and component technologies, see the “Supported Standards for Use with IKE” section in the “Configuring Internet Key Exchange for IPsec VPNs” module in the *Internet Key Exchange for IPsec VPNs Configuration Guide*.

Benefits of IKEv2

Dead Peer Detection and Network Address Translation-Traversal

Internet Key Exchange Version 2 (IKEv2) provides built-in support for Dead Peer Detection (DPD) and Network Address Translation-Traversal (NAT-T).

Certificate URLs

Certificates can be referenced through a URL and hash, instead of being sent within IKEv2 packets, to avoid fragmentation.

Denial of Service Attack Resilience

IKEv2 does not process a request until it determines the requester, which addresses to some extent the Denial of Service (DoS) problems in IKEv1, which can be spoofed into performing substantial cryptographic (expensive) processing from false locations.

EAP Support

IKEv2 allows the use of Extensible Authentication Protocol (EAP) for authentication.

Multiple Crypto Engines

If your network has both IPv4 and IPv6 traffic and you have multiple crypto engines, choose one of the following configuration options:

- One engine handles IPv4 traffic and the other engine handles IPv6 traffic.
- One engine handles both IPv4 and IPv6 traffic.

Reliability and State Management (Windowing)

IKEv2 uses sequence numbers and acknowledgments to provide reliability, and mandates some error-processing logistics and shared state management.

Internet Key Exchange Version 2 CLI Constructs

IKEv2 Proposal

An Internet Key Exchange Version 2 (IKEv2) proposal is a collection of transforms used in the negotiation of Internet Key Exchange (IKE) security associations (SAs) as part of the IKE_SA_INIT exchange. The transform types used in the negotiation are as follows:

- Encryption algorithm
- Integrity algorithm
- Pseudo-Random Function (PRF) algorithm
- Diffie-Hellman (DH) group

See the “IKEv2 Smart Defaults” section for information about the default IKEv2 proposal. See the “Configuring Advanced IKEv2 CLI Constructs” section for information about how to override the default IKEv2 proposal and to define new proposals.

IKEv2 Policy

An IKEv2 policy contains proposals that are used to negotiate the encryption, integrity, PRF algorithms, and DH group in the IKE_SA_INIT exchange. It can have match statements, which are used as selection criteria to select a policy during negotiation.

See the “IKEv2 Smart Defaults” section for information about the default IKEv2 policy. See the “Configuring Advanced IKEv2 CLI Constructs” section for information about how to override the default IKEv2 policy and to define new policies.

IKEv2 Profile

An IKEv2 profile is a repository of nonnegotiable parameters of the IKE SA, such as local or remote identities and authentication methods and services that are available to authenticated peers that match the profile. An IKEv2 profile must be attached to either a crypto map or an IPsec profile on the initiator. An IKEv2 profile is not mandatory on the responder.

IKEv2 Key Ring

An IKEv2 key ring is a repository of symmetric and asymmetric preshared keys and is independent of the IKEv1 key ring. The IKEv2 key ring is associated with an IKEv2 profile and hence supports a set of peers that match the IKEv2 profile. The IKEv2 key ring gets its VPN routing and forwarding (VRF) context from the associated IKEv2 profile.

IKEv2 Smart Defaults

The IKEv2 Smart Defaults feature minimizes the FlexVPN configuration by covering most of the use cases. IKEv2 smart defaults can be customized for specific use cases, though this is not recommended.

See the “Configuring Advanced IKEv2 CLI Constructs” section for information about how to modify the default IKEv2 constructs.

The following rules apply to the IKEv2 Smart Defaults feature:

1. A default configuration is displayed in the corresponding **show** command with **default** as a keyword and with no argument. For example, the **show crypto ikev2 proposal default** command displays the default IKEv2 proposal and the **show crypto ikev2 proposal** command displays the default IKEv2 proposal, along with any user-configured proposals.
2. A default configuration is displayed in the **show running-config all** command; it is not displayed in the **show running-config** command.
3. You can modify the default configuration, which is displayed in the **show running-config all** command.
4. A default configuration can be disabled using the **no** form of the command; for example, **no crypto ikev2 proposal default**. A disabled default configuration is not used in negotiation but the configuration is displayed in the **show running-config** command. A disabled default configuration loses any user modification and restores system-configured values.
5. A default configuration can be reenabled using the default form of the command, which restores system-configured values; for example, **default crypto ikev2 proposal**.
6. The default mode for the default transform set is transport; the default mode for all other transform sets is tunnel.

Note Cisco no longer recommends using MD5 (including HMAC variant) and Diffie-Hellman (DH) groups 1, 2 and 5; instead, you should use SHA-256 and DH Groups 14 or higher. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

The following table lists the commands that are enabled with the IKEv2 Smart Defaults feature, along with the default values.

Table 295: IKEv2 Command Defaults

Command Name	Default Values
crypto ikev2 authorization policy	Device# show crypto ikev2 authorization policy default IKEv2 Authorization policy: default route set interface route accept any tag: 1 distance: 2
crypto ikev2 proposal	Device# show crypto ikev2 proposal IKEv2 proposal: default Encryption: AES-CBC-256 Integrity: SHA512 SHA384 PRF: SHA512 SHA384 DH Group: DH_GROUP_256_ECP/Group 19 DH_GROUP_2048_MODP/Group 14 DH_GROUP_521_ECP/Group 21 DH_GROUP_1536_MODP/Group 5
crypto ikev2 policy	Device# show crypto ikev2 policy default IKEv2 policy: default Match fvrf: any Match address local: any Proposal: default
crypto ipsec profile	Device# show crypto ipsec profile default IPSEC profile default Security association lifetime: 4608000 kilobytes/3600 seconds Responder-Only (Y/N): N PFS (Y/N): N Transform sets={ default: { esp-aes esp-sha-hmac }, }
crypto ipsec transform-set	Device# show crypto ipsec transform-set default Transform set default: { esp-aes esp-sha-hmac } will negotiate = { Tunnel, },

Note Before you can use the default IPsec profile, explicitly specify the **crypto ipsec profile** command on a tunnel interface using the **tunnel protection ipsec profile default** command.

Note The 'default' keyword which needs explicit mapping to other CLIs is not supported on a device running on YANG configuration

IKEv2 Suite-B Support

Suite-B is a set of cryptographic algorithms promulgated by the National Security Agency as part of its Cryptographic Modernization Program. Suite-B for Internet Key Exchange (IKE) and IPsec is defined in RFC 4869. The Suite-B components are as follows:

- Advanced Encryption Standard (AES) 128- and 256-bit keys configured in the IKEv2 proposal. For data traffic, AES should be used in Galois Counter Mode (GCM) that is configured in the IPsec transform set.
- Elliptic Curve Digital Signature Algorithm (ECDSA) configured in the IKEv2 profile.
- Secure Hashing Algorithm 2 (SHA-256 and SHA-384) configured in the IKEv2 proposal and IPsec transform set.

Suite-B requirements comprise four user-interface suites of cryptographic algorithms for use with IKE and IPsec. Each suite consists of an encryption algorithm, a digital-signature algorithm, a key-agreement algorithm, and a hash- or message-digest algorithm. See the “Configuring Security for VPNs with IPsec” feature module for detailed information about Cisco Suite-B support.

AES-GCM Support

An authenticated encryption algorithm provides a combined functionality of encryption and integrity. Such algorithms are called combined mode algorithms. The Support of AES-GCM as an IKEv2 Cipher on IOS feature provides the use of authenticated encryption algorithms for encrypted messages in IKEv2 protocol by adding the Advanced Encryption Standard in Galois/Counter Mode (AES-GCM). AES-GCM supports the key size of 128- and 256-bits—AES-GCM-128 and AES-GCM-256.

Note If AES-GCM is the only encryption algorithm, integrity algorithms cannot be added to the proposal.

Auto Tunnel Mode Support in IKEv2

When configuring a VPN headend in a multiple vendor scenario, you must be aware of the technical details of the peer or responder. For example, some devices may use IPsec tunnels while others may use generic routing encapsulation (GRE) or IPsec tunnel, and sometimes, a tunnel may be IPv4 or IPv6. In the last case, you must configure an Internet Key Exchange (IKE) profile and a virtual template.

The Tunnel Mode Auto Selection feature eases the configuration and spares you about knowing the responder’s details. This feature automatically applies the tunneling protocol (GRE or IPsec) and transport protocol (IPv4 or IPv6) on the virtual template as soon as the IKE profile creates the virtual access interface. This feature is useful on dual stack hubs aggregating multivendor remote access, such as Cisco AnyConnect VPN Client, Microsoft Windows7 Client, and so on.

Note The Tunnel Mode Auto Selection feature eases the configuration for a responder only. The tunnel must be statically configured for an initiator.

The Tunnel Mode Auto Selection feature can be activated using the **auto mode** keywords in the **virtual-template** command in the IKEv2 profile configuration.

How to Configure Internet Key Exchange Version 2

Configuring Basic Internet Key Exchange Version 2 CLI Constructs

To enable IKEv2 on a crypto interface, attach an Internet Key Exchange Version 2 (IKEv2) profile to the crypto map or IPsec profile applied to the interface. This step is optional on the IKEv2 responder.

Note The difference between IKEv1 and IKEv2 is that you need not enable IKEv1 on individual interfaces because IKEv1 is enabled globally on all interfaces on a device.

Perform the following tasks to manually configure basic IKEv2 constructs:

Configuring the IKEv2 Keyring

Perform this task to configure the IKEv2 key ring if the local or remote authentication method is a preshared key.

IKEv2 key ring keys must be configured in the peer configuration submode that defines a peer subblock. An IKEv2 key ring can have multiple peer subblocks. A peer subblock contains a single symmetric or asymmetric key pair for a peer or peer group identified by any combination of the hostname, identity, and IP address.

IKEv2 key rings are independent of IKEv1 key rings. The key differences are as follows:

- IKEv2 key rings support symmetric and asymmetric preshared keys.
- IKEv2 key rings do not support Rivest, Shamir, and Adleman (RSA) public keys.
- IKEv2 key rings are specified in the IKEv2 profile and are not looked up, unlike IKEv1, where keys are looked up on receipt of MM1 to negotiate the preshared key authentication method. The authentication method is not negotiated in IKEv2.
- IKEv2 key rings are not associated with VPN routing and forwarding (VRF) during configuration. The VRF of an IKEv2 key ring is the VRF of the IKEv2 profile that refers to the key ring.
- A single key ring can be specified in an IKEv2 profile, unlike an IKEv1 profile, which can specify multiple key rings.
- A single key ring can be specified in more than one IKEv2 profile, if the same keys are shared across peers matching different profiles.
- An IKEv2 key ring is structured as one or more peer subblocks.

On an IKEv2 initiator, the IKEv2 key ring key lookup is performed using the peer's hostname or the address, in that order. On an IKEv2 responder, the key lookup is performed using the peer's IKEv2 identity or the address, in that order.

Note You cannot configure the same identity in more than one peer.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 keyring** *keyring-name*
4. **peer** *name*
5. **description** *line-of-description*
6. **hostname** *name*
7. **address** {*ipv4-address* [*mask*] | *ipv6-address* *prefix*}
8. **identity** {**address** {*ipv4-address* | *ipv6-address*} | **fqdn domain** *domain-name* | **email domain** *domain-name* | **key-id** *key-id*}
9. **pre-shared-key** {**local** | **remote**} [**0** | **6**] *line hex hexadecimal-string*
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 keyring <i>keyring-name</i> Example: Device(config)# crypto ikev2 keyring kyr1	Defines an IKEv2 key ring and enters IKEv2 key ring configuration mode.
Step 4	peer <i>name</i> Example: Device(config-ikev2-keyring)# peer peer1	Defines the peer or peer group and enters IKEv2 key ring peer configuration mode.
Step 5	description <i>line-of-description</i> Example: Device(config-ikev2-keyring-peer)# description this is the first peer	(Optional) Describes the peer or peer group.
Step 6	hostname <i>name</i> Example: Device(config-ikev2-keyring-peer)# hostname host1	Specifies the peer using a hostname.

	Command or Action	Purpose
Step 7	<p>address <i>{ipv4-address [mask] ipv6-address prefix}</i></p> <p>Example:</p> <pre>Device(config-ikev2-keyring-peer)# address 10.0.0.1 255.255.255.0</pre>	<p>Specifies an IPv4 or IPv6 address or range for the peer.</p> <p>Note This IP address is the IKE endpoint address and is independent of the identity address.</p>
Step 8	<p>identity <i>{address {ipv4-address ipv6-address} fqdn domain domain-name email domain domain-name key-id key-id}</i></p> <p>Example:</p> <pre>Device(config-ikev2-keyring-peer)# identity address 10.0.0.5</pre>	<p>Identifies the IKEv2 peer through the following identities:</p> <ul style="list-style-type: none"> • E-mail • Fully qualified domain name (FQDN) . <p>Note When FQDN is used to identify the peer in the keyring configuration, use the IP address of the peer along with the FQDN</p> <pre>crypto ikev2 keyring key1 peer headend-1 address 1.1.1.1 >>>>>>>> identity fqdn NFVIS-headend-1.cisco.com pre-shared-key Cisco123</pre> <ul style="list-style-type: none"> • IPv4 or IPv6 address • Key ID <p>Note The identity is available for key lookup on the IKEv2 responder only.</p>
Step 9	<p>pre-shared-key <i>{local remote} [0 6] line hex hexadecimal-string</i></p> <p>Example:</p> <pre>Device(config-ikev2-keyring-peer)# pre-shared-key local key1</pre>	<p>Specifies the preshared key for the peer.</p>
Step 10	<p>end</p> <p>Example:</p> <pre>Device(config-ikev2-keyring-peer)# end</pre>	<p>Exits IKEv2 key ring peer configuration mode and returns to privileged EXEC mode.</p>

What to Do Next

After configuring the IKEv2 key ring, configure the IKEv2 profile. For more information, see the “Configuring IKEv2 Profile (Basic)” section.

Configuring an IKEv2 Profile (Basic)

Perform this task to configure the mandatory commands for an IKEv2 profile.

An IKEv2 profile is a repository of nonnegotiable parameters of the IKE security association (SA) (such as local or remote identities and authentication methods) and services available to authenticated peers that match the profile. An IKEv2 profile must be configured and associated with either a crypto map or an IPsec profile on the IKEv2 initiator. Use the **set ikev2-profile** *profile-name* command to associate a profile with a crypto map or an IPsec profile. To disassociate the profile, use the **no** form of the command.

The following rules apply to match statements:

- An IKEv2 profile must contain a match identity or a match certificate statement; otherwise, the profile is considered incomplete and is not used. An IKEv2 profile can have more than one match identity or match certificate statements.
- An IKEv2 profile must have a single match Front Door VPN routing and forwarding (FVRF) statement.
- When a profile is selected, multiple match statements of the same type are logically ORed, and multiple match statements of different types are logically ANDed.
- The match identity and match certificate statements are considered to be the same type of statements and are ORed.
- Configuration of overlapping profiles is considered a misconfiguration. In the case of multiple profile matches, no profile is selected.

Use the **show crypto ikev2 profile** *profile-name* command to display the IKEv2 profile.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 profile** *profile-name*
4. **description** *line-of-description*
5. **aaa accounting** {**psk** | **cert** | **eap**} *list-name*
6. **authentication** {**local** {**rsa-sig** | **pre-share** [**key** {**0** | **6**} *password*]} | **ecdsa-sig** | **eap** [**gtc** | **md5** | **ms-chapv2**] [**username** *username*] [**password** {**0** | **6**} *password*]} | **remote** {**eap** [**query-identity** | **timeout** *seconds*] | **rsa-sig** | **pre-share** [**key** {**0** | **6**} *password*]} | **ecdsa-sig**}}
7. **dpd** *interval* *retry-interval* {**on-demand** | **periodic**}
8. **dynamic**
9. **identity local** {**address** {*ipv4-address* | *ipv6-address*} | **dn** | **email** *email-string* | **fqdn** *fqdn-string* | **key-id** *opaque-string*}
10. **initial-contact force**
11. **ivrf** *name*
12. **keyring** {**local** *keyring-name* | **aaa** *list-name* [**name-mangler** *mangler-name* | **password** *password*] }
13. **lifetime** *seconds*
14. **match** {**address local** {*ipv4-address* | *ipv6-address* | **interface** *name*} | **certificate** *certificate-map* | **fvr** {*fvr-name* | **any**} | **identity remote address** {*ipv4-address* [*mask*] | *ipv6-address* *prefix*} | {**email** [*domain string*] | **fqdn** [*domain string*]} *string* | **key-id** *opaque-string*}
15. **nat keepalive** *seconds*
16. **pki trustpoint** *trustpoint-label* [**sign** | **verify**]
17. **virtual-template** *number* **mode auto**
18. **shutdown**
19. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables the privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	crypto ikev2 profile profile-name Example: Device(config)# crypto ikev2 profile profile1	Defines an IKEv2 profile and enters the IKEv2 profile configuration mode.
Step 4	description line-of-description Example: Device(config-ikev2-profile)# description This is an IKEv2 profile	(Optional) Describes the profile.
Step 5	aaa accounting {psk cert eap} list-name Example: Device(config-ikev2-profile)# aaa accounting eap list1	(Optional) Enables authentication, authorization, and accounting (AAA) accounting method lists for IPsec sessions. Note If the psk , cert , or eap keyword is not specified, the AAA accounting method list is used irrespective of the peer authentication method.
Step 6	authentication {local {rsa-sig pre-share [key {0 6} password]} ecdsa-sig eap [gtc md5 ms-chapv2] [username username] [password {0 6} password]} remote {eap [query-identity timeout seconds] rsa-sig pre-share [key {0 6} password]} ecdsa-sig}} Example: Device(config-ikev2-profile)# authentication local ecdsa-sig	Specifies the local or remote authentication method. <ul style="list-style-type: none"> • rsa-sig—Specifies RSA-sig as the authentication method. • pre-share—Specifies the preshared key as the authentication method. • ecdsa-sig—Specifies ECDSA-sig as the authentication method. • eap—Specifies EAP as the remote authentication method. • query-identity—Queries the EAP identity from the peer. • timeout seconds—Specifies the duration, in seconds, to wait for the next IKE_AUTH request after sending the first IKE_AUTH response. Note You can specify only one local authentication method but multiple remote authentication methods.

	Command or Action	Purpose
Step 7	<p>dpd interval retry-interval {on-demand periodic}</p> <p>Example:</p> <pre>Device(config-ikev2-profile)# dpd 30 6 on-demand</pre>	<p>This step is optional. Configures Dead Peer Detection (DPD) globally for peers matching the profile. By default, the Dead Peer Detection (DPD) is disabled.</p> <p>Note In the example in this step, the first DPD is sent after 30 seconds when there is no incoming ESP traffic. After waiting for 6 seconds (which is the specified retry interval), DPD retries are sent aggressively 5 times in intervals of 6 seconds each. So, a total of 66 seconds ($30 + 6 + 6 * 5 = 66$) elapses before a crypto session is torn down because of DPD.</p>
Step 8	<p>dynamic</p> <p>Example:</p> <pre>Device(config-ikev2-profile)# dynamic</pre>	<p>Configures a dynamic IKEv2 profile. This keyword has been introduced in the Cisco IOS XE 17.2.1 release.</p> <p>Note When you configure a dynamic profile, you cannot configure local or remote authentication and identity using the command line interface.</p>
Step 9	<p>identity local {address {ipv4-address ipv6-address} dn email email-string fqdn fqdn-string key-id opaque-string}</p> <p>Example:</p> <pre>Device(config-ikev2-profile)# identity local email abc@example.com</pre>	<p>This is an optional step. Specifies the local IKEv2 identity type.</p> <p>Note If the local authentication method is a preshared key, the default local identity is the IP address. If the local authentication method is a Rivest, Shamir, and Adleman (RSA) signature, the default local identity is a Distinguished Name.</p>
Step 10	<p>initial-contact force</p> <p>Example:</p> <pre>Device(config-ikev2-profile)# initial-contact force</pre>	<p>Enforces initial contact processing if the initial contact notification is not received in the IKE_AUTH exchange.</p>
Step 11	<p>ivrf name</p> <p>Example:</p> <pre>Device(config-ikev2-profile)# ivrf vrf1</pre>	<p>This is an optional step. Specifies a user-defined VPN routing and forwarding (VRF) or global VRF if the IKEv2 profile is attached to a crypto map.</p> <ul style="list-style-type: none"> If you use the IKEv2 profile for tunnel protection, you must configure the Inside VRF (IVRF) for the tunnel interface on the tunnel interface. <p>Note IVRF specifies the VRF for cleartext packets. The default value for IVRF is FVRF.</p>
Step 12	<p>keyring {local keyring-name aaa list-name [name-mangler mangler-name password password]}</p> <p>Example:</p> <pre>Device(config-ikev2-profile)# keyring aaa keyring1 name-mangler mangler1</pre>	<p>Specifies the local or AAA-based key ring that must be used with the local and remote preshared key authentication method.</p> <p>Note You can specify only one key ring. Local AAA is not supported for AAA-based preshared keys.</p>

	Command or Action	Purpose
		<p>Note Depending on your release, the local keyword and the name-mangler <i>mangler-name</i> keyword-argument pair should be used.</p> <p>Note When using AAA, the default password for a Radius access request is "cisco". You can use the password keyword within the keyring command to change the password.</p> <p>Note To remove the keyring from the IKEv2 profile, use the no keyring {aaa local ppk} keyring-name command.</p>
Step 13	<p>lifetime <i>seconds</i></p> <p>Example:</p> <pre>Device(config-ikev2-profile)# lifetime 1000</pre>	Specifies the lifetime, in seconds, for the IKEv2 SA.
Step 14	<p>match {address local {<i>ipv4-address</i> <i>ipv6-address</i> interface name} certificate <i>certificate-map</i> fvr {<i>fvr-name</i> any} identity remote address {<i>ipv4-address [mask]</i> <i>ipv6-address prefix</i>} {email [<i>domain string</i>] fqdn [<i>domain string</i>]} <i>string</i> key-id <i>opaque-string</i>}</p> <p>Example:</p> <pre>Device(config-ikev2-profile)# match address local interface Ethernet 2/0</pre>	Uses match statements to select an IKEv2 profile for a peer.
Step 15	<p>nat keepalive <i>seconds</i></p> <p>Example:</p> <pre>Device(config-ikev2-profile)# nat keepalive 500</pre>	<p>(Optional) Enables NAT keepalive and specifies the duration in seconds.</p> <ul style="list-style-type: none"> • By default, NAT is disabled.
Step 16	<p>pki trustpoint <i>trustpoint-label</i> [sign verify]</p> <p>Example:</p> <pre>Device(config-ikev2-profile)# pki trustpoint tsp1 sign</pre>	<p>Specifies Public Key Infrastructure (PKI) trustpoints for use with the RSA signature authentication method.</p> <p>Note If the sign or verify keyword is not specified, the trustpoint is used for signing and verification.</p> <p>Note In contrast to IKEv1, a trustpoint must be configured in an IKEv2 profile for certificate-based authentication to succeed. There is no fallback for globally configured trustpoints if this command is not present in the configuration. The trustpoint configuration applies to the IKEv2 initiator and responder.</p>
Step 17	<p>virtual-template <i>number</i> mode auto</p> <p>Example:</p> <pre>Device(config-ikev2-profile)# virtual-template 1 mode auto</pre>	<p>This is an optional step. Specifies the virtual template for cloning a virtual access interface (VAI).</p> <ul style="list-style-type: none"> • mode auto - Enables the tunnel mode auto selection feature.

	Command or Action	Purpose
		Note For the IPsec Dynamic Virtual Tunnel Interface (DVTI), a virtual template must be specified in an IKEv2 profile, without which an IKEv2 session is not initiated.
Step 18	shutdown Example: Device(config-ikev2-profile)# shutdown	(Optional) Shuts down the IKEv2 profile.
Step 19	end Example: Device(config-ikev2-profile)# end	Exits the IKEv2 profile configuration mode and returns to the privileged EXEC mode.

Configuring Advanced Internet Key Exchange Version 2 CLI Constructs

This section describes the global IKEv2 CLI constructs and how to override the IKEv2 default CLI constructs. IKEv2 smart defaults support most use cases and hence, we recommend that you override the defaults only if they are required for specific use cases not covered by the defaults.

Perform the following tasks to configure advanced IKEv2 CLI constructs:

Configuring Global IKEv2 Options

Perform this task to configure global IKEv2 options that are independent of peers.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 certificate-cache** *number-of-certificates*
4. **crypto ikev2 cookie-challenge** *number*
5. **crypto ikev2 diagnose error** *number*
6. **crypto ikev2 dpd** *interval* *retry-interval* {**on-demand** | **periodic**}
7. **crypto ikev2 http-url** **cert**
8. **crypto ikev2 limit** {**max-in-negotiation-sa** *limit* | **max-sa** *limit*}
9. **crypto ikev2 nat** **keepalive** *interval*
10. **crypto ikev2 window** *size*
11. **crypto logging ikev2**
12. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 certificate-cache <i>number-of-certificates</i> Example: Device(config)# crypto ikev2 certificate-cache 750	Defines the cache size for storing certificates fetched from HTTP URLs.
Step 4	crypto ikev2 cookie-challenge <i>number</i> Example: Device(config)# crypto ikev2 cookie-challenge 450	Enables an IKEv2 cookie challenge only when the number of half-open security associations (SAs) exceeds the configured number. <ul style="list-style-type: none"> • Cookie challenge is disabled by default.
Step 5	crypto ikev2 diagnose error <i>number</i> Example: Device(config)# crypto ikev2 diagnose error 500	Enables IKEv2 error diagnostics and defines the number of entries in the exit path database. <ul style="list-style-type: none"> • IKEv2 error diagnostics is disabled by default.
Step 6	crypto ikev2 dpd <i>interval</i> <i>retry-interval</i> {on-demand periodic} Example: Device(config)# crypto ikev2 dpd 30 6 on-demand	Allows live checks for peers as follows: <ul style="list-style-type: none"> • Dead Peer Detection (DPD) is disabled by default. <p>Note In the example in this step, the first DPD is sent after 30 seconds when there is no incoming ESP traffic. After waiting for 6 seconds (which is the specified retry interval), DPD retries are sent aggressively 5 times in intervals of 6 seconds each. So, a total of 66 seconds ($30 + 6 + 6 * 5 = 66$) elapses before a crypto session is torn down because of DPD.</p>
Step 7	crypto ikev2 http-url cert Example: Device(config)# crypto ikev2 http-url cert	Enables the HTTP CERT support. <ul style="list-style-type: none"> • HTTP CERT is disabled by default.
Step 8	crypto ikev2 limit {max-in-negotiation-sa <i>limit</i> max-sa <i>limit</i>} Example:	Enables connection admission control (CAC). <ul style="list-style-type: none"> • Connection admission control is enabled by default.
Step 9	crypto ikev2 nat keepalive <i>interval</i> Example: Device(config)# crypto ikev2 nat keepalive 500	Enables the Network Address Translation (NAT) keepalive that prevents the deletion of NAT entries in the absence of any traffic when there is NAT between Internet Key Exchange (IKE) peers. <ul style="list-style-type: none"> • NAT keepalive is disabled by default.
Step 10	crypto ikev2 window <i>size</i>	Allows multiple IKEv2 request-response pairs in transit.

	Command or Action	Purpose
	Example: Device(config)# crypto ikev2 window 15	<ul style="list-style-type: none"> The default window size is 5.
Step 11	crypto logging ikev2 Example: Device(config)# crypto logging ikev2	Enables IKEv2 syslog messages. <ul style="list-style-type: none"> IKEv2 syslog messages are disabled by default.
Step 12	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Configuring IKEv2 Fragmentation

Perform this task to enable automatic fragmentation of large IKEv2 packets.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto ikev2 fragmentation [mtu *mtu-size*]
4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 fragmentation [mtu <i>mtu-size</i>] Example: Device(config)# crypto ikev2 fragmentation mtu 100	Configures IKEv2 fragmentation. <ul style="list-style-type: none"> The MTU range is from 96 to 1500 bytes. The default MTU size is 576 for IPv4 packets and 1280 bytes for IPv6 packets. <p>Note The MTU size refers to the IP or UDP encapsulated IKEv2 packets.</p>
Step 4	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Configuring IKEv2 Proposal

Refer to the “IKEv2 Smart Defaults” section for information on the default IKEv2 proposal.

Perform this task to override the default IKEv2 proposal or to manually configure the proposals if you do not want to use the default proposal.

An IKEv2 proposal is a set of transforms used in the negotiation of IKEv2 SA as part of the IKE_SA_INIT exchange. An IKEv2 proposal is regarded as complete only when it has at least an encryption algorithm, an integrity algorithm, and a Diffie-Hellman (DH) group configured. If no proposal is configured and attached to an IKEv2 policy, the default proposal in the default IKEv2 policy is used in negotiation.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

Although the IKEv2 proposal is similar to the **crypto isakmp policy** command, the IKEv2 proposal differs as follows:

- An IKEv2 proposal allows configuring one or more transforms for each transform type.
- An IKEv2 proposal does not have any associated priority.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 proposal** *name*
4. **encryption** *encryption-type...*
5. **integrity** *integrity-type...*
6. **group** *group-type...*
7. **prf** *prf-algorithm*
8. **end**
9. **show crypto ikev2 proposal** [*name* | **default**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto ikev2 proposal <i>name</i> Example: Device(config)# crypto ikev2 proposal proposal1	Overrides the default IKEv2 proposal, defines an IKEv2 proposal name, and enters IKEv2 proposal configuration mode.
Step 4	encryption <i>encryption-type...</i> Example: Device(config-ikev2-proposal)# encryption aes-cbc-128 aes-cbc-192	Specifies one or more transforms of the encryption type, which are as follows: <ul style="list-style-type: none"> • 3des (No longer recommended) • aes-cbc-128 • aes-cbc-192 • aes-cbc-256 • aes-gcm-128 • aes-gcm-256
Step 5	integrity <i>integrity-type...</i> Example: Device(config-ikev2-proposal)# integrity sha1	Specifies one or more transforms of the integrity algorithm type, which are as follows: <ul style="list-style-type: none"> • The md5 keyword specifies MD5 (HMAC variant) as the hash algorithm. (No longer recommended) • The sha1 keyword specifies SHA-1 (HMAC variant) as the hash algorithm. • The sha256 keyword specifies SHA-2 family 256-bit (HMAC variant) as the hash algorithm. • The sha384 keyword specifies SHA-2 family 384-bit (HMAC variant) as the hash algorithm. • The sha512 keyword specifies SHA-2 family 512-bit (HMAC variant) as the hash algorithm. <p>Note An integrity algorithm type cannot be specified if you specify Advanced Encryption Standard (AES) in Galois/Counter Mode (AES GCM) as the encryption type.</p>
Step 6	group <i>group-type...</i> Example: Device(config-ikev2-proposal)# group 14	Specifies the Diffie-Hellman (DH) group identifier. <ul style="list-style-type: none"> • The default DH group identifiers are group 2 and 5 in the IKEv2 proposal. • 1—768-bit DH (No longer recommended). • 2—1024-bit DH (No longer recommended). • 5—1536-bit DH (No longer recommended). • 14—Specifies the 2048-bit DH group. • 15—Specifies the 3072-bit DH group. • 16—Specifies the 4096-bit DH group.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • 19—Specifies the 256-bit elliptic curve DH (ECDH) group. • 20—Specifies the 384-bit ECDH group. • 24—Specifies the 2048-bit DH group. <p>The group chosen must be strong enough (have enough bits) to protect the IPsec keys during negotiation. A generally accepted guideline recommends the use of a 2048-bit group after 2013 (until 2030). Either group 14 or group 24 can be selected to meet this guideline. Even if a longer-lived security method is needed, the use of Elliptic Curve Cryptography is recommended, but group 15 and group 16 can also be considered.</p>
Step 7	prf <i>prf-algorithm</i> Example: <pre>Device(config-ikev2-proposal)# prf sha256 sha512</pre>	<p>Specifies one or more of the Pseudo-Random Function (PRF) algorithm, which are as follows:</p> <ul style="list-style-type: none"> • md5 • sha1 • sha256 • sha384 • sha512 <p>Note This step is mandatory if the encryption type is AES-GCM—aes-gmc-128 or aes-gmc-256. If the encryption algorithm is not AES-GCM, the PRF algorithm is the same as the specified integrity algorithm. However, you can specify a PRF algorithm, if required.</p>
Step 8	end Example: <pre>Device(config-ikev2-proposal)# end</pre>	Exits IKEv2 proposal configuration mode and returns to privileged EXEC mode.
Step 9	show crypto ikev2 proposal [<i>name</i> default] Example: <pre>Device# show crypto ikev2 proposal default</pre>	(Optional) Displays the IKEv2 proposal.

What to Do Next

After you create the IKEv2 proposal, attach it to a policy so that the proposal is picked for negotiation. For information about completing this task, see the “Configuring IKEv2 Policy” section.

Configuring IKEv2 Policies

See the “IKEv2 Smart Defaults” section for information about the default IKEv2 policy.

Perform this task to override the default IKEv2 policy or to manually configure the policies if you do not want to use the default policy.

An IKEv2 policy must contain at least one proposal to be considered as complete and can have match statements, which are used as selection criteria to select a policy for negotiation. During the initial exchange, the local address (IPv4 or IPv6) and the Front Door VRF (FVRF) of the negotiating SA are matched with the policy and the proposal is selected.

The following rules apply to the match statements:

- An IKEv2 policy without any match statements will match all peers in the global FVRF.
- An IKEv2 policy can have only one match FVRF statement.
- An IKEv2 policy can have one or more match address local statements.
- When a policy is selected, multiple match statements of the same type are logically ORed and match statements of different types are logically ANDed.
- There is no precedence between match statements of different types.
- Configuration of overlapping policies is considered a misconfiguration. In the case of multiple, possible policy matches, the first policy is selected.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 policy *name***
4. **proposal *name***
5. **match fvrf {*fvrf-name* | any}**
6. **match address local {*ipv4-address* | *ipv6-address*}**
7. **end**
8. **show crypto ikev2 policy [*policy-name* | default]**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 policy <i>name</i> Example: Device(config)# crypto ikev2 policy policy1	Overrides the default IKEv2 policy, defines an IKEv2 policy name, and enters IKEv2 policy configuration mode.
Step 4	proposal <i>name</i> Example: Device(config-ikev2-policy)# proposal proposal1	Specifies the proposals that must be used with the policy. • The proposals are prioritized in the order of listing.

	Command or Action	Purpose
		Note You must specify at least one proposal. You can specify additional proposals with each proposal in a separate statement.
Step 5	match fvrfl {fvrfl-name any} Example: Device(config-ikev2-policy)# match fvrfl any	(Optional) Matches the policy based on a user-configured FVRF or any FVRF. <ul style="list-style-type: none"> The default is global FVRF. Note The match fvrfl any command must be explicitly configured in order to match any VRF. The FVRF specifies the VRF in which the IKEv2 packets are negotiated.
Step 6	match address local {ipv4-address ipv6-address} Example: Device(config-ikev2-policy)# match address local 10.0.0.1	(Optional) Matches the policy based on the local IPv4 or IPv6 address. <ul style="list-style-type: none"> The default matches all the addresses in the configured FVRF.
Step 7	end Example: Device(config-ikev2-policy)# end	Exits IKEv2 policy configuration mode and returns to privileged EXEC mode.
Step 8	show crypto ikev2 policy [policy-name default] Example: Device# show crypto ikev2 policy policy1	(Optional) Displays the IKEv2 policy.

Configuration Examples for Internet Key Exchange Version 2

Configuration Examples for Basic Internet Key Exchange Version 2 CLI Constructs

Example: Configuring the IKEv2 Key Ring

Example: IKEv2 Key Ring with Multiple Peer Subblocks

The following example shows how to configure an Internet Key Exchange Version 2 (IKEv2) key ring with multiple peer subblocks:

```
crypto ikev2 keyring keyring-1
 peer peer1
   description peer1
   address 209.165.200.225 255.255.255.224
   pre-shared-key key-1
 peer peer2
```

Example: IKEv2 Key Ring with Symmetric Preshared Keys Based on an IP Address

```

description peer2
hostname peer1.example.com
pre-shared-key key-2
peer peer3
description peer3
hostname peer3.example.com
identity key-id abc
address 209.165.200.228 255.255.255.224
pre-shared-key key-3

```

Example: IKEv2 Key Ring with Symmetric Preshared Keys Based on an IP Address

The following example shows how to configure an IKEv2 key ring with symmetric preshared keys based on an IP address. The following is the initiator's key ring:

```

crypto ikev2 keyring keyring-1
peer peer1
description peer1
address 209.165.200.225 255.255.255.224
pre-shared-key key1

```

The following is the responder's key ring:

```

crypto ikev2 keyring keyring-1
peer peer2
description peer2
address 209.165.200.228 255.255.255.224
pre-shared-key key1

```

Example: IKEv2 Key Ring with Asymmetric Preshared Keys Based on an IP Address

The following example shows how to configure an IKEv2 key ring with asymmetric preshared keys based on an IP address. The following is the initiator's key ring:

```

crypto ikev2 keyring keyring-1
peer peer1
description peer1 with asymmetric keys
address 209.165.200.225 255.255.255.224
pre-shared-key local key1
pre-shared-key remote key2

```

The following is the responder's key ring:

```

crypto ikev2 keyring keyring-1
peer peer2
description peer2 with asymmetric keys
address 209.165.200.228 255.255.255.224
pre-shared-key local key2
pre-shared-key remote key1

```

Example: IKEv2 Key Ring with Asymmetric Preshared Keys Based on a Hostname

The following example shows how to configure an IKEv2 key ring with asymmetric preshared keys based on the hostname. The following is the initiator's key ring:

```

crypto ikev2 keyring keyring-1
peer host1
description host1 in example domain
hostname host1.example.com

```

```
pre-shared-key local key1
pre-shared-key remote key2
```

The following is the responder's keyring:

```
crypto ikev2 keyring keyring-1
peer host2
description host2 in abc domain
hostname host2.example.com
pre-shared-key local key2
pre-shared-key remote key1
```

Example: IKEv2 Key Ring with Symmetric Preshared Keys Based on an Identity

The following example shows how to configure an IKEv2 key ring with symmetric preshared keys based on an identity:

```
crypto ikev2 keyring keyring-4
peer abc
description example domain
identity fqdn example.com
pre-shared-key abc-key-1
peer user1
description user1 in example domain
identity email user1@example.com
pre-shared-key abc-key-2
peer user1-remote
description user1 example remote users
identity key-id example
pre-shared-key example-key-3
```

Example: IKEv2 Key Ring with a Wildcard Key

The following example shows how to configure an IKEv2 key ring with a wildcard key:

```
crypto ikev2 keyring keyring-1
peer cisco
description example domain
address 0.0.0.0 0.0.0.0
pre-shared-key example-key
```

Example: Matching a Key Ring

The following example shows how a key ring is matched:

```
crypto ikev2 keyring keyring-1
peer cisco
description example.com
address 0.0.0.0 0.0.0.0
pre-shared-key xyz-key
peer peer1
description abc.example.com
address 10.0.0.0 255.255.0.0
pre-shared-key abc-key
peer host1
description host1@abc.example.com
address 10.0.0.1
pre-shared-key host1-example-key
```

Example: Configuring the Profile

In the example shown, the key lookup for peer 10.0.0.1 first matches the wildcard key example-key, then the prefix key example-key, and finally the host key host1-example-key. The best match host1-example-key is used.

```
crypto ikev2 keyring keyring-2
 peer host1
  description host1 in abc.example.com sub-domain
  address 10.0.0.1
  pre-shared-key host1-example-key
 peer host2
  description example domain
  address 0.0.0.0 0.0.0.0
  pre-shared-key example-key
```

In the example shown, the key lookup for peer 10.0.0.1 would first match the host key host1-abc-key. Because this is a specific match, no further lookup is performed.

Example: Configuring the Profile**Example: IKEv2 Profile Matched on Remote Identity**

The following profile supports peers that identify themselves using fully qualified domain name (FQDN) example.com and authenticate with the RSA signature using trustpoint-remote. The local node authenticates itself with a preshared key using keyring-1.

```
crypto ikev2 profile profile2
 match identity remote fqdn example.com
 identity local email router2@example.com
 authentication local pre-share
 authentication remote rsa-sig
 keyring keyring-1
 pki trustpoint trustpoint-remote verify
 lifetime 300
 dpd 10 5 on-demand
 virtual-template 1
```

Example: IKEv2 Profile Supporting Two Peers

The following example shows how to configure an IKEv2 profile supporting two peers that use different authentication methods:

```
crypto ikev2 profile profile2
 match identity remote email user1@example.com
 match identity remote email user2@example.com
 identity local email router2@cisco.com
 authentication local rsa-sig
 authentication remote pre-share
 authentication remote rsa-sig
 keyring keyring-1
 pki trustpoint trustpoint-local sign
 pki trustpoint trustpoint-remote verify
 lifetime 300
 dpd 10 5 on-demand
 virtual-template 1
```

Example: Configuring FlexVPN with Dynamic Routing Using Certificates and IKEv2 Smart Defaults

The following examples show a connection between a branch device (initiator, using a static virtual tunnel interface [sVTI]) and a central device (responder, using a dynamic virtual tunnel interface [dVTI]) with dynamic routing over the tunnel. The example uses IKEv2 smart defaults, and the authentication is performed using certificates (RSA signatures).

Note A RSA modulus size of 2048 is recommended.

The peers use the FQDN as their IKEv2 identity, and the IKEv2 profile on the responder matches the domain in the identity FQDN.

The configuration on the initiator (branch device) is as follows:

```
hostname branch
ip domain name cisco.com
!
crypto ikev2 profile branch-to-central
  match identity remote fqdn central.cisco.com
  identity local fqdn branch.cisco.com
  authentication local rsa-sig
  authentication remote rsa-sig
  pki trustpoint CA
!
crypto ipsec profile svti
  set ikev2-profile branch-to-central
!
interface Tunnel0
  ip address 172.16.0.101 255.255.255.0
  tunnel source Ethernet0/0
  tunnel mode ipsec ipv4
  tunnel destination 10.0.0.100
  tunnel protection ipsec profile svti
!
interface Ethernet0/0
  ip address 10.0.0.101 255.255.255.0
!
interface Ethernet1/0
  ip address 192.168.101.1 255.255.255.0
!
router rip
  version 2
  passive-interface Ethernet1/0
  network 172.16.0.0
  network 192.168.101.0
  no auto-summary
```

The configuration on the responder (central router) is as follows:

```
hostname central
ip domain name cisco.com
!
crypto ikev2 profile central-to-branch
  match identity remote fqdn domain cisco.com
  identity local fqdn central.cisco.com
  authentication local rsa-sig
  authentication remote rsa-sig
  pki trustpoint CA
  virtual-template 1
!
```

```

interface Loopback0
 ip address 172.16.0.100 255.255.255.0
!
interface Ethernet0/0
 ip address 10.0.0.100 255.255.255.0
!
interface Ethernet1/0
 ip address 192.168.100.1 255.255.255.0
!
interface Virtual-Template1 type tunnel
 ip unnumbered Loopback0
 tunnel source Ethernet0/0
 tunnel mode ipsec ipv4
 tunnel protection ipsec profile default
!
router rip
 version 2
 passive-interface Ethernet1/0
 network 172.16.0.0
 network 192.168.100.0
 no auto-summary

```

Configuration Examples for Advanced Internet Key Exchange Version 2 CLI Constructs

Example: Configuring the Proposal

Example: IKEv2 Proposal with One Transform for Each Transform Type

This example shows how to configure an IKEv2 proposal with one transform for each transform type:

```

crypto ikev2 proposal proposal-1
 encryption aes-cbc-128
 integrity sha1
 group 14

```

Example: IKEv2 Proposal with Multiple Transforms for Each Transform Type

This example shows how to configure an IKEv2 proposal with multiple transforms for each transform type:

```

crypto ikev2 proposal proposal-2
 encryption aes-cbc-128 aes-cbc-192
 integrity sha1
 group 14

```

Note Cisco no longer recommends using 3DES, MD5 (including HMAC variant), and Diffie-Hellman(DH) groups 1, 2 and 5; instead, you should use AES, SHA-256 and DH Groups 14 or higher. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

The IKEv2 proposal proposal-2 shown translates to the following prioritized list of transform combinations:

- aes-cbc-128, sha1, 14
- aes-cbc-192, sha1, 14

Example: IKEv2 Proposals on the Initiator and Responder

The following example shows how to configure IKEv2 proposals on the initiator and the responder. The proposal on the initiator is as follows:

```
crypto ikev2 proposal proposal-1
 encryption aes-cbc-192 aes-cbc-128
 integrity sha-256 sha1
 group 14 24
```

The proposal on the responder is as follows:

```
crypto ikev2 proposal proposal-2
 encryption aes-cbc-128 aes-cbc-192
 peer
 integrity sha1 sha-256
 group 24 14
```

The selected proposal will be as follows:

```
encryption aes-cbc-128
 integrity sha1
 group 14
```

In the proposals shown for the initiator and responder, the initiator and responder have conflicting preferences. In this case, the initiator is preferred over the responder.

Example: Configuring the Policy

Example: IKEv2 Policy Matched on a VRF and Local Address

The following example shows how an IKEv2 policy is matched based on a VRF and local address:

```
crypto ikev2 policy policy2
 match vrf vrf1
 match local address 10.0.0.1
 proposal proposal-1
```

Example: IKEv2 Policy with Multiple Proposals That Match All Peers in a Global VRF

The following example shows how an IKEv2 policy with multiple proposals matches the peers in a global VRF:

```
crypto ikev2 policy policy2
 proposal proposal-A
 proposal proposal-B
 proposal proposal-B
```

Example: IKEv2 Policy That Matches All Peers in Any VRF

The following example shows how an IKEv2 policy matches the peers in any VRF:

```
crypto ikev2 policy policy2
 match vrf any
 proposal proposal-1
```

Example: Matching a Policy

Do not configure overlapping policies. If there are multiple possible policy matches, the best match is used, as shown in the following example:

```
crypto ikev2 policy policy1
 match fvrf fvrf1
crypto ikev2 policy policy2
 match fvrf fvff1
 match local address 10.0.0.1
```

The proposal with FVRF as fvrf1 and the local peer as 10.0.0.1 matches policy1 and policy2, but policy2 is selected because it is the best match.

Where to Go Next

After configuring IKEv2, proceed to configure IPsec VPNs. For more information, see the “Configuring Security for VPNs with IPsec” module.

Feature Information for Configuring Internet Key Exchange Version 2 (IKEv2)

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 296: Feature Information for Configuring Internet Key Exchange Version 2 (IKEv2)

Feature Name	Releases	Feature Information
IPv6 Support for IPsec and IKEv2		<p>This feature allows IPv6 addresses to be added to IPsec and IKEv2 protocols.</p> <p>The following commands were introduced or modified: address (IKEv2 keyring), identity (IKEv2 keyring), identity local, match (IKEv2 policy), match (IKEv2 profile), show crypto ikev2 session, show crypto ikev2 sa, show crypto ikev2 profile, show crypto ikev2 policy, debug crypto condition, clear crypto ikev2 sa.</p>
Suite-B Support in IOS SW Crypto		<p>Suite-B adds support for the SHA-2 family (HMAC variant) hash algorithm used to authenticate packet data and verify the integrity verification mechanisms for the IKEv2 proposal configuration. HMAC is a variant that provides an additional level of hashing.</p> <p>Suite-B also allows the Elliptic Curve Digital Signature Algorithm (ECDSA) signature (ECDSA-sig), as defined in RFC 4754, to be the authentication method for IKEv2.</p> <p>Suite-B requirements comprise of four user interface suites of cryptographic algorithms for use with IKE and IPsec that are described in RFC 4869. Each suite consists of an encryption algorithm, a digital signature algorithm, a key agreement algorithm, and a hash or message digest algorithm. See the Configuring Security for VPNs with IPsec module for more information about Cisco IOS Suite-B support.</p> <p>The following commands were introduced or modified: authentication, group, identity (IKEv2 profile), integrity, match (IKEv2 profile).</p>
Support of AES-GCM as an IKEv2 Cipher on IOS		<p>The AES-GCM Support on IKEv2 feature describes the use of authenticated encryption algorithms with the Encrypted Payload of the Internet Key Exchange version 2 (IKEv2) protocol by adding the Advanced Encryption Standard (AES) in Galois/Counter Mode (AES-GCM).</p> <p>The following commands were introduced or modified: encryption (IKEv2 proposal), prf, show crypto ikev2 proposal.</p>
Tunnel Mode Auto Selection		<p>The Tunnel Mode Auto Selection feature eases the configuration and spares you about knowing the responder's details. This feature automatically applies the tunneling protocol (GRE or IPsec) and transport protocol (IPv4 or IPv6) on the virtual template as soon as the IKE profile creates the virtual access interface.</p> <p>The following commands were introduced or modified: virtual-template (IKEv2 profile), show crypto ikev2 profile.</p>

CHAPTER 223

Configuring Quantum-Safe Encryption Using Postquantum Preshared Keys

This module describes quantum-safe encryption using Postquantum Preshared Keys (PPK). This feature implements RFC 8784 and Cisco Secure Key Integration Protocol (SKIP) for quantum-safe encryption of IKEv2 and IPsec packets using PPKs.

- [Restrictions for Quantum-Safe Encryption Using Postquantum Preshared Keys, on page 2953](#)
- [Supported Platforms, on page 2953](#)
- [Information About Quantum-Safe Encryption Using Postquantum Preshared Keys, on page 2954](#)
- [How to Configure Quantum-Safe Encryption Using Postquantum Preshared Keys, on page 2957](#)
- [Configuration Examples for Quantum-Safe Encryption Using Postquantum Preshared Keys, on page 2962](#)

- [Additional References for Quantum-Safe Encryption Using Postquantum Preshared Keys, on page 2965](#)
- [Feature Information for Quantum-Safe Encryption Using Postquantum Preshared Keys, on page 2966](#)

Restrictions for Quantum-Safe Encryption Using Postquantum Preshared Keys

- The Quantum-Safe Encryption Using Postquantum Preshared Keys feature is applicable to all IKEv2 and IPsec VPNs such as, FlexVPN (SVTI-DVTI) and DMVPN, except for GETVPN.
- When you configure PPK using SKIP, the key source should send the key format in the hex format.

Supported Platforms

The Quantum-Safe Encryption Using Postquantum Preshared Keys feature is available on the following platforms:

From Cisco IOS XE Release 17.12.1a	From Cisco IOS XE Release 17.11.1a
Cisco 1000 Series Integrated Services Routers	Cisco Catalyst 8000V Edge Software
Cisco Catalyst 8500 Series Edge Platforms	Cisco Catalyst 8300 Series Edge Platforms

From Cisco IOS XE Release 17.12.1a	From Cisco IOS XE Release 17.11.1a
	Cisco ASR 1000 Series Aggregation Services Routers

Information About Quantum-Safe Encryption Using Postquantum Preshared Keys

The following sections provide detailed information relating to the Quantum-Safe Encryption Using Postquantum Preshared Keys feature.

Impact of Quantum Computers on Cryptography

Quantum computers pose a serious challenge to the cryptographic algorithms and protocols deployed widely today. A quantum computer can solve Diffie-Hellman (DH) and Elliptic Curve Diffie-Hellman (ECDH) problems in polynomial time, and this can compromise the security of existing IKEv2 systems. A man-in-the-middle storing the VPN communications today can decrypt them later when a quantum computer is available.

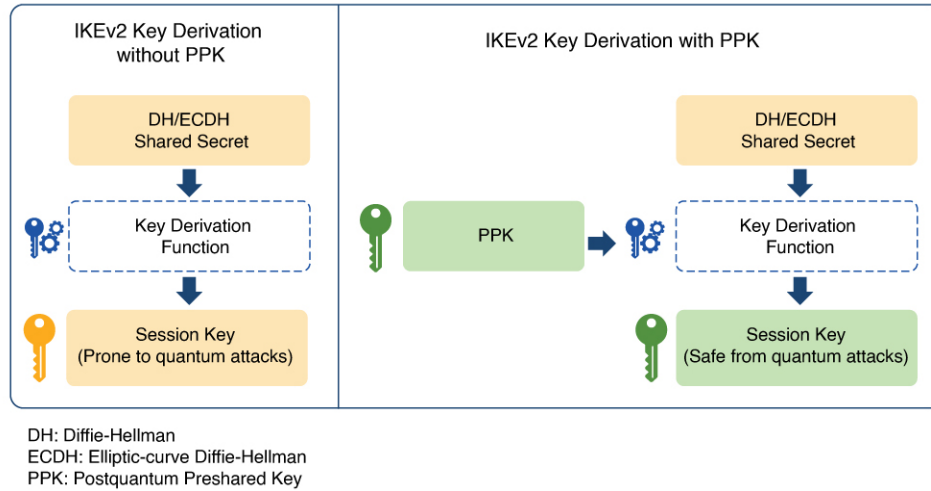

Postquantum Preshared Keys

Session keys that are based on preshared keys are not vulnerable to quantum attacks if the preshared keys have sufficient entropy and the pseudorandom function (PRF), encryption, and authentication transformations are quantum secure. The resulting system is then believed to be secure against classical attackers of today or future attackers with a quantum computer.

RFC 8784 (Mixing Preshared Keys in IKEv2 for Postquantum Security) describes an extension to the IKEv2 protocol to allow it to be resistant to a quantum computer by using preshared keys known as PPKs. The RFC defines negotiation of PPK capability, communication of PPK ID, mixing of PPK as an additional input in the session key derivation, and optional fallback to non-PPK-based session.

Figure 1 shows the IKEv2 key derivation with and without PPK.

Figure 117: IKEv2 Key Derivation - With and Without PPK

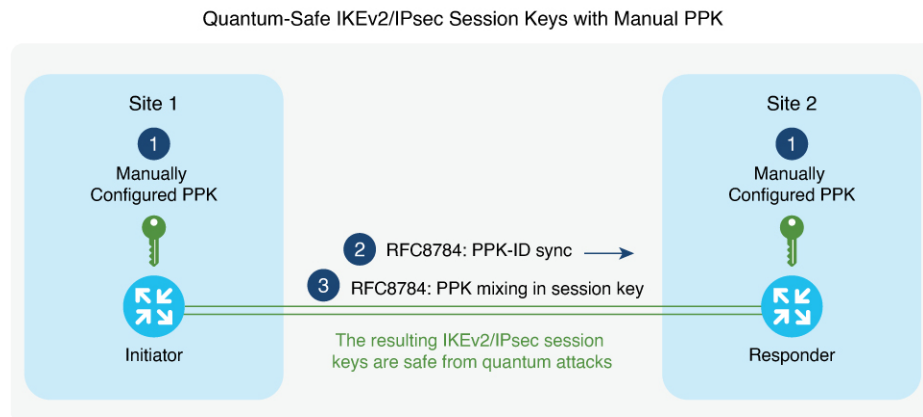

Manual Postquantum Preshared Keys

The simplest provisioning mechanism to provide the same PPKs on the IKEv2 and IPsec initiator and responder pair is to manually configure the PPKs on both sides. The PPKs configured manually are known as manual PPKs.

With a manual PPK, the administrator must ensure that the PPK is of sufficient size and entropy and it is rotated frequently.

Figure 2 shows quantum-safe IKEv2 and IPsec session keys with a manual PPK.

Figure 118: Quantum-Safe IKEv2 and IPsec Session Keys with Manual PPK

Cisco Secure Key Integration Protocol and Dynamic Postquantum Preshared Keys

Cisco SKIP is an HTTPS-based protocol that allows encryption devices such as routers, to import PPKs from an external key source. The externally imported PPKs known as dynamic PPKs offer the benefits of automated provisioning and refresh and better entropy of PPKs.

Cisco SKIP uses TLS1.2 with PSK-DHE cipher suite to make the SKIP protocol quantum-safe. The encryption devices must implement the SKIP client and the external key source must implement the SKIP server.

For an external key source to be SKIP compliant, it must implement the Cisco SKIP protocol and must use an out-of-band synchronization mechanism to provide the same PPK to the two encryption devices—initiator and responder. The external key source can be a Quantum Key Distribution (QKD) device, software, or cloud-based key source or service.

The external key source must meet the following expectations to be SKIP-compliant:

- Must implement SKIP protocol or API, as defined in the Cisco SKIP specification.
- Must provide the same PPK to the encryption device pair—initiator and responder—using an out-of-band synchronization mechanism.

Note Key source vendors, such as QKD vendors, should contact their Cisco representative to implement the Cisco SKIP protocol.

Figure 3 shows quantum-safe IKEv2 and IPsec session keys using dynamic PPK.

Figure 119: Quantum-Safe IKEv2 and IPsec Session Keys with Dynamic PPK

The IKEv2 initiator and responder are connected to their local key source and configured with the SKIP client that specifies the IP address and port of the key source and the preshared key for the TLS1.2 session. The PPK sources are configured with the SKIP parameters, including the local key source identity and the list of identities of the peer key sources.

The following is a high-level operation of the Cisco SKIP protocol:

1. The IKEv2 initiator places a request for a PPK from its key source. The key source replies with a PPK and the corresponding PPK ID.

2. The initiator-side key source synchronizes the PPK to the responder-side key source using an out-of-band mechanism that is specific to the type of key source. The IKEv2 initiator communicates the PPK ID to the IKEv2 responder over IKEv2 using the RFC 8784 extensions.
3. The IKEv2 responder requests from its key source, the PPK corresponding to the PPK ID received from the IKEv2 initiator. The key source replies with the PPK corresponding to the PPK ID.
4. The IKEv2 initiator and responder mix the PPK in the key derivation, as specified in RFC 8784. The resulting IKEv2 and IPsec session keys are quantum-safe.

How to Configure Quantum-Safe Encryption Using Postquantum Preshared Keys

The following sections describe the processes involved in configuring quantum-safe encryption using postquantum preshared keys.

Configuring Manual Postquantum Preshared Keys

Perform the following tasks to configure the manual PPK.

Configuring Manual Postquantum Preshared Keys in an IKEv2 Keyring

Follow these steps to configure the manual PPK for one or more peers or groups of peers, in the IKEv2 keyring.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 keyring** *keyring-name*
4. **peer** *name*
5. Run one of the following commands:
 - **address** {*ipv4-address mask* | *ipv6-address prefix*}
 - **identity** {**address** {*ipv4-address* | *ipv6-address*} | **fqdn domain** *domain-name* | **email domain** *domain-name* | **key-id** *key-id*}
6. **ppk manual id** *ppk-id* **key** [**0** | **6** | **hex**] *password* [**required**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# configure terminal	
Step 3	crypto ikev2 keyring <i>keyring-name</i> Example: Device(config)# crypto ikev2 keyring keyring1	Defines an IKEv2 keyring and enters IKEv2 keyring configuration mode.
Step 4	peer <i>name</i> Example: Device(config-ikev2-keyring)# peer peer1	Defines the peer or peer group and enters IKEv2 keyring peer configuration mode.
Step 5	Run one of the following commands: <ul style="list-style-type: none"> • address {<i>ipv4-address mask</i> <i>ipv6-address prefix</i>} • identity {address {<i>ipv4-address</i> <i>ipv6-address</i>} fqdn domain <i>domain-name</i> email domain <i>domain-name</i> key-id <i>key-id</i>} Example: Device(config-ikev2-keyring-peer)# address 10.0.0.1 255.0.0.0 Example: Device(config-ikev2-keyring-peer)# identity address 10.0.0.1	Specifies the remote IKEv2 peers based on WAN IP address or IKEv2 identity. <ul style="list-style-type: none"> • The address command specifies an IPv4 or IPv6 address or range for the peer or group of peers. Note This IP address is the IKE endpoint address and is independent of the identity address. <ul style="list-style-type: none"> • The identity command identifies the IKEv2 peer through the following identities: <ul style="list-style-type: none"> • E-mail • Fully qualified domain name (FQDN) • IPv4 or IPv6 address • Key ID Note The identity command is available for key lookup only on the IKEv2 responder.
Step 6	ppk manual id <i>ppk-id</i> key [0 6 hex] <i>password</i> [required] Example: Device(config-ikev2-keyring-peer)# ppk manual id ppk_id key cisco123	Configures PPK ID and PPK for the identified peers. <ul style="list-style-type: none"> • ppk manual: Indicates that the PPK ID and the PPK are configured manually. • id <i>ppk-id</i>: Specifies the PPK ID. • key <i>password</i>: Specifies the PPK. • required: Indicates that the quantum-safe encryption using PPK is mandatory and there must be no fallback to a normal IKEv2 or IPsec session. Note The <i>ppk-id</i> and the PPK must match on both the peers.

Configuring an IKEv2 Keyring in an IKEv2 Profile

SUMMARY STEPS

1. **crypto ikev2 profile** *profile-name*
2. **keyring ppk** *keyring-name*
3. **exit**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	crypto ikev2 profile <i>profile-name</i> Example: Device(config-ikev2-keyring-peer)# crypto ikev2 profile profile1	Defines an IKEv2 profile and enters IKEv2 profile configuration mode.
Step 2	keyring ppk <i>keyring-name</i> Example: Device(config-ikev2-profile)# keyring ppk keyring1	Specifies the keyring that has either manual or dynamic PPK configured. Note To remove the keyring from the IKEv2 profile, use the no keyring {aaa local ppk} keyring-name command.
Step 3	exit Example: Device(config-ikev2-profile)# exit	Exits IKEv2 profile configuration mode and returns to global configuration mode.
Step 4	exit Example: Device(config)# exit	Exits global configuration mode and enters privileged EXEC mode.

Configuring Dynamic Postquantum Preshared Keys

Perform the following tasks to configure the dynamic PPK.

Configuring a Secure Key Integration Protocol Client

SKIP client configuration specifies the parameters required to securely communicate with and request PPKs from an external SKIP-compliant key source.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto skip-client** *skip-client-name*
4. **server** {**ipv4** *ipv4-address* | **ipv6** *ipv6-address* | **fqdn** *domain-name*} **port** *port-number*
5. **psk id** *id-name* **key** [**0** | **6** | **hex**] *password*

6. exit

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto skip-client <i>skip-client-name</i> Example: Device(config-crypto-skip-client)# crypto skip-client skip-client-cfg	Specifies the name of SKIP client configuration block and enters SKIP client configuration mode.
Step 4	server { ipv4 <i>ipv4-address</i> ipv6 <i>ipv6-address</i> fqdn <i>domain-name</i> } port <i>port-number</i> Example: Device(config-crypto-skip-client)# server ipv4 10.10.0.3 port 9993	Specifies the IP address or FQDN and port to connect to the external key source.
Step 5	psk id <i>id-name</i> key [0 6 hex] <i>password</i> Example: Device(config-crypto-skip-client)# psk id psk-id key 0 cisco123	Specifies the preshared key identity and the preshared key for the SKIP TLS session.
Step 6	exit Example: Device(config-crypto-skip-client)# exit	Exits SKIP client configuration mode and returns to global configuration mode.

Configuring a Secure Key Integration Protocol Client in an IKEv2 Keyring

Follow these steps to configure the manual PPK for one or more peers or groups of peers in the IKEv2 keyring.

SUMMARY STEPS

1. **crypto ikev2 keyring** *keyring-name*
2. **peer** *name*
3. Execute one of the following commands:
 - **address** {*ipv4-address mask* | *ipv6-address prefix*}
 - **identity** {**address** {*ipv4-address* | *ipv6-address*} | **fqdn domain** *domain-name* | **email domain** *domain-name* | **key-id** *key-id*}
4. **ppk dynamic** *skip-client-name* [**required**]

DETAILED STEPS

	Command or Action	Purpose
Step 1	crypto ikev2 keyring <i>keyring-name</i> Example: Device(config)# crypto ikev2 keyring keyring1	Defines an IKEv2 keyring and enters IKEv2 keyring configuration mode.
Step 2	peer <i>name</i> Example: Device(config-ikev2-keyring)# peer peer1	Defines the peer or peer group and enters IKEv2 keyring peer configuration mode.
Step 3	Execute one of the following commands: <ul style="list-style-type: none"> • address {<i>ipv4-address mask</i> <i>ipv6-address prefix</i>} • identity {address {<i>ipv4-address</i> <i>ipv6-address</i>} fqdn domain <i>domain-name</i> email domain <i>domain-name</i> key-id <i>key-id</i>} Example: Device(config-ikev2-keyring-peer)# address 10.0.0.1 255.0.0.0 Example: Device(config-ikev2-keyring-peer)# identity address 10.0.0.1	Specifies the remote IKEv2 peers based on WAN IP address or IKEv2 identity. The address command specifies an IPv4 or IPv6 address or range for the peer or group of peers. Note This IP address is the IKE endpoint address and is independent of the identity address. The identity command identifies the IKEv2 peer through the following identities: <ul style="list-style-type: none"> • E-mail • Fully qualified domain name (FQDN) • IPv4 or IPv6 address • Key ID Note The identity command is available for key lookup only on the IKEv2 responder.
Step 4	ppk dynamic <i>skip-client-name</i> [required] Example: Device(config-ikev2-keyring-peer)# ppk dynamic skip-client1	Specifies the external key source to use for dynamic PPKs. <ul style="list-style-type: none"> • ppk dynamic: Indicates that the PPK is imported dynamically from an external key source. • required: Indicates that the quantum-safe encryption using PPK is mandatory and there must be no fallback to a normal IKEv2 or IPsec session.

Configuring an IKEv2 Keyring in an IKEv2 Profile

SUMMARY STEPS

1. **crypto ikev2 profile** *profile-name*
2. **keyring ppk** *keyring-name*
3. **exit**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	crypto ikev2 profile <i>profile-name</i> Example: Device(config-ikev2-keyring-peer)# crypto ikev2 profile profile1	Defines an IKEv2 profile and enters IKEv2 profile configuration mode.
Step 2	keyring ppk <i>keyring-name</i> Example: Device(config-ikev2-profile)# keyring ppk keyring1	Specify the keyring that has either manual or dynamic PPK configured. Note To remove the keyring from the IKEv2 profile, use the no keyring {aaa local ppk} keyring-name command.
Step 3	exit Example: Device(config-ikev2-profile)# exit	Exits IKEv2 profile configuration mode and returns to global configuration mode.
Step 4	exit Example: Device(config)# exit	Exits global configuration mode and enters privileged EXEC mode.

Configuration Examples for Quantum-Safe Encryption Using Postquantum Preshared Keys

The following sections provide detailed configuration examples relating to the configuration of quantum-safe encryption using PPKs.

Example: Configuring the Manual Postquantum Preshared Keys

Example: Initiator Configuration

The following example shows how to manually configure a PPK for an initiator:

```

conf t
hostname Router1
!
crypto ikev2 keyring ppk-keyring
peer 1
address 10.10.0.1 255.255.255.0
ppk manual id ppk_id key cisco123
!
crypto ikev2 profile prof
match identity remote address 10.10.0.1
authentication local pre-share key cisco
authentication remote pre-share key cisco
keyring ppk ppk-keyring
!

```

```

crypto ipsec profile prof
set ikev2-profile prof
!
interface Tunnel0
ip address 10.10.0.1 255.255.255.0
tunnel source GigabitEthernet1
tunnel destination 10.10.10.1
tunnel protection ipsec profile prof
!
interface GigabitEthernet1
ip address 10.10.10.2 255.255.255.0
no shut
!

```

Example: Responder Configuration

The following example shows how to manually configure a PPK for a responder:

```

conf t
hostname Router2
!
crypto ikev2 keyring ppk-keyring
peer 1
address 10.10.0.1 255.255.255.0
ppk manual id ppk_id key cisco
!
crypto ikev2 profile prof
match identity remote address 10.10.0.1
authentication local pre-share key cisco
authentication remote pre-share key cisco
keyring ppk ppk-keyring
!
crypto ipsec profile prof
set ikev2-profile prof
!
interface Tunnel0
ip address 10.10.0.2 255.255.255.0
tunnel source GigabitEthernet1
tunnel destination 10.10.10.2
tunnel protection ipsec profile prof
!
interface GigabitEthernet1
ip address 10.10.0.1 255.255.255.0
no shut
!

```

Example: Configuring the Dynamic Postquantum Preshared Keys

Example: Initiator Configuration

The following example shows how to configure a dynamic PPK for an initiator:

```

conf t
hostname Router1
!
crypto skip-client skip-client-cfg
server ipv4 10.10.0.4 port 9991
psk id psk-id1 key 0 cisco123
!
crypto ikev2 keyring ppk-keyring
peer 1

```

Example: Responder Configuration

```

address 10.10.0.1 255.255.255.0
ppk dynamic skip-client-cfg
!
crypto ikev2 profile prof
match identity remote address 10.10.0.1
authentication local pre-share key cisco
authentication remote pre-share key cisco
keyring ppk ppk-keyring
!
crypto ipsec profile prof
set ikev2-profile prof
!
interface Tunnel0
ip address 10.10.0.2 255.255.255.0
tunnel source GigabitEthernet1
tunnel destination 10.10.10.1
tunnel protection ipsec profile prof
!
interface GigabitEthernet1
ip address 10.10.10.2 255.255.255.0
no shut
!
interface GigabitEthernet1
ip address 10.10.10.3 255.255.255.0
no shut
!

```

Example: Responder Configuration

The following example shows how to configure a dynamic PPK for a responder:

```

conf t
hostname Router2
!
crypto skip-client skip-client-cfg
server ipv4 10.10.0.4 port 9992
psk id vedge-sim-1 key 0 cisco123
!
crypto ikev2 keyring ppk-keyring
peer 1
address 10.10.0.1 255.255.255.0
ppk dynamic skip-client-cfg
!
crypto ikev2 profile prof
match identity remote address 10.10.0.1
authentication local pre-share key cisco
authentication remote pre-share key cisco
keyring ppk ppk-keyring
!
crypto ipsec profile prof
set ikev2-profile prof
!
interface Tunnel0
ip address 10.10.0.2 255.255.255.0
tunnel source GigabitEthernet1
tunnel destination 10.10.10.2
tunnel protection ipsec profile prof
!
interface GigabitEthernet1
ip address 10.10.10.1 255.255.255.0
no shut
!
interface GigabitEthernet1

```

```
ip address 10.10.10.4 255.255.255.0
!
```

Verifying the Postquantum Preshared Keys Configuration

Use the **show crypto ikev2 sa detailed** command to display information about the current IKEv2 security associations. The `Quantum Resistance Enabled` message displayed in the output indicates that PPK-based quantum-safe encryption is enabled.

The following is a sample output from the **show crypto ikev2 sa detailed** command:

```
IPv4 Crypto IKEv2 SA
Tunnel-id      Local                               Remote                               fvrf/ivrf      Status
   3           <src IP>/SrcPort                   <Dst IP>/DstPort                   none/none      READY

Encr: AES-CBC, keysize: 256, PRF: SHA512, Hash: SHA512, DH Grp:19,
Auth sign:
.
.
.
Initiator of SA : No
Quantum Resistance Enabled
```

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for Quantum-Safe Encryption Using Postquantum Preshared Keys

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 297: Feature Information for Quantum-Safe Encryption Using Postquantum Preshared Keys

Feature Name	Releases	Feature Information
Quantum-Safe Encryption Using Postquantum Preshared Keys	Cisco IOS XE Release 17.11.1a	The feature implements RFC 8784 and Cisco Secure Key Integration Protocol (SKIP) for quantum-safe encryption of IKEv2 and IPsec packets using Postquantum Preshared Keys (PPKs). The PPKs that are configured manually are known as manual PPKs, and the PPKs that are imported from an external key source using the SKIP protocol are known as dynamic PPKs.

CHAPTER 224

Configuring the FlexVPN Server

This module describes FlexVPN server features, IKEv2 commands required to configure the FlexVPN server, remote access clients, and the supported RADIUS attributes.

Note Security threats, as well as cryptographic technologies to help protect against such threats, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

- [Restrictions for the FlexVPN Server, on page 2969](#)
- [Information About the FlexVPN Server, on page 2970](#)
- [How to Configure the FlexVPN Server, on page 2980](#)
- [Configuration Examples for the FlexVPN Server, on page 2990](#)
- [Additional References for Configuring the FlexVPN Server, on page 2995](#)
- [Feature Information for Configuring the FlexVPN Server, on page 2996](#)

Restrictions for the FlexVPN Server

Dual-Stack Tunnel Interface and VRF-Aware IPsec

When configuring a dual-stack tunnel interface in a VPN routing and forwarding (VRF)-aware IPsec scenario, you cannot use the **ip vrf forwarding** command to configure an Inside VPN routing and forwarding (IVRF) instance because this is not a valid configuration. Use the **vrf forwarding vrf-name** command to define the IVRF of the tunnel interface, where the *vrf-name* argument is defined using the **vrf definition** command with IPv4 and IPv6 address families inside the definition.

SSO Restrictions

- For an ESP reload (no standby ESP), the SA sequence number restarts from 0. The peer router drops packets that do not have the expected sequence number. You may need to explicitly reestablish IPsec sessions to work around this issue for systems that have a single ESP after an ESP reload. Traffic disruption might happen over the IPsec sessions in such cases for the duration of the reload.

IP Address Assignment When Configuring Virtual Template Interfaces for FlexVPN

- When setting up Virtual Template Interfaces (VTI) for FlexVPN on IOS platforms, it is essential to use the **ip unnumbered** command for IP address assignment. Directly assigning a static IP address and subnet mask to a Virtual Template Interface is not supported and can lead to cloning errors with the Virtual Access (VA) interfaces.

The correct configuration practice is as follows:

```
interface Virtual-Template1 type tunnel
ip unnumbered <interface-ref>
```

Information About the FlexVPN Server

Peer Authentication Using EAP

The FlexVPN server supports peer authentication using the Extensible Authentication protocol (EAP) and acts as a pass-through authenticator relaying EAP messages between the client and the backend EAP server. The backend EAP server is typically a RADIUS server that supports EAP authentication.

Note While a FlexVPN client authenticates the FlexVPN server using EAP, the FlexVPN server must be authenticated by using certificates.

The FlexVPN server is configured to authenticate FlexVPN clients that use EAP by configuring the **authentication remote eap** command in IKEv2 profile configuration mode. FlexVPN clients authenticate using EAP by skipping the AUTH payload in the IKE_AUTH request.

If the **query-identity** keyword is configured, the FlexVPN server queries the EAP identity from the client; otherwise, the FlexVPN client's IKEv2 identity is used as the EAP identity. However, if the **query-identity** keyword is not configured and the FlexVPN client's IKEv2 identity is an IPv4 or IPv6 address, the session is terminated because IP addresses cannot be used as the EAP identity.

The FlexVPN server starts the EAP authentication by passing the FlexVPN client's EAP identity to the EAP server; the FlexVPN server then relays EAP messages between the remote access (RA) client and the EAP server until the authentication is complete. If the authentication succeeds, the EAP server is expected to return the authenticated EAP identity to the FlexVPN server in the EAP success message.

After EAP authentication, the EAP identity used for the IKEv2 configuration is obtained from the following sources in the given order:

- The EAP identity provided by the EAP server with the EAP success message.
- The EAP identity queried from the client when the **query-identity** keyword is configured.
- The FlexVPN client IKEv2 identity used as the EAP identity.

The figure below shows IKEv2 exchange for EAP authentication without the **query-identity** keyword.

Figure 120: IKEv2 Exchange Without the query-identity Keyword

IKEv2 RA client	IKEv2 RA server	RADIUS-EAP server
HDR, SAi1, KEi, Ni →

209141

IKEv2 Configuration Mode

IKEv2 configuration mode allows IKE peers to exchange configuration information such as IP addresses and routes. The configuration information is obtained from IKEv2 authorization. Both pull and push models are supported. The pull model involves the exchange of configuration requests and replies; the push model involves the exchange of configuration sets and acknowledgements.

The following table describes the conditions when the initiator and the responder send different configuration payload types:

Table 298: Configuration Payload Types

Configuration Payload Type	Sent By...	When...
CFG_REQUEST	Initiator	The initiator is the FlexVPN client or if the config-exchange request command is enabled in the IKEv2 profile.
CFG_REPLY	Responder	The responder receives the CFG_REQUEST.
CFG_SET	Initiator and responder	Initiator—The config-exchange set send command is enabled in the IKEv2 profile. Responder—The CFG_REQUEST is not received, the configuration data is available, and the config-exchange set send command is enabled in the IKEv2 profile.
CFG_ACK	Initiator and responder	Initiator—The config-exchange set accept command is enabled in the IKEv2 profile. Responder—The config-exchange set accept command is enabled in the IKEv2 profile.

Note The commands to send configuration requests and configuration set payloads are enabled by default.

Depending on your release, the IKEv2 initiator can trigger a configuration mode when the initiator is a FlexVPN client, or any static tunnel interface initiating IKEv2 can trigger configuration mode by enabling the **config-mode** command in the IKEv2 profile.

The IKEv2 FlexVPN server supports the following standard IPv4 configuration attributes:

- INTERNAL_IP4_ADDRESS
- INTERNAL_IP4_NETMASK
- INTERNAL_IP4_DNS
- INTERNAL_IP4_NBNS
- INTERNAL_IP4_SUBNET

The IKEv2 FlexVPN server supports the following standard IPv6 configuration attributes:

- INTERNAL_IP6_ADDRESS
- INTERNAL_IP6_DNS
- INTERNAL_IP6_SUBNET

Note IPv6 configuration attributes are only supported by the Microsoft Windows IKEv2 client.

The INTERNAL_IP4_SUBNET and INTERNAL_IP6_SUBNET configuration attributes, controlled by the **route set** and **aaa attribute list** commands in the IKEv2 authorization policy, are not supported when you configure a static virtual tunnel interface (SVTI)-to-SVTI tunnel. In such cases, static routing or dynamic routing must be used instead of the IKEv2-based route exchange.

The IKEv2 FlexVPN server supports the following standard common configuration attribute:

- APPLICATION_VERSION

Note This attribute is only sent for Cisco Anyconnect and FlexVPN clients.

The IKEv2 FlexVPN server supports the following Cisco Unity configuration attributes:

- MODECFG_BANNER
- MODECFG_DEFDOMAIN
- MODECFG_SPLITDNS_NAME
- MODECFG_BACKUPSERVERS
- MODECFG_PFS
- MODECFG_SMARTCARD_REMOVAL_DISCONNECT

Note The Cisco Unity attributes are sent only for Cisco Anyconnect and FlexVPN clients.

The IKEv2 FlexVPN server supports the following Cisco FlexVPN configuration attributes:

- MODECFG_CONFIG_URL
- MODECFG_CONFIG_VERSION

Note The Cisco FlexVPN attributes are sent only for Cisco FlexVPN clients.

The INTERNAL_IP4_ADDRESS attribute value is derived from the following sources in the given order:

- The Framed-IP-Address attribute received in AAA user authorization.
- The local IP address pool.
- The DHCP server.

The DHCP server, if configured, allocates addresses only if the local IP address pool is not configured. However, if an error occurs when allocating IP addresses from the local pool, the next address source DHCP server is not used for allocating the addresses.

The value for INTERNAL_IP4_NETMASK attribute is derived as follows:

- If the IP address is obtained from the DHCP server, the netmask is also obtained from the DHCP server.

- If the IP address is obtained from either the Framed-IP-Address attribute in AAA user authorization or the local IP address pool, the netmask is derived from the IPv4 netmask attribute received in the user or group authorization. If the netmask is not available, the INTERNAL_IP4_NETMASK attribute is not included in the configuration reply. If the netmask is available, the INTERNAL_IP4_NETMASK attribute is included only if the INTERNAL_IP4_ADDRESS attribute is included in the configuration reply.

An IPv4 address is allocated and included in the reply only if the client requests an address. If the client requests multiple IPv4 addresses, only one IPv4 address is sent in the reply. If available, the remaining attributes are included in the reply even though the client does not request them. If the client requests an IPv4 address and the FlexVPN server is unable to assign an address, an INTERNAL_ADDRESS_FAILURE message is returned to the client.

It is always recommended that the prefix length should be used as 128 on ipv6 local pool configuration.

For example, if clients are 4 , **ipv6 local pool pool1 afe0::/126 128** needed to be configured for the prefix length. If clients are 16, **ipv6 local pool pool1 afe0::/124 128** needed to be configured for the prefix length.

IKEv2 Authorization

IKEv2 authorization provides a policy for an authenticated session by using the AAA. The policy can be defined locally or on the RADIUS server, and contains local and/or remote attributes. The username for authorization can either be derived from the peer identity using the **name-mangler** keyword or be directly specified in the command. IKEv2 authorization is mandatory only if the peer requests an IP address via configuration mode.

IKEv2 authorization types are as follows:

- User authorization—Use the **aaa authorization user** command in the IKEv2 profile to enable user authorization. User authorization is based on the user-specific portion of the peer IKE identity such as fqdn-hostname. The attributes from user authorization are called user attributes.
- Group authorization—Use the **aaa authorization group** command in the IKEv2 profile to enable group authorization. Group authorization is based on the generic portion of the peer IKE identity such as fqdn-domain. The attributes from group authorization are called group attributes.
- Implicit user authorization—Use the **aaa authorization user cached** command in the IKEv2 profile to enable implicit user authorization. Implicit authorization is performed as part of EAP authentication or when obtaining the AAA preshared key. The attributes from implicit user authorization are called cached attributes.

Note Depending on your release, the **aaa authorization user cached** command may or may not be available. Explicit user authorization is performed only when implicit user authorization does not return any attributes or does not have the Framed-IP-Address attribute.

Merging and Overriding Attributes

Attributes from different sources are merged before they are used. The precedence of merging attributes is as follows:

- When merging duplicate attributes, the source of the attribute has a higher precedence.
- When merging user and cached attributes, user attributes have higher precedence.

- When merging merged-user-attributes and group attributes, merged-user attributes have a higher precedence, by default. However, this precedence can be reversed using the **aaa author group override** command.

IKEv2 Authorization Policy

An IKEv2 authorization policy defines the local authorization policy and contains local and/or remote attributes. Local attributes, such as VPN routing and forwarding (VRF) and the QOS policy, are applied locally. Remote attributes, such as routes, are pushed to the peer via the configuration mode. Use the **crypto ikev2 authorization policy** command to define the local policy. The IKEv2 authorization policy is referred from the IKEv2 profile via the **aaa authorization** command.

IKEv2 Name Mangler

The IKEv2 name mangler is used to derive the username for IKEv2 authorization and obtain the AAA preshared key from the peer IKE identity.

IKEv2 Multi-SA

The IKEv2 Multi-SA feature allows an IKEv2 Dynamic Virtual Tunnel Interface (DVTI) session on the IKEv2 responder to support multiple IPsec Security Associations (SA). The maximum number of IPsec SAs per DVTI session is either obtained from AAA authorization or configured on the IPsec profile. The value from AAA has a higher priority. Any change to the *max-flow-limit* argument in the IPsec profile is not applied to the current session but is applied to subsequent sessions. The IKEv2 Multi-SA feature makes the configuration of the IKEv2 profile in the IPsec profile optional. This optional configuration allows IPsec DVTI sessions using the same virtual template to have different IKEv2 profiles, thus saving the number of virtual template configurations.

Note The IKEv2 Multi-SA feature allows multiple IPsec SAs that have non-any-any proxies. However, when the IPsec SA proxies are any-any, a single IPsec SA is allowed.

For more information, see the “Multi-SA Support for Dynamic Virtual Tunnel Interfaces for IKEv2” module in the *Security for VPNs with IPsec Configuration Guide*.

AnyConnect Profile Download

The FlexVPN AnyConnect Profile Download feature enables a device running Cisco IOS XE software to connect and push the profile information in IKEv2 protocol to Cisco AnyConnect Secure Mobility client.

Cisco AnyConnect Secure Mobility client contains profiles used for configuring the settings for VPN. These profiles can be manually configured or can be downloaded from a headend. The headend can be configured to deploy profiles globally for all Cisco AnyConnect Secure Mobility client users.

Use the **anyconnect profile** command to match a VPN profile against an IKEv2 profile.

Note Crypto SSL profile is not mandatory to configure AnyConnect Profile Download feature.

Supported RADIUS Attributes

The following tables list the RADIUS attributes supported by the IKEv2 FlexVPN server:

- The Scope field defines the direction of the attribute and the usage on the FlexVPN server or client.
 - Inbound—FlexVPN server to RADIUS
 - Outbound—RADIUS to the FlexVPN server
 - Local—Used locally by the FlexVPN server
 - Remote—Pushed to the client by the FlexVPN server
- The “Local configuration” field specifies the IKEv2 authorization policy command that is used to configure the attribute locally on the FlexVPN server.
- Cisco AV Pair is a Cisco Vendor Specific Attribute (VSA) with vendor-id 9 and vendor-type 1. The VSAs are encapsulated in the Radius IETF attribute 26 Vendor-Specific. The Cisco AV pair is specified as a string of format “protocol:attribute=value”.

Example:

```
cisco-avpair = "ipsec:ipv6-addr-pool=v6-pool"
```

The following example shows the Cisco AV pair for a standard access-list.

```
cisco-avpair = "ipsec:route-set=access-list 99"
```

Table 299: Inbound and Bidirectional IETF RADIUS Attributes

Attribute	Scope
User-Name	Inbound and outbound (bidirectional)
User-Password	Inbound
Calling-Station-Id	Inbound
Service-Type	Inbound
EAP-Message	Bidirectional
Message-Authenticator	Bidirectional

Table 300: Outbound IETF and Cisco AV Pair RADIUS Attributes

Attribute	Type	Scope	Local configuration
Tunnel-Type	IETF	Local	N/A
Tunnel-Medium-Type	IETF	Local	N/A

Attribute	Type	Scope	Local configuration
Tunnel-Password	IETF	Local	N/A
ipsec:ikev2-password-local	Cisco AV Pair	Local	N/A
ipsec:ikev2-password-remote	Cisco AV Pair	Local	N/A
ipsec:addr-pool	Cisco AV Pair	Local	pool
ipsec:group-dhcp-server	Cisco AV Pair	Local	dhcp server
ipsec:dhcp-giaddr	Cisco AV Pair	Local	dhcp giaddr
ipsec:dhcp-timeout	Cisco AV Pair	Local	dhcp timeout
ipsec:ipv6-addr-pool	Cisco AV Pair	Local	ipv6 pool
ipsec:route-set=interface	Cisco AV Pair	Local	route set interface
ipsec:route-set=prefix	Cisco AV Pair	Local	N/A
ipsec:route-accept	Cisco AV Pair	Local	route accept any
ip:interface-config	Cisco AV Pair	Local	aaa attribute list
ipsec:ipsec-flow-limit	Cisco AV Pair	Local	ipsec flow-limit
Framed-IP-Address	IETF	Remote	N/A
Framed-IP-Netmask	IETF	Remote	netmask
ipsec:dns-servers	Cisco AV Pair	Remote	DNS
ipsec:wins-servers	Cisco AV Pair	Remote	wins
ipsec:route-set=access-list (See Note 1.)	Cisco AV Pair	Remote	route set access-list (See Note 1.)
ipsec:addrv6	Cisco AV Pair	Remote	n/a
ipsec:prefix-len	Cisco AV Pair	Remote	n/a
ipsec:ipv6-dns-servers-addr	Cisco AV Pair	Remote	ipv6 dns
ipsec:route-set=access-list ipv6	Cisco AV Pair	Remote	route set access-list ipv6
ipsec:banner	Cisco AV Pair	Remote	banner
ipsec:default-domain	Cisco AV Pair	Remote	def-domain
ipsec:split-dns	Cisco AV Pair	Remote	split-dns
ipsec:ipsec-backup-gateway	Cisco AV Pair	Remote	backup-gateway
ipsec:pfs	Cisco AV Pair	Remote	pfs

Attribute	Type	Scope	Local configuration
ipsec:include-local-lan	Cisco AV Pair	Remote	include-local-lan
ipsec:smartcard-removal-disconnect	Cisco AV Pair	Remote	smartcard-removal- disconnect
ipsec:configuration-url	Cisco AV Pair	Remote	configuration url
ipsec:configuration-version	Cisco AV Pair	Remote	configuration version

**Note**

- 1. The RADIUS attribute to set an access list on IKEv2 FlexVPN server only supports a standard access list. An extended access list is not supported.

Supported Remote Access Clients

The FlexVPN server interoperates with the Microsoft Windows7 IKEv2 client, Cisco IKEv2 AnyConnect client, and Cisco FlexVPN client.

Microsoft Windows7 IKEv2 Client

The Microsoft Windows 7 IKEv2 client sends an IP address as the Internet Key Exchange (IKE) identity that prevents the Cisco IKEv2 FlexVPN server from segregating remote users based on the IKE identity. To allow the Windows 7 IKEv2 client to send the email address (user@domain) as the IKE identity, apply the hotfix documented in KB975488 (<http://support.microsoft.com/kb/975488>) on Microsoft Windows 7 and specify the email address string in either the Username field when prompted or the CommonName field in the certificate depending on the authentication method.

For certificate-based authentication, the FlexVPN server and Microsoft Windows 7 client certificates must have an Extended Key Usage (EKU) field as follows:

- For the client certificate, EKU field = client authentication certificate.
- For the server certificate, EKU field = server authentication certificate
- The certificates can be obtained from the Microsoft Certificate Server or the IOS CA server.

For EAP authentication, the Microsoft Windows 7 IKEv2 client expects an EAP identity request before any other EAP requests. Ensure that you configure the **query-identity** keyword in the IKEv2 profile on the IKEv2 FlexVPN server to send an EAP identity request to the client.

Cisco IKEv2 AnyConnect Client

For certificate-based authentication, the FlexVPN server and the AnyConnect client certificates must have an Extended Key Usage (EKU) field as follows:

- For the client certificate, EKU field = client authentication certificate
- For the server certificate, EKU field = server authentication certificate

If the FlexVPN server authenticates to AnyConnect client using certificates, a SubjectAltName extension is required in the FlexVPN server certificate that contains the server's IP address or fully qualified domain name

(FQDN). Additionally, HTTP certified URLs must be disabled on the FlexVPN server using the **no crypto ikev2 http-url cert** command.

The following example displays the XML tags specific to EAP-MD5 authentication of IKEv2 sessions in the AnyConnect client profile:

```
<PrimaryProtocol>IPsec
  <StandardAuthenticationOnly>true
    <AuthMethodDuringIKENegotiation>
      EAP-MD5
    </AuthMethodDuringIKENegotiation>
    <IKEIdentity>DEPT24</IKEIdentity>
  </StandardAuthenticationOnly>
</PrimaryProtocol>
```

Note For every flap or FlexVPN tunnel that is enabled, the following message is displayed:

```
*Jan 22 22:52:09.833: %SYS-5-CONFIG_P: Configured programmatically by process Crypto INT
from console as console
*Jan 22 22:52:09.840: %LINEPROTO-5-UPDOWN: Line protocol on Interface Virtual-Access2,
changed state to up
```

For more information, refer to AnyConnect client 3.0 documentation at this link:

http://www.cisco.com/en/US/docs/security/vpn_client/anyconnect/anyconnect30/release/notes/anyconnect30m.html#wp1268255.

How to Configure the FlexVPN Server

Configuring the IKEv2 Profile for the FlexVPN Server

This task describes the IKEv2 profile commands required for configuring the FlexVPN server in addition to the basic IKEv2 profile commands. Refer to the “Configuring IKEv2 Profile (Basic)” task in the *Configuring Internet Key Exchange Version 2 (IKEv2)* feature module for information about configuring the basic IKEv2 profile.

Perform this task to configure the IKEv2 profile for the FlexVPN Server:

Step 1 enable

Example:

Enables privileged EXEC mode.

```
Device> enable
```

Enter your password, if prompted.

Step 2 configure terminal

Example:

Enters the global configuration mode.

```
Device# configure terminal
```

Step 3 `crypto ikev2 profile profile-name`

Defines an IKEv2 profile name and enters IKEv2 profile configuration mode.

Example:

```
Device(config)# crypto ikev2 profile profile1
```

Step 4 `aaa authentication eap list-name`**Example:**

```
Device(config-ikev2-profile)# aaa authentication eap list1
```

(Optional) Specifies the AAA authentication list for the EAP authentication when implementing the IKEv2 remote access server.

- **eap**—Specifies the external EAP server.
- *list-name*—The AAA authentication list name.

Step 5 `authentication {local {rsa-sig | pre-share [key {0 | 6} password]} | ecdsa-sig | eap [gtc | md5 | ms-chapv2] [username username] [password {0 | 6} password]} | remote {eap [query-identity | timeout seconds] | rsa-sig | pre-share [key {0 | 6} password]} | ecdsa-sig}`**Example:**

```
Device(config-ikev2-profile)# authentication local ecdsa-sig
```

Specifies the local or remote authentication method.

- **rsa-sig**—Specifies RSA-sig as the authentication method.
- **pre-share**—Specifies the preshared key as the authentication method.
- **ecdsa-sig**—Specifies ECDSA-sig as the authentication method.
- **eap**—Specifies EAP as the remote authentication method.
- **query-identity**—Queries the EAP identity from the peer.
- **timeout seconds**—Specifies the duration, in seconds, to wait for the next IKE_AUTH request after sending the first IKE_AUTH response.

Note You can specify only one local authentication method but multiple remote authentication methods.

Step 6 Execute both or one of the following:

- **aaa authorization user {eap | psk} {cached | list aaa-listname [aaa-username | name-mangler mangler-name]}**
- **aaa authorization user cert list aaa-listname {aaa-username | name-mangler mangler-name}**

Example:

```
Device(config-ikev2-profile)# aaa authorization user eap cached
```

Example:

```
Device(config-ikev2-profile)# aaa authorization user cert list list1 name-mangler mangler1
```

Specifies the AAA method list and username for user authorization.

- **user**—Specifies user authorization.
- **cert**—Specifies that the peers must be authenticated using certificates.

- **eap**—Specifies that the peers must be authenticated using EAP.
- **psk**—Specifies that the peers must be authenticated using preshared keys.
- **cached**—Specifies that the attributes received during EAP authentication or obtained from the AAA preshared key must be cached.
- *aaa-listname*—AAA method list name.
- *aaa-username*—Specifies the username that must be used in the AAA authorization request.
- **name-mangler**—Specifies the name mangler that derives the AAA authorization username from the peer identity.
- *mangler-name*—Name mangler to be used.

- Note**
- For **psk** and **eap** authentication methods, specifying the *aaa-username* argument or the **name-mangler** keyword is optional and if not specified, the peer identity is used as the username.
 - For **psk** and **eap** authentication methods, you can simultaneously configure two variants for user authorization with the **cached** and **list** keyword respectively.
 - Specifying the *aaa-username* argument or the **name-mangler** keyword is mandatory for **cert** authentication, as the peer identity of type distinguished name (DN) cannot be used.

Step 7 Execute both or one of the following:

- **aaa authorization group [override] {eap | psk} list *aaa-listname* [*aaa-username* | **name-mangler** *mangler-name*]**
- **aaa authorization group [override] cert list *aaa-listname* {*aaa-username* | **name-mangler** *mangler-name*}**

Example:

```
Device(config-ikev2-profile)# aaa authorization group override psk list list1
```

Example:

```
Device(config-ikev2-profile)# aaa authorization group cert list list1 name-mangler mangler1
```

Specifies the AAA method list and username for group authorization.

- **group**—Specifies group authorization.
- **override**—(Optional) Specifies that attributes from group authorization should take precedence while merging attributes. By default, user attributes take precedence.
- **cert**—Specifies that peers must be authenticated using certificates.
- **eap**—Specifies that peers must be authenticated using EAP.
- **psk**—Specifies that peers must be authenticated using preshared keys.
- *aaa-listname*—AAA method list name.
- *aaa-username*—Username that must be used in the AAA authorization request.
- **name-mangler**—Specifies the name mangler that derives the AAA authorization username from the peer identity.
- *mangler-name*—Name mangler to be used.

- Note**
- For **psk** and **eap** authentication methods, specifying the *aaa-username* argument or the **name-mangler** keyword is optional and if not specified, the peer identity is used as the username.
 - For **psk** and **eap** authentication methods, you can simultaneously configure two variants for user authorization with the **cached** and **list** keyword respectively.
 - Specifying the *aaa-username* argument or the **name-mangler** keyword is mandatory for **cert** authentication, as the peer identity of type distinguished name (DN) cannot be used.

Step 8 **config-exchange** {**request** | **set** {**accept** | **send**}}

Example:

```
Device(config-ikev2-profile)# config-exchange set accept
```

(Optional) Enables configuration exchange options.

- **request**—Enables the configuration exchange request.
- **set**—Enables the configuration exchange request set options.
- **accept**—Accepts the configuration exchange request set.
- **send**—Enables sending of the configuration exchange set.

Note The request and set options are enabled by default.

Step 9 **end**

Example:

```
Device(config-ikev2-profile)# end
```

Exits IKEv2 profile configuration mode and returns to privileged EXEC mode.

Configuring the IKEv2 Name Mangler

Perform this task to specify the IKEv2 name mangler, which is used to derive a name for authorization requests and obtain AAA preshared keys. The name is derived from specified portions of different forms of remote IKE identities or the EAP identity. The name mangler specified here is referred to in the IKEv2 profile.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 name-mangler** *mangler-name*
4. **dn** {**common-name** | **country** | **domain** | **locality** | **organization** | **organization-unit** | **state**}
5. **eap** {**all** | **dn** {**common-name** | **country** | **domain** | **locality** | **organization** | **organization-unit** | **state**} | **prefix** | **suffix** {**delimiter** {**.** | **@** | ****}}
6. **email** {**all** | **domain** | **username**}
7. **fqdn** {**all** | **domain** | **hostname**}
8. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 name-mangler <i>mangler-name</i> Example: Device(config)# crypto ikev2 name-mangler mangler1	Defines a name mangler and enters IKEv2 name mangler configuration mode.
Step 4	dn {common-name country domain locality organization organization-unit state} Example: Device(config-ikev2-name-mangler)# dn state	Derives the name from any of the following fields in the remote identity of type DN (distinguished name). <ul style="list-style-type: none"> • common-name • country • domain • locality • organization • organization-unit • state
Step 5	eap {all dn {common-name country domain locality organization organization-unit state} prefix suffix {delimiter {. @ \}}} Example: Device(config-ikev2-name-mangler)# eap prefix delimiter @	Derives the name from the remote identity of type EAP (Extensible Authentication Protocol). <ul style="list-style-type: none"> • all—Derives the name from the entire EAP identity. • dn—Derives the name from any of the following fields in the remote EAP identity of type DN: <ul style="list-style-type: none"> • common-name • country • domain • locality • organization • organization-unit • state • prefix—Derives the name from the prefix in the EAP identity. • suffix—Derives the name from the suffix in the EAP identity.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • delimiter {<code>.</code> <code>@</code> <code>\</code>}—Specifies the delimiter in the EAP identity that separates the prefix and the suffix.
Step 6	email { all domain username } Example: <pre>Device(config-ikev2-name-mangler)# email username</pre>	Derives the name from the remote identity of type e-mail. <ul style="list-style-type: none"> • all—Derives the name from the entire remote IKE identity of type e-mail. • domain—Derives the name from the domain part of the remote IKE identity. • username—Derives the name from the username part of the remote IKE identity.
Step 7	fqdn { all domain hostname } Example: <pre>Device(config-ikev2-name-mangler)# fqdn domain</pre>	Derives the name from the remote identity of type FQDN (Fully Qualified Domain Name). <ul style="list-style-type: none"> • all—Derives the name from the entire remote IKE identity of type FQDN. • domain—Derives the name from the domain part of the remote IKE identity. • hostname—Derives the name from the hostname part of the remote IKE identity.
Step 8	end Example: <pre>Device(config-ikev2-name-mangler)# end</pre>	Exits IKEv2 name mangler configuration mode and returns to privileged EXEC mode.

Configuring the IKEv2 Authorization Policy

Perform this task to configure the IKEv2 authorization policy.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 authorization policy** *policy-name*
4. **aaa attribute list** *list-name*
5. **backup-gateway** *string*
6. **banner** *banner-text*
7. **configuration url** *url*
8. **configuration version** *version*
9. **def-domain** *domain-name*
10. **dhcp** {**giaddr** *ip-address* | **server** {*ip-address* | *hostname*} | **timeout** *seconds*}
11. [**ipv6**] **dns** *primary-server* [*secondary-server*]
12. **include-local-lan**

13. **ipsec flow-limit** *number*
14. **netmask** *mask*
15. **pfs**
16. **[ipv6] pool** *name*
17. **route set** {**interface** *interface* | **access-list** {*access-list-name* | *access-list-number* | **ipv6** *access-list-name*}}
18. **route accept any** [**tag** *value*] [**distance** *value*]
19. **route redistribute** *protocol* [**route-map** *map-name*]
20. **route set remote** {**ipv4** *ip-address mask* | **ipv6** *ip-address/mask*}
21. **smartcard-removal-disconnect**
22. **split-dns** *string*
23. **session-lifetime** *seconds*
24. **route set access-list** {*acl-number* | [**ipv6**] *acl-name*}
25. **wins** *primary-server* [*secondary-server*]
26. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 authorization policy <i>policy-name</i> Example: Device(config)# crypto ikev2 authorization policy policy1	Specifies the IKEv2 authorization policy and enters IKEv2 authorization policy configuration mode.
Step 4	aaa attribute list <i>list-name</i> Example: Device(config-ikev2-author-policy)# aaa attribute list list1	Specifies an AAA attribute list. Note The AAA attribute list referred to in this command should be defined in global configuration mode.
Step 5	backup-gateway <i>string</i> Example: Device(config-ikev2-author-policy)# backup-gateway gateway1	Allows you to specify up to ten backup server names. This parameter is pushed to the client via the nonstandard Cisco Unity configuration attribute. This parameter specifies the backup servers that the client can use.
Step 6	banner <i>banner-text</i> Example: Device(config-ikev2-author-policy)# banner This is IKEv2	Specifies the banner. This parameter is sent to the client via the nonstandard Cisco Unity configuration attribute.

	Command or Action	Purpose
Step 7	<p>configuration url <i>url</i></p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# configuration url http://www.cisco.com</pre>	Specifies the configuration URL. This parameter is sent to the client via the nonstandard Cisco FlexVPN configuration attribute. The client can use this URL to download the configuration.
Step 8	<p>configuration version <i>version</i></p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# configuration version 2.4</pre>	Specifies the configuration version. This parameter is sent to the client via the nonstandard Cisco FlexVPN configuration attribute. This parameter is sent with the configuration URL to specify the version that the client can download.
Step 9	<p>def-domain <i>domain-name</i></p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# def-domain cisco</pre>	Specifies the default domain. This parameter is sent to the client via the nonstandard Cisco Unity configuration attribute. This parameter specifies the default domain that the client can use.
Step 10	<p>dhcp {giaddr <i>ip-address</i> server {<i>ip-address</i> <i>hostname</i>} timeout <i>seconds</i>}</p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# dhcp giaddr 192.0.2.1</pre>	<p>Specifies the DHCP server to lease an IP address that is assigned to the remote access client.</p> <ul style="list-style-type: none"> • giaddr <i>ip-address</i>—Specifies the gateway IP address (giaddr). • server {<i>ip-address</i> <i>hostname</i>}—Specifies the IP address or hostname of the DHCP server. The hostname is resolved during configuration. • timeout <i>seconds</i>—Specifies the wait time in seconds for the response from the DHCP server. <p>Note You can specify only one DHCP server. It is assumed that the DHCP server can be reached via the global routing table, and therefore, the DHCP packets are forwarded to the global routing table.</p>
Step 11	<p>[ipv6] dns <i>primary-server</i> [<i>secondary-server</i>]</p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# dns 198.51.100.1 198.51.100.100</pre>	<p>Specifies the IP addresses of primary and secondary Domain Name Service (DNS) servers that are sent to the client in the configuration reply.</p> <ul style="list-style-type: none"> • ipv6—(Optional) Specifies an IPv6 address for the DNS server. To specify an IPv4 address, execute the command without this keyword. • <i>primary-server</i>—IP address of the primary DNS server. • <i>secondary-server</i>—(Optional) IP address of the secondary DNS server.
Step 12	<p>include-local-lan</p> <p>Example:</p>	Includes local LAN. This parameter is sent to the client via the nonstandard Cisco Unity configuration attribute.

	Command or Action	Purpose
	Device(config-ikev2-author-policy)# include-local-lan	
Step 13	ipsec flow-limit <i>number</i> Example: Device(config-ikev2-author-policy)# ipsec flow-limit 12500	Specifies the maximum number of IPsec SAs that an IKEv2 dVTI session on the IKEv2 responder can have. The range is from 0 to 50000. By default, the command is disabled, and there is no limit on the number of IPsec flows per dVTI session. A value of 0 will not allow any IPsec SAs.
Step 14	netmask <i>mask</i> Example: Device(config-ikev2-author-policy)# netmask 255.255.255.0	Specifies the netmask of the subnet from which the IP address is assigned to the client. <ul style="list-style-type: none"> • <i>mask</i>—Subnet mask address.
Step 15	pfs Example: Device(config-ikev2-author-policy)# pfs	Enables Password Forward Secrecy (PFS). This parameter is sent to the client via the nonstandard Cisco Unity configuration attribute. This parameter specifies whether the client should use PFS.
Step 16	[ipv6] pool <i>name</i> Example: Device(config-ikev2-author-policy)# pool abc	Defines a local IP address pool for assigning IP addresses to the remote access client. <ul style="list-style-type: none"> • ipv6—(Optional) Specifies an IPv6 address pool. To specify an IPv4 address, execute the command without this keyword.. • <i>name</i>—Name of the local IP address pool. <p>Note The local IP address pool must already be defined using the ip local pool command.</p>
Step 17	route set { interface <i>interface</i> access-list { <i>access-list-name</i> <i>access-list-number</i> ipv6 <i>access-list-name</i> }}	Specifies the route set parameters to the peer via configuration mode and allows running routing protocols such as Border Gateway Protocol (BGP) over VPN. <ul style="list-style-type: none"> • interface—Specifies the route interface. • access-list—Specifies the route access list. • <i>access-list-name</i>—Access list name. • <i>access-list-number</i>—Standard access list number. • ipv6—Specifies an IPv6 access list.
Step 18	route accept any [tag <i>value</i>] [distance <i>value</i>] Example: Device(config-ikev2-author-policy)# route accept any tag 10	Filters the routes received from the peer and specify the tag and metric values to install these routes. <ul style="list-style-type: none"> • any—Accepts all routes received from the peer. • tag <i>value</i>—(Optional) Specifies the tag ID for the static routes added by IKEv2. The range is from 1 to 497777.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • distance value—(Optional) Specifies the distance for the static routes added by IKEv2. The range is from 1 to 255.
Step 19	<p>route redistribute <i>protocol</i> [route-map <i>map-name</i>]</p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# route redistribute connected</pre>	<p>Filters the routes received from the peer and specify the tag and metric values to install these routes.</p> <ul style="list-style-type: none"> • protocol—Source protocol from which routes are redistributed. It can be one of the following keywords: connected or static. • route-map map-name—(Optional) Route map that should be filtered to import routes from one source routing protocol to another routing protocol. If a map name is not specified, all routes are redistributed.
Step 20	<p>route set remote {ipv4 <i>ip-address mask</i> ipv6 <i>ip-address/mask</i>}</p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# route set remote ipv6 2001:DB8::1/32</pre>	Configures IP addresses of inside networks.
Step 21	<p>smartcard-removal-disconnect</p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# smartcard-removal-disconnect</pre>	Enables smartcard removal disconnect. This parameter is sent to the client via the nonstandard Cisco Unity configuration attribute. This parameter specifies that the client should terminate the session when the smart card is removed.
Step 22	<p>split-dns <i>string</i></p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# split-dns abc1</pre>	Allows you to specify up to ten split domain names. This parameter is sent to the client via the nonstandard Cisco Unity configuration attribute. This parameter specifies the domain names that the client should use for private networks.
Step 23	<p>session-lifetime <i>seconds</i></p> <p>Example:</p> <pre>Device(config-ikev2-author-policy)# session-lifetime 1000</pre>	<p>Specifies the IKEv2 session lifetime.</p> <ul style="list-style-type: none"> • seconds seconds—The range is from 120 to 25920000, which converts to two minutes to 300 days.
Step 24	<p>route set access-list {<i>acl-number</i> [ipv6] <i>acl-name</i>}</p> <p>Example:</p> <pre>Device(config-ikev2-client-config-group)# route set access-list 110</pre>	<p>Specifies the subnets that are pushed to the remote peer via configuration mode.</p> <ul style="list-style-type: none"> • acl-number—Access list number (ACL). The ACL number can only be specified for an IPv4 ACL. • ipv6—(Optional) Specifies an IPv6 access control list (ACL). To specify an IPv4 attribute, execute the command without this keyword. • acl-name—Access list name.

	Command or Action	Purpose
		Note You can only specify standard, simple access lists for IPv4 addresses.
Step 25	wins <i>primary-server</i> [<i>secondary-server</i>] Example: Device(config-ikev2-author-policy)# wins 203.0.113.1 203.0.113.115	Specifies the internal Windows Internet Naming Service (WINS) server addresses that are sent to the client in the configuration reply. <ul style="list-style-type: none"> • <i>primary-server</i>—IP address of the primary WINS server. • <i>secondary-server</i>—(Optional) IP address of the secondary WINS server.
Step 26	end Example: Device(config-ikev2-author-policy)# end	Exits IKEv2 authorization policy configuration mode and returns to privileged EXEC mode.

Configuration Examples for the FlexVPN Server

Example: Configuring the FlexVPN Server

Example: Configuring the FlexVPN Server to Authenticate Peers Using EAP

This example shows how to configure the FlexVPN server to authenticate peers using EAP.

  permit ipv6 host 2001:DB8:1::30 any
!

```

Example: Configuring AnyConnect Profile Download

The following example shows how to configure the FlexVPN AnyConnect Profile Download feature:

Note You do not modify the Local Policy files on the Anyconnect Client machine. After the configuration of Anyconnect Profile Download feature on IKEv2, the required XML profiles get automatically downloaded on the client device.

Note You should disable either the HTTPS server (ip http secure-server) or SSL policy (crypto ssl policy) for the profile download feature, otherwise, if both these features are enabled at the same time and the device receives an incoming SSL VPN connection, the device may crash.

```
no ip http secure-server
crypto ssl policy ssl-policy
  pki trustpoint CA1 sign
  ip address local 10.0.0.1 port 443
  no shutdown
crypto ssl profile ssl_prof
  match policy ssl-policy
crypto vpn anyconnect profile ANY-PROF bootflash:profile.xml
crypto ikev2 profile ikev2_profile
  anyconnect profile ANY-PROF
```

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for Configuring the FlexVPN Server

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 301: Feature Information for Configuring the FlexVPN Server

Feature Name	Releases	Feature Information
IKEv2 headend support for remote access clients	Cisco IOS XE Release 3.5S	This feature provides IKEv2 support for Anyconnect 3.0, FlexVPN hardware client, and multi SA support for VTI. The following commands were introduced or modified: aaa attribute list, backup-gateway, banner, config-mode set, configuration url, configuration version, def-domain, dhcp, dns, include-local-lan, max flow limit, pfs, pool, route accept, route set interface, smartcard-removal-disconnect, split-dns, subnet-acl.

CHAPTER 225

Configuring the FlexVPN Client

This module describes the FlexVPN client features and the Internet Key Exchange Version 2 (IKEv2) commands required to configure the FlexVPN client.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

- [Restrictions for the FlexVPN Client, on page 2997](#)
- [Information About the FlexVPN Client, on page 2998](#)
- [How to Configure the FlexVPN Client, on page 3004](#)
- [Configuration Examples for the FlexVPN Client, on page 3009](#)
- [Additional References for Configuring the FlexVPN Client, on page 3010](#)
- [Feature Information for Configuring the FlexVPN Client, on page 3011](#)

Restrictions for the FlexVPN Client

EAP as the Local Authentication Method

- Extensible Authentication Protocol (EAP) as the local authentication method, is supported only on the IKEv2 initiator, and as the remote authentication, is supported only on the IKEv2 responder.
- If EAP is specified as the local authentication method, the remote authentication method must be certificate based.
- If the **authentication remote eap query-identity** command is not configured on the FlexVPN server, the client cannot have an IPv4 or IPv6 address as the local identity because these IP addresses cannot be used as the username for the EAP authentication method.

Dual-Stack Tunnel Interface and VRF-Aware IPsec

When configuring a dual-stack tunnel interface in a VPN routing and forwarding (VRF)-aware IPsec scenario, you cannot use the **ip vrf forwarding** command to configure an Inside VPN routing and forwarding (IVRF)

instance because this is not a valid configuration. Use the **vrf forwarding** *vrf-name* command to define the IVRF of the tunnel interface, where the *vrf-name* argument is defined using the **vrf definition** command with IPv4 and IPv6 address families inside the definition.

SSO Restrictions

- For an ESP reload (no standby ESP), the SA sequence number restarts from 0. The peer router drops packets that do not have the expected sequence number. You may need to explicitly reestablish IPsec sessions to work around this issue for systems that have a single ESP after an ESP reload. Traffic disruption might happen over the IPsec sessions in such cases for the duration of the reload.

Information About the FlexVPN Client

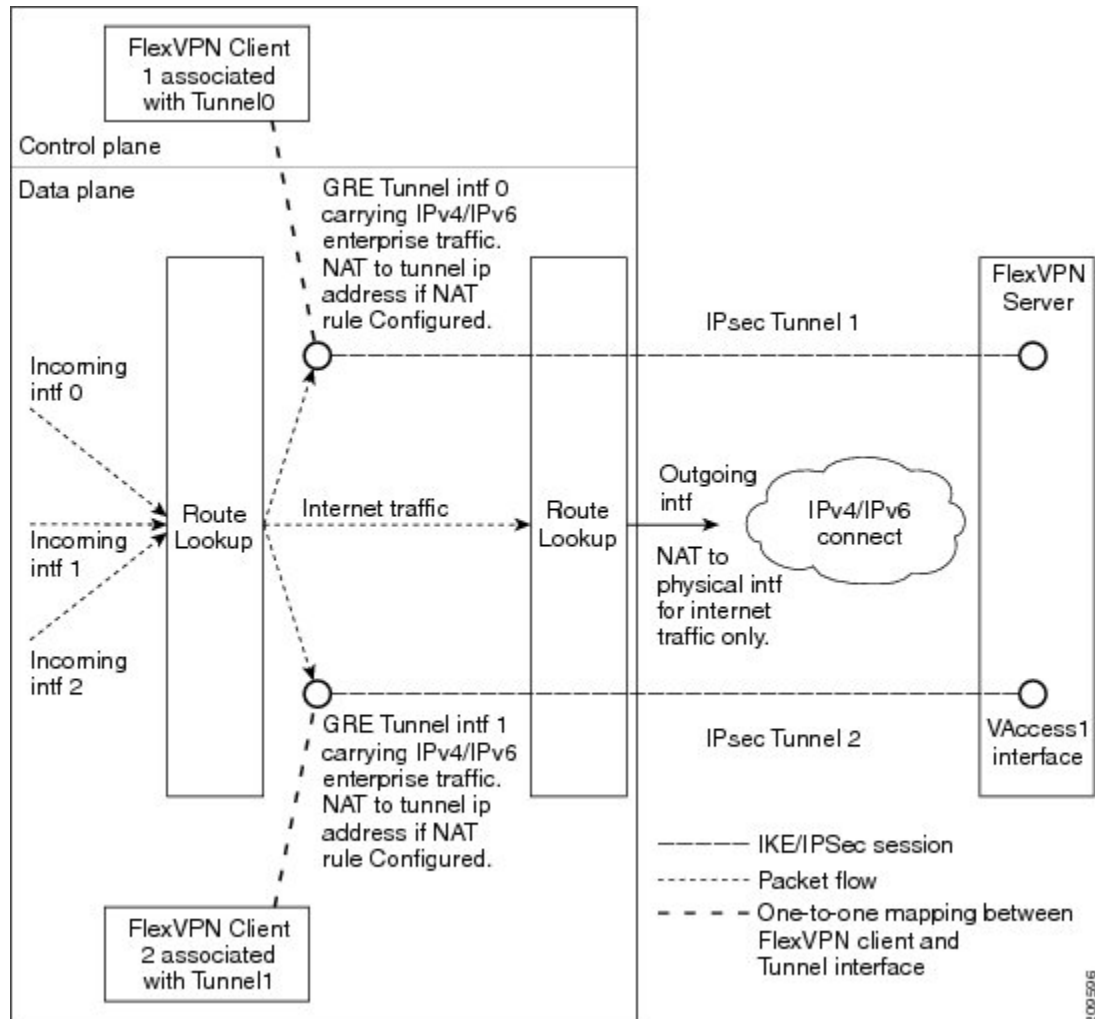

IKEv2 FlexVPN Client

The IKEv2 FlexVPN Client feature establishes a secure IPsec VPN tunnel between a FlexVPN client and a FlexVPN server. The IKEv2 FlexVPN Client feature provides the following benefits:

- Unified tunnel infrastructure
- IPv4/IPv6 proxy support over IPv4/IPv6 transport
- Backward compatibility with some features supported by EasyVPN
- Flexibility for running dynamic routing protocols

Each FlexVPN client is associated with a unique tunnel interface, which implies that the IPsec security association (SA) retrieved by the specific FlexVPN client is bound to the tunnel interface. The figure below shows the association between the FlexVPN client and the tunnel interface.

Figure 122: Association of the FlexVPN Client and the Tunnel Interface

The sequence of operation is as follows:

- **Routing**—The FlexVPN server pushes the network list as part of the mode configuration response. The client adds routes on the tunnel interface to these networks. As part of the configuration mode set, the client sends the routes to its network. The IP address is configured on the tunnel interface so that the server can add routes to the client-side network.
- **NAT**—Network Address Translation (NAT) rules must be configured explicitly using route maps. If the rules match, the hosts behind the FlexVPN client are translated to the tunnel IP address. This IP address can be obtained as one of the attributes pushed during mode configuration by the FlexVPN server.
- **Encapsulation and encryption**—Generic routing encapsulation (GRE) and IPsec encapsulation modes are supported. GRE supports both IPv4 and IPv6 traffic. The traffic that reaches the tunnel interface is encapsulated by the GRE header, followed by IPsec protection. The encrypted traffic is then routed to the outgoing interface.

The features supported by the FlexVPN client are described in the following sections:

Tunnel Activation

The FlexVPN client can be connected automatically or manually through user intervention. The FlexVPN client connects automatically to the tunnel when the FlexVPN configuration is complete. If the tunnel times out or fails, the tunnel automatically reconnects and retries the connection indefinitely. To configure an automatic tunnel connection, use the **connect** command with the **auto** keyword in the IKEv2 FlexVPN profile.

In a manual connection, the FlexVPN client waits for user intervention to execute a command before establishing a connection. When the client times out or fails to connect, subsequent connections require user intervention. To configure a manual connection, use the **crypto ikev2 client flexvpn connect** command with the *flexvpn-name* argument in privileged EXEC mode. To terminate the connection, use the **clear crypto ikev2 client flexvpn connect** command with the *flexvpn-name* argument.

Tracking-Based Tunnel Activation

The Tracking-Based Tunnel Activation feature is mainly used in backup scenarios. The FlexVPN client registers with the tracking system to obtain notifications for change in the state of an object. This notification prompts the client to perform an appropriate action for tunnel activation. The **track** keyword in the **connect** command informs the tracking process that the client is interested in tracking an object, which is identified by an object number. The tracking process, in turn, informs the client when the state of the objects changes.

If the **track** keyword in the **connect** command is set to activate the tunnel when the object goes up, the client triggers the connection upon receiving the notification that the object is in the UP state. If the **track** keyword in the **connect** command is set to activate the tunnel when the object goes down, the client triggers the connection upon receiving the notification that the object is in the DOWN state.

Backup Features

A FlexVPN client can connect to various peers or servers in a predetermined order. The list of peers is called the gateway list or backup gateway list and is built using the following lists:

- Static backup gateway list or static list
- Downloaded backup gateway list or downloaded list

The static backup gateway list is configured in the FlexVPN profile by providing a list of peers with a sequence number. The downloaded backup gateway list is downloaded dynamically and is obtained during the mode configuration response. The downloaded list complements the static gateway list to build the backup gateway list. The downloaded list is inserted after the peer from which the list is downloaded.

If an existing connection with a peer from the gateway list goes down, the client tries to establish a connection with the next peer in the gateway list. If a downloaded list is available and connection with a static peer fails, the client tries to connect, in sequence, with the peers from the downloaded list. If the client fails to establish a connection with all the peers in the downloaded list, the client tries to connect to the next peer in the static list, and the downloaded list is deleted.

Backup Gateways

Use the **peer** command to add a peer to the backup gateway list. To remove the backup gateway list, use the **no peer** command.

Peers are ordered by preference; the lower the sequence number, the higher the preference.

If a connection is established with a new peer and the peer is not a part of the downloaded list, the peer adds the downloaded list to the backup gateway list, and the existing backup gateway list is replaced with the new list.

You can configure a static peer and attach it to a track object. A peer is a “possible peer” if the track object of the peer is in the UP state.

Note Peers that are not attached to a track object, including peers in the downloaded list, are classified as “possible peers” because these peers are always in the UP state.

The peer selection process works as follows: when a connection is established, the gateway list is looked up and the first possible peer is selected. A peer is selected according to the following rule: a static peer can be associated with the track object with a desired status (UP or DOWN). If the status of the track object matches the configured status, the peer is said to be a “possible peer.”

Note If the peer is identified by either a Domain Name Service (DNS) name or a fully qualified domain name (FQDN), the name is resolved dynamically.

The peer selection process is followed by the selection of a new peer or when the existing criteria fail, which happens in the following scenarios:

- The active peer stops responding to liveness checks.
- The DNS resolution of the peer name fails.
- The IKE negotiation with the peer fails.
- The peer is no longer a “possible peer” (its corresponding track object goes DOWN).

Note When you configure multiple FlexVPN peers on a FlexVPN client and when you clear the IKEv2 SA on the primary peer, the clearance will trigger a new peer selection on the client.

Reactivate Primary Peer

The Reactivate Primary Peer feature ensures that the highest-priority peer is always connected. If the track object of the highest-priority peer matches the object status, the existing connection with the lower-priority peer is disconnected, and the connection to the higher-priority peer is established. Use the **peer reactivate** command to enable this feature.

Note A track object must be associated with statically configured peers.

Dial Backup (Primary or Backup Tunnels)

The FlexVPN client registers with the tracking system to get notifications about the change in the state of the object. The **connect track** command is used to inform the tracking process that the client is interested in tracking an object, which is identified by the object number. The tracking process, in turn, informs the client when the state of this objects changes. This notification prompts the client to take further action to bring up or bring down the primary or backup connections when the state of the tracked object is UP or DOWN.

The Dial Backup feature can be configured as follows:

- When both primary and backup tunnels are FlexVPN tunnels,
 - Any one tunnel is active at a time.
 - Both client profiles are configured using the **connect track** command, referencing the same track object.
 - If the primary tunnel tracks the status when the object is UP, the secondary tunnel tracks the status of the object when the object is DOWN.
- When one tunnel is the FlexVPN tunnel,
 - The remaining tunnels can be on any secured connection.
 - The primary connection is not FlexVPN, and the backup connection is FlexVPN.
 - The client profile is configured using the **connect track** command with an object, which traces the ability to reach the primary peer through the primary outgoing interface.

Backup Group

The Backup Group feature allows the FlexVPN client to omit a peer when a FlexVPN client that belongs to a group has established a session with the same peer. When a FlexVPN client belonging to a group initiates a connection with a peer, the FlexVPN client validates if another FlexVPN client in the same group has established a session with the same peer. If a connection exists, the FlexVPN client omits this peer and validates the next peer in the sequence. Use the **backup group** command with the *group-number* argument to configure the backup group.

Dual FlexVPN Support

The Dual FlexVPN Support feature provides the ability to configure two FlexVPN tunnels that share the same inside and outside interfaces. The two FlexVPN tunnels use route injections to direct appropriate traffic through the corresponding tunnel interface. When the tunnel is up, the tunnel “learns” the network list from the server. If the server forwards a network list, FlexVPN installs specific routes to the destination networks in its routing table, directing the traffic to these networks out of the tunnel interface.

Note Only one FlexVPN connection can be established with a default route through the tunnel interface.

Split DNS Support

The Split DNS functionality enables the FlexVPN client to act as a Domain Name System (DNS) proxy. During FlexVPN negotiations, the DNS list is downloaded during mode configuration. This list is configured as a DNS view list on the inside interfaces associated with the FlexVPN profile. The view list is used to match requests based on the domain names with the DNS query and then forward the match requests to the DNS server. Other DNS queries are used to match the default view (global DNS configuration) and are forwarded to the ISP DNS.

If no inside interfaces are mentioned in the FlexVPN client profile, the DNS view is applied to all interfaces except the tunnel interface and the tunnel source interfaces of all configured profiles. When the DNS query request reaches the inside interface, the matching DNS view is obtained, and the request is forwarded to the DNS IP address.

NAT

The Network Address Translation (NAT) feature in FlexVPN enables traffic to be translated to an IP address based on the interface to which the traffic is routed. If a packet is received on one interface that is configured with the **ip nat inside** command and is being sent out another interface that is configured with the **ip nat outside** command, the packet is translated to the IP address configured on the second interface.

Network List from the Server

Routes for enterprise traffic are dynamically installed by a client through the tunnel interface. The traffic takes the default route via the outgoing physical interface. The enterprise traffic is translated to the tunnel IP address, and the Internet traffic is translated to the external outgoing interface IP address.

Default Route List from the Server

A default route must be configured on the device with the higher sequence number via the tunnel interface. The tunnel interface is configured with the **ip nat outside** command, and the IP address of the tunnel interface is assigned by the IP address sent by the client. The enterprise traffic from inside interfaces is translated to the sent address. NAT is achieved by configuring NAT rules with the help of route maps. The route maps define rules based on the outgoing interface, by which the globally configured NAT rules are applied based on routing.

IPv4 traffic going out the tunnel interface is translated to the sent IPv4 address.

Note If NAT is not required, NAT rules associated with the tunnel interface must not be configured.

How the FlexVPN Client learns about the Network List

The FlexVPN client learns about the list of networks behind a peer in one of the following ways:

- Mode configuration push—The FlexVPN server sends the list of network attributes as a configuration mode parameter to the client. The FlexVPN client installs the routes to these networks through the tunnel interface that has the highest metric. The client also communicates its networks to the server in the mode configuration set or acknowledgment (SET/ACK) exchange so that the server can add those routes via the virtual access interface.
- Running routing protocols—The FlexVPN client and server run routing protocols over the tunnel interface to establish network routes, which allows the client and the server the flexibility to add or remove networks without disconnecting the existing session. The tunnel addresses are communicated during mode configuration to establish routes with peers.

WINS NBNS and DOMAIN Name

The FlexVPN server pushes the domain name, Windows Internet Naming Service (WINS), or NetBios Name Server (NBNS) attributes during mode configuration. These attributes are dynamically updated to the DHCP server that runs on the FlexVPN client.

Event Tracing

The Event Tracing feature is used for debugging purposes. Events posted to the FlexVPN client are logged, and the information is used for debugging. Event tracing is a combination of a fast mechanism that logs a few

bytes of trace information in a buffer area and a display mechanism that extracts and decodes the debug data. The FlexVPN client maintains its buffer and can be enabled during normal operation.

Extensible Authentication Protocol as a Local Authentication Method

The FlexVPN client supports EAP as a local authentication method. Supported EAP authentication methods are Microsoft Challenge Handshake Authentication Protocol Version 2 (MSCHAPv2), message digest algorithm 5 (MD5), and Generic Token Card (GTC). The EAP authentication process is as follows:

- Use the **authentication local eap** command in IKEv2 profile configuration mode to authenticate the FlexVPN client by using EAP.
- After the FlexVPN client receives the IKE_AUTH response from the peer, enter the **crypto eap credentials** command.
- If the EAP-Identity Request is received in the IKE_AUTH response, the EAP username and password must be specified.
- If an EAP-Identity Request is not received in the IKE_AUTH response, only the password is specified because the local IKEv2 identity is used as the username.

Note EAP as the local authentication method must be used with the FlexVPN client, but EAP can also be used on the IKEv2 initiator. If the EAP server initially proposes an unsupported authentication method, the FlexVPN EAP initiator responds with an EAP Negative Acknowledgment (NAK) packet, requesting EAP-MSCHAPv2, EAP-MD5, or EAP-GTC as the desired authentication method. The FlexVPN EAP responder selects one of the authentication methods.

How to Configure the FlexVPN Client

Configuring the IKEv2 VPN Client Profile

This task describes the IKEv2 commands required for configuring the FlexVPN client and the basic IKEv2 commands. Refer to the “Configuring Basic Internet Key Exchange Version 2 CLI Constructs” task in the *Configuring Internet Key Exchange Version 2 (IKEv2)* module for information about configuring the basic IKEv2 profile.

Note When you enter a typo in authorization list under ikev2 profile, it automatically goes back to the default list.

Refer to the “How to Configure the FlexVPN Client” section for information about configuring an IKEv2 profile for the FlexVPN server.

Configuring the Tunnel Interface

Perform this task to configure the tunnel interface that is referred to by the FlexVPN client.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel *number***
4. **ip address {*ipv4-address* | **negotiated**}**
5. **tunnel mode gre ip**
6. **tunnel mode ipsec ipv4**
7. **tunnel source {*ip-address* | *interface* | **dynamic**}**
8. **tunnel destination dynamic**
9. **tunnel protection ipsec-profile *profile-name***
10. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 1	Creates a tunnel interface and enters interface configuration mode.
Step 4	ip address {<i>ipv4-address</i> negotiated} Example: Device(config-if)# ip address negotiated	(Optional) Assigns an IPv4 address to the tunnel interface.
Step 5	tunnel mode gre ip Example: Device(config-if)# tunnel mode gre ip	(Optional) Enables generic route encapsulation (GRE) mode for the tunnel interface.
Step 6	tunnel mode ipsec ipv4 Example: Device(config-if)# tunnel mode ipsec ipv4	(Optional) Enables IPsec encapsulation.
Step 7	tunnel source {<i>ip-address</i> <i>interface</i> dynamic} Example: Device(config-if)# tunnel source 10.0.0.1	Specifies the source for the tunnel interface.
Step 8	tunnel destination dynamic Example:	Specifies the destination for the tunnel interface.

	Command or Action	Purpose
	<code>Device(config-if)# tunnel destination dynamic</code>	
Step 9	tunnel protection ipsec-profile <i>profile-name</i> Example: <code>Device(config-if)# tunnel protection ipsec-profile ipsecprofile1</code>	Associates a tunnel interface with an IPsec profile.
Step 10	end Example: <code>Device(config-if)# end</code>	Exits interface configuration mode and returns to privileged EXEC mode.

Configuring the FlexVPN Client

Use the **monitor event-trace flexvpn** command to enable event tracing.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 client flexvpn** *client-name*
4. **peer** *sequence* {*ipv4-address* | *ipv6-address* | **fqdn** *fqdn-name* [**dynamic** | **ipv6**]} [**track** *track-number* [**up** | **down**]]
5. **connect** {**manual** | **auto** | **track** *track-number* [**up** | **down**]}
6. **client inside** *interface-type interface-number*
7. **client connect tunnel** *interface-number*
8. **source** *sequence-number interface-type interface-number* **track** *track-number*
9. **peer reactivate**
10. **backup group** {*group-number* | **default**}
11. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <code>Device> enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <code>Device# configure terminal</code>	Enters global configuration mode.
Step 3	crypto ikev2 client flexvpn <i>client-name</i> Example: <code>Device(config)# crypto ikev2 client flexvpn client1</code>	Defines an IKEv2 FlexVPN client profile and enters IKEv2 FlexVPN client profile configuration mode.

	Command or Action	Purpose
Step 4	<p>peer <i>sequence</i> {<i>ipv4-address</i> <i>ipv6-address</i> fqdn <i>fqdn-name</i> [dynamic ipv6]} [track <i>track-number</i> [up down]]</p> <p>Example:</p> <pre>Device(config-ikev2-flexvpn)# peer 1 10.0.0.1</pre>	Defines a static peer using an IP address or hostname.
Step 5	<p>connect {manual auto track <i>track-number</i> [up down]}]</p> <p>Example:</p> <pre>Device(config-ikev2-flexvpn)# connect track 10 up</pre>	<p>Connects the FlexVPN tunnel.</p> <p>Note Any change to this command terminates the active session.</p>
Step 6	<p>client inside <i>interface-type interface-number</i></p> <p>Example:</p> <pre>Device(config-ikev2-flexvpn)# client inside GigabitEthernet 0/1</pre>	<p>(Optional) Specifies the inside interface.</p> <ul style="list-style-type: none"> You can specify more than one inside interface in a FlexVPN client profile. The inside interfaces can be shared across FlexVPN client profiles. <p>Note Any change to this command terminates the active session.</p>
Step 7	<p>client connect tunnel <i>interface-number</i></p> <p>Example:</p> <pre>Device(config-ikev2-flexvpn)# client connect tunnel 1</pre>	<p>Assigns the tunnel interface created in the “Configuring the Tunnel Interface” task to the FlexVPN client.</p> <ul style="list-style-type: none"> You can configure only one tunnel interface for a FlexVPN client profile. <p>Note Any change to this command terminates the active session.</p>
Step 8	<p>source <i>sequence-number interface-type interface-number</i> track <i>track-number</i></p> <p>Example:</p> <pre>Device(config-ikev2-flexvpn)# source 1 GigabitEthernet 0/1 track 11</pre>	<p>Adds sequence numbers to the tunnel source address.</p> <ul style="list-style-type: none"> The tunnel source address has the lowest sequence number for which the track object number is in UP state. <p>Note Any change to this command terminates the active session.</p>
Step 9	<p>peer reactivate</p> <p>Example:</p> <pre>Device(config-ikev2-flexvpn)# peer reactivate</pre>	Enables the reactivate primary peer feature.
Step 10	<p>backup group {<i>group-number</i> default}</p> <p>Example:</p> <pre>Device(config-ikev2-flexvpn)# backup group default</pre>	<p>Assigns the client to a backup group.</p> <ul style="list-style-type: none"> By default, all clients belong to backup group 0. <p>Note Any change to this command terminates the active session.</p>

	Command or Action	Purpose
Step 11	end Example: Device(config-ikev2-flexvpn)# end	Exits IKEv2 FlexVPN client profile configuration mode and returns to privileged EXEC mode.

Configuring EAP as the Local Authentication Method

Perform this task to configure Extensible Authentication Protocol (EAP) as the local authentication method on the FlexVPN client.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 profile** *profile-name*
4. **authentication local eap**
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 profile <i>profile-name</i> Example: Device(config)# crypto ikev2 profile profile1	Defines an IKEv2 profile and enters IKEv2 profile configuration mode.
Step 4	authentication local eap Example: Device(config-ikev2-profile)# authentication local eap	Specifies EAP as the local authentication method. <p>Note This command is supported only on the IKEv2 initiator.</p>
Step 5	end Example: Device(config-ikev2-profile)# end	Exits IKEv2 profile configuration mode and returns to privileged EXEC mode.

Configuration Examples for the FlexVPN Client

Example: Configuring the IKEv2 FlexVPN Client Profile

The following example shows how to configure the IKEv2 FlexVPN client profile:

```
crypto ikev2 client flexvpn flex
  peer 1 10.0.0.1
  connect manual
  client connect Tunnel0
!
crypto ikev2 authorization policy flex
  subnet-acl 199
  route set interface
  route accept any
!
crypto ikev2 keyring key
  peer dtvi
  address 0.0.0.0 0.0.0.0
  pre-shared-key cisco
!
crypto ikev2 profile prof
  match identity remote address 10.0.0.1 255.0.0.0
  authentication local pre-share
  authentication remote pre-share
  keyring key
  aaa authorization group psk list local-group-author-list flex
  config-mode set
!
crypto ipsec transform-set trans esp-aes
!
crypto ipsec profile ipsecprof
  set transform-set trans
  set pfs group2
  set ikev2-profile prof
!
interface Tunnel0
  ip address negotiated
  tunnel source Ethernet0/0
  tunnel destination dynamic
  tunnel mode ipsec ipv4
  tunnel protection ipsec-profile ipsecprof
!
interface Ethernet0/0
  ip address 172.16.0.1 255.240.0.0
  ip virtual-reassembly in
!
  ip route 0.0.0.0 0.0.0.0 2.2.2.2
access-list 199 permit ip 10.20.20.20 0.0.0.255 any
access-list 199 permit ip 10.30.30.30 0.0.0.255 any
```

Example: Configuring EAP as a Local Authentication Method

The following example shows how to configure EAP as a local authentication method:

```
crypto ikev2 profile profile1
 authentication remote rsa-sig
 authentication local eap
```

When the session is brought up, a prompt appears to enter the EAP credentials, as follows:

Enter the command "crypto eap credentials profile1"

```
Device# crypto eap credentials profile1
```

Enter the Username for profile profile1: cisco

Enter the password for username cisco

Feature Information for Configuring the FlexVPN Client

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 302: Feature Information for Configuring FlexVPN Client

Feature Name	Releases	Feature Information
IKEv2 Remote Access Hardware Client		<p>The IKEv2 Remote Access Hardware Client feature provides support for remote access connectivity and the extensions necessary to support diverse solutions such as mobility, NAT traversal, reliability, and enhanced denial of service (DoS) attack resilience.</p> <p>The following commands were introduced or modified: backup group, client connect tunnel, client inside, connect, crypto ikev2 client flexvpn, interface, ip address, peer, peer reactivate, source tunnel destination, tunnel mode, tunnel protection, tunnel source.</p>
IPv6 Remote Access for IPsec VPN		<p>The IPv6 Remote Access for IPsec VPN feature provides IPv6 support and support for EAP as the local authentication method for the IKEv2 FlexVPN client.</p> <p>The following commands were modified: authentication (IKEv2 profile), peer.</p>

CHAPTER 226

Configuring FlexVPN Spoke to Spoke

Last Published Date: March 28, 2014

The FlexVPN Spoke to Spoke feature enables a FlexVPN client to establish a direct crypto tunnel with another FlexVPN client leveraging virtual tunnel interfaces (VTI), Internet Key Exchange Version 2 (IKEv2), and Next Hop Resolution Protocol (NHRP) to build spoke-to-spoke connections.

- [Prerequisites for FlexVPN Spoke to Spoke, on page 3013](#)
- [Information About FlexVPN Spoke to Spoke, on page 3013](#)
- [How to Configure FlexVPN Spoke to Spoke, on page 3015](#)

- [Additional References for Configuring FlexVPN Spoke to Spoke, on page 3028](#)
- [Feature Information for FlexVPN Spoke to Spoke, on page 3029](#)

Prerequisites for FlexVPN Spoke to Spoke

IKEv2, the FlexVPN server, and the FlexVPN spoke must be configured.

Information About FlexVPN Spoke to Spoke

FlexVPN and NHRP

FlexVPN is Cisco's implementation of the IKEv2 standard featuring a unified paradigm and CLI that combines site to site, remote access, hub and spoke topologies and partial meshes (spoke to spoke direct). FlexVPN offers a simple but modular framework that extensively uses the tunnel interface paradigm while remaining compatible with legacy VPN implementations using the crypto maps.

The FlexVPN server provides the server side functionality of FlexVPN. The FlexVPN client establishes a secure IPsec VPN tunnel between a FlexVPN client and another FlexVPN server.

NHRP is an Address Resolution Protocol (ARP)-like protocol that alleviates nonbroadcast multiaccess (NBMA) network problems. With NHRP, NHRP entities attached to an NBMA network dynamically learn the NBMA address of the other entities that are part of that network, allowing these entities to directly communicate without requiring traffic to use an intermediate hop.

The FlexVPN Spoke to Spoke feature integrates NHRP and FlexVPN client (spoke) to establish a direct crypto channel with another client in an existing FlexVPN network. The connections are built using virtual tunnel interfaces (VTI), IKEv2 and NHRP, where NHRP is used for resolving the FlexVPN clients in the network.

The following is recommended in FlexVPN:

- Routing entries are not exchanged between spokes.
- Different profiles are used for the spokes and the **config-exchange** command is not configured for the spokes.

The FlexVPN IPv6 Direct Spoke to Spoke feature supports the use of IPv6 addresses for FlexVPN spokes. The support for IPv6 addresses provides support for IPv6 over IPv4, IPv4 over IPv6, and IPv6 over IPv6 transports.

Note Spoke to Spoke FlexVPN does not support dynamic AAA authorization.

NHRP Resolution Request and Reply in FlexVPN

The following diagram illustrates the NHRP resolution request and reply in FlexVPN.

Figure 123: NHRP Resolution Request and Reply

Due to bidirectional traffic, similar events occur in both directions at Spoke1, Spoke2, and hub. For clarity, events from Host1 to Host2 are discussed. Assume that there is a network N1 (192.168.1.0/24) behind Spoke1 and another network N2 (192.168.2.0/24) behind Spoke2. The network between the two spokes is matched through an access control list (ACL). This is because ACLs are applied on the IKEv2 policies on both spokes.

The network along with its prefix information from both the spokes is conveyed to the hub via IKEv2 information payload exchanges. This causes a route addition in the routing table by IKEv2 at the hub as follows:

- 192.168.1.0/24—Connected via virtual access interface1

- 192.168.2.0/24—Connected via virtual access interface2

The hub will push a summarized route via IKEv2 to both spokes, and the spokes will install the route in their routing table as follows:

- 192.168.0.0/16—next hop <tunnel address of the hub> - interface Tunnel 1

Note The routing protocol can also add the route to the routing table.

Assuming that traffic moves from N1 to N2, the traffic flow is as follows:

1. Host1 sends traffic destined to Host2. The traffic reaches the LAN interface of spoke1, looks up the route, hits the summarized route, and routes the packet to interface tunnel 1.
2. When the traffic reaches the hub's virtual access interface1, the traffic looks up the route table for a route entry for N2, either directly connected over virtual access interface 2 or via a point-to-point tunnel interface.
3. The traffic from Host1 to Host2 traverses the hub through virtual access interface1 and virtual access interface2. The hub determines that ingress and the egress interfaces (virtual access interface1 and virtual access interface2) belong to same NHRP network (network D configured on both the interfaces). The hub sends out an NHRP redirect message to spoke1 on virtual access interface1.
4. On receiving the redirect, Spoke1 initiates a resolution request for Host2 over the point-to-point tunnel interface (the same interface over which it received the redirect). The resolution request traverses the routed path (Spoke1-hub-spoke2). On receiving the resolution request, Spoke2 determines that it is the exit point and needs to respond to the resolution request.
5. Spoke2 receives the resolution request on the tunnel interface and retrieves the virtual template number from the tunnel interface. The virtual template number is used to create the virtual access interface to start a crypto channel and establishes IKEv2 and IPsec security associations (SAs). Once the crypto SAs between the two spokes are up, Spoke2 installs the necessary NHRP cache entries for Spoke1 and its network under the newly created virtual access interface and sends out the resolution reply over the virtual access interface.
6. After receiving the resolution request over the virtual access interface, Spoke1 installs the necessary cache entries for Spoke2 and its network. Spoke1 also deletes the temporary cache entry pointing to the hub to resolve the network under tunnel interface1.
7. NHRP adds shortcut routes as next-hop override (NHO) or H route. For more information on shortcut switching, refer to [Shortcut Switching Enhancements for NHRP in DMVPN Networks](#).

How to Configure FlexVPN Spoke to Spoke

Configuring the Virtual Tunnel Interface on the FlexVPN Server

Before you begin

The FlexVPN server and client must be configured.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface virtual-template *number* type tunnel**
4. **ip unnumbered loopback *number***
5. Do one of the following:
 - **ip nhrp network-id *number***
 - **ipv6 nhrp network-id *number***
6. **ip nhrp redirect [timeout *seconds*]**
7. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface virtual-template <i>number</i> type tunnel Example: Device(config)# interface virtual-template 1 type tunnel	Creates a virtual template interface that can be configured and applied dynamically to create virtual access interfaces.
Step 4	ip unnumbered loopback <i>number</i> Example: Device(config-if)# ip unnumbered loopback 0	Assigns the IP address of an existing interface (usually a loopback interface) to the virtual tunnel interface.
Step 5	Do one of the following: • ip nhrp network-id <i>number</i> • ipv6 nhrp network-id <i>number</i> Example: Device(config-if)# ip nhrp network-id 1 Example: Device(config-if)# ipv6 nhrp network-id 1	Enables NHRP on the interface.
Step 6	ip nhrp redirect [timeout <i>seconds</i>] Example: Device(config-if)# ip nhrp redirect	Enables redirect traffic indication if traffic is forwarded with the NHRP network. To avoid sending duplicate redirects, use the timeout keyword and the <i>seconds</i> argument to indicate when to expire a redirect entry created.

	Command or Action	Purpose
Step 7	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.

Configuring NHRP Shortcuts on the FlexVPN Spoke

Perform this task to configure NHRP shortcuts on the tunnel interface on the FlexVPN spoke.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. Do one of the following:
 - **ip nhrp shortcut** *virtual-template-number*
 - **ipv6 nhrp shortcut** *virtual-template-number*
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 1	Configures the FlexVPN client interface and enters interface configuration mode.
Step 4	Do one of the following: <ul style="list-style-type: none"> • ip nhrp shortcut <i>virtual-template-number</i> • ipv6 nhrp shortcut <i>virtual-template-number</i> Example: Device(config-if)# ip nhrp shortcut 1 Example: Device(config-if)# ipv6 nhrp shortcut 1	Enables NHRP shortcuts on the FlexVPN client tunnel interface. This is necessary to establish spoke-to-spoke tunnels. The virtual-template number specified in this configuration and the virtual-template number specified in the Configuring the Virtual Tunnel Interface on the FlexVPN Spoke, on page 3018 task must be same.

	Command or Action	Purpose
Step 5	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.

Configuring the Virtual Tunnel Interface on the FlexVPN Spoke

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface virtual-template *number* type tunnel**
4. **ip unnumbered tunnel *number***
5. Do one of the following:
 - **ip nhrp network-id *number***
 - **ipv6 nhrp network-id *number***
6. Do one of the following:
 - **ip nhrp shortcut *virtual-template-number***
 - **ipv6 nhrp shortcut *virtual-template-number***
7. **ip nhrp redirect [timeout *seconds*]**
8. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface virtual-template <i>number</i> type tunnel Example: Device(config)# interface virtual-template 1 type tunnel	Creates a virtual template interface that can be configured and applied dynamically to create virtual access interfaces.
Step 4	ip unnumbered tunnel <i>number</i> Example: Device(config-if)# ip unnumbered tunnel 1	Assigns the IPv4 address of the FlexVPN tunnel interface to the virtual tunnel interface.

	Command or Action	Purpose
Step 5	Do one of the following: <ul style="list-style-type: none"> • ip nhrp network-id <i>number</i> • ipv6 nhrp network-id <i>number</i> Example: Device(config-if)# ip nhrp network-id 1 Example: Device(config-if)# ipv6 nhrp network-id 1	Enables NHRP on the interface.
Step 6	Do one of the following: <ul style="list-style-type: none"> • ip nhrp shortcut <i>virtual-template-number</i> • ipv6 nhrp shortcut <i>virtual-template-number</i> Example: Device(config-if)# ip nhrp shortcut 1 Example: Device(config-if)# ipv6 nhrp shortcut 1	Enables NHRP shortcut switching on an interface. Note The current virtual template number must be specified. The virtual template number must be same as configured on the FlexVPN client tunnel interface.
Step 7	ip nhrp redirect [<i>timeout seconds</i>] Example: Device(config-if)# ip nhrp redirect	Enables NHRP redirects on the virtual tunnel interface. This is useful when networks move from one spoke to another. <ul style="list-style-type: none"> • To avoid sending duplicate redirects, use the timeout keyword and the <i>seconds</i> argument to indicate when to expire a redirect entry created.
Step 8	exit Example: Device(config-if)# exit	Exits interface configuration mode and returns to global configuration mode.

Verifying the FlexVPN Spoke Configuration

Use the following commands to verify the FlexVPN spoke configuration.

SUMMARY STEPS

1. **show crypto ikev2 client flexvpn**
2. **show ipv6 route**
3. **show ipv6 nhrp**

DETAILED STEPS

Step 1 **show crypto ikev2 client flexvpn**

Example:

```
Device# show crypto ikev2 client flexvpn
```

Verifying the FlexVPN Spoke Configuration

```

Profile : flexblk
Current state:ACTIVE
Peer : 4001::2000:1
Source : Ethernet0/0
ivrf : IP DEFAULT
fvrf : IP DEFAULT
Backup group: None
Tunnel interface : Tunnel0

```

Displays the FlexVPN connection status between the FlexVPN server and client.

Step 2 **show ipv6 route****Example:**

```
Device# show ipv6 route
```

```

IPv6 Routing Table - default - 15 entries
Codes: C - Connected, L - Local, S - Static, U - Per-user Static route
       B - BGP, HA - Home Agent, MR - Mobile Router, R - RIP
       H - NHRP, I1 - ISIS L1, I2 - ISIS L2, IA - ISIS interarea
       IS - ISIS summary, D - EIGRP, EX - EIGRP external, NM - NEMO
       ND - ND Default, NDp - ND Prefix, DCE - Destination, NDr - Redirect
       l - LISP
       O - OSPF Intra, OI - OSPF Inter, OE1 - OSPF ext 1, OE2 - OSPF ext 2
       ON1 - OSPF NSSA ext 1, ON2 - OSPF NSSA ext 2
C   3001::/112 [0/0]
    via Tunnel0, directly connected
S   3001::1/128 [2/0], tag 1
    via 3001::1, Virtual-Access1 [Shortcut]
    via Virtual-Access1, directly connected
L   3001::2/128 [0/0]
    via Tunnel0, receive
S   3001::3/128 [2/0], tag 1
    via Tunnel0, directly connected
C   4001::2000:0/112 [0/0]
    via Ethernet0/0, directly connected
L   4001::2000:3/128 [0/0]
    via Ethernet0/0, receive
S   5001::/64 [2/0], tag 1
    via Tunnel0, directly connected
C   5001::2000:0/112 [0/0]
    via Loopback0, directly connected
L   5001::2000:1/128 [0/0]
    via Loopback0, receive
D   5001::3000:0/112 [90/28288000]
    via FE80::A8BB:CCFF:FE01:F400, Tunnel0
D   5001::4000:0/112 [90/28288000]
    via FE80::A8BB:CCFF:FE01:F400, Tunnel0
H   5001::4000:1/128 [250/1]
    via 3001::1, Virtual-Access1
C   5001::5000:0/112 [0/0]
    via Loopback1, directly connected
L   5001::5000:1/128 [0/0]
    via Loopback1, receive
L   FF00::/8 [0/0]
    via Null0, receive

```

Displays the IPv6 routes and Next Hop Resolution Protocol (NHRP) mapping information.

Step 3 **show ipv6 nhrp****Example:**

```
Device# show ipv6 nhrp

3001::1/128 via 3001::1
  Virtual-Access1 created 00:01:52, expire 01:58:14
  Type: dynamic, Flags: router implicit rib nho
  NBMA address: 172.17.1.9
  (Claimed NBMA address: 172.16.2.1)
5001::4000:1/128 via 3001::1
  Virtual-Access1 created 00:00:56, expire 01:59:03
  Type: dynamic, Flags: router rib
  NBMA address: 172.17.1.9
  (Claimed NBMA address: 172.16.2.1)
5001::5000:1/128 via 3001::2
  Virtual-Access1 created 00:01:52, expire 01:58:14
  Type: dynamic, Flags: router unique local
  NBMA address: 172.17.2.10
```

Example:

```
Device# show ipv6 nhrp

3001::1/128 via 3001::1
  Virtual-Access1 created 00:01:52, expire 01:58:14
  Type: dynamic, Flags: router implicit rib nho
  NBMA address: 4001::2000:2
5001::4000:1/128 via 3001::1
  Virtual-Access1 created 00:00:56, expire 01:59:03
  Type: dynamic, Flags: router rib
  NBMA address: 4001::2000:2
5001::5000:1/128 via 3001::2
  Virtual-Access1 created 00:01:52, expire 01:58:14
  Type: dynamic, Flags: router unique local
  NBMA address: 4001::2000:3
```

Displays the NHRP cache entries. In the first example, the output indicates that the transport is IPv4 (NBMA address). The remote spoke is behind Network Address Translation (NAT), as indicated by the Claimed NBMA address field, which is the pre-NAT address of the remote spoke. The cache entries also show the flags associated with each spoke, indicating the kind of route that has been inserted for each entry in the routing table. Next-Hop-Override (NHO) indicates the shortcut route. The *rib* flag indicates addition of an NHRP H route for that cache entry. The second example indicates that the transport is IPv6 (NBMA address). The remote spoke is not behind NAT, as indicated by the absence of claimed address in the output.

Troubleshooting Tips for FlexVPN Spoke Configuration

Here are few tips for troubleshooting FlexVPN spoke configuration:

1. Verify the connection between the spokes.
2. Check the configuration on the client (spoke) and the server.
3. Check the reachability of the remote hosts behind the spokes.
4. Verify the routing protocol configuration that is used to advertise the routes.
5. Verify that IKEv2 and IPsec are configured properly.
6. Verify the NHRP shortcut configuration on the spoke and the redirect configuration on the server (hub).

Problem	Troubleshooting Tips
Spoke to hub connection is not created.	<p data-bbox="922 289 1481 352">A connection may not be created due to the absence of virtual access interfaces created at the hub.</p> <ul data-bbox="954 373 1481 663" style="list-style-type: none"><li data-bbox="954 373 1481 436">• Check the connectivity between the hub and spoke.<li data-bbox="954 443 1481 533">• Use the show crypto session command to check the state of security associations (SAs) on the hub and spoke.<li data-bbox="954 539 1481 663">• If SAs are active (as displayed in the show crypto session command), verify the output of the show crypto ikev2 client flexvpn command on the state of FlexVPN on the spoke.

Problem	Troubleshooting Tips
Spoke to spoke tunnel is not created.	<p>Traffic must flow from spoke to spoke via the hub to initiate a spoke to spoke tunnel.</p> <ul style="list-style-type: none"> • Verify the hub configuration to check if NHRP redirect is enabled. • Verify the spoke configuration to check if NHRP shortcut is enabled. • Verify the configuration in the FlexVPN server (hub) by using the show ip [ipv6] nhrp traffic command whether the hub has sent a traffic indirection to the spoke. • Verify the spokes have received the traffic and sent a resolution request by using either the show ip [ipv6] nhrp traffic command. • Verify the presence of NHRP cache entries for remote host and spoke on either spoke by using the show ip [ipv6] nhrp command. • Use the show ip [ipv6] nhrp traffic command on the remote spoke to verify that the resolution request is received. • Use the show crypto ikev2 sa command and the show crypto session command to verify that the spoke has received the resolution request and initiated a crypto session. • Use the show ip [ipv6] interface brief command to check if the virtual-access interface is present on both spokes. • Use the show ip [ipv6] nhrp traffic command on the spokes to verify that the resolution reply has been sent, and received by the peer on the virtual-access interface. • Use the show ip [ipv6] nhrp command to verify that the complete NHRP cache entries are present for the remote host and on all the spokes. • Use the show ip [ipv6] route command to check for the presence of H routes and/or next-hop-override (NHO) routes.

Configuration Examples for FlexVPN Spoke to Spoke

Example: Configuring FlexVPN Spoke to Spoke with Static Routing

The following example shows how to configure FlexVPN spoke to spoke with IKE-propagated static routing on the FlexVPN server and the FlexVPN client. The following is the configuration on the FlexVPN server:

Example: Configuring FlexVPN Spoke to Spoke with Static Routing

```

hostname hub
!
crypto ikev2 authorization policy default
  pool flex-pool
  def-domain cisco.com
  route set interface
  route set access-list flex-route
!
crypto ikev2 profile default
  match identity remote fqdn domain cisco.com
  identity local fqdn hub.cisco.com
  authentication local rsa-sig
  authentication remote rsa-sig
  pki trustpoint CA
  aaa authorization group cert list default default
  virtual-template 1
!
crypto ipsec profile default
  set ikev2-profile default
!
interface Loopback0
  ip address 172.16.1.1 255.255.255.255
!
interface Ethernet0/0
  ip address 10.0.0.100 255.255.255.0
!
interface Virtual-Template1 type tunnel
  ip unnumbered Loopback0
  ip nhrp network-id 1
  ip nhrp redirect
  tunnel protection ipsec profile default
!
ip local pool flex-pool 172.16.0.1 172.16.0.254
!
ip access-list standard flex-route
  permit any

```

The following is the configuration on the first FlexVPN client:

```

hostname spokel
!
crypto ikev2 authorization policy default
  route set interface
  route set access-list flex-route
!
crypto ikev2 profile default
  match identity remote fqdn domain cisco.com
  identity local fqdn spokel.cisco.com
  authentication local rsa-sig
  authentication remote rsa-sig
  pki trustpoint CA
  aaa authorization group cert list default default
  virtual-template 1
!
crypto ipsec profile default
  set ikev2-profile default
!
interface Tunnel0
  ip address negotiated
  ip nhrp network-id 1
  ip nhrp shortcut virtual-template 1
  ip nhrp redirect
  tunnel source Ethernet0/0
  tunnel destination 10.0.0.100

```

```
tunnel protection ipsec profile default
!
interface Ethernet0/0
 ip address 10.0.0.110 255.255.255.0
!
interface Ethernet1/0
 ip address 192.168.110.1 255.255.255.0
!
interface Virtual-Template1 type tunnel
 ip unnumbered Tunnel0
 ip nhrp network-id 1
 ip nhrp shortcut virtual-template 1
 ip nhrp redirect
 tunnel protection ipsec profile default
!
ip access-list standard flex-route
 permit 192.168.110.0 0.0.0.255
```

The following is the configuration on the second FlexVPN client:

```
hostname spoke2
!
crypto ikev2 authorization policy default
 route set interface
 route set access-list flex-route
!
crypto ikev2 profile default
 match identity remote fqdn domain cisco.com
 identity local fqdn spoke2.cisco.com
 authentication local rsa-sig
 authentication remote rsa-sig
 pki trustpoint CA
 aaa authorization group cert list default default
 virtual-template 1
!
crypto ipsec profile default
 set ikev2-profile default
!
interface Tunnel0
 ip address negotiated
 ip nhrp network-id 1
 ip nhrp shortcut virtual-template 1
 ip nhrp redirect
 tunnel source Ethernet0/0
 tunnel destination 10.0.0.100
 tunnel protection ipsec profile default
!
interface Ethernet0/0
 ip address 10.0.0.120 255.255.255.0
!
interface Ethernet1/0
 ip address 192.168.120.1 255.255.255.0
!
interface Virtual-Template1 type tunnel
 ip unnumbered Tunnel0
 ip nhrp network-id 1
 ip nhrp shortcut virtual-template 1
 ip nhrp redirect
 tunnel protection ipsec profile default
!
ip access-list standard flex-route
 permit 192.168.120.0 0.0.0.255
```

Example: Configuring FlexVPN Spoke to Spoke with Dynamic Routing using BGP

The following example shows how to configure FlexVPN spoke to spoke with dynamic routing, using BGP on the FlexVPN server (with dynamic neighbor discovery) and the FlexVPN client. The following is the configuration on the FlexVPN server:

```
hostname hub
!
crypto ikev2 authorization policy default
  pool flex-pool
  def-domain cisco.com
  route set interface
!
crypto ikev2 profile default
  match identity remote fqdn domain cisco.com
  identity local fqdn hub.cisco.com
  authentication local rsa-sig
  authentication remote rsa-sig
  pki trustpoint CA
  aaa authorization group cert list default default
  virtual-template 1
!
crypto ipsec profile default
  set ikev2-profile default
!
interface Loopback0
  ip address 172.16.1.1 255.255.255.255
!
interface Ethernet0/0
  ip address 10.0.0.100 255.255.255.0
!
interface Virtual-Template1 type tunnel
  ip unnumbered Loopback0
  ip nhrp network-id 1
  ip nhrp redirect
  tunnel protection ipsec profile default
!
ip local pool flex-pool 172.16.0.1 172.16.0.254
!
router bgp 65100
  bgp router-id 10.0.0.100
  bgp log-neighbor-changes
  bgp listen range 172.16.0.0/24 peer-group spokes
  neighbor spokes peer-group
  neighbor spokes remote-as 65100
  neighbor spokes transport connection-mode passive
  neighbor spokes update-source Loopback0
!
  address-family ipv4
    neighbor spokes activate
    neighbor spokes default-originate
    neighbor spokes prefix-list no-default in
  exit-address-family
!
ip prefix-list no-default seq 5 deny 0.0.0.0/0
ip prefix-list no-default seq 10 permit 0.0.0.0/0 le 32
```

The following is the configuration on the first FlexVPN client:

```
hostname spokel
!
crypto ikev2 authorization policy default
  route set interface
!
crypto ikev2 profile default
  match identity remote fqdn domain cisco.com
  identity local fqdn spokel.cisco.com
  authentication local rsa-sig
  authentication remote rsa-sig
  pki trustpoint CA
  aaa authorization group cert list default default
  virtual-template 1
!
crypto ipsec profile default
  set ikev2-profile default
!
interface Tunnel0
  ip address negotiated
  ip nhrp network-id 1
  ip nhrp shortcut virtual-template 1
  ip nhrp redirect
  tunnel source Ethernet0/0
  tunnel destination 10.0.0.100
  tunnel protection ipsec profile default
!
interface Ethernet0/0
  ip address 10.0.0.110 255.255.255.0
!
interface Ethernet1/0
  ip address 192.168.110.1 255.255.255.0
!
interface Virtual-Templatel type tunnel
  ip unnumbered Tunnel0
  ip nhrp network-id 1
  ip nhrp shortcut virtual-template 1
  ip nhrp redirect
  tunnel protection ipsec profile default
!
router bgp 65100
  bgp router-id 10.0.0.110
  bgp log-neighbor-changes
  neighbor hubs peer-group
  neighbor hubs remote-as 65100
  neighbor hubs update-source Tunnel0
  neighbor 172.16.1.1 peer-group hubs
!
  address-family ipv4
    network 192.168.110.0
    neighbor 172.16.1.1 activate
  exit-address-family
```

The following is the configuration on the second FlexVPN client:

```
hostname spoke2
!
crypto ikev2 authorization policy default
  route set interface
  route set access-list flex-route
!
crypto ikev2 profile default
  match identity remote fqdn domain cisco.com
  identity local fqdn spoke2.cisco.com
  authentication local rsa-sig
```

```

authentication remote rsa-sig
pki trustpoint CA
aaa authorization group cert list default default
virtual-template 1
!
crypto ipsec profile default
 set ikev2-profile default
!
interface Tunnel0
 ip address negotiated
 ip nhrp network-id 1
 ip nhrp shortcut virtual-template 1
 ip nhrp redirect
 tunnel source Ethernet0/0
 tunnel destination 10.0.0.100
 tunnel protection ipsec profile default
!
interface Ethernet0/0
 ip address 10.0.0.120 255.255.255.0
!
interface Ethernet1/0
 ip address 192.168.120.1 255.255.255.0
!
interface Virtual-Template1 type tunnel
 ip unnumbered Tunnel0
 ip nhrp network-id 1
 ip nhrp shortcut virtual-template 1
 ip nhrp redirect
 tunnel protection ipsec profile default
!
router bgp 65100
 bgp router-id 10.0.0.120
 bgp log-neighbor-changes
 neighbor hubs peer-group
 neighbor hubs remote-as 65100
 neighbor hubs update-source Tunnel0
 neighbor 172.16.1.1 peer-group hubs
!
 address-family ipv4
  network 192.168.120.0
  neighbor 172.16.1.1 activate
 exit-address-family

```

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for FlexVPN Spoke to Spoke

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 303: Feature Information for FlexVPN Spoke to Spoke

Feature Name	Releases	Feature Information
FlexVPN Spoke to Spoke		<p>The FlexVPN Spoke to Spoke feature enables a FlexVPN client to establish a direct crypto channel with another FlexVPN client. The feature leverages VTIs, IKEv2, and NHRP to build spoke to spoke connections.</p> <p>In Cisco IOS Release 15.2(2)T, this feature was introduced.</p> <p>The following commands were introduced or modified: ip unnumbered loopback0, tunnel source, tunnel mode gre ip, nhrp network-id, ip nhrp redirect, ip nhrp shortcut.</p>
FlexVPN IPv6 Direct Spoke to Spoke		<p>The FlexVPN IPv6 Direct Spoke to Spoke feature supports the use of IPv6 addresses for FlexVPN spokes. The support for IPv6 addresses provides support for IPv6 over IPv4, IPv4 over IPv6, and IPv6 over IPv6 transports.</p> <p>The following commands were introduced or modified: ipv6 nhrp shortcut.</p>

CHAPTER 227

Configuring IKEv2 Load Balancer

The IKEv2 Load Balancer feature provides support for enabling clusters of FlexVPN gateways and distributes incoming Internet Key Exchange Version 2 (IKEv2) connection requests among FlexVPN gateways. This feature redirects the incoming FlexVPN or AnyConnect client requests to the least loaded FlexVPN gateway based on the system and crypto load factors.

Prerequisites for IKEv2 Load Balancer

- For the server-side configuration, the Hot Standby Router Protocol (HSRP) and FlexVPN server (IKEv2 profile) must be configured.
- For the client-side configuration, the FlexVPN client must be configured.

Restrictions for IKEv2 Load Balancer

- In Cisco IOS XE 17.13.1a release, IKEv2 load balancer is only supported on C8500-12X platform.
- Redirection of an IKEv2 request is only supported using IP address and not a FQDN (Fully Qualified Domain Name).
- The limit to number of nodes that can be set up in a cluster is 10.
- In Cisco IOS XE 17.13.1a release, if you are configuring IKEv2 in an IPv6 deployment, the IKEv2 load balancer only supports a single VIP (Virtual IP address).

- For headend systems, it is recommended to configure DPD to operate on an 'on demand' basis. Periodic DPD checks should be avoided as they can generate excessive control-plane traffic, leading to increased CPU utilization and potential system instability.
- The Idle Timer is set to expire when there is no traffic between two IPsec SA peers. Upon expiration, the system deletes the session.

Information About IKEv2 Load Balancer

Overview of IKEv2 Load Balancer

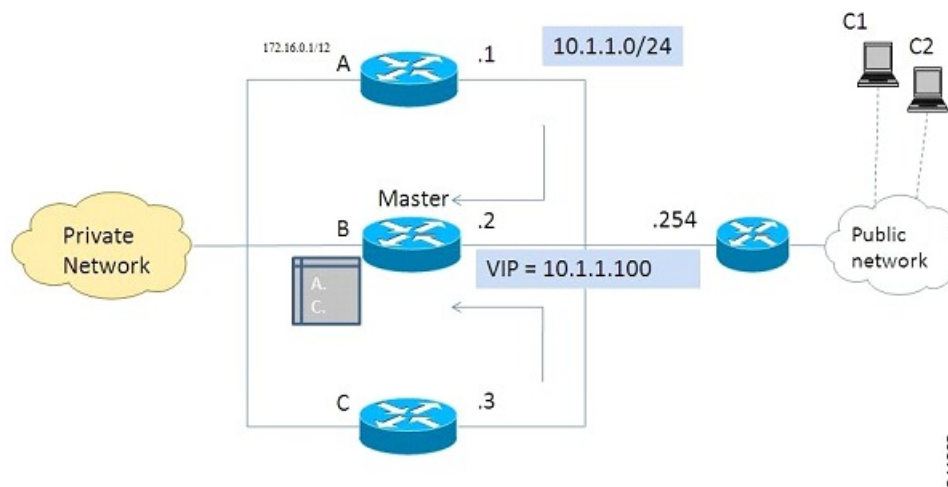

The IKEv2 Load Balancer Support feature provides a Cluster Load Balancing (CLB) solution by redirecting requests from remote access clients to the Least Loaded Gateway (LLG) in the Hot Standby Router Protocol (HSRP) group or cluster. An HSRP cluster is a group of gateways or FlexVPN servers in a LAN or in an enterprise network. The CLB solution works with the Internet Key Exchange Version 2 (IKEv2) redirect mechanism defined in RFC 5685 by redirecting requests to the LLG in the HSRP cluster.

Note To plan a cluster network, it is important to consider the number of clients hosted on the network and define the maximum number of SAs allowed on cluster headend.

The figure below shows the working of the IKEv2 cluster load balancing solution in both IPv4 and IPv6 deployments.

Figure 124: IKEv2 Cluster Load Balancing Solutions for IPv4 deployments

344203

Figure 125: IKEv2 Cluster Load Balancing Solutions for IPv6 deployments

1. An active HSRP gateway is elected as primary in the HSRP group and takes ownership of the Virtual IP address (VIP) for the group. The primary maintains a list of gateways in the cluster, keeps track of the load on each gateway, and redirects the FlexVPN client requests to the LLG.
2. The remaining gateways, termed as subordinates, send load updates to the primary at periodic intervals.
3. When an IKEv2 client connects to the HSRP VIP, the request first reaches the primary, which in turn, redirects the request to the LLG in the cluster.

Note To configure IKEv2 cluster load balancing in an IPv6 environment, it is mandatory that the VIP and IPv6 address of the WAN is in the same subnet of the cluster.

The components of the CLB solution are as follows:

- HSRP
- CLB primary
- CLB subordinate
- CLB communication
- IKEv2 redirects mechanism

Hot Standby Router Protocol

Hot Standby Router Protocol (HSRP) is used to elect the primary HSRP or Active Router (AR). For HSRP to elect a designated device, you must configure the VIP for one device in the group. This address is learned by other devices in the group. The IP address that is assigned to the primary is used as the VIP for the group.

The HSRP active router (also called primary CLB) receives the IKEv2 requests and redirects these requests to the LLG in the cluster. The redirection is performed at the IKEv2 protocol level thereby achieving the following:

- All requests from the FlexVPN client reach the primary HSRP as the VIP is configured on the FlexVPN clients. The configuration of FlexVPN clients is minimized because the FlexVPN clients must only know the VIP of the HSRP cluster.
- The primary CLB is run on the same gateway as the primary HSRP, thereby maintaining the load information of all subordinate CLBs. The primary CLB enables effective redirection of requests and avoids multiple redirects and loops.

Primary CLB

A primary CLB runs on the primary HSRP or Active Router (AR). The primary receives updates from subordinate CLBs and sorts them based on their load condition to calculate the least loaded gateway (LLG). The primary sends the IP address of the LLG to IKEv2 (on the FlexVPN server). The IP address is sent to the initiator (FlexVPN client), which initiates an IKEv2 session with the LLG. The primary redirects incoming IKEv2 client connections towards the LLG. For more information, see [IKEv2 Redirect Mechanism, on page 3035](#).

Note If the IKEv2 cluster on the primary router is shutdown, the IKEv2 cluster on the secondary router also goes to shutdown state

Subordinate CLB

A CLB subordinate runs on all devices in an HSRP group except on the Active Router (AR). The subordinates are responsible for sending periodic load updates to the server. A CLB subordinate is a fully functional IKEv2 gateway which supplies information to the primary CLB. Apart from updates, CLB subordinates send messages for aliveness assurance to the primary CLB.

CLB Load Management Mechanism

The CLB Load Management Mechanism is a TCP-based protocol that runs between the primary CLB and the CLB subordinates. The CLB load management mechanism informs the primary CLB about the load on the CLB subordinates. Based on this information, the primary CLB selects the LLG to handle the session on each new incoming IKEv2 connection.

Note Secondary nodes periodically update their cluster IP. To avoid synchronization issues, ensure proper management of these updates within your network management routine.

Benefits of IKEv2 Load Balancer

- The IKEv2 Load Balancer Support feature is easy to configure and cost-effective.
- A FlexVPN client need not know the IP addresses of all gateways in the cluster. The client need only know the virtual IP address of the cluster.

- The entire crypto session is redirected to a node in the cluster.

IKEv2 Redirect Mechanism

The IKEv2 redirect mechanism enables a VPN gateway to redirect a FlexVPN client request to another VPN gateway based on load conditions and maintenance requirements.

The IKEv2 redirect mechanism is performed on security association (SA) initialization (IKE_SA_INIT) and on SA authentication (IKE_AUTH).

Redirect During IKEv2 Initial Exchange (SA Initialization)

A FlexVPN client, or an AnyConnect client indicates support for Internet Key Exchange Version 2 (IKEv2) redirect mechanism by including a REDIRECT_SUPPORTED notification message in the initial IKE_SA_INIT request. Use the **crypto ikev2 redirect client** command to enable the redirect mechanism on a client. Use the **crypto ikev2 redirect gateway init** command to enable redirect at IKE_SA_INIT on the gateway.

To redirect an IKEv2 request to another new gateway, the gateway that receives the IKE_SA_INIT request selects the IP address or the fully qualified domain name (FQDN) of the new gateway (in this case, the LLG) with help of the crypto load balancer (CLB) module. The gateway replies with an IKE_SA_INIT response that contains a REDIRECT notification message. The notification includes information such as the new gateway and the nonce value from the payload in the IKE_SA_INIT request. When a client receives the IKE_SA_INIT response, it verifies the nonce value sent in the IKE_SA_INIT request and the gateway information provided in the redirect notification, and confirms whether the redirect notification is as per the configuration.

Note If the nonce value does not match, the client discards the response and waits for another response, thereby preventing denial of service (DoS) attacks on the initiator. DoS attacks could be caused by an attacker injecting incorrect redirect payloads in IKE_SA_INIT responses.

In the IKE_SA_INIT exchange with the new gateway, the client message contains the REDIRECTED_FROM notification payload. The REDIRECTED_FROM notification payload consists of the IP address of the original VPN gateway that redirected the client. The IKEv2 exchange then proceeds as it would have proceeded with the original gateway.

Note The client may be redirected again by the new gateway if the new gateway also cannot serve the client. The client does not include the REDIRECT_SUPPORTED payload again in the IKE_SA_INIT exchange with the new gateway after the redirect. The presence of the REDIRECTED_FROM notification payload in the IKE_SA_INIT exchange with the new gateway indicates to the new gateway that the client supports the IKEv2 redirects mechanism.

Redirect During IKE_AUTH Exchange (SA Authentication)

A thorough security analysis shows that redirect during IKE_AUTH is neither more nor less secure than redirect during IKE_INIT. However, for performance and scalability reasons, we recommend redirect during IKE_INIT. Use the **crypto ikev2 redirect gateway auth** command to enable the redirect mechanism on the

gateway. Use the **redirect gateway auth** command to enable redirect on authentication for selected IKEv2 profiles.

In this method, the client authorization payload is verified before sending the redirect notification payload. A client also verifies the gateway authorization payload before acting on the redirect notification. As the authorization payload is exchanged and successfully verified, the IKEv2 security association (SA) is validated successfully and the INITIAL_CONTACT is processed to decide on redirecting the request. If there is a redirect, the gateway creates the IKE SA and sends the IKE_AUTH response with the redirect notification.

A child SA is not created in this method. The IKE_AUTH does not contain a payload pertaining to a child SA. When the client receives the IKE_AUTH response, the client verifies the gateway authentication payload and deletes the IKEv2 SA with the gateway by sending a delete notification. The client acts on the redirect notification payload to establish connection with the new gateway. The client does not wait for an acknowledgment for the delete notification before establishing a connection with the new gateway. If the IKE_AUTH exchange involves the Extensible Authentication Protocol (EAP) authentication, the gateway has the choice of sending the redirect payload in the first or last IKE_AUTH response. The EAP authentication is included in the first IKE_AUTH response because it is not necessary to provide credentials for each redirect.

Compatibility and Interoperability

The IKEv2 redirect mechanism is based on RFC 5685. The gateway (IKEv2 responder) is compatible with clients (IKEv2 initiator) that implement the standard. Similarly, the client (initiator) implementation must be compatible with third party servers (responder) implementing the standard. The load management mechanism is Cisco proprietary and is only supported on Cisco IOS devices.

Handling Redirect Loops

A client request could be redirected multiple times in a sequence because of either an incorrect configuration or a denial of service (DoS) attack. In some cases, a client could enter a loop with two or more gateways redirecting the client to the other gateway thereby denying service to the client. To prevent this, a client can be configured, using the **crypto ikev2 redirect client** command with the **max-redirects number** keyword argument pair, to not accept more than a specific number of redirects for a particular IKEv2 security association (SA) setup.

IKEv2 Cluster Reconnect

The IKEv2 cluster reconnect feature allows Cisco AnyConnect client to reconnect to any server in the cluster. The **crypto ikev2 reconnect key** is introduced on the server to encrypt the opaque data pushed to the client. During failure detection, the client does reconnect with new or existing server without having to prompt for authentication credentials again.

There are only two key index values, 1 and 2 and at any point in time, any one of the keys configured using this will be active. The Cisco IOS server will be able to decrypt the reconnect data as long as the reconnect key is configured using the reconnect key CLI on the IOS server. This is true even if the key is only the back-up key.

This feature does not support when the **anyconnect-eap** keyword as authentication method in the IKEv2 profile through the **authentication** command.

How to Configure IKEv2 Load Balancer for IPv4 Deployments

Configuring an HSRP Group for Load Balancing

Hot Standby Router Protocol (HSRP) is used to elect the primary HSRP or Active Router (AR). For HSRP to elect a designated device, you must configure the VIP for one device in the group. This address is learned by other devices in the group. The IP address that is assigned to the primary is used as the VIP for the group. The HSRP active router (also called primary CLB) receives the IKEv2 requests and redirects these requests to the LLG in the cluster. The redirection is performed at the IKEv2 protocol level thereby achieving the following:

- All requests from the FlexVPN client reach the primary HSRP as the VIP is configured on the FlexVPN clients. The configuration of FlexVPN clients is minimized because the FlexVPN clients must only know the VIP of the HSRP cluster.
- The primary CLB is run on the same gateway as the primary HSRP, thereby maintaining the load information of all CLB subordinates. The CLB primary enables effective redirection of requests and avoids multiple redirects and loops.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip address** *ip-address mask [secondary]*
5. **standby** [*group-number*] **priority** *priority*
6. **standby** *group-name*
7. **exit**
8. Repeat Steps 3 to 7 to configure an HSRP group for another cluster.

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface <i>type number</i> Example: Device(config)# interface GigabitEthernet 0/0/0	Configures an interface type and enters interface configuration mode.

	Command or Action	Purpose
Step 4	ip address <i>ip-address mask</i> [secondary] Example: Device(config-if)# ip address 10.0.0.1 255.255.255.0	Specifies a primary or secondary IP address for an interface.
Step 5	standby [<i>group-number</i>] priority <i>priority</i> Example: Device(config-if)# standby 1 priority 110	Configures the HSRP priority.
Step 6	standby <i>group-name</i> Example: Device(config-if)# standby group1	Specifies the name of the HSRP standby group.
Step 7	exit Example: Device(config-if)# exit	Exits to global configuration mode.
Step 8	Repeat Steps 3 to 7 to configure an HSRP group for another cluster.	—

Configuring the Load Management Mechanism

Before you begin

Note Starting with Cisco IOS XE 17.14.1a, the default setting for load deficit normalization has been updated to 5. Ensure that your configuration aligns with this new default, unless your deployment requires a custom setting.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 cluster**
4. **holdtime** *milliseconds*
5. **master** {**overload-limit** *percent* | **weight** {**crypto-load** *weight-number* | **system-load** *weight-number*}}
6. **port** *port-number*
7. **slave** {**hello** *milliseconds* | **max-session** *number* | **priority** *number* | **update** *milliseconds*}
8. **standby-group** *group-name*
9. **shutdown**
10. **exit**
11. **crypto ikev2 reconnect key** *key index active name*
12. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 cluster Example: Device(config)# crypto ikev2 cluster	Defines an IKEv2 cluster policy and enters IKEv2 cluster configuration mode.
Step 4	holdtime <i>milliseconds</i> Example: Device(config-ikev2-cluster)# holdtime 10000	(Optional) Specifies the time, in milliseconds, to receive messages from a peer. <ul style="list-style-type: none"> • If no messages are received within the configured time, the peer is declared “dead.”
Step 5	master {<i>overload-limit percent</i> weight {<i>crypto-load weight-number</i> system-load weight-number}} Example: Device(config-ikev2-cluster)# master weight crypto-load 10	Specifies settings for the primary in the HSRP cluster. <ul style="list-style-type: none"> • overload-limit <i>percent</i>—The threshold load of the cluster. The load limit to decide when a device is busy and to ignore it when redirecting it for requests. • weight—Specifies the weight of a load attribute. Range: 0 to 100. Default: 100. • crypto-load <i>weight-number</i>—The IKE and IPsec security association (SA) load. • system-load <i>weight-number</i>—The system and memory load.
Step 6	port <i>port-number</i> Example: Device(config-ikev2-cluster)# port 2000	(Optional) Specifies the cluster primary listen port.
Step 7	slave {<i>hello milliseconds</i> max-session number priority number update milliseconds} Example: Device(config-ikev2-cluster)# slave max-session 90	Specifies settings for subordinate gateways in the HSRP group. <ul style="list-style-type: none"> • hello <i>milliseconds</i>—The hello interval, in milliseconds, for a subordinate gateway. • max-session <i>number</i>—The maximum number of SAs allowed on a subordinate. This keyword is mandatory and cannot be skipped.

	Command or Action	Purpose
		<p>Note When specifying the the maximum number of SA's using max-session keyword, specify a value that includes some buffer for crypto sessions as rekeys and retransmissions, create some extra sessions and these sessions continue to exist for a while before they are deleted. Providing a buffer also supports fault tolerance between master and secondary server.</p> <ul style="list-style-type: none"> • priority number—The subordinate priority. • update milliseconds—The interval, in milliseconds, between two update messages for a subordinate gateway.
Step 8	<p>standby-group <i>group-name</i></p> <p>Example:</p> <pre>Device(config-ikev2-cluster)# standby-group group1</pre>	<p>Defines the HSRP group containing the subordinates.</p> <ul style="list-style-type: none"> • <i>group-name</i>—The group name is derived from the <i>group-name</i> argument specified in the standby name command.
Step 9	<p>shutdown</p> <p>Example:</p> <pre>Device(config-ikev2-cluster)# shutdown</pre>	(Optional) Disables the IKEv2 cluster policy.
Step 10	<p>exit</p> <p>Example:</p> <pre>Device(config-ikev2-cluster)# exit</pre>	Exits IKEv2 cluster configuration mode and returns to global configuration mode.
Step 11	<p>crypto ikev2 reconnect key <i>key index active name</i></p> <p>Example:</p> <pre>Device(config)# crypto ikev2 reconnect key 1 active test123</pre>	<p>Enables the IKEv2 opaque data support for session reconnect.</p> <p>Note The ikev2 cluster reconnect feature is enabled for encryption only when the active keyword is present in the ikev2 reconnect key active name key-string. The active keyword is mandatory to enable the cluster reconnect feature. If you use the ikev2 reconnect key key-name key-string command without the active keyword in the command, the headend will only be able to decrypt.</p>
Step 12	<p>end</p> <p>Example:</p> <pre>Device(config-ikev2-cluster)# end</pre>	Exits IKEv2 cluster configuration mode and returns to privileged EXEC mode.

Activating the IKEv2 Redirect Mechanism on the Server

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto ikev2 redirect gateway init
4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 redirect gateway init Example: Device(config)# crypto ikev2 redirect gateway init	Enables the IKEv2 redirect mechanism on the gateway during SA initiation.
Step 4	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Activating the IKEv2 Redirect Mechanism on the Client

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto ikev2 redirect client [max-redirects *number*]
4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 redirect client [max-redirects number] Example: Device(config)# crypto ikev2 redirect client max-redirects 15	Enables the IKEv2 redirect mechanism on the FlexVPN client. <ul style="list-style-type: none"> • max-redirects number—(Optional) Specifies the maximum number of redirects that can be configured on the FlexVPN client for redirect loop detection.
Step 4	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Configure Dead Peer Detection

Dead Peer Detection allows you to configure your router to query the liveness of its Internet Key Exchange (IKE) peer at regular intervals. While DPD is optional in some configurations, it is recommended for IKEv2 cluster functionality and is mandatory for Cluster Load Balancing (CLB) under all conditions. Ensure that DPD is configured on both primary and secondary nodes when setting up a cluster configuration.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **dpd interval retry-interval {on-demand | periodic}**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	dpd interval retry-interval {on-demand periodic} Example: Device(config)# crypto ikev2 dpd 500 50 on-demand	Allows live checks for peers as follows: <ul style="list-style-type: none"> • on-demand: Specifies the on-demand mode to send keepalive, only in the absence of any incoming data traffic, to check liveness of the peer before sending any data. DPD on-demand is required on both primary

	Command or Action	Purpose
		<p>and secondary nodes for cluster configuration and is essential for ensuring the proper function of IKEv2 cluster functionality.</p> <ul style="list-style-type: none"> • periodic: Specifies the periodic mode to send keepalives regularly at the specified interval. DPD is mandatory for CLB to maintain a reliable state and peer availability under all conditions.
Step 4	<p>exit</p> <p>Example:</p> <pre>Device(config-if)# exit</pre>	Exits to global configuration mode.

Configuration Examples for IKEv2 Load Balancer for IPv4 Deployments

Example: Configuring an HSRP Group for Load Balancing

The following example shows RouterA configured as the active router for an Hot Standby Router Protocol (HSRP) group with a priority of 110. The default priority level is 100. This HSRP group is assigned the group name of group1. The group name is referred in the cluster policy.

```
Device(config)# hostname RouterA
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 10.0.0.1 255.255.255.0
Device(config-if)# standby 1 priority 110
Device(config-if)# standby group1
Device(config-if)# end
```

Example: Configuring the Load Management Mechanism

The following example shows how to configure the load management mechanism in IKEv2:

```
Device> enable
Device# configure terminal
Device(config)# crypto ikev2 cluster
Device(config-ikev2-cluster)# holdtime 10000
Device(config-ikev2-cluster)# master crypto-load 10
Device(config-ikev2-cluster)# port 2000
Device(config-ikev2-cluster)# slave priority 90
Device(config-ikev2-cluster)# standby-group group1
Device(config-ikev2-cluster)# shutdown
Device(config-ikev2-cluster)# end
```

Example: Configuring the Redirect Mechanism

The following example shows how to enable the redirect mechanism on a client and during initiation on a gateway:

```
Device> enable
Device# configure terminal
Device(config)# crypto ikev2 redirect client
Device(config)# crypto ikev2 redirect gateway init
Device(config)# end
```

Example: Configuring the Cluster Reconnect Key

The following example shows how to enable the reconnect key on a server:

```
Device> enable
Device# configure terminal
Device(config)# crypto ikev2 reconnect key 1 active key
Device(config)# crypto ikev2 reconnect key 2 test
Device(config)# end
```

How to Configure IKEv2 Load Balancer for IPv6 Deployments

Configuring an HSRP Group for Load Balancing

Note From Cisco IOS XE 17.13.1a load balancing support for IKEv2 cluster in an IPv6 topology is introduced. The configuration steps for IPv6 topology now reference the keywords `primary` and `secondary` that correspond to keywords `master` and `slave` used in the IPv4 topology.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type number*
4. **ip address** *ip-address mask* [**secondary**]
5. **standby** [*group-number*] **priority** *priority*
6. **standby** *group-name*
7. **standbydelaymimumum** [*seconds*]
8. **standby version 2**
9. **exit**
10. Repeat Steps 3 to 7 to configure an HSRP group for another cluster.

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface type number Example: Device(config)# interface GigabitEthernet 0/0/0	Configures an interface type and enters interface configuration mode.
Step 4	ip address ip-address mask [secondary] Example: Device(config-if)# ip address 10.0.0.1 255.255.255.0	Specifies a primary or secondary IP address for an interface.
Step 5	standby [group-number] priority priority Example: Device(config-if)# standby 1 priority 110	Configures the HSRP priority.
Step 6	standby group-name Example: Device(config-if)# standby group1	Specifies the name of the HSRP standby group.
Step 7	standbydelaymimimum [seconds] Example: Device(config-if)# standby delay minimum 120	Configures the HSRP priority.
Step 8	standby version 2 Example: Device(config-if)# standby version 2	Configures the HSRP priority.
Step 9	exit Example: Device(config-if)# exit	Exits to global configuration mode.
Step 10	Repeat Steps 3 to 7 to configure an HSRP group for another cluster.	—

Configuring the Load Management Mechanism

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 cluster**
4. **holdtime** *milliseconds*
5. **primary** {**overload-limit** *percent* | **weight** {**crypto-load** *weight-number* | **system-load** *weight-number*}}
6. **port** *port-number*
7. **secondary** {**hello** *milliseconds* | **max-session** *number* | **priority** *number* | **update** *milliseconds*}
8. **standby-group** *group-name*
9. **shutdown**
10. **exit**
11. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 cluster Example: Device(config)# crypto ikev2 cluster	Defines an IKEv2 cluster policy and enters IKEv2 cluster configuration mode.
Step 4	holdtime <i>milliseconds</i> Example: Device(config-ikev2-cluster)# holdtime 10000	(Optional) Specifies the time, in milliseconds, to receive messages from a peer. <ul style="list-style-type: none">• If no messages are received within the configured time, the peer is declared “dead.”
Step 5	primary { overload-limit <i>percent</i> weight { crypto-load <i>weight-number</i> system-load <i>weight-number</i> }} Example: Device(config-ikev2-cluster)# primary weight crypto-load 10	Specifies settings for the primary in the HSRP cluster. <ul style="list-style-type: none">• overload-limit <i>percent</i>—The threshold load of the cluster. The load limit to decide when a device is busy and to ignore it when redirecting it for requests.• weight—Specifies the weight of a load attribute. Range: 0 to 100. Default: 100.• crypto-load <i>weight-number</i>—The IKE and IPsec security association (SA) load.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • system-load <i>weight-number</i>—The system and memory load.
Step 6	port <i>port-number</i> Example: Device(config-ikev2-cluster)# port 2000	(Optional) Specifies the cluster primary listen port.
Step 7	secondary { hello <i>milliseconds</i> max-session <i>number</i> priority <i>number</i> update <i>milliseconds</i> } Example: Device(config-ikev2-cluster)# slave max-session 90	Specifies settings for subordinate gateways in the HSRP group. <ul style="list-style-type: none"> • hello <i>milliseconds</i>—The hello interval, in milliseconds, for a subordinate gateway. • max-session <i>number</i>—The maximum number of SAs allowed on a subordinate. This keyword is mandatory and cannot be skipped. • priority <i>number</i>—The subordinate priority. • update <i>milliseconds</i>—The interval, in milliseconds, between two update messages for a subordinate gateway. <p>Note When specifying the the maximum number of SA's using max-session keyword, specify a value that includes some buffer for crypto sessions as rekeys and retransmissions, create some extra sessions and these sessions continue to exist for a while before they are deleted. Providing a buffer also supports fault tolerance between master and secondary server.</p>
Step 8	standby-group <i>group-name</i> Example: Device(config-ikev2-cluster)# standby-group group1	Defines the HSRP group containing the subordinates. <ul style="list-style-type: none"> • <i>group-name</i>—The group name is derived from the <i>group-name</i> argument specified in the standby name command.
Step 9	shutdown Example: Device(config-ikev2-cluster)# shutdown	(Optional) Disables the IKEv2 cluster policy.
Step 10	exit Example: Device(config-ikev2-cluster)# exit	Exits IKEv2 cluster configuration mode and returns to global configuration mode.
Step 11	end Example: Device(config-ikev2-cluster)# end	Exits IKEv2 cluster configuration mode and returns to privileged EXEC mode.

Activating the IKEv2 Redirect Mechanism on the Server

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto ikev2 redirect gateway init
4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 redirect gateway init Example: Device(config)# crypto ikev2 redirect gateway init	Enables the IKEv2 redirect mechanism on the gateway during SA initiation.
Step 4	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Activating the IKEv2 Redirect Mechanism on the Client

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto ikev2 redirect client [max-redirects *number*]
4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 redirect client [max-redirects number] Example: Device(config)# crypto ikev2 redirect client max-redirects 15	Enables the IKEv2 redirect mechanism on the FlexVPN client. • max-redirects number —(Optional) Specifies the maximum number of redirects that can be configured on the FlexVPN client for redirect loop detection.
Step 4	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Configuring Optional Parameters for IKEv2 Load Balancer Support

Configuring Idle Timer

You can configure the IPsec SA Idle timer to drop SAs for inactive peers after specified time. This is an optional configuration.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec security-association idle-time seconds**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ipsec security-association idle-time seconds	Configures the IPsec SA idle timer.

	Command or Action	Purpose
	<p>Example:</p> <pre>Device(config)# crypto ipsec security-association idle-time 600</pre>	<p>The seconds argument specifies the time, in seconds, that the idle timer will allow an inactive peer to maintain an SA. Valid values for the seconds argument range from 60 to 86400.</p> <p>Note When specifying the idle timer, it is important to consider the rate of incoming and outgoing traffic and then set the timer accordingly.</p>
Step 4	<p>exit</p> <p>Example:</p> <pre>Device(config-if)# exit</pre>	Exits to global configuration mode.

Configure Dead Peer Detection

Dead Peer Detection allows you to configure your router to query the liveliness of its Internet Key Exchange (IKE) peer at regular intervals. While DPD is optional in some configurations, it is recommended for IKEv2 cluster functionality and is mandatory for Cluster Load Balancing (CLB) under all conditions. Ensure that DPD is configured on both primary and secondary nodes when setting up a cluster configuration.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **dpd interval retry-interval {on-demand | periodic}**
4. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Device> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	<p>dpd interval retry-interval {on-demand periodic}</p> <p>Example:</p> <pre>Device(config)# crypto ikev2 dpd 500 50 on-demand</pre>	<p>Allows live checks for peers as follows:</p> <ul style="list-style-type: none"> • on-demand: Specifies the on-demand mode to send keepalive, only in the absence of any incoming data traffic, to check liveliness of the peer before sending any data. DPD on-demand is required on both primary and secondary nodes for cluster configuration and is essential for ensuring the proper function of IKEv2 cluster functionality.

	Command or Action	Purpose
		<ul style="list-style-type: none"> periodic: Specifies the periodic mode to send keepalives regularly at the specified interval. DPD is mandatory for CLB to maintain a reliable state and peer availability under all conditions.
Step 4	exit Example: Device(config-if)# exit	Exits to global configuration mode.

Configuration Examples for IKEv2 Load Balancer for IPv6 Deployments

Example: Configuring an HSRP Group for Load Balancing

The following example shows RouterA configured as the active router for an Hot Standby Router Protocol (HSRP) group with a priority of 110. The default priority level is 100. This HSRP group is assigned the group name of group1. The group name is referred in the cluster policy.

```
Device(config)# hostname RouterA
Device(config)# interface GigabitEthernet 0/0/0
Device(config-if)# ip address 2001:DB8::1
Device(config-if)# standby 1 priority 110
Device(config-if)# standby group 1
Device(config-if)# standby version 1
Device(config-if)# end
```

Example: Configuring the Load Management Mechanism

The following example shows how to configure the load management mechanism in IKEv2:

```
Device> enable
Device# configure terminal
Device(config)# crypto ikev2 cluster
Device(config-ikev2-cluster)# holdtime 10000
Device(config-ikev2-cluster)# primary crypto-load 10
Device(config-ikev2-cluster)# port 2000
Device(config-ikev2-cluster)# secondary priority 90
Device(config-ikev2-cluster)# standby-group group1
Device(config-ikev2-cluster)# shutdown
Device(config-ikev2-cluster)# end
```

Example: Configuring the Redirect Mechanism

The following example shows how to enable the redirect mechanism on a client and during initiation on a gateway:

```

Device> enable
Device# configure terminal
Device(config)# crypto ikev2 redirect client
Device(config)# crypto ikev2 redirect gateway init
Device(config)# end

```

Verifying IKEv2 Load Balancer Configuration

To display the configuration of Internet Key Exchange Version 2 (IKEv2) cluster policy, use the **show crypto ikev2 cluster** command in privileged EXEC mode

The following is sample output from the **show crypto ikev2 cluster** command for an HSRP primary gateway:

```
Device# show crypto ikev2 cluster
```

```

Role           : CLB Primary
Status        : Up
CLB Secondary  : 2
Cluster IP    : 2001:DB8::10
Hold time     : 15000 msec
Overload limit : 80%
Codes        : '*' Least loaded, '-' Overloaded

Load statistics:
  Gateway      Role   Last-seen  Prio   Load   IKE   FQDN
-----
2001:DB8::1   Primary --         100   26.6%  3996
2001:DB8::2   Second 00:01.452  100   26.6%  3999
2001:DB8::3   Second 00:00.271  100   26.6%  4006

```

Note The secondary server shares crypto load and system load details based on the configuration of the update message. These factors help in identifying an LLG. These details are not static and therefore the load is not distributed equally or in a linear manner.

The following is sample output from the **show crypto ikev2 cluster** command for an HSRP secondary gateway:

```
Device# show crypto ikev2 cluster
```

```

Role           : CLB Secondary
Status        : Up
Cluster IP    : 1:1:1::100
Hold time     : 15000 msec
Hello-interval : 5000 msec
Update-interval: 6000 msec

Load statistics:
  Gateway      Last-Ack  Prio   Load   IKE   FQDN
-----
1:1:1::2      00:02.671  100   51.0%  2793

```

To display the configuration of Internet Key Exchange Version 2 (IKEv2) cluster policy with additional details, use the **show crypto ikev2 cluster details** command in privileged EXEC mode.

```
Device# show crypto ikev2 cluster details
```

```

Gateway      Priority   In-neg   Crypto   CPU   Mem   Composite Prioritized

```

```

-----
1:1:1::6      100      2.5%     17.4%    43%     20%     43.0%    43.0%
1:1:1::3      100      0.0%     17.5%    39%     23%     39.0%    39.0%
1:1:1::2      100      0.0%     17.0%    40%     18%     40.0%    40.0%
1:1:1::5      100      0.0%     18.9%    43%     17%     43.0%    43.0%
1:1:1::1      100      0.0%     16.3%    40%     19%     40.0%    40.0%
1:1:1::4      100      0.0%     16.3%    42%     16%     42.0%    42.0%

```

To display Internet Key Exchange Version 2 (IKEv2) security association (SA) statistics, use the **show crypto ikev2 cluster stats** command in privileged EXEC mode.

Device# show crypto ikev2 cluster stats

```

Gateway      Priority  In-neg    Crypto   CPU    Mem    Composite Prioritized
-----
1:1:1::6     100     2.5%     17.4%   43%   20%   43.0%   43.0%
1:1:1::3     100     0.0%     17.5%   39%   23%   39.0%   39.0%

Technical Assistance

Description	Link
The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for IKEv2 Load Balancer for IPv4 and IPv6 Deployments

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 304: Feature Information for IKEv2 Load Balancer

Feature Name	Releases	Feature Information
IKEv2 fast convergence with cluster reconnect for Anyconnect	15.6(1)T Cisco IOS XE Release 3.17S	The IKEv2 fast convergence with cluster reconnect for Anyconnect feature enables the Cisco AnyConnect client to reconnect to any server in the cluster. The following command was introduced or modified: crypto ikev2 reconnect key

Feature Name	Releases	Feature Information
IKEv2 Load Balancer Support	Cisco IOS XE Release 3.8S	<p>The IKEv2 Load Balancer Support feature distributes incoming IKEv2 requests from FlexVPN clients among IKEv2 FlexVPN servers or gateways by redirecting requests to the least loaded gateway.</p> <p>The following commands were introduced or modified: crypto ikev2 cluster, crypto ikev2 redirect, holdtime, primary (IKEv2), port (IKEv2), redirect gateway, subordinate (IKEv2), standby-group, show crypto ikev2 cluster, show crypto ikev2 sa.</p>
IKEv2 Load Balancer Support for IPv6 deployments	Cisco IOS XE Release 17.13.1a	Support for IKEv2 Load Balancer in IPv6 deployments was introduced only for C8500-12X platform.

CHAPTER 228

Configuring IKEv2 Fragmentation

The IKE Fragmentation adhering to RFC feature implements fragmentation of Internet Key Exchange Version 2 (IKEv2) packets as proposed in the IETF **draft-ietf-ipsecme-ikev2-fragmentation-10** document.

- [Information About Configuring IKEv2 Fragmentation, on page 3057](#)
- [How to Configure Configuring IKEv2 Fragmentation, on page 3060](#)
- [Configuration Examples for Configuring IKEv2 Fragmentation, on page 3061](#)
- [Additional References for Configuring IKEv2 Fragmentation, on page 3066](#)
- [Feature Information for Configuring IKEv2 Fragmentation, on page 3066](#)

Information About Configuring IKEv2 Fragmentation

IKEv2 Fragmentation

The Internet Key Exchange Version 2 (IKEv2) fragmentation protocol splits large IKEv2 message into a set of smaller ones, called IKE Fragment Messages. The IKEv2 fragmentation methodology, implemented on Cisco IOS software through the IKEv2 Remote Access Headend feature, is a Cisco proprietary method, which restricts interoperability with non-Cisco peers. The fragmentation is performed only on an encrypted IKEv2 packet, and hence, a peer cannot decrypt or authenticate the message until the peer receives all fragments. The IKE Fragmentation adhering to RFC feature implements the IETF **draft-ietf-ipsecme-ikev2-fragmentation-10** document by encrypting packets after fragmentation, enabling interoperability with non-Cisco peers while continuing to support the Cisco proprietary fragmentation method.

Note By default, IKEv2 fragmentation is disabled, though show run all shows crypto ikev2 fragmentation mtu is 576 B.

Negotiation Between Peers

Effective with the IKE Fragmentation adhering to RFC feature, the support for the IETF standard fragmentation method is added the IKE_SA_INIT message as a notify payload, while Cisco proprietary Fragmentation method continues to be indicated using the Vendor ID payload in the same IKE_SA_INIT message. When fragmentation is enabled, support for both methodologies is displayed as appropriate in the **show crypto ikev2 sa detail** command. The maximum transmission unit (MTU) is configured locally and is not negotiated or

exchanged along with the messages. After the INIT exchange, the peers in a network configured with either methodology are aware of the authentication method that must be used and whether the AUTH message can be fragmented.

The following is a sample output from device when debug is enabled showing capability negotiation in INIT request message.

```
*Oct 14 08:45:24.732: IKEv2:(SESSION ID = 0,SA ID = 1):Next payload: SA, version: 2.0
Exchange type: IKE_SA_INIT, flags: INITIATOR Message id: 0, length: 524
Payload contents:
SA Next payload: KE, reserved: 0x0, length: 144
...
Security protocol id: IKE, spi size: 0, type: NAT_DETECTION_DESTINATION_IP
NOTIFY(IKEV2_FRAGMENTATION_SUPPORTED) Next payload: VID, reserved: 0x0, length: 8
Security protocol id: Unknown - 0, spi size: 0, type: IKEV2_FRAGMENTATION_SUPPORTED
VID Next payload: NONE, reserved: 0x0, length: 20
```

In the above output, the INIT request contains the initiator's message to a responder indicating support for both IETF standard fragmentation method and Cisco proprietary fragmentation method through the IKEV2_FRAGMENTATION_SUPPORTED and VID values in the message.

The following is a sample output from device when debug is enabled showing capability negotiation in INIT response message.

```
*Oct 14 08:45:24.732: IKEv2:(SESSION ID = 0,SA ID = 1):Next payload: SA, version: 2.0
Exchange type: IKE_SA_INIT, flags: INITIATOR Message id: 0, length: 524
Payload contents:
SA Next payload: KE, reserved: 0x0, length: 144
last proposal: 0x0, reserved: 0x0, length: 140
...
NOTIFY(IKEV2_FRAGMENTATION_SUPPORTED) Next payload: VID, reserved: 0x0, length: 8
Security protocol id: Unknown - 0, spi size: 0, type: IKEV2_FRAGMENTATION_SUPPORTED <-----
Response, supporting both
VID Next payload: NONE, reserved: 0x0, length: 20 <----- Response, supporting both
```

In the above output, the response request contains the responder's message to the initiator indicating support for both IETF standard fragmentation method and Cisco proprietary fragmentation method through the IKEV2_FRAGMENTATION_SUPPORTED and VID values in the message.

Fragmentation Support for Older Releases

To ensure fragmentation support for older releases having Cisco proprietary fragmentation method, IKEv2 continues to use the Vendor ID along with the IKEv2 notification payload type for the IETF standard fragmentation method. If both fragmentation methods are supported, IKEv2 prefers the IETF standard fragmentation method.

The following table indicates how the fragmentation type is determined based on the capability of peers. CISCO refers to Cisco proprietary fragmentation method and STD refers to the IETF standard fragmentation method.

Peer 1 Capability	Peer 2 Capability	Active Fragmentation Type on the Security Association
STD + CISCO	STD + CISCO	STD
STD	STD	STD
CISCO	CISCO	CISCO

Peer 1 Capability	Peer 2 Capability	Active Fragmentation Type on the Security Association
CISCO	STD + CISCO	CISCO
STD	STD + CISCO	STD
STD	CISCO	None
None	None or STD + CISCO or STD or CISCO	None

Encryption, Decryption, and Retransmission of Fragments

Fragmentation and Encryption

A packet is fragmented either based on the maximum transmission unit (MTU) value specified in the **crypto ikev2 fragmentation** command or the default MTU value. IKE messages that only contain the encrypted payload are fragmented. A new payload type—Encrypted and Authenticated Fragment—in the announcement message indicates the fragment number out of the total fragments. This payload is annotated as SKF and the value is 53.

Before the outgoing packet is encrypted, the packet length is checked. The security association established is also verified if the SA is enabled with the IETF standard fragmentation method. The following is a sample output from device displaying the transmission of fragmented packets.

```
*Oct 16 10:31:22.221: IKEv2:(SESSION ID = 0,SA ID = 3):Next payload: SKF, version: 2.0
Exchange type: INFORMATIONAL, flags: INITIATOR Message id: 1, length: 244
Payload contents:
SKF Next payload: COOP, reserved: 0x90, length: 216
SKF Fragment number: 1 OF Total Fragments: 3
*Oct 16 10:31:22.222: IKEv2:(SESSION ID = 0,SA ID = 3):Next payload: SKF, version: 2.0
Exchange type: INFORMATIONAL, flags: INITIATOR Message id: 1, length: 244
Payload contents:
SKF Next payload: COOP, reserved: 0x90, length: 216
SKF Fragment number: 2 OF Total Fragments: 3
*Oct 16 10:31:22.222: IKEv2:(SESSION ID = 0,SA ID = 3):Next payload: SKF, version: 2.0
Exchange type: INFORMATIONAL, flags: INITIATOR Message id: 1, length: 244
Payload contents:
SKF Next payload: COOP, reserved: 0x90, length: 216
SKF Fragment number: 3 OF Total Fragments: 3
```

The line “SKF Next payload: COOP, reserved: 0x90, length: 216” and “SKF Fragment number: 1 OF Total Fragments: 3” indicate that the message is a Cooperative key server announcement (ANN) packet fragmented into three fragments.

Decryption and Defragmentation

When incoming fragments are received on a responder, each fragment is decrypted and stored temporarily. During defragmentation (assembling the fragments to the original pack), duplicate fragments, fragment numbers outside of total fragment number, and fragments having an entirely different fragment number are dropped. The fragments are added in ascending order of fragment number and not according to the received order), that way, packet assembly is faster. However, out of order fragments are allowed and processed. Each fragment is verified to ensure that all fragments that pertain to a message are received. If all fragments are

received, the packet is assembled from the fragments and processed as a newly received message. Acknowledgment (ACK) message is sent when the original packet is assembled, and not for each fragment.

Retransmissions

IKEv2 retransmissions happen as prompted by IKEv2 retransmission timers. The fragments once constructed and sent out for the first time, are held in a list, ready to be resent when the retransmission timers are triggered. When a retransmitted request is received, IKEv2 resends the response. The response is resent when the first fragment (#1) retransmission is received. The remaining fragment numbers are ignored, thereby allowing faster processing of the response.

Enabling Fragmentation

Use the **crypto ikev2 fragmentation** command to globally enable fragmentation per security association (SA). Fragmentation is enabled on SA when both peers indicate support for fragmentation after INIT exchange on each peers, to be used for IKE_AUTH exchange.

Note This command was introduced through IKEv2 Remote Access Headend feature and has not changed.

You can specify the maximum transmission unit (MTU), in bytes, using the **mtu** *mtu-size* keyword-argument pair. The MTU size refers to the IP or UDP encapsulated IKEv2 packets. The MTU range is from 68 to 1500 bytes. The default MTU size is 576 for IPv4 packets and 1280 bytes for IPv6 packets.

Effective with the IKE Fragmentation adhering to RFC feature, the **crypto ikev2 fragmentation** command:

- Affects future SAs only and does not affect the existing, old SAs.
- Supports Cisco proprietary fragmentation method and the IETF standard fragmentation method.

The **show crypto ikev2 sa detail** command displays the following information:

- The fragmentation method enabled on the peer. If the enabled fragmentation method is IETF standard fragmentation, the output displays the MTU, which is in use.
- Whether fragmentation is enabled on both peers or enabled on the local peer only.

IPv6 Support

The IKE Fragmentation adhering to RFC feature adds support for fragmenting IPv6 packets in IPv6 IKE endpoints when the IETF standard fragmentation method is used. The default MTU value is 1280 bytes and is used when the MTU is not specified in the **crypto ikev2 fragmentation** command. The MTU used in fragmentation is displayed in the output of the **show crypto ikev2 sa detail** command.

How to Configure Configuring IKEv2 Fragmentation

Configuring IKEv2 Fragmentation

Perform this task to enable automatic fragmentation of large IKEv2 packets.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto ikev2 fragmentation [mtu *mtu-size*]
4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 fragmentation [mtu <i>mtu-size</i>] Example: Device(config)# crypto ikev2 fragmentation mtu 100	Configures IKEv2 fragmentation. <ul style="list-style-type: none"> • The MTU range is from 96 to 1500 bytes. The default MTU size is 576 for IPv4 packets and 1280 bytes for IPv6 packets. <p>Note The MTU size refers to the IP or UDP encapsulated IKEv2 packets.</p>
Step 4	end Example: Device(config)# end	Exits global configuration mode and returns to privileged EXEC mode.

Configuration Examples for Configuring IKEv2 Fragmentation

Example: IETF Fragmentation Enabled Displaying Configured MTU

The following is a sample output stating IETF standard fragmentation method is enabled. This statement is displayed when the responder supports IETF standard fragmentation method also. The output also displays the MTU in use.

```
Device# show crypto ikev2 sa detail
```

```
IPv4 Crypto IKEv2 SA
```

```

Feature Information for Configuring IKEv2 Fragmentation

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 305: Feature Information for Configuring IKEv2 Fragmentation

Feature Name	Releases	Feature Information
IKEv2 Fragmentation adhering to RFC		<p>The IKE Fragmentation adhering to RFC feature implements fragmentation of Internet Key Exchange Version 2 (IKEv2) packets as proposed in the IETF draft-ietf-ipsecme-ikev2-fragmentation-10 document.</p> <p>The following command was modified: show crypto ikev2 sa.</p>

CHAPTER 229

Configuring IKEv2 Reconnect

The IOS IKEv2 support for AutoReconnect feature of AnyConnect feature helps in reestablishing IKEv2 negotiation without user interaction with the Cisco AnyConnect client.

- [Prerequisites for Configuring IKEv2 Reconnect, on page 3069](#)
- [Restrictions for Configuring IKEv2 Reconnect, on page 3069](#)
- [Information About Configured IKEv2 Reconnect, on page 3070](#)
- [How to Configure IKEv2 Reconnect, on page 3071](#)
- [Configuration Examples for Configuring IKEv2 Reconnect, on page 3072](#)
- [Additional References for Configuring IKEv2 Reconnect, on page 3073](#)
- [Feature Information for Configuring IKEv2 Reconnect, on page 3073](#)

Prerequisites for Configuring IKEv2 Reconnect

- You must enable the BypassDownloader function in the AnyConnectLocalPolicy file by setting the <BypassDownloader> value to true. If your device does not support SSL, the BypassDownloader function will not work. You must disable the function manually by setting the <BypassDownloader> value to false, else the connection will fail.

Restrictions for Configuring IKEv2 Reconnect

- The preshared key authorization method cannot be configured on the Internet Key Exchange Version 2 (IKEv2) profile. This is because the IOS IKEv2 support for AutoReconnect feature of AnyConnect feature uses the preshared key authorization method and configuring the preshared key on the same IKEv2 profile may lead to confusion.
- The following commands cannot be configured on the IKEv2 profile: **authentication local pre-share**, **authentication remote pre-share**, **keyring**, **aaa authorization group psk**, and **aaa authorization user psk**.

Information About Configured IKEv2 Reconnect

IKEv2 and Cisco AnyConnect Client Reconnect Feature

The Auto Reconnect feature in the Cisco AnyConnect client helps the Cisco AnyConnect VPN client to remember the session for a period of time and to resume the connection after establishing the secure channel. As the Cisco AnyConnect Client is extensively used with Internet Key Exchange Version 2 (IKEv2), IKEv2 extends the Auto Reconnect feature support on Cisco IOS software through the IOS IKEv2 support for Auto Reconnect feature of AnyConnect feature.

Auto Reconnect in the Cisco AnyConnect client occurs in the following scenarios:

- The intermediate network is down. The Cisco AnyConnect client tries to resume the session when it is up.
- The Cisco AnyConnect client device switches between networks. This results in source IP or port change, which brings down the existing security association (SA) and, hence, the Cisco AnyConnect client tries to resume the SA using the Auto Reconnect feature.
- The Cisco AnyConnect client device tries to resume SA after returning from sleep or hibernate mode.

Advantages of Using the Auto Reconnect Feature

- The copy attributes used in the original session are reused without querying the authentication, authorization, and accounting (AAA) server.
- The Cisco IOS gateway does not have to contact the RADIUS server for reconnecting to the client.
- No user interaction for authentication or authorization is needed during resuming the session.
- The authentication method is the preshared key when reconnecting a session. This authentication method is quick compared to other authentication methods (that include Rivest, Shamir, and Adelman (RSA) signature authentication method, Elliptic Curve Digital Signature Algorithm (ECDSA) signature (ECDSA-sig) authentication method, and Extensible Authentication Protocol (EAP) authentication method). The preshared key authentication method helps in resuming a session on the IOS software with minimal resources.
- The unused security associations (SAs) are removed thereby freeing the crypto resources.

Auto Reconnect and DPD

Dead Peer Detection (DPD) is configured to confirm the availability of a peer send by sending queries to a peer. If there are no responses from the peer, the security association created for that peer is deleted. You need not configure DPD in a reconnect profile if DPD configured on the FlexVPN server because in both configuration scenarios, the purpose is the same . However, if the feature is enabled, DPD is queued as on demand DPD in IKEv2, which also stores the platform specific handle when deleting the SA.

Message Exchanges Between Cisco IOS Gateway and Cisco AnyConnect Client

The Cisco AnyConnect client contacts the Cisco IOS gateway to establish a security association (SA). During authorization or AUTH exchange (CFGMODE_REQ payload of IKE_AUTH request), IKEv2 checks if the IOS IKEv2 support for the Auto Reconnect feature of AnyConnect feature is enabled in the IKEv2 profile using the **reconnect** command, selects the IKEv2 policy of the chosen IKEv2 profile, and sends the session

ID and the session token attributes to the Cisco AnyConnect client in CFGMODE_REPLY payload of the IKE_AUTH response. The authorization method is the preshared key between the client and Cisco IOS software for the SA.

IKEv2 periodically sends dead peer detection (DPD) messages to the Cisco AnyConnect client to validate if the client is active. The Cisco AnyConnect client responds to the DPD messages, which the Cisco IOS gateway understands as an active client and creates a security association (SA) with the client. However, if the client does not reconnect within 30 minutes, which is the default reconnect timeout period, the Cisco IOS gateway assumes that the client is inactive and deletes the SA for that client. The Cisco AnyConnect client needs to start a fresh connection.

Use the **show crypto ikev2 stats reconnect** command to view the connection statistics and the **clear crypto ikev2 session** command to delete the SA with the client.

How to Configure IKEv2 Reconnect

Enabling IKEv2 Reconnect

Perform this task to enable the IOS IKEv2 support for AutoReconnect feature of AnyConnect feature.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 profile** *profile-name*
4. **reconnect** [*timeout seconds*]
5. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 profile <i>profile-name</i> Example: Device(config)# crypto ikev2 profile profile1	Defines an IKEv2 profile and enters IKEv2 profile configuration mode.
Step 4	reconnect [<i>timeout seconds</i>] Example: Device(config-ikev2-profile)# reconnect timeout 900	Enables the IKEv2 support for the Auto Reconnect feature.

	Command or Action	Purpose
Step 5	end Example: Device(config-ikev2-profile)# end	Exits IKEv2 profile configuration mode and returns to privileged EXEC mode.

Troubleshooting IKEv2 Reconnect Configuration

Use the following commands to verify or clear the IOS IKEv2 support for AutoReconnect feature of AnyConnect feature configuration.

SUMMARY STEPS

1. **enable**
2. **show crypto ikev2 stats reconnect**

DETAILED STEPS

- Step 1** **enable**
 Enables privileged EXEC mode.
- Enter your password if prompted.

Example:

```
Device> enable
```

- Step 2** **show crypto ikev2 stats reconnect**
 Displays the reconnect statistics.

Example:

```
Device# show crypto ikev2 stats reconnect
```

```
Total incoming reconnect connection:    10
Success reconnect connection:           10
Failed reconnect connection:             0
Reconnect capable active session count:  4
Reconnect capable inactive session count: 6
```

Configuration Examples for Configuring IKEv2 Reconnect

Example: Enabling IKEv2 Reconnect

The following example shows how to enable the IOS IKEv2 support for AutoReconnect feature of AnyConnect feature.

```

Device> enable
Device# configure terminal
Device(config)# crypto ikev2 profile profile1
Device(config-ikev2-profile)# reconnect timeout 600
Device(config-ikev2-profile)# end

```

CHAPTER 230

Configuring MPLS over FlexVPN

Last Published Date: March 28, 2014

The MPLS over FlexVPN feature implements Multiprotocol Label Switching (MPLS) over a dynamically established IPsec tunnel thereby supporting duplicate address spaces.

- [Prerequisites for MPLS over FlexVPN, on page 3075](#)
- [Information About Configuring MPLS over FlexVPN, on page 3075](#)
- [How to Configure MPLS over FlexVPN, on page 3078](#)
- [Configuration Examples for Configuring MPLS over FlexVPN, on page 3079](#)
- [Additional References for Configuring MPLS over FlexVPN, on page 3087](#)
- [Feature Information for Configuring MPLS over FlexVPN, on page 3088](#)

Prerequisites for MPLS over FlexVPN

- Internet Key Exchange Version 2 (IKEv2) and IPsec must be configured.
- MPLS must be configured.
- NHRP redirect must be configured.

Information About Configuring MPLS over FlexVPN

MPLS and FlexVPN

Network domains having overlapping addressing spaces use VPN routing and forwarding (VRF) to segregate traffic so that data intended for one domain does not enter another domain. Data security between the provider-edge (PE) devices is achieved by defining an tunnel interface with IPsec protection for every VRF. This ensures that traffic from every domain passes over the corresponding IPsec tunnel. However as the number of domains and nodes grow in a network, this may not be scalable because every protected domain requires a separate IPsec tunnel and an interface.

Multiprotocol Label Switching (MPLS) provides the ability to assign labels per VRF or per prefix, which identifies the correct VRF into which data needs to be routed to. This can be achieved with just a single MPLS-aware interface having IPsec protection and a single IPsec tunnel between the PEs.

The MPLS over FlexVPN feature provides a solution to achieve communication between overlapping addresses in customer networks when a remote customer network needs to be discovered dynamically using Next Hop

Resolution Protocol (NHRP) and at the same time secure the data traffic between the PE devices using IPsec. This solution can be used by customers who have deployed MPLS network and want to extend their MPLS network to a newly configured network (determined dynamically) in a different region over the Internet in a secure way.

The components of the MPLS over FlexVPN solution are as follows:

- IPsec—Secures the data traffic between the spoke and the hub and between the spokes after the remote spoke is discovered dynamically.
- Internet Key Exchange Version 2 (IKEv2)—Adds static routes to the peer's tunnel overlay address as a directly connected route. This route results in adding an implicit null label to the Label Information Base (LIB) for the peer's tunnel overlay address.

Note IKEv2 is used instead of LDP because LDP involves establishing TCP channel with every LDP neighbor. Enabling LDP keeps the spoke-to-spoke channel active due to the LDP hello traffic thereby never bringing down the spoke-to-spoke channel. Therefore, the **mpls ip** command must never be executed on the tunnel interface or virtual template when configuring the MPLS over FlexVPN feature.

- NHRP—Used to resolve the remote overlay address and dynamically discover the transport end point needed to establish a secure tunnel. If a multipoint generic routing encapsulation (GRE) interface is used, the tunnel end point database stores the mapping between the overlay and corresponding nonbroadcast multiaccess (NBMA) address.
- MPLS—Enables MPLS tag switching for data packets. By default, Label Distribution Protocol (LDP) is not enabled and is not enabled between the spokes because LDP keepalive will try to keep the spoke-spoke tunnel up and is not desired in the absence of data traffic.
- MPLS Forwarding Infrastructure (MFI)—Allocates and releases labels by the applications; NHRP is an application that call MFI for label management.
- Multiprotocol BGP (MP-BGP)—Distributes overlay labels for the network on different VRFs.

Working of MPLS over FlexVPN

The following figure along description explains the working of MPLS over FlexVPN solution:

Figure 126: Spoke to Hub to Spoke Topology

The MPLS over FlexVPN solution has the following assumptions:

- Multiprotocol BGP (MP-BGP) allows distributing labels per VPN routing and forwarding (VRF) or per prefix.
 - Label 10 is assigned to VRF A for packets that arrive from hub to spoke A.
 - Label 20 is assigned to VRF A for packets that arrive from the hub to spoke B.
 - Label 30 is assigned to VRF A on the hub for packets that arrive from spoke A to the hub.
 - Label 40 is assigned to VRF B on the hub for packets that arrive from spoke B to the hub.
1. IKEv2 and IPsec security associations are established from each spoke to the hub. IKEv2 installs implicit null label values for the spoke's overlay address that is received in the mode config reply and mode config set.

Note Implicit null label is installed since the spoke and hub are always next-hop to each other in the overlay space.

2. MP-BGP exchanges the label per VRF or label per prefix with all the VRFs.
3. After the labels and routes have been exchanged, data forwarding begins. When the first data packet destined for 192.168.2.1 arrives on spoke A on VRF A, it is forwarded to the hub. The packet is label encapsulated using generic routing encapsulation (GRE), only containing the overlay label, and encrypted.
4. The data packet is decrypted when it reaches the hub on the physical (virtual access) interface or the tunnel interface which is 172.17.0.1 and 10.0.0.1 respectively. The overlay label is looked up in the hub, the packet is encapsulated using GRE, encrypted and sent to spoke B.

5. An NHRP redirect packet is sent from the hub to spoke A. As label 30 identifies the VRF on which the data packet arrived, the VRF information is conveyed to NHRP.
6. NHRP processes the redirect packet and triggers an NHRP resolution request. An NHRP mapping entry is created and VRF A is associated for the prefix that needs to be resolved.
7. The resolution request is sent to the hub, which looks up its overlay label and sends the resolution request to the appropriate destination, which in this case is Spoke B.
8. NHRP resolution request arrives on Spoke B and creates a virtual access interface or an multipoint GRE (mGRE) interface on Spoke B.
9. An IKEv2 and IPsec session is initiated from Spoke B to Spoke A resulting in the creation of a virtual access interface or mGRE interface on Spoke A. NHRP adds the route for IP address of Spoke A tunnel via the newly created virtual access interface.
10. NHRP resolution reply from Spoke B carries the label value that may be used by Spoke A for sending data over the spoke-to-spoke tunnel. Therefore, NHRP allocates a label from the MPLS forwarding instance (MFI) and sends this label information to Spoke A to be used for the spoke-to-spoke tunnel.

Note MFI tracks the labels. If a label is already allocated and assigned to MP-BGP for a particular VRF, the label is returned to NHRP. MFI tracks the number of applications using this a particular label and returns the label back to pool only when all the applications have released the label.

11. NHRP resolution reply also contains an implicit null label for the IP address of the virtual access interface or mGRE interface on Spoke B. In this example, the reply would be 192.168.2.0/24, label 40, 10.0.0.12, 172.16.2.1, [implicit-NULL].
12. NHRP resolution reply is received at the virtual access interface or mGRE interface on Spoke A. The NHRP request ID present in reply packet is matched with the request ID of the request that was initially sent by Spoke A to know the VRF for which the request was sent. NHRP cache is looked up to find the NHRP entry and the entry is termed “Complete”. NHRP inserts a route into the VRF routing table with the label information.
13. Routes and labels are setup between Spoke A and Spoke B. Data is now label encapsulated and encrypted over the spoke-to-spoke dynamically established tunnel between Spoke A and Spoke B.

IVRF Support for FlexVPN

The Inside VPN Routing and Forwarding (IVRF) support for FlexVPN provides the capability of performing the following NHRP routing operations in the IVRF configured on the tunnel interface:

- Sending NHRP resolution request after performing the route lookup.
- Forwarding of NHRP resolution request on the hub.
- Creating an H route or next-hop override (NHO) in the IVRF when creating a shortcut tunnel
- Deleting the H route or NHO from the IVRF when the shortcut tunnel is deleted

How to Configure MPLS over FlexVPN

Configuring MPLS over FlexVPN

Perform this task to configure MPLS over FlexVPN.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface tunnel** *number*
4. **mpls nhrp**
5. **end**
6. **show mpls forwarding-table**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	interface tunnel <i>number</i> Example: Device(config)# interface tunnel 1	Configures the FlexVPN client interface and enters interface configuration mode.
Step 4	mpls nhrp Example: Device(config-if)# mpls nhrp	Enables MPLS tag switching without enabling Label Distribution Protocol (LDP).
Step 5	end Example: Device(config-if)# end	Exits interface configuration mode and returns to global configuration mode.
Step 6	show mpls forwarding-table Example: Device# show mpls forwarding-table	Displays information about the Multiprotocol Label Switching (MPLS) Label Forwarding Information Base (LFIB).

Configuration Examples for Configuring MPLS over FlexVPN

Description	Link
The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for Configuring MPLS over FlexVPN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 307: Feature Information for Configuring MPLS over FlexVPN

Feature Name	Releases	Feature Information
MPLS over FlexVPN		The following commands were introduced or modified: clear ip nhrp , clear ipv6 nhrp , mpls nhrp , show dmvpn , show ip nhrp , show ipv6 nhrp .

CHAPTER 231

Configuring IKEv2 Packet of Disconnect

The IKEv2 Remote Access Change of Authorization (CoA)—Packet of Disconnect feature terminates an active crypto IKEv2 session on Cisco supported devices.

- [Information About IKEv2 Packet of Disconnect, on page 3089](#)
- [How to Configure IKEv2 Packet of Disconnect, on page 3090](#)
- [Configuration Examples for IKEv2 Packet of Disconnect, on page 3091](#)
- [Additional References for IKEv2 Packet of Disconnect, on page 3095](#)
- [Feature Information for IKEv2 Packet of Disconnect, on page 3096](#)

Information About IKEv2 Packet of Disconnect

Disconnect Request

The Packet of Disconnect (POD) is a RADIUS disconnect_request packet and is intended to be used in situations where the authenticating agent server wants to disconnect a crypto session.

When the POD is Needed

The Packet of Disconnect is required in the following situations:

- Enforce reauthentication—As a network administrator, you might want to terminate a user on FlexVPN server to forcefully reauthenticate if a session is connected for a very long duration.
- Apply a new policy—As a network administrator, you may want to terminate an active crypto session and apply the new policy on the session when the client reconnects.
- Free resources—A session may need to be terminated to free resources and exit rekey.

IKEv2 Packet of Disconnect

The IKEv2 Remote Access Change of Authorization (CoA)—Packet of Disconnect feature uses the RADIUS Packet of Disconnect (POD) feature to delete a crypto session. The crypto session is deleted to update VPN users to the new user or group policy on the AAA server.

1. AAA passes the attribute key-value pair list, provided by the RADIUS server, to IKEv2.

2. IKEv2 parses the list and locates the Audit-Session-ID, a Cisco AV pair, as a key and validates the pair value.
3. IKEv2 searches the session and deletes the specific session.
4. IKEv2 notifies AAA and AAA notifies the RADIUS server.
5. The session pertaining to the Audit-Session-ID is deleted.

Parameters in IKEv2 Packet of Disconnect

RFC 3576 specifies the following POD codes that are supported for IKEv2 Packet of Disconnect:

- 40 - Disconnect-Request
- 41 - Disconnect-ACK
- 42 - Disconnect-NAK

The Disconnect-ACK code indicates that a session existed for an audit-session-ID and that the session, pertaining to an audit-session-ID was terminated successfully. The Disconnect-NAK code indicates that there are no session corresponding to the audit-session-ID. No reply message is sent to the gateway.

How to Configure IKEv2 Packet of Disconnect

Configuring AAA on the FlexVPN Server

There is no IKEv2-specific configuration required on the FlexVPN server for the IKEv2 Remote Access Change of Authorization (CoA)—Packet of Disconnect feature. You only need to configure authentication, authorization, and accounting (AAA) on the FlexVPN server. For additional information on AAA configuration, see .

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa server radius dynamic-author**
5. **client** *{hostname | ip-address}* [**server-key** *string* | **vrf** *vrf-id*]
6. **port** *number*
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	aaa new-model Example: Device(config)# aaa new-model	Enables AAA globally.
Step 4	aaa server radius dynamic-author Example:	Sets up the local AAA server for the dynamic authorization service and enters dynamic authorization local server configuration mode. <ul style="list-style-type: none"> In this mode, the RADIUS application commands are configured.
Step 5	client {hostname ip-address} [server-key string vrf vrf-id] Example: Device(config-locsvr-da-radius)# client 192.168.0.5 server-key cisco	Configures the IP address or hostname of the AAA server client. <ul style="list-style-type: none"> Use the server-key keyword and <i>string</i> argument to configure the server key at the client level. <p>Note Configuring the server key at the client level overrides the server key configured at the global level.</p>
Step 6	port number Example: Device(config-locsvr-da-radius)# port 1812	Configures the UDP port.
Step 7	end Example: Device(config-locsvr-da-radius)# end	Exits dynamic authorization local server configuration mode and returns to privileged EXEC mode.

Configuration Examples for IKEv2 Packet of Disconnect

Example: Terminating an IKEv2 Session

The following is a sample output from the **show aaa sessions** command. This command must be executed to identify the IKEv2 session that needs to be terminated.

```
Device# show aaa sessions

Total sessions since last reload: 32
Session Id: 3
  Unique Id: 14
  User Name: *not available*
```

Example: Terminating an IKEv2 Session

```

    IP Address: 0.0.0.0
    Idle Time: 0
    CT Call Handle: 0
Session Id: 30
    Unique Id: 41
    User Name: pskuser2.g1.engdt.com
    IP Address: 0.0.0.0
    Idle Time: 0
    CT Call Handle: 0
Session Id: 32
    Unique Id: 43
    User Name: pskuser4.g2.engdt.com
    IP Address: 0.0.0.0
    Idle Time: 0
    CT Call Handle: 0

```

In the above output, ID 41 and 43 pertain to IKEv2 sessions. Optionally, you can run the **show aaa user** command to view detailed information about the session.

```
Device# show aaa user 41
```

```

```

The following output is displayed on the FlexVPN server when disconnecting a session for a specific audit-session-id. The terminate session request is sent to the RADIUS server via a RADIUS client.

In this example, the session for the audit-session-ID, which is L2L433010101ZO2L4C0A8CA02ZH119404ZP37 is terminated and, hence, not visible in the output.

```

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for IKEv2 Packet of Disconnect

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 308: Feature Information for IKEv2 Packet of Disconnect

Feature Name	Releases	Feature Information
IKEv2 Remote Access Change of Authorization (CoA)—Packet of Disconnect		The IKEv2 Remote Access Change of Authorization (CoA)—Packet of Disconnect feature terminates an active crypto IKEv2 session on Cisco supported devices. No commands were introduced by this feature.

CHAPTER 232

Configuring IKEv2 Change of Authorization Support

The FlexVPN - IKEv2 CoA for QoS and ACL feature supports RADIUS Change of Authorization (CoA) on an active IKEv2 crypto session.

- [Prerequisites for IKEv2 Change of Authorization Support, on page 3099](#)
- [Restrictions for IKEv2 Change of Authorization Support, on page 3099](#)
- [Information About IKEv2 Change of Authorization Support, on page 3099](#)
- [How to Configure IKEv2 Change of Authorization Support, on page 3100](#)
- [Configuration Examples for IKEv2 Change of Authorization Support, on page 3104](#)
- [Additional References for IKEv2 Change of Authorization Support, on page 3105](#)
- [Feature Information for IKEv2 Change of Authorization Support, on page 3105](#)

Prerequisites for IKEv2 Change of Authorization Support

- IKEv2 must be registered as a component, via a registry entry, on Cisco AAA component.

Restrictions for IKEv2 Change of Authorization Support

- This feature supports change of authorization (CoA) packets received from RADIUS-based AAA server only.

Information About IKEv2 Change of Authorization Support

RADIUS Change of Authorization

The RADIUS Change of Authorization (CoA) provides a mechanism to change the attributes of an authentication, authorization, and accounting (AAA) session after it is authenticated. When a policy changes for a user or user group in AAA, administrators can send the RADIUS CoA packets from the AAA server such as a Cisco Secure Access Control Server (ACS) to reinitialize authentication and apply the new policy.

A standard RADIUS interface is typically used in a pulled model, in which the request originates from a device attached to a network and the response is sent from the queried servers. Cisco software supports the RADIUS CoA request defined in RFC 5176 that is used in a pushed model, in which the request originates from the external server to the device attached to the network, and enables the dynamic reconfiguring of sessions from external authentication, authorization, and accounting (AAA) or policy servers.

For more information on RADIUS CoA, see *Authentication, Authorization, and Accounting Configuration Guide, Cisco IOS Release 15M&T* or *Authentication, Authorization, and Accounting Configuration Guide, Cisco IOS XE Release 3S*

Working of Change of Authorization on IKEv2

The FlexVPN - IKEv2 CoA for QoS and ACL feature allows to change attributes of an active IKEv2 crypto session to apply a new authorization attributes. The Cisco AAA component receives a Change of Authorization (CoA) packet from a AAA server and checks if the received CoA packet is meant for any of the components registered with it. If a component sees that the CoA packet is meant for itself, it processes it further. Based on the fields in the CoA packet, if the packet is relevant for a given component, such as IKEv2, the packet is consumed by that component. AAA will not forward the packet to the next component in the list.

In case of this feature, after IKEv2 receives a CoA packet, IKEv2 verifies the CoA packet for the Cisco (AV) pairs. IKEv2 identifies the session based on the audit-session-id which is already stored in the RADIUS server.

If the CoA packet contains attributes not supported by IKEv2, IKEv2 discards the packet and sends a CoA-NACK to AAA component.

Supported AV Pairs for IKEv2 Change of Authorization

The FlexVPN - IKEv2 CoA for QoS and ACL feature supports the following Cisco AV pairs:

- ip:interface-config
- ip:sub-policy-In
- ip:sub-policy-Out
- ip:sub-qos-policy-in
- ip:sub-qos-policy-out
- ipsec:inacl
- ipsec:outacl

How to Configure IKEv2 Change of Authorization Support

Configuring Change of Authorization on the FlexVPN Server

There is no IKEv2-specific configuration required for this feature. on the FlexVPN server for the IKEv2 Change of Authorization (CoA) Support feature. You only need to configure the RADIUS Change of Authorization on the FlexVPN server. For more information on AAA configuration, see the RADIUS Change

of Authorization feature module in the *Authentication, Authorization, and Accounting Configuration Guide, Cisco IOS Release 15M&T*.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **aaa new-model**
4. **aaa server radius dynamic-author**
5. **client** {*ip-address* | *name* [**vrf** *vrf-name*]} **server-key** [0 | 7] *string*
6. **port** *port-number*
7. **auth-type** {**any** | **all** | **session-key**}
8. **ignore session-key**
9. **ignore server-key**
10. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. Enter your password, if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters the global configuration mode.
Step 3	aaa new-model Example: Device(config)# aaa new-model	Enables authentication, authorization, and accounting (AAA) globally.
Step 4	aaa server radius dynamic-author Example: Device(config)# aaa server radius dynamic-author	Enters dynamic authorization local server configuration mode and specifies a RADIUS client from which a device accepts Change of Authorization (CoA) and disconnect requests. Configures the device as a AAA server to facilitate interaction with an external policy server.
Step 5	client { <i>ip-address</i> <i>name</i> [vrf <i>vrf-name</i>]} server-key [0 7] <i>string</i> Example: Device(config-locsvr-da-radius)# client 10.0.0.1	Configures the RADIUS key to be shared between a device and RADIUS clients.
Step 6	port <i>port-number</i> Example: Device(config-locsvr-da-radius)# port 3799	Specifies the port on which a device listens for RADIUS requests from configured RADIUS clients. Note The default port for packet of disconnect is 1700. Port 3799 is required to interoperate with ACS 5.1.

	Command or Action	Purpose
Step 7	auth-type {any all session-key} Example: Device(config-locsvr-da-radius)# auth-type all	Specifies the type of authorization that the device must use for RADIUS clients. The client must match the configured attributes for authorization.
Step 8	ignore session-key Example: Device(config-locsvr-da-radius)# ignore session-key	(Optional) Configures the device to ignore the session key.
Step 9	ignore server-key Example: Device(config-locsvr-da-radius)# ignore server-key	(Optional) Configures the device to ignore the server key.
Step 10	exit Example: Device(config-locsvr-da-radius)# exit	Returns to the global configuration mode.

Verifying IKEv2 Change of Authorization Support

Use the following show commands to view the success of change of authorization (CoA) on Cisco Devices.

SUMMARY STEPS

1. enable
2. show platform hardware qfp active feature qos all output all
3. show platform hardware qfp active feature qos all input all

DETAILED STEPS

Step 1 enable

Example:

```
Device> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 show platform hardware qfp active feature qos all output all

Example:

```
Device# show platform hardware qfp active feature qos all output all
```

```

Displays the feature status.

Configuration Examples for IKEv2 Change of Authorization Support

Example: Triggering a Change of Authorization

The following sample output is displayed when an administrator triggers a change of authorization (CoA). The session is identified based on the audit-session-id, a dynamic string, which is an encoded form of 6 tuple information of a session with peer.

IKEv2 receives a change of authorization (CoA) packet from a RADIUS server. The session is identified based on audit-session-id.

```

*Oct 6 23:38:55.250: RADIUS: COA received from id 125 10.106.210.176:58712, CoA Request,

Feature Information for IKEv2 Change of Authorization Support

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 309: Feature Information for IKEv2 Change of Authorization Support

Feature Name	Releases	Feature Information
FlexVPN - IKEv2 CoA for QoS and ACL		The FlexVPN - IKEv2 CoA for QoS and ACL feature supports RADIUS Change of Authorization (CoA) on an active IKEv2 crypto session. No commands were modified or updated by this feature.

CHAPTER 233

Configuring Aggregate Authentication

The FlexVPN RA - Aggregate Auth Support for AnyConnect feature implements aggregate authentication method by extending support for Cisco AnyConnect client that uses the proprietary AnyConnect EAP authentication method to establish a secure tunnel over the Internet between Cisco AnyConnect client and FlexVPN server.

- [Prerequisites for Configuring Aggregate Authentication, on page 3107](#)
- [Information for Configuring Aggregate Authentication, on page 3107](#)
- [How to Configure Aggregate Authentication, on page 3110](#)
- [Configuration Examples for Aggregate Authentication, on page 3112](#)
- [Additional References for Configuring Aggregate Authentication, on page 3113](#)
- [Feature Information for Configuring Aggregate Authentication, on page 3113](#)

Prerequisites for Configuring Aggregate Authentication

- You must enable the BypassDownloader function in the AnyConnectLocalPolicy file by setting the <BypassDownloader> value to true. If your device does not support SSL, the BypassDownloader function will not work. You must disable the function manually by setting the <BypassDownloader> value to false, else the connection will fail.

Information for Configuring Aggregate Authentication

Cisco AnyConnect and FlexVPN

To establish a VPN connection, the VPN client must obtain user credentials using authentication methods such as, extensible authentication protocol (EAP), Extended Authentication (XAUTH), etc. and forward the user credentials to a hub, which contacts an access control server. The access control server sends an external database or active directory (AD) to validate the credentials.

FlexVPN server (as a hub) works with Cisco Secure Access Control Server to validate user credentials to establish VPN connections. However, Cisco AnyConnect uses EAP to obtain user credentials and does not support XAUTH. On the other hand, Cisco Secure Access Control Server does not support EAP-MD5 with external database (in this case AD). This leads to a scenario where either Cisco Secure Access Control Server must support EAP-MD5 or FlexVPN must authenticate the information from Cisco AnyConnect separately and connect separately with Cisco Secure Access Control Server. FlexVPN can use the Aggregate

Authentication method to authentication information from Cisco AnyConnect. Implementing aggregate authentication method on FlexVPN server would provide a window to add more feature support on Cisco IOS software.

The FlexVPN RA - Aggregate Auth Support for AnyConnect feature implements aggregate authentication method by extending support for Cisco AnyConnect client that uses the proprietary AnyConnect EAP authentication method to establish a secure tunnel over the Internet using Cisco AnyConnect and FlexVPN server. This is a server-specific feature and works with Cisco AnyConnect.

How Aggregate Authentication Works

Internet Key Exchange Version 2 supports Cisco AnyConnect that uses the proprietary AnyConnect EAP authentication method by implementing basic aggregate authentication where authentication is performed via authentication, authorization, and accounting (AAA) using the remote RADIUS server. The following is an example of a network topology explains aggregate authentication implementation on Cisco IOS software.

Figure 127: FlexVPN Server Connected to RADIUS Server

In this diagram:

- Cisco Secure Access Control Server acts as a RADIUS server for authorization.
- The credentials are stored in Microsoft Active Directory, which acts as the active directory for authentication.

Note Microsoft Active Directory is referred for example purpose only. It does not matter where the credentials are stored.

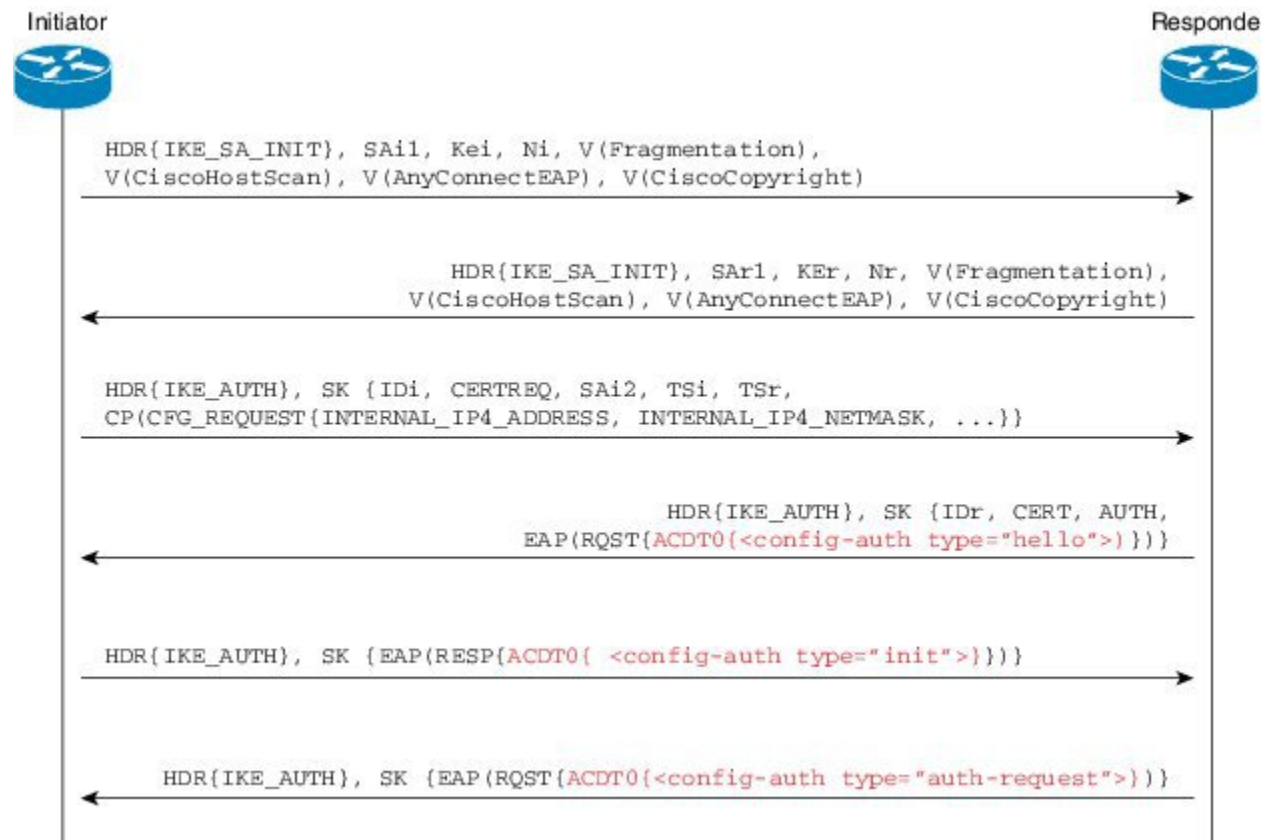

- Cisco device acts as FlexVPN server.
 - Windows 7 PC acts as Cisco AnyConnect client.
1. To initiate a VPN connection, Cisco AnyConnect client verifies a FlexVPN server using certifications.
 2. After verifying the certificates, Cisco AnyConnect client sends Cisco AnyConnect EAP loaded message to FlexVPN server.

3. When FlexVPN server receives Cisco AnyConnect EAP loaded message from Cisco AnyConnect, FlexVPN server downloads the message and strips the message of EAP.
4. FlexVPN establishes a connection with RADIUS server for authorization and Microsoft Active Directory (AD) for authentication, and forwards the stripped message to verify the credentials provided by Cisco AnyConnect client.
5. When the credentials are verified and approved by RADIUS server and Microsoft Active Directory (AD), an appropriate reply is sent to FlexVPN server, which in turn replies to Cisco AnyConnect and a VPN connection is established.

IKE Exchanges Using Cisco AnyConnect EAP

Authentication in IKE using AnyConnect EAP is a variation of the standards EAP model as described in RFC 3748. When using AnyConnect EAP the public configuration or authentication XML is transported via EAP payloads. The following figure illustrates the typical message flow used by Cisco AnyConnect.

Figure 128: IKE Exchanges using AnyConnect EAP

1. Cisco AnyConnect client initiates IKE connection to FlexVPN server. The client sends vendor ID payloads to indicate support for Cisco AnyConnect EAP in addition to the typical IKE payloads. The client identifies itself as a Cisco product by including the Cisco copyright vendor ID.
2. The server gateway sends vendor ID payloads to indicate fragmentation and AnyConnect EAP support and identifies itself as a Cisco product by including the Cisco copyright vendor ID.

3. The configuration payload requests the tunnel configuration. The client indicates its desire to use Cisco AnyConnect EAP authentication by omitting the AUTH Payload from this message.
4. The Aggregate Authentication and Configuration protocol is carried over EAP
5. FlexVPN server sends a EAP success message.
6. Cisco AnyConnect client sends the AUTH payload.
7. FlexVPN server sends the AUTH payload and the tunnel configuration attributes that Cisco AnyConnect client requested.

Dual-Factor Authentication Support with IKEv2

The aggregate authentication implementation on Cisco IOS software can be extended for dual-factor authentication. Double authentication can be done by introducing new AnyConnect EAP exchange during Aggregate Authentication which exchange and validate the device certificate information. This mechanism of authenticating 'device' as well as 'user' is called 'Double Authentication'.

Note AnyConnect EAP is AnyConnect client specific authentication method and does not apply to any other client.

How to Configure Aggregate Authentication

Configuring the FlexVPN Server for Aggregate Authentication

Perform this task to configure aggregate authentication on the FlexVPN server.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 profile *profile-name***
4. **aaa accounting anyconnect-eap *list-name***
5. **match identity remote key-id *opaque-string***
6. **authentication remote anyconnect-eap aggregate [cert-request]**
7. **authentication local rsa-sig**
8. **pki trustpoint *trustpoint-label***
9. **aaa authentication anyconnect-eap *list-name***
10. **aaa authorization group anyconnect-eap list *aaa-listname* name-mangler *mangler-name***
11. **aaa authorization user anyconnect-eap cached**
12. **aaa authorization user anyconnect-eap list *aaa-listname* name-mangler *mangler-name***
13. **end**
14. **show crypto ikev2 session detailed**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ikev2 profile <i>profile-name</i> Example: Device(config)# crypto ikev2 profile profile1	Defines an IKEv2 profile name and enters IKEv2 profile configuration mode.
Step 4	aaa accounting anyconnect-eap <i>list-name</i> Example: Device(config-ikev2-profile)# aaa accounting anyconnect-eap list1	Enables authentication, authorization, and accounting (AAA) accounting method lists when the IKEv2 remote authentication method is AnyConnect EAP.
Step 5	match identity remote key-id <i>opaque-string</i> Example: Device(config-ikev2-profile)# match identity remote key-id aggauth_user3@abc.com	Matches a profile based on the identity of the type remote key ID.
Step 6	authentication remote anyconnect-eap aggregate [cert-request] Example: Device(config-ikev2-profile)# authentication remote anyconnect-eap aggregate cert-request	Specifies aggregate authentication for Cisco AnyConnect EAP. <ul style="list-style-type: none">• cert-request - requests certificate from Cisco AnyConnect client for double authentication.
Step 7	authentication local rsa-sig Example: Device(config-ikev2-profile)# authentication local rsa-sig	Specifies Rivest, Shamir, and Adelman (RSA) signature as the local authentication method.
Step 8	pki trustpoint <i>trustpoint-label</i> Example: Device(config-ikev2-profile)# pki trustpoint CA1	Specifies Public Key Infrastructure (PKI) trustpoints for use with the RSA signature authentication method.
Step 9	aaa authentication anyconnect-eap <i>list-name</i> Example: Device(config-ikev2-profile)# aaa authentication anyconnect-eap list1	Specifies authentication, authorization, and accounting (AAA) authentication list for Cisco AnyConnect EAP authentication. <ul style="list-style-type: none">• anyconnect-eap—Specifies AAA AnyConnect EAP authentication.• <i>list-name</i>—The AAA authentication list name.

	Command or Action	Purpose
Step 10	aaa authorization group anyconnect-eap list <i>aaa-listname name-mangler mangler-name</i> Example: <pre>Device(config-ikev2-profile)# aaa authorization group anyconnect-eap list list1 name-mangler mangler1</pre>	Specifies the AAA authorization for each group policy when the remote authentication method is AnyConnect EAP and derives the name mangler.
Step 11	aaa authorization user anyconnect-eap cached Example: <pre>Device(config-ikev2-profile)# aaa authorization user anyconnect-eap cached</pre>	Specifies the AAA authorization for each user policy when the remote authentication method is AnyConnect EAP and uses cached attributes from the AnyConnect EAP authentication.
Step 12	aaa authorization user anyconnect-eap list <i>aaa-listname</i> name-mangler <i>mangler-name</i> Example: <pre>Device(config-ikev2-profile)# aaa authorization user anyconnect-eap list list1 name-mangler mangler1</pre>	Specifies the AAA method list for the remote authentication method and derives the name mangler.
Step 13	end Example: <pre>Device(config-ikev2-profile)# end</pre>	Exits IKEv2 profile configuration mode and returns to privileged EXEC mode.
Step 14	show crypto ikev2 session detailed Example: <pre>Device# show crypto ikev2 session detailed</pre>	Displays the status of active Internet Key Exchange Version 2 (IKEv2) sessions.

Configuration Examples for Aggregate Authentication

Example: Configuring Aggregate Authentication

The following example shows how to configure aggregate authentication on the FlexVPN server to enable the establishment of a secure tunnel between Cisco AnyConnect Client and FlexVPN server.

```
Device> enable
Device# configure terminal
Device(config)# crypto ikev2 profile profile1
Device(config-ikev2-profile)# aaa accounting anyconnect-eap list1
Device(config-ikev2-profile)# match identity remote key-id aggauth_user1@example.com
Device(config-ikev2-profile)# authentication remote anyconnect-eap aggregate cert-request
Device(config-ikev2-profile)# authentication local rsa-sig
Device(config-ikev2-profile)# pki trustpoint CA1
Device(config-ikev2-profile)# aaa authentication anyconnect-eap list1
Device(config-ikev2-profile)# aaa authorization group anyconnect-eap list list1 name-mangler
mangler1
Device(config-ikev2-profile)# aaa authorization user anyconnect-eap cached
Device(config-ikev2-profile)# aaa authorization user anyconnect-eap list list1 name-mangler
```

```
mangler1
Device(config-ikev2-profile)# end
```

CHAPTER 234

Appendix: FlexVPN RADIUS Attributes

This chapter describes the RADIUS attributes supported by FlexVPN server.

- [FlexVPN RADIUS Attributes, on page 3115](#)

FlexVPN RADIUS Attributes

The following are the RADIUS attributes categories used by FlexVPN Server:

- Inbound and bidirectional IETF RADIUS attributes
- Outbound Local
- Outbound Remote

Note For inbound attributes sent by the FlexVPN server to RADIUS that are not listed below, the value is set by the AAA system.

Attribute	User-Name
Type	IETF
Format	String
Attribute ID	1
Description	<p>This attribute is sent by the FlexVPN server to Radius and is derived as follows:</p> <ul style="list-style-type: none">• AAA based preshared keys—Peer IKEv2 identity• EAP authentication—Peer EAP identity• User or group authorization—Output of the name mangler or the string specified in the IKEv2 profile authorization commands• Accounting—Peer EAP identity or IKEv2 identity <p>This attribute may also be received from Radius in Access-Accept after successful EAP authentication and specifies the authenticated peer EAP identity.</p>

Attribute	User-Password
Type	IETF
Format	String
Attribute ID	2
Description	This attribute is sent by the FlexVPN server to RADIUS and is derived as follows: <ul style="list-style-type: none"> • AAA based preshared keys—"cisco" • User/group authorization—"cisco"

Attribute	Calling-Station-ID
Type	IETF
Format	String
Attribute ID	31
Description	This attribute is sent by FlexVPN server to RADIUS and is derived as follows: <ul style="list-style-type: none"> • AAA based pre-shared keys—IKEv2 initiator address • EAP authentication—IKEv2 initiator address • User/group authorization—IKEv2 initiator address

Attribute	Service-Type
Type	IETF
Format	String
Attribute ID	6
Description	This attribute is used by FlexVPN server for EAP authentication and the value of this attribute is set to 'Login'.

Attribute	EAP-Message
Type	IETF
Format	String
Attribute ID	79
Description	This attribute is used by FlexVPN server for EAP authentication to relay EAP packets between EAP server and the Remote Access Client.

Attribute	Message-Authenticator
-----------	-----------------------

Type	IETF
Format	String
Attribute ID	80
Description	This attribute is sent by FlexVPN server for EAP authentication. The value for this attribute is set by AAA subsystem.
Attribute	Framed-Pool
Type	IETF
Format	String
Attribute ID	88
Local config	pool name
Radius config	Framed-Pool= <i>pool-name</i>
Description	Specifies the name of IPv4 address pool that is used by FlexVPN server to allocate the IPv4 address to assign to the client. The allocated address is pushed to client via IKEv2 standard config attribute INTERNAL_IP4_ADDRESS.
Attribute	ipsec:group-dhcp-server
Type	Cisco AV Pair
Format	String
Local config	dhcp server { <i>ipaddr</i> <i>host</i> }
Radius config	cisco-avpair="ipsec: group-dhcp-server= <i>ipaddr</i> "
Description	Specifies the IPv4 DHCP server that is used by FlexVPN server to lease IPv4 address to assign to the client. The leased address is pushed to client via IKEv2 standard config attribute INTERNAL_IP4_ADDRESS.
Attribute	ipsec:dhcp-giaddr
Type	Cisco AV Pair
Format	IPAddr
Local config	dhcp giaddr <i>ipaddr</i>
Radius config	cisco-avpair="ipsec: dhcp-giaddr= <i>ipaddr</i> "
Description	Specifies the IPv4 DHCP gateway IP address that is used by FlexVPN server to contact the DHCP server.
Attribute	ipsec:dhcp-timeout

Type	Cisco AV Pair
Format	Integer
Local config	dhcp timeout <i>seconds</i>
Radius config	cisco-avpair="ipsec:dhcp-timeout= <i>seconds</i> "
Description	Specifies the time to wait for response from IPv4 DHCP server that is used by FlexVPN server to timeout response from the DHCP server.

Attribute	ipsec:ipv6-addr-pool
Type	Cisco AV Pair
Format	String
Local config	ipv6 <i>pool name</i>
Radius config	cisco-avpair="ipsec:ipv6-addr-pool= <i>pool-name</i> "
Description	Specifies the name of IPv6 address pool used by FlexVPN server to allocate the IPv6 address to assign to the client. The allocated address is pushed to the client via IKEv2 standard config attribute INTERNAL_IP6_ADDRESS.

Attribute	ipsec:route-set=prefix
Type	Cisco AV Pair
Format	String
Local config	N/A
Radius config	cisco-avpair="ipsec:route-set=prefix <i>prefix/length</i> "
Example	ipsec:route-set=prefix 192.168.1.0/24
Description	Specifies a subnet protected by FlexVPN server. This is pushed to the client via IKEv2 standard configuration attribute INTERNAL_IP4_SUBNET. Note This AV pair was introduced in Cisco IOS Release 15.2(2)T.

Attribute	ipsec:route-set=interface
Type	Cisco AV Pair
Format	String
Local config	route set interface
Radius config	cisco-avpair="ipsec:route-set=interface"

Description	This attribute is used locally and enables sending of VPN interface IP address to the peer via IKEv2 standard config attribute INTERNAL_IP4_SUBNET. This allows running routing protocols such as BGP over VPN. Note In Cisco IOS Release 15.2(2)T, this AV pair replaced the “ipsec:route-set-interface” AV pair.
Attribute	ipsec:route-accept
Type	Cisco AV Pair
Format	String
Local config	route accept any [tag <i>tag-id</i>] [distance <i>distance</i>]
Radius config	cisco-avpair=“ipsec:route-accept=any [tag: <i>tag</i>] [distance: <i>distance</i>]”
Example	ipsec:route-accept=any tag=100
Description	This attribute is used locally and specifies the filter for the subnets received from the peer via IKEv2 standard config attribute INTERNAL_IP4_SUBNET. The attribute also specifies the tag and distance for the routes added by IKEv2 for the filtered subnets. Note In Cisco IOS Release 15.2(2)T, the AV pair “ipsec:route-accept=any” replaced “ipsec:route-accept=accept acl:any” and the AV pair “ipsec:route-accept=none” replaced “ipsec:route-accept=deny”.
Attribute	ipsec:ipsec-flow-limit
Type	Cisco AV Pair
Format	Integer
Local config	ipsec flow-limit <i>limit</i>
Radius config	cisco-avpair=“ipsec:ipsec-flow-limit= <i>limit</i> ”
Description	This attribute is used by FlexVPN server and specifies the maximum number of IPsec SAs that an IPsec dVTI session can have. There is no limit by default. This parameter is similar to the crypto ipsec profile and set security-policy limit commands.
Attribute	ip:interface-config
Type	Cisco AV Pair
Format	String
Local config	aaa attribute list <i>list</i> attribute type interface-config <i>string</i>
Radius config	cisco-avpair=“ip:interface-config=interface cmd string”
Example	ip:interface-config=ip vrf forwarding red

Description	This attribute is used locally and specifies an interface configuration mode command string that is applied on the virtual access interface for the session. For local configuration, the IKEv2 authorization policy points to an AAA attribute list that must have interface-config attribute.
Attribute	Tunnel-Type
Type	IETF
Format	Integer
Attribute ID	64
Radius config	Tunnel-Type=type
Description	This attribute specifies the tunnel type (ESP, AH, GRE, etc.) and is received when FlexVPN server fetches preshared key for the session from RADIUS server.
Attribute	Tunnel-Medium-Type
Type	IETF
Format	Integer
Attribute ID	65,
Radius config	Tunnel-Medium-Type=type
Description	This attribute specifies the tunnel transport type (IPv4, IPv6, etc.) and is received when FlexVPN server fetches preshared key for the session from the RADIUS server.
Attribute	Tunnel-Password
Type	IETF
Format	String
Attribute ID	69
Radius config	Tunnel-Password=string
Description	This attribute specifies the symmetric preshared key and is received when FlexVPN server fetches preshared key for the session from RADIUS server.
Attribute	ipsec:ikev2-password-local
Type	Cisco AV Pair
Format	String
Radius config	cisco-avpair="ipsec:ikev2-password-local= <i>string</i> "
Description	This attribute specifies the local preshared key and is received when FlexVPN server fetches preshared key for the session from RADIUS server.

Attribute	ipsec:ikev2-password-remote
Type	Cisco AV Pair
Format	String
Radius config	cisco-avpair="ipsec:ikev2-password-remote= <i>string</i> "
Description	This attribute specifies the remote preshared key and is received when FlexVPN server fetches preshared key for the session from RADIUS server.
Attribute	Framed-IP-Address
Type	IETF
Format	IPAddr
Attribute ID	8
Radius config	Framed-IP-Address= <i>ipaddr</i>
Description	Specifies IPv4 address assigned to the client. This is pushed to the client via IKEv2 standard configuration attribute INTERNAL_IP4_ADDRESS.
Attribute	Framed-IP-Netmask
Type	IETF
Format	IPAddr
Attribute ID	9
Local config	netmask <i>mask</i>
Radius config	Framed-IP-Netmask= <i>mask</i>
Description	Specifies the subnet mask of the IPv4 address assigned to the client. This is pushed to client via IKEv2 standard configuration attribute INTERNAL_IP4_NETMASK.
Attribute	ipsec:dns-servers
Type	Cisco AV Pair
Format	String
Local config	dns <i>primary</i> [<i>secondary</i>]
Radius config	cisco-avpair="ipsec:dns-servers= <i>primary secondary</i> "
Description	Specifies the primary and secondary IPv4 DNS servers for the client. This is pushed to the client via IKEv2 standard config attribute INTERNAL_IP4_DNS.
Attribute	ipsec:wins-servers

Type	Cisco AV Pair
Format	String
Local config	wins <i>primary</i> [<i>secondary</i>]
Radius config	cisco-avpair="ipsec:wins-servers= <i>primary secondary</i> "
Description	Specifies the primary and secondary IPv4 WINS servers for the client. This is pushed to the client via IKEv2 standard configuration attribute INTERNAL_IP4_NBNS.
Attribute	ipsec:route-set=access-list
Type	Cisco AV Pair
Format	String
Local config	route set access-list { <i>acl-name</i> <i>acl-number</i> }
Radius config	cisco-avpair="ipsec:route-set=access-list { <i>acl-name</i> <i>acl-number</i> }"
Description	Specifies the IPv4 subnets protected by FlexVPN server. This is pushed to the client via IKEv2 standard configuration attribute INTERNAL_IP4_SUBNET. Note In Cisco IOS Release 15.2(2)T, this AV pair replaced the "ipsec:inacl" AV pair.
Attribute	ipsec:addrv6
Type	Cisco AV Pair
Format	String
Radius config	cisco-avpair="ipsec:addrv6= <i>ipv6-addr</i> "
Description	Specifies the IPv6 address assigned to the client. This is pushed to client via IKEv2 standard configuration attribute INTERNAL_IP6_ADDRESS in the first 16 bytes.
Attribute	ipsec:prefix-len
Type	Cisco AV Pair
Format	Integer
Local config	N/A
Radius config	cisco-avpair="ipsec:prefix-len= <i>value</i> "
Example	ipsec:prefix-len=24
Description	Specifies the prefix length of the IPv6 address assigned to the client. This is pushed to client via IKEv2 standard configuration attribute INTERNAL_IP6_ADDRESS in the last (17 th) byte.
Attribute	ipsec:ipv6-dns-servers-addr

Type	Cisco AV Pair
Format	String
Local config	ipv6 dns <i>primary</i> [<i>secondary</i>]
Radius config	cisco-avpair="ipsec: ipv6-dns-servers-addr=ipaddr1 *ipaddr2"
Description	Specifies the primary and secondary IPv6 DNS servers for the client. This is pushed to the client via IKEv2 standard configuration attribute INTERNAL_IP6_DNS.
Attribute	ipsec:route-set=access-list ipv6
Type	Cisco AV Pair
Format	String
Local config	route set access-list ipv6 acl-name
Radius config	cisco-avpair="ipsec:route-set=access-list ipv6 <i>acl-name</i> "
Description	Specifies IPv6 subnets protected by the FlexVPN server. This is pushed to the client via IKEv2 standard configuration attribute INTERNAL_IP6_SUBNET. Note In Cisco IOS Release 15.2(2)T, this AV pair replaced the " ipsec:ipv6-subnet-acl" AV pair.
Attribute	ipsec:banner
Type	Cisco AV Pair
Format	String
Local config	banner <i>text</i>
Radius config	cisco-avpair="ipsec:banner= <i>text</i> "
Description	Specifies the banner text. This is pushed to the client via Cisco Unity attribute MODECFG_BANNER.
Attribute	ipsec:default-domain
Type	Cisco AV Pair
Format	String
Local config	def-domain <i>name</i>
Radius config	cisco-avpair="ipsec:default-domain= <i>name</i> "
Description	Specifies the default domain. This is pushed to the client via Cisco Unity attribute MODECFG_DEFDOMAIN.
Attribute	ipsec:split-dns

Type	Cisco AV Pair
Format	String
Local config	split-dns name
Radius config	cisco-avpair="ipsec:split-dns=name"
Description	Specifies the split DNS name. This is pushed to the client via Cisco Unity attribute MODECFG_SPLITDNS_NAME. You can configure up to 10 split DNS names.

Attribute	ipsec:ipsec-backup-gateway
Type	Cisco AV Pair
Format	String
Local config	backup-gateway <i>name</i>
Radius config	cisco-avpair="ipsec:ipsec-backup-gateway= <i>name</i> "
Description	Specifies the backup gateway. This is pushed to the client via Cisco Unity attribute MODECFG_BACKUPSERVERS. You can configure up to 10 backup gateways.

Attribute	ipsec:pfs
Type	Cisco AV Pair
Format	Integer
Local config	pfs
Radius config	cisco-avpair="ipsec:pfs= <i>value</i> "
Description	Specifies IPsec PFS (Perfect Forward Secrecy) enable/disable. This is pushed to the client via Cisco Unity attribute MODECFG_PFS. The value must be 0 to disable and 1 to enable.

Attribute	ipsec:include-local-lan
Type	Cisco AV Pair
Format	Integer
Local config	include-local-lan
Radius config	cisco-avpair="ipsec:include-local-lan= <i>value</i> "
Description	Enables or disables include local LAN. This is pushed to the client via Cisco Unity attribute MODECFG_INCLUDE_LOCAL_LAN. The value must be 0 to disable and 1 to enable.

Attribute	ipsec:smartcard-removal-disconnect
Type	Cisco AV Pair

Format	Integer
Local config	smartcard-removal-disconnect
Radius config	cisco-avpair="ipsec:smartcard-removal-disconnect = <i>value</i> "
Description	Enables or disables smartcard removal disconnect. This is pushed to the client via Cisco Unity attribute MODECFG_SMARTCARD_REMOVAL_DISCONNECT. The value must be 0 to disable and 1 to enable.
Attribute	ipsec:configuration-url
Type	Cisco AV Pair
Format	String
Local config	configuration url <i>url</i>
Radius config	cisco-avpair="ipsec:configuration-url= <i>url</i> "
Description	Specifies the URL for configuration download. This is pushed to the client via Cisco FlexVPN attribute MODECFG_CONFIG_URL.
Attribute	ipsec:configuration-version
Type	Cisco AV Pair
Format	Integer
Local config	configuration version <i>version</i>
Radius config	cisco-avpair="ipsec:configuration-version= <i>version</i> "
Description	Specifies the version of the configuration to download. This is pushed to the client via Cisco FlexVPN attribute MODECFG_CONFIG_VERSION.
Attribute	Route-set remote
Type	Cisco AV Pair
Format	String
Local config	route set remote {ipv4 ip-address mask ipv6 ip-address/mask}
Radius config	cisco-avpair="ipsec:route-set=remote {ipv4 network subnet_mask ipv6 network/subnet_mask}"
Description	Specifies a subnet protected by FlexVPN server. This is pushed to the client through IKEv2 standard configuration attribute INTERNAL_IP4_SUBNET. While route-set prefix is working with a subnet mask represented in decimal fashion [e.g. /24], route-set remote requires the standard subnet mask representation. [e.g. 255.255.255.0] Note This AV pair was introduced in Cisco IOS Release 3.10.0S

Attribute	Route-set local
Type	Cisco AV Pair
Format	String
Local config	route set local {ipv4 ip-address mask ipv6 ip-address/mask}
Radius config	cisco-avpair="ipsec:route-set=local {ipv4 network subnet_mask ipv6 network/subnet_mask}"
Description	<p>This attribute is useful in an extranet scenario where you do not necessary trust the routing information that you receive from the remote device. In other words, remote routes can be denied and route addition can be locally controlled by using this AV pair.</p> <p>Note This AV pair was introduced in Cisco IOS Release 3.10.0S.</p>

CHAPTER 235

Appendix: IKEv2 and Legacy VPNs

This module provides examples on how to configure IKEv2 on crypto map based configurations.

Note Crypto maps are considered a legacy configuration construct. It is recommended that you migrate existing crypto map based setups to use tunnel protection and virtual interfaces.

- [Example: Configuring Crypto-Map-Based IKEv2 Peers Using Preshared Key Authentication Method, on page 3127](#)
- [Example: Configuring Crypto Map-Based IKEv2 Peers Using Certification Authentication Method, on page 3130](#)
- [Example: Configuring Crypto Map- and dVTI-Based IKEv2 Peers, on page 3134](#)
- [Example: Configuring IPsec Using sVTI-Based IKEv2 Peers, on page 3136](#)
- [Example: Configuring IKEv2 on DMVPN Networks, on page 3139](#)

Example: Configuring Crypto-Map-Based IKEv2 Peers Using Preshared Key Authentication Method

The following example shows how to configure crypto-map-based IKEv2 peers using the preshared key authentication method between a static crypto-map IKEv2 initiator and a dynamic crypto-map IKEv2 responder. The initiator configuration is as follows:

```
crypto ikev2 proposal prop-1
  encryption aes-cbc-128
  integrity sha1
  group 14
!
crypto ikev2 policy pol-1
  match fvrf any
  proposal prop-1
!
crypto ikev2 keyring v2-kr1
  peer abc
  address 209.165.200.231 255.255.255.224
  pre-shared-key abc
!
!
```

Example: Configuring Crypto-Map-Based IKEv2 Peers Using Preshared Key Authentication Method

```

crypto ikev2 profile prof
  match fvrf any
  match identity remote fqdn dmap-responder
  identity local fqdn smap-initiator
  authentication local pre-share
  authentication remote pre-share
  keyring v2-kr1
!
!
crypto ipsec transform-set trans esp-aes-cbc-128 esp-sha-hmac
!
crypto map cmap 1 ipsec-isakmp
  set peer 209.165.200.225
  set transform-set trans
  set ikev2-profile prof
  match address ikev2list
!
interface Loopback0
  ip address 209.165.200.226 255.255.255.224
!
interface Ethernet0/0
  ip address 209.165.200.227 255.255.255.224
  crypto map cmap
!
ip route 209.165.200.229 255.255.255.224 209.165.200.225
!
ip access-list extended ikev2list
  permit ip any any
!

```

The responder configuration is as follows:

```

crypto ikev2 proposal prop-1
  encryption aes-cbc-128
  integrity sha1
  group 14
!
crypto ikev2 policy pol-1
  match fvrf any
  proposal prop-1
!
crypto ikev2 keyring v2-kr1
  peer abc
  address 209.165.200.228
  pre-shared-key abc
!
!
crypto ikev2 profile prof
  match fvrf any
  match identity remote fqdn smap-initiator
  identity local fqdn dmap-responder
  authentication local pre-share
  authentication remote pre-share
  keyring v2-kr1
  ivrf global
!
!
crypto ipsec transform-set trans esp-aes-cbc-128 esp-sha-hmac
!
crypto dynamic-map dmap 1
  set transform-set trans
  set reverse-route tag 222
  set ikev2-profile prof

```

```

match address ikev2list
!
crypto map cmap 1 ipsec-isakmp dynamic dmap
!
interface Loopback0
 ip address 209.165.200.230 255.255.255.224
!
interface Ethernet0/0
 ip address 209.165.200.231 255.255.255.224
 crypto map cmap
!
ip route 209.165.200.233 255.255.255.224 209.165.200.228
!
ip access-list extended ikev2list
 permit ip any any
!

```

To initiate the connection between the initiator and the responder, enter the following command at the initiator's CLI:

```

ping 209.165.200.230 source 209.165.200.226
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 209.165.200.230, timeout is 2 seconds:
Packet sent with a source address of 209.165.200.226
%IKEV2-5-OSAL_INITIATE_TUNNEL: Received request to establish an IPsec tunnel; local traffic
 selector = Address Range: 209.165.200.226-209.165.200.226 Protocol: 1 Port Range: 0-65535;
 remote traffic selector = Address Range: 209.165.200.230-209.165.200.230 Protocol: 1 Port
 Range: 0-65535
%IKEV2-5-SA_UP: SA UP
.!!!!
Success rate is 80 percent (4/5), round-trip min/avg/max = 8/11/12 ms

```

To display the session details, enter the following **show** commands:

```

show crypto session
Crypto session current status
Interface: Ethernet0/0
Session status: UP-ACTIVE
Peer: 209.165.200.225 port 500
 IKEv2 SA: local 209.165.200.228/500 remote 209.165.200.231/500 Active
 IPSEC FLOW: permit ip 0.0.0.0/0.0.0.0 0.0.0.0/0.0.0.0
 Active SAs: 2, origin: crypto map
show crypto ikev2 sa detail

DPD configured for 0 seconds, retry 0
NAT-T is not detected

```

Example: Configuring Crypto Map-Based IKEv2 Peers Using Certification Authentication Method

The following example shows how to configure crypto-map-based IKEv2 peers using the certificate authentication method between a static crypto-map IKEv2 initiator, a dynamic crypto-map IKEv2 responder, and a CA server. The initiator configuration is as follows:

```
crypto pki trustpoint ca-server
  enrollment url http://10.1.1.3:80
  revocation-check none
!
crypto pki certificate map cmap-1 1
  subject-name eq hostname = responder
!
!
crypto pki certificate chain ca-server

Example: Configuring IKEv2 on DMVPN Networks

DMVPN uses a tunnel protection CLI that is identical between IKEv1 and IKEv2. The IPsec profile applied on a DMVPN tunnel only refers to an IKEv2 profile. The DMVPN Hub configuration is as follows:

```
crypto ikev2 keyring cisco-ikev2-keyring
  peer dmvpn-node
  address 0.0.0.0 0.0.0.0
  pre-shared-key cisco123
!
crypto ikev2 profile cisco-ikev2-profile
  keyring cisco-ikev2-keyring
  authentication local pre-share
  authentication remote pre-share
  match identity remote address 0.0.0.0 0.0.0.0
!
crypto ipsec profile cisco-ipsec-ikev2
  set transform-set cisco-ts
  set ikev2-profile cisco-ikev2-profile
!
interface Tunnel 0
  ip address 1.1.1.99 255.255.255.0
  no ip redirects
  ip nhrp network-id 99
  ip nhrp authentication CISCO
  ip nhrp map multicast dynamic
  ip nhrp redirect
  no ip split-horizon eigrp 1
  tunnel source Ethernet0/0
  tunnel mode gre multipoint
  tunnel protection ipsec profile cisco-ipsec
!
interface Tunnel1
  ip address 2.2.2.99 255.255.255.0
  no ip redirects
  ip nhrp network-id 100
  ip nhrp authentication CISCO
  ip nhrp map multicast dynamic
  no ip split-horizon eigrp 1
  tunnel source Ethernet0/1
  tunnel mode gre multipoint
  tunnel protection ipsec profile cisco-ipsec-ikev2
```

The IKEv2 configuration is as follows:

```
crypto ikev2 profile cisco-ikev2-profile
  keyring cisco-ikev2-keyring
  authentication pre-shared
  match local address 0.0.0.0
crypto ipsec profile cisco-ipsec-ikev2
  set transform-set cisco-ts
  set ikev2-profile cisco-ikev2-profile

CHAPTER 236

Cisco Group Encrypted Transport VPN

Cisco Group Encrypted Transport VPN (GET VPN) is a set of features that are necessary to secure IP multicast group traffic or unicast traffic over a private WAN that originates on or flows through a Cisco IOS device. GET VPN combines the keying protocol Group Domain of Interpretation (GDOI) with IP security (IPsec) encryption to provide users with an efficient method to secure IP multicast traffic or unicast traffic. GET VPN enables the router to apply encryption to nontunneled (that is, “native”) IP multicast and unicast packets and eliminates the requirement to configure tunnels to protect multicast and unicast traffic.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption](#) (NGE) white paper.

This document describes how to configure, verify, and troubleshoot Cisco GET VPN.

Cisco Group Encrypted Transport VPN provides the following benefits:

- Provides data security and transport authentication, helping to meet security compliance and internal regulation by encrypting all WAN traffic
 - Enables high-scale network meshes and eliminates complex peer-to-peer key management with group encryption keys
 - For Multiprotocol Label Switching (MPLS) networks, maintains network intelligence such as full-mesh connectivity, natural routing path, and quality of service (QoS)
 - Grants easy membership control with a centralized key server
 - Helps ensure low latency and jitter by enabling full-time, direct communications between sites, without requiring transport through a central hub
 - Reduces traffic loads on customer premises equipment (CPE) and provider-edge (PE) encryption devices by using the core network for replication of multicast traffic, avoiding packet replication at each individual peer site

Prerequisites for Cisco Group Encrypted Transport VPN

- You must be using Cisco IOS XE Release 2.3 or later.
- You should be knowledgeable about IPsec and Internet Key Exchange (IKE).
- You should know how to configure multicast and unicast routing on a Cisco IOS XE global router.
- When the IKE policy is configured, the IKE lifetime should be set to the minimum of 5 minutes so that unnecessary resources are not wasted on the maintenance of the IKE security association (SA). After the registration IKE SA is established, the registration SAs no longer have to be maintained because the rekey SA has been created and will be used to accept future rekeys.
- When the group rekey lifetime is configured with 300 seconds and forced rekey with policy change is performed, you might face network issues. To overcome this issue, one of the following is recommended for group rekey (KEK):
 - Set the lifetime to three times of TEK lifetime configured in transform-set.
 - Set the group rekey lifetime to default value, which is 24 hours (86400 seconds)
 - Configure rekey lifetime as 7200 seconds (2 hours)

Restrictions for Cisco Group Encrypted Transport VPN

- When access control entries are removed from the crypto policy on a primary key server (KS), IPsec packet drops are observed on the group members (GMs), in inbound and outbound directions.
- If you are encrypting high packet rates for counter-based antireplay, ensure that you do not make the lifetime too long or it can take several hours for the sequence number to wrap. For example, if the packet rate is 100 kilopackets per second, the lifetime should be configured as fewer than 11.93 hours so that the SA is used before the sequence number wraps.
- Cisco ASR 1000 Series Aggregation Routers with virtual-ppp interface cannot be configured as GETVPN group member.
- In Cisco IOS XE software, an inclusive port range for users to access a network cannot be matched in the extended ACL using the **permit** command.
- For unicast traffic and counter-based antireplay, the sequence numbers may be out of sync between the group members if one of the group members goes down and comes back up. For example: There is traffic from group member 1 to group member 2, and the last sequence number is n . Group member 1 goes down and comes back up. The sequence number of the SA at group member 1 now starts with 1, but group member 2 is expecting continuation from the previous sequence number ($n + 1$). This situation causes subsequent traffic from group member 1 to be dropped until the sequence number on group member 1 reaches n or the next rekey.

- When you configure transport mode traffic selectors, it is possible to have transport mode SAs. SAs occur when the packet size exceeds the MTU, and the packet cannot be forwarded.
- Transport mode should be used only for Group Encrypted Transport VPN Mode (GM) to GM traffic.
- If you are overriding the don't fragment bit (df-bit) setting in the IP header of encapsulated packets, you must configure the override commands in global configuration mode. GET VPN does not honor the interface configuration. This restriction is limited only to GET VPN. IPsec accepts both global configuration- and interface-specific override commands.
- Counter-based antireplay is not recommended and works only if there are two group members in a group.
- The GET VPN Time-Based Anti-Replay feature does not support Encapsulating Security Payload (ESP) transport mode in Cisco ASR 1000 Series Aggregation Services Routers and Cisco 4330 Integrated Services Router.
- Because Path MTU Discovery (PMTUD) does not work for GET VPN, there is a possibility that encapsulated packets could be dropped when the df-bit is set and the MTU of an intermediate link is less than the size of the encapsulated packet. In such an event, the router that drops the packet sends a notification to the source IP address on the packet, indicating that the packet has been dropped because the router could not fragment the packet due to the df-bit setting. In GET VPN, this message goes past the encapsulating endpoint directly to the source of the data due to the header preservation feature of GET VPN. Thus, the encapsulating router never knows that it has to fragment the packet to a smaller size before setting the df-bit after encapsulation. It continues to set the df-bit on the packets and they continue to be dropped at the intermediate router. (This is known as null-routing the traffic.)
- In Cisco IOS XE Release 3.5S and earlier releases, key servers cannot be configured using Cisco IOS XE images. They must be configured using Cisco IOS T-based or mainline-based images. This is not a restriction in Cisco IOS XE Release 3.6S and newer releases.
- Because of crypto engine optimization, the time-based antireplay (TBAR) overhead is 16 bytes instead of 12 bytes.
- GET VPN uses TBAR Cisco Metadata Protocol to carry TBAR information. Cisco IOS software uses 12-byte header and Cisco IOS XE uses 16-byte header. Cisco IOS XE software configured on GETVPN group members and using TBAR for anti-replay will have an effective mtu ("cleartext mtu") of the ipsec traffic as 4 bytes lower than group members that configured with Cisco IOS software. When migrating GET VPN group member from Cisco IOS software to Cisco IOS XE software, the reduction in the 4 bytes might result in unexpected performance issues.
- To ensure normal traffic flow for a GET VPN configuration on Cisco ASR 1000 Series Aggregation Services Routers, a TBAR window size greater than 20 seconds is recommended in Cisco IOS XE Release 3.12S and earlier releases, Cisco IOS XE Release 3.14S and Cisco IOS XE Release 3.15S. In Cisco IOS XE Release 3.13S, Cisco IOS XE Release 3.16S and later releases, a TBAR window size lesser than 20 seconds is permitted.
- Crypto maps are not supported on tunnel interface and port-channel interface. However, as an exception to the rule, crypto map for GDOI is supported on tunnel interfaces.
- Crypto maps are not supported on VLAN interfaces.
- RSVP as used in Mediatrace sets the "Router Alert" IP option flag. The Cavium N2 crypto accelerator does not support the use of IP options. Therefore, Mediatrace will fail with IPsec encryption on ASR1000 with Cavium N2. Mediatrace will fail with GETVPN encryption (IPSec with header preservation) on ASR1000 with Cavium N2.

- Deny statements can only be added locally to a GM. Permit statements are not supported in locally configured policies. In case of a conflict, a local policy overrides the policy downloaded from a KS.
- In Cisco ASR 1000 Series Aggregation Services Routers, when there is a failure to reregister, the outbound flow from QFP is not removed since a dummy ACE is pushed instead of a real ACE. As a result, when the SA expires, the GM will continue to encrypt outbound traffic using an expired SPI, instead of dropping the traffic locally. The traffic eventually gets dropped on the receiving GM due to an invalid SPI mechanism.
- While configuring an IPv6 access list on a Key Server, do not use the **ahp** option with the **permit** or **deny** commands.
- A Cisco IOS XE platform running as a GETVPN group member can only support one GETVPN-ipv4 group member instance and one GETVPN-ipv6 group member instance.
- GETVPN Group-Member does not support GETVPN crypto-map on the port-channel interface.
- **SSO Restrictions**
 - Cisco ASR 1000 Series Routers support stateful IPsec sessions on Embedded Services Processor (ESP) switchover. During ESP switchover, all IPsec sessions will stay up and no user intervention is needed to maintain IPsec sessions.
 - For an ESP reload (no standby ESP), the SA sequence number restarts from 0. The peer router drops packets that do not have the expected sequence number. You may need to explicitly reestablish IPsec sessions to work around this issue for systems that have a single ESP after an ESP reload. Traffic disruption might happen over the IPsec sessions in such cases for the duration of the reload.
 - The Cisco ASR 1000 Series Router currently does not support Stateful Switchover (SSO) IPsec sessions on Route Processors (RPs). The IPsec sessions will go down on initiation of the switchover, but will come back up when the new RP becomes active. No user intervention is needed. Traffic disruption might happen over the IPsec sessions for the duration of the switchover, until the sessions are back up.
 - Cisco ASR 1000 Series Router does not support stateful ISSU for IPsec sessions. Before performing an ISSU, you must explicitly terminate all existing IPsec sessions or tunnels prior to the operation and reestablish them post ISSU. Specifically, ensure that there are no half-open or half-established IPsec tunnels present before performing ISSU. To do this, we recommend a interface shutdown in the case of interfaces that may initiate a tunnel setup, such as a routing protocol initiating a tunnel setup, or interfaces that have keepalive enabled, or where there is an auto trigger for an IPsec session. Traffic disruption over the IPsec sessions during ISSU is obvious in this case.
- **Interface Configuration Restrictions**
 - Only one IPv4 GETVPN group is allowed per interface on IOS-XE.
 - It is recommended to configure only one IPv4 and one IPv6 GETVPN group on the same interface to avoid conflicts and ensure efficient operation of GETVPN.
- **Unsupported Configuration Restrictions**
 - Multiple GETVPN groups under one crypto map are not supported on IOS-XE. Implementing such a configuration can lead to unpredictable behavior and is therefore not recommended.
 - It is recommended as a best practice to configure a single GETVPN group within the crypto map to ensure optimal functionality and prevent configuration issues.

Information About Cisco Group Encrypted Transport VPN

Cisco Group Encrypted Transport VPN Overview

Networked applications such as voice and video increase the need for instantaneous, branch-interconnected, and QoS-enabled WANs. The distributed nature of these applications results in increased demands for scale. At the same time, enterprise WAN technologies force businesses to trade off between QoS-enabled branch interconnectivity and transport security. As network security risks increase and regulatory compliance becomes essential, GET VPN, a next-generation WAN encryption technology, eliminates the need to compromise between network intelligence and data privacy.

With GET, Cisco provides tunnelless VPN, which eliminates the need for tunnels. Meshed networks, by removing the need for point-to-point tunnels, can scale higher while maintaining network-intelligence features critical to voice and video quality. GET is a standards-based security model that is based on the concept of “trusted” group members. Trusted member routers use a common security methodology that is independent of any point-to-point IPsec tunnel relationship. Also, “any-any” networks, by using trusted groups instead of point-to-point tunnels, can scale higher while maintaining network-intelligence features (such as QoS, routing, and multicast), which are critical to voice and video quality.

GET-based networks can be used in a variety of WAN environments, including IP and MPLS. MPLS VPNs that use this encryption technology are highly scalable, manageable, and cost-effective, and they meet government-mandated encryption requirements. The flexible nature of GET allows security-conscious enterprises either to manage their own network security over a service provider WAN service or to offload encryption services to their providers. GET simplifies securing large Layer 2 or MPLS networks that require partial or full-mesh connectivity.

Cisco Group Encrypted Transport VPN Architecture

GET VPN encompasses Multicast Rekeying, a way to enable encryption for “native” multicast packets, and unicast rekeying over a private WAN. Multicast Rekeying and GET VPN is based on GDOI as defined in Internet Engineering Task Force (IETF) RFC 3547. In addition, there are similarities to IPsec in the area of header preservation and SA lookup. Dynamic distribution of IPsec SAs has been added, and tunnel overlay properties of IPsec have been removed. The figure below further illustrates the GET VPN concepts and relationships.

Figure 129: GET VPN Concepts and Relationships

Key Distribution Group Domain of Interpretation

GDOI

GDOI is defined as the Internet Security Association Key Management Protocol (ISAKMP) Domain of Interpretation (DOI) for group key management. In a group management model, the GDOI protocol operates between a group member and a group controller or key server (GCKS), which establishes SAs among authorized group members. The ISAKMP defines two phases of negotiation. GDOI is protected by a Phase 1 ISAKMP security association. The Phase 2 exchange is defined in RFC 6407. The topology shown in the figure below and the corresponding explanation show how this protocol works.

Group Member

The group member registers with the key server to get the IPsec SA or SAs that are necessary to communicate with the group. The group member provides the group ID to the key server to get the respective policy and keys for this group. These keys are refreshed periodically, and before the current IPsec SAs expire, so that there is no loss of traffic.

The output of the **show crypto isakmp sa detail** command will show the security association (SA) Authentication as “rsig” because the RSA signature is used for key encryption key (KEK) rekey authentication in GET VPN.

Key Server

The responsibilities of the key server include maintaining the policy and creating and maintaining the keys for the group. When a group member registers, the key server downloads this policy and the keys to the group member. The key server also rekeys the group before existing keys expire.

Note In Cisco IOS XE Release 3.5S and earlier releases, key servers are not supported on the Cisco ASR 1000 series routers. They must be configured using Cisco IOS T-based or mainline-based images. This is not a restriction on Cisco IOS XE Release 3.6S and newer releases.

The key server has two responsibilities: servicing registration requests and sending rekeys. A group member can register at any time and receive the most current policy and keys. When a group member registers with the key server, the key server verifies the group ID that the group member is attempting to join. If this ID is a valid group ID, the key server sends the SA policy to the group member. After the group member acknowledges that it can handle the downloaded policy, the key server downloads the respective keys.

There are two types of keys that the key server can download: the key encryption key (KEK) and the traffic encryption key (TEK). The TEK becomes the IPsec SA with which the group members within the same group communicate. The KEK encrypts the rekey message.

The GDOI server sends out rekey messages if an impending IPsec SA expiration occurs or if the policy has changed on the key server (using the command-line interface [CLI]). With CSCti89255, KEK rekeys before the KEK timer expires. The group member also starts a timer and expects to receive refreshed keys before timer expiration. If they are not received, the group member initiates a jittered re-registration prior to KEK expiry. KEK is deleted when the KEK lifetime expires.

The rekey messages may also be retransmitted periodically to account for possible packet loss. Packet loss can occur because rekey messages are sent without the use of any reliable transport. If the rekey mechanism is multicast, there is no efficient feedback mechanism by which receivers can indicate that they did not receive a rekey message, so retransmission seeks to bring all receivers up to date. If the rekey mechanism is unicast, the receivers will send an acknowledgment message.

Figure 130: Protocol Flows That Are Necessary for Group Members to Participate in a Group

The topology shows the protocol flows that are necessary for group members to participate in a group, which are as follows:

1. Group members register with the key server. The key server authenticates and authorizes the group members and downloads the IPsec policy and keys that are necessary for them to encrypt and decrypt IP multicast packets.
2. As needed, the key server “pushes” a rekey message to the group members. The rekey message contains a new IPsec policy and keys to use when old IPsec SAs expire. Rekey messages are sent in advance of the SA expiration time to ensure that valid group keys are always available.
3. The group members are authenticated by the key server and communicate with other authenticated group members that are in the same group using the IPsec SAs that the group members have received from the key server.

How Protocol Messages Work with Cisco Software

Multicast Rekeying uses the GDOI protocol (RFC 6407) to distribute the policy and keys for the group. The GDOI protocol is between a key server and a group member. The key server creates and maintains the policy and keys, and it downloads the policy and keys to the authenticated group members.

The GDOI protocol is protected by an ISAKMP Phase 1 exchange. The GDOI key server and the GDOI group member must have the same ISAKMP policy. This Phase 1 ISAKMP policy should be strong enough to protect the GDOI protocol that follows. The GDOI protocol is a four-message exchange that follows the Phase 1 ISAKMP policy. The Phase 1 ISAKMP exchange can occur in main mode or aggressive mode.

The figure below shows the ISAKMP Phase 1 exchange.

Figure 131: ISAKMP Phase 1 Exchange and GDOI Registration

The ISAKMP Phase 1 messages and the four GDOI protocol messages are referred to as the GDOI registration, and the entire exchange that is shown is a unicast exchange between the group member and the key server.

During the registration, if the rekey mechanism is multicast, the group member receives the address of the multicast group and registers with the multicast group that is required to receive the multicast rekeys.

The GDOI protocol uses User Datagram Protocol (UDP) port 848 (with Network Address Translation-Traversal (NAT-T), it floats to 4500).

IPsec

IPsec is a well-known RFC that defines an architecture to provide various security services for traffic at the IP layer. The components and how they fit together with each other and into the IP environment are described in IETF RFC 2401.

Communication Flow Between Key Servers and Group Members to Update IPsec SAs

Key servers and group members are the two components of the GET VPN architecture. The key server holds and supplies group authentication keys and IPsec SAs to the group members.

Group members provide encryption service to the interesting traffic (traffic that is worthy of being encrypted and secured by IPsec).

Communication among the key server and group members is encrypted and secured. GDOI supports the use of two keys: the TEK and the KEK. The TEK is downloaded by the key server to all the group members. The downloaded TEK is used by all the group members to communicate securely among each other. This key is essentially the group key that is shared by all the group members. The group policies and IPsec SAs are refreshed by the key server using periodic rekey messages to the group members. The KEK is also downloaded by the key server and is used by the group members to decrypt the incoming rekey messages from the key server.

The key server generates the group policy and IPsec SAs for the GDOI group. The information generated by the key server includes multiple TEK attributes, traffic encryption policy, lifetime, source and destination, a Security Parameter Index (SPI) ID that is associated with each TEK, and the rekey policy (one KEK).

The figure below illustrates the communication flow between group members and the key server. The key server, after receiving registration messages from a group member, generates the information that contains the group policy and new IPsec SAs. The new IPsec SA is then downloaded to the group member. The key server maintains a table that contains the IP address of each group member per group. When a group member registers, the key server adds its IP address in its associated group table, thus allowing the key server to monitor an active group member. A key server can support multiple groups. A group member can be part of multiple groups.

Figure 132: Communication Flow Between Group Members and the Key Server

IPsec and ISAKMP Timers

IPsec and ISAKMP SAs are maintained by the following timers:

- **TEK lifetime**-Determines the lifetime of the IPsec SA. Before the end of the TEK lifetime, the key server sends a rekey message, which includes a new TEK encryption key and transforms as well as the existing KEK encryption keys and transforms. The TEK lifetime is configured only on the key server, and the lifetime is "pushed down" to the group members using the GDOI protocol. The TEK lifetime value depends on the security policy of the network. If the **set security-association lifetime** command is not configured, the default value of 86,400 seconds takes effect. To configure a TEK lifetime, see the "Configuring an IPsec Lifetime Timer" section.
- **KEK lifetime**-Determines the lifetime of the GET VPN rekey SAs. Before the end of the lifetime, the key server sends a rekey message, which includes a new KEK encryption key and transforms and new TEK encryption keys and transforms. The KEK lifetime is configured only on the key server, and the lifetime is pushed down to group members dynamically using the GDOI protocol. The KEK lifetime value should be greater than the TEK lifetime value (it is recommended that the KEK lifetime value be at least three times greater than the TEK lifetime value). If the **rekey lifetime** command is not configured, the default value of 86,400 seconds takes effect. To configure a KEK lifetime, see the "Configuring a Multicast Rekey" section.
- **ISAKMP SA lifetime**-Defines how long each ISAKMP SA should exist before it expires. The ISAKMP SA lifetime is configured on a group member and on the key server. If the group members and key servers do not have a cooperative key server, the ISAKMP SA is not used after the group member registration. In this case (no cooperative key server), the ISAKMP SA can have a short lifetime (a minimum of 60 seconds). If there is a cooperative key server, all key servers must have long lifetimes to keep the ISAKMP SA "up" for cooperative key server communications. If the **lifetime** command is not configured, the default value of 86,400 seconds takes effect. To configure an ISAKMP SA lifetime, see the "Configuring an ISAKMP Lifetime Timer" section.

Address Preservation

The following section describes address preservation in GET VPN.

As shown in the figure below, IPsec-protected data packets carry the original source and destination in the outer IP header rather than replacing them with tunnel endpoint addresses. This technique is known as IPsec Tunnel Mode with Address Preservation.

Figure 133: Header Preservation

Address preservation allows GET VPN to use the routing functionality present within the core network. Address preservation allows routing to deliver the packets to any customer-edge (CE) device in the network that advertises a route to the destination address. Any source and destination matching the policy for the group will be treated in a similar manner. In the situation where a link between IPsec peers is not available, address preservation also helps combat traffic “route absence” situations.

Header preservation also maintains routing continuity throughout the enterprise address space and in the WAN. As a result, end host addresses of the campus are exposed in the WAN (for MPLS, this applies to the edge of the WAN). For this reason, GET VPN is applicable only when the WAN network acts as a “private” network (for example, in an MPLS network).

Secure Data Plane Multicast

The multicast sender uses the TEK that is obtained from the key server and encrypts the multicast data packet with header preservation before it switches out the packet. The replication of the multicast packet is carried out in the core on the basis of the (S, G) state that is retained in the multicast data packet. This process is illustrated in the figure below.

Figure 134: Secure Data Plane Multicast Process

Secure Data Plane Unicast

The unicast sender uses the TEK that is obtained from the key server and encrypts the unicast data packet with header preservation before it switches out the packet to the destination. This process is illustrated in the figure below.

Figure 135: Secure Data Plane Unicast Process

Cisco Group Encrypted Transport VPN Features

Rekeying

Rekey messages are used to refresh IPsec SAs. When the IPsec SAs or the rekey SAs are about to expire, one single rekey message for a particular group is generated on the key server. No new IKE sessions are created for the rekey message distribution. The rekey messages are distributed by the key server over an existing IKE SA.

Rekeying can use multicast or unicast messages. GET VPN supports both unicast and multicast rekeying.

With CSCti89255, KEK rekeys before the KEK timer expires. The group member also starts a timer and expects to receive refreshed keys before timer expiration. If they are not received, the group member initiates a jittered re-registration prior to KEK expiry. KEK is deleted when the KEK lifetime expires. This ensure the following:

- A safer KEK expiry checking mechanism
- A safer KEK re-registration mechanism
- Avoids use of KEK beyond configured lifetime

The following subsections give detailed rekeying information:

Rekey Sequence Number

Before the end of a TEK/KEK lifetime, KS sends a rekey message with the sequence number incremented by 1. However, if a secondary KS has become the primary KS in the time since the last rekey message was sent, the new primary KS increments the sequence number of the rekey message by 10.

The primary KS and secondary KS synchronize sequence numbers every 20 seconds.

The following example shows how the sequence number of rekey messages changes in a deployment consisting of a primary KS, KS1, and a secondary KS, KS2. For the sake of the example, we assume the sequence number has the initial value 1.

We also assume that the deployment has a large number of GMs and that the KS may need to retry the delivery of rekey messages. The sequence number is incremented by 1 for each retry.

1. When it is time to send a rekey message, KS1 increments the sequence number to 2.
2. Suppose that KS1 resends the rekey message thrice so that all the GMs receive the message. With each retry, the sequence number is incremented by 1. So, the value of the sequence number at the end of this rekey is 5.
3. When it is time to send the next rekey message, suppose that KS1 sends the rekey message only once. So, the sequence number at the end of this second rekey is 6.
4. Before the next rekey message is sent, suppose KS2 becomes the primary KS.
5. When it is time to send the rekey message, KS2 increments the sequence number by 10. So, the rekey message is sent with the sequence number 16.
6. Suppose that KS2 resends the rekey message twice so that all the GMs receive the message. With each retry, the sequence number is incremented by 1. So, the value of the sequence number at the end of this rekey is 18.
7. Before the next rekey message is sent, suppose that KS1 becomes the primary KS.
8. When it is time to send the rekey message, KS1 increments the sequence number by 10. So, the rekey message is sent with the sequence number 28. Suppose that KS1 sends the rekey message only once. The sequence number at the end of the rekey is 28.
9. When it is time to send the next rekey message, KS1 increments the sequence number by 1. Suppose KS1 sends the rekey message only once. The sequence number at the end of the rekey is 29.

The following table summarizes the change in sequence numbers during each rekey operation:

Rekey #	1(3 retries)	2(0 retries)	3(2 retries)	4(0 retries)	5(0 retries)
Sequence #	2,3,4,5	6	16,17,18	28	29

Rekey Sequence-Number Check

The rekey sequence-number check between the key server and the group member is conducted as follows:

1. Antireplay in GROUPKEY-PUSH messages is restored as specified in RFC 6407.
 - The group member drops any rekey message that has a sequence number lower than or equal to that of the last received rekey message.
 - The group member accepts any rekey message that has a sequence number higher than that of the last received rekey message, no matter how large the difference.

- The sequence number is reset to 1 at the first rekey message after the KEK rekey, not at the KEK rekey message itself.

Multicast Rekeying

Multicast rekeys are sent out using an efficient multicast rekey. Following a successful registration, the group member registers with a particular multicast group. All the group members that are registered to the group receives this multicast rekey. Multicast rekeys are sent out periodically on the basis of the configured lifetime on the key server. Multicast rekeys are also sent out if the IPsec or rekey policy is changed on the key server. Triggered by the configuration change, the rekey sends out the new updated policy to all the group members with an efficient multicast rekey.

The key server pushes the rekey time back as follows:

- If the TEK timeout is 300 seconds:

$\text{tek_rekey_offset} = 90$ (because $300 < 900$)

If retransmissions are configured, the rekey timer is moved back more.

For three retransmissions every 10 seconds: 3×10

So the rekey will actually happen at $(300 - 90 - 30) = 180$ seconds

- If the TEK timeout is 3600 seconds:

$\text{tek_rekey_offset} = 3600 \times 10 \text{ percent} = 360$ seconds

If retransmissions are configured, the rekey timer is moved back more.

For three retransmissions every 10 seconds: 3×10

So the rekey will actually happen at $(3600 - 360 - 30) = 3210$ seconds

When a KEK expires and when the transport mode is multicast, a multicast KEK rekey is sent. When a multicast KEK rekey is sent, the group member replaces the old KEK with the new KEK. Because it is a multicast rekey, and the retransmissions are sent, the old KEK continues to be used for encryption. This situation occurs because the group member does not receive the new KEK rekey. Hence the group member that received the multicast KEK rekey does not have the old KEK, and hence it drops these retransmissions.

The group member that did not initially receive the KEK key now receives the KEK retransmission and replaces the old KEK with the new KEK and will drop the retransmissions that will follow. For example, if five retransmissions are configured and a multicast KEK rekey with sequence number 1 is received at group member 1, all the other retransmissions with sequence numbers 2 3 4 5 6 will be dropped at the group member because the group member does not have the old KEK.

If group member 2 does not get the KEK rekey with sequence number 1 and it receives the retransmission with sequence number 2, it will drop the other retransmissions 3, 4, 5, 6.

Configuration Requirements for Multicast Rekeying

When a group member registers to a key server, it installs the KEK SA into its database. When the rekey transport is multicast the group member will use IGMP to join the multicast stream defined by the key server. The IGMP join is transmitted from the interface that contains the crypto map.

Note The IGMP traffic should be excluded from encryption via either the ACL defined on the key server or a local deny ACL on the group member.

When the key server is not reachable via the same interface as the one configured with the crypto map, it will have to manually join the stream.

Unicast Rekeying and SAs

In a large unicast group, to alleviate latency issues, the key server generates rekey messages for only a small number of group members at a time. The key server is ensured that all group members receive the same rekey messages for the new SA before the expiration of the old SA. Also, in a unicast group, after receiving the rekey message from the key server, a group member sends an encrypted acknowledge (ACK) message to the key server using the keys that were received as part of the rekey message. When the key server receives this ACK message, it notes this receipt in its associated group table, which accomplishes the following:

- The key server keeps a current list of active group members.
- The key server sends rekey messages only to active members.

In addition, in a unicast group, the key server removes the group member from its active list and stops sending the rekey messages to that particular group member if the key server does not receive an ACK message for three consecutive rekeys. If no ACK message is received for three consecutive rekeys, the group member has to fully re-register with the key server after its current SA expires if the group member is still interested in receiving the rekey messages. The ejection of a nonresponsive group member is accomplished only when the key server is operating in the unicast rekey mode. The key server does not eject group members in the multicast rekey mode because group members cannot send ACK messages in that mode.

As in multicast rekeying, if retransmission is configured, each rekey will be retransmitted the configured number of times.

Rekey transport modes and authentication can be configured under a GDOI group.

If unicast rekey transport mode is not defined, multicast is applied by default.

If the TEK rekey is not received, the group member re-registers with the key server 60 seconds before the current IPsec SA expires. The key server has to send out the rekey before the group member re-registration occurs. If no retransmission is configured, the key server sends the rekey `tek_rekey_offset` before the SA expires. The `tek_rekey_offset` is calculated based on the configured rekey lifetime. If the TEK rekey lifetime is less than 900 seconds, the `tek_rekey_offset` is set to 90 seconds. If the TEK rekey lifetime is configured as more than 900 seconds, the `tek_rekey_offset` = (configured TEK rekey lifetime)/10. If retransmission is configured, the rekey occurs earlier than the `tek_rekey_offset` to let the last retransmission be sent 90 seconds before the SA expires.

The key server uses the formula in the following example to calculate when to start sending the rekey to all unicast group members. The unicast rekey process on the key server sends rekeys to unicast group members in groups of 50 within a loop. The time spent within this loop is estimated to be 5 seconds.

A key server rekeys group members in groups of 50, which equals two loops. For example, for 100 group members:

Number of rekey loops = (100 group members)/50 = 2 loops:

- Time required to rekey one loop (estimation) = 5 seconds
- Time to rekey 100 group members in two loops of 50: 2 x 5 seconds = 10 seconds

So the key server pushes the rekey time back as follows:

- If the TEK timeout is 300: 300 - 10 = 290

But the start has to be earlier than the TEK expiry (as in the multicast case):

- Because $300 < 900$, $\text{tek_rekey_offset} = 90$
- So 90 seconds is subtracted from the actual TEK time: $290 - \text{tek_rekey_offset} = 200$ seconds

If retransmissions are configured, the rekey timer is moved back more:

- For three retransmissions every 10 seconds: $200 - (3 \times 10) = 170$
- If the TEK timeout is 3600 seconds: $3600 - 10 = 3590$

But the start has to be earlier than the TEK expiry (as in the multicast case):

- Because $3600 > 900$, $\text{tek_rekey_offset} = 3600 \times 10 \text{ percent} = 360$
- So 360 seconds is subtracted from the actual TEK time: $3590 - \text{tek_rekey_offset} = 3230$ seconds

If retransmissions are configured, the rekey timer is moved back more:

- For three retransmissions every 10 seconds: $3230 - (3 \times 10) = 3200$ seconds

The tek_rekey_offset formula applies to unicast and multicast rekeying.

Rekey Behavior After Policy Changes

The table below provides a list of rekey behavior based on the security policy changes.

Table 311: Rekey Behavior After Security Policy Changes

Policy Changes	Rekey Sent?	Rekey Behavior After Policy Changes
TEK: SA lifetime	No	The old SA remains active until its lifetime expires. The new lifetime will be effective after the next scheduled rekey.
TEK: IPSEC transformset	Yes	The SAs of the old transform set remain active until its lifetime expires.
TEK: IPSEC profile	Yes	The SAs of the old profile remain active until its lifetime expires.
TEK:matching ACL	Yes	Outbound packet classification will use the new access control list (ACL) immediately. The old SAs are still kept in the SA database.
TEK:enable replay counter	Yes	The old SA without counter replay remains active until its lifetime expires.
TEK:change replay counter	No	The SA with a new replay counter will be sent out in the next scheduled rekey.
TEK:disable replay counter	Yes	The old SA with counter replay enabled remains active until its lifetime expires.
TEK:enable receive-only	Yes	Receive-only mode is activated immediately after rekey.
TEK:disable receive-only	Yes	Receive-only mode is deactivated immediately after rekey.
KEK:SA lifetimebehavior	No	Change is applied with the next rekey.

Policy Changes	Rekey Sent?	Rekey Behavior After Policy Changes
KEK:change authentication key	Yes	Change is applied with the next rekey.
KEK:changing crypto algorithm	Yes	Change is applied immediately.

Enter the following commands for the policy changes to take effect immediately:

- Use the **clear crypto gdoi [group]** command on the key server.
- Use the **clear crypto gdoi [group]** command on all the group members.

Note The key server sends rekeys for policy updates after the administrator exits configuration mode, ensuring that the rekeys are sent when appropriate.

Note Passive-mode behavior before changing to bidirectional mode on a group member is as follows:

If you change the SA mode on the key server to “no sa receive-only,” and exit configuration mode, the rekey is sent to the group member, and you can see the state on the group member changing from “inbound only” to “inbound optional;” the state will change to “both” after an interval set by a built-in timer; about five minutes.

The key server shows this state as “both” immediately; this is done by design because all group members might be in the process of being updated.

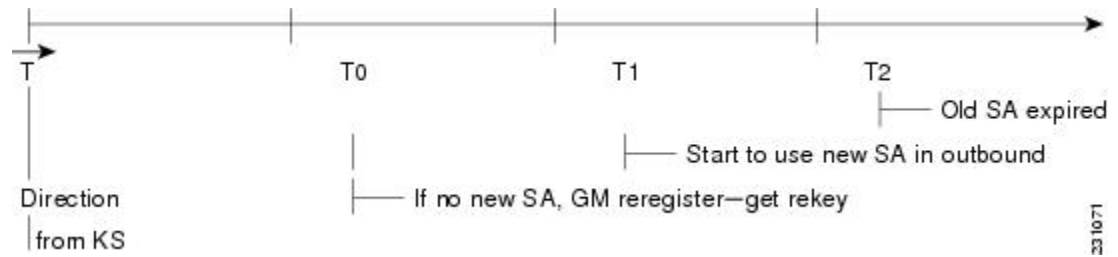

IPsec SA Usage on the Group Members

When a rekey is received and processed on a group member, the new IPsec SA (the SPI) is installed. There is a period of time when the old and the new IPsec SAs are used. After a certain specified interval, the old IPsec SA is deleted. This overlap ensures that all group members receive the current rekey and insert the new IPsec SAs. This behavior is independent of the transport method (multicast or unicast rekey transport) for the rekeys from the key server.

Approximately 30 seconds before the old SA expires, the group member starts to use the new SA in the outbound direction to encrypt the packet. Approximately 60 seconds before the old SA expires, if no new SA is received on the group member side via a rekey from the key server, the group member reregisters.

In the figure below, time T2 is when the old SA expires. T1 is 30 seconds before T2, which is when the group member (GM) starts to use the new SA in the outbound direction. T0 is another 30 seconds before T2. If no new SA is received at T0, the group member has to reregister. T is another 30 seconds from T0. The key server should send a rekey at T.

Figure 136: IPsec SA Usage on a Group Member

Configuration Changes Can Trigger a Rekey By a Key Server

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

Configuration changes on a key server can trigger a rekey by the key server. Please refer to the following sample configuration as you read through the changes that will or will not cause a rekey that are described following the example.

```
crypto ipsec transform-set gdoi-p esp-aes esp-sha-hmac
!
crypto ipsec profile gdoi-p
 set security-association lifetime seconds 900
 set transform-set gdoi-p
!
crypto gdoi group diffint
 identity number 3333
 server local
  rekey algorithm aes 128
  rekey address ipv4 121
  rekey lifetime seconds 3600
  no rekey retransmit
  rekey authentication mypubkey rsa mykeys
 sa ipsec 1
  profile gdoi-p
  match address ipv4 120
  replay counter window-size 3
```

The following configuration changes on the key server will trigger a rekey from the key server:

- Any change in the TEK configuration (“sa ipsec 1” in the example):
 - If the ACL (“match address ipv4 120” in the above example) is changed. Any addition, deletion, or change in the ACL causes a rekey.
 - If TEK replay is enabled or disabled on the key server, rekey is sent.
 - Removal or addition of the IPsec profile in the TEK (“profile gdoi-p” in the example).
 - Changing from multicast to unicast transport.
 - Changing from unicast to multicast transport.

The following configuration changes on the key server will not trigger a rekey from the key server:

- Replay counter window size is changed under the TEK (“sa ipsec 1” in the example).

- Configuring or removing rekey retransmit.
- Removing or configuring the rekey ACL.
- Changing the TEK lifetime (“set security-association lifetime seconds 300” in the example) or changing the KEK lifetime (“rekey lifetime seconds 500” in the example).
- Adding, deleting, or changing the rekey algorithm (“rekey algorithm aes 128” in the example).

Commands That Trigger a Rekey

The table below is a comprehensive list of GET VPN command changes, and it shows which commands will or will not trigger a rekey. Commands are broken out based on the configuration mode in which they are entered. The table also shows when the commands take effect, regardless of whether they trigger a rekey.

Note When the KEK lifetime is changed in the GDOI group, the changes take place only when the current KEK expires and a new one is generated. You can force the changes to take place, by issuing the rekey command, **crypto gdoi ks rekey**, on the key server.

Table 312: Commands That Trigger a Rekey

Description	Command	Rekey Triggered	When Triggered	When Change Takes Effect
Mode = (config)	configure terminal	—	—	—
Change/delete ACL used in GDOI group (example: rekey address ipv4 access-list-number[options])	[no] access-list access-list-number[options]	No	—	Immediately
Change/delete ACL used in IPsec profile (example: match address ipv4 access-list-id name[options])	[no] access-list access-list-number[options]	Yes	End configuration mode	show running-config command output on key server indicates that the policy is incomplete, the packet is still encrypted/decrypted by the existing SA, downloaded ACLs are cleared but multidimensional-tree entries are still present (by displaying show crypto ruleset command output), and no new SAs are downloaded and old SAs are still active in encrypt/decrypt.

Description	Command	Rekey Triggered	When Triggered	When Change Takes Effect
Add/remove ISAKMP preshared key (arbitrary key)	crypto isakmp key address <i>peer-address</i>	No	—	Immediately
Add/remove ISAKMP preshared key (group member key)	crypto isakmp key address <i>peer-address</i>	No	—	After key encryption key (KEK) SA expires (re-registration)
Add IPsec profile	crypto ipsec profile	No	—	Immediately
Add/remove ISAKMP policy	crypto isakmp policy <i>priority</i>	No	—	Immediately
Mode = (ipsec-profile)	crypto ipsec profile <i>name</i>	—	—	—
Change SA lifetime (in IPsec profile)	set security-association lifetime <i>seconds</i>	No	—	Next rekey
Change transform-set	set transform-set <i>transform-set-name</i>	Yes	End configuration mode	The SAs of the old transform set remain active until the lifetime expires.
Mode = (config-gdoi-group)	crypto gdoi group <i>group-name</i>	—	—	—
Change identity number	identity number <i>number</i>	No	—	Must immediately configure on the group member. The other group members keep using the TEKs and KEKs of the old group ID.
Mode = (gdoi-local-server)	server local	—	—	—
Change from unicast to multicast transport	rekey transport unicast	Yes	Immediately	After triggered rekey
Change from multicast to unicast transport	[no] rekey transport unicast	Yes	End configuration mode	After triggered rekey
Change rekey address	rekey address ipv4 { <i>access-list-number</i> <i>access-list-name</i> }	Yes	End configuration mode	After triggered rekey (however, changing the ACL itself will not trigger a multicast rekey)

Description	Command	Rekey Triggered	When Triggered	When Change Takes Effect
Change rekey lifetime	rekey lifetime seconds <i>number-of-seconds</i>	No	—	Next rekey, but lifetime starts decrementing when the command is issued (the current lifetime is sent out with the rekey).
Enable/disable rekey retransmit	rekey retransmit <i>number-of-seconds</i> [number <i>number-of-retransmissions</i>]	No	—	Next rekey
Enable rekey authentication	rekey authentication mypubkey rsa <i>key-name</i>	Yes	End configuration mode	After triggered rekey
Disable rekey authentication	[no] rekey authentication	No	—	Immediately
Change rekey authentication key	rekey authentication mypubkey rsa <i>key-name</i>	Yes	End configuration mode	After triggered rekey
Change rekey encryption	rekey algorithm <i>type-of-encryption-algorithm</i>	Yes	End configuration mode	New algorithm takes effect immediately.
Mode = (gdoi-sa-ipsec)	sa ipsec <i>sequence-number</i>	—	—	—
Change profile	profile <i>ipsec-profile-name</i>	Yes	End configuration mode	SAs of the old profile are still in effect until the lifetime expires.
Change ACL match	match address [options]	Yes	End configuration mode	After triggered rekey
Enable counter replay	replay counter window-size <i>seconds</i>	Yes	End configuration mode	Old SA without counter replay is still inactive until the lifetime expires.
Change replay counter value	replay counter window-size <i>seconds</i>	No	—	Next rekey
Enable time-based antireplay	replay time window-size <i>seconds</i>	Yes	End configuration mode	New SA with time-based antireplay enabled is sent, but the old SA with time-based antireplay disabled is still active until the lifetime expires.

Description	Command	Rekey Triggered	When Triggered	When Change Takes Effect
Change time-based antireplay window	replay time window-size <i>seconds</i>	No	—	New time-based antireplay window is effective only after entering the clear crypto gdoi command on both the key server and group member.
Mode = (gdoi-coop-ks-config)	redundancy	—	—	—
Enable redundancy	redundancy	No	—	Must immediately configure on other key servers
Change local priority	local priority <i>number</i>	No	—	Immediately but does not force key server election
Add/remove peer address	[no] peer address ipv4 <i>ip-address</i>	No	—	Next cooperative (COOP) message
Disable redundancy	[no] redundancy	No	—	Must immediately configure on other key servers

When a timeout is caused by a pseudotime synchronization, the key server checks if either the KEK or the TEK timer is scheduled to expire in next 60 seconds, and if so, combines that timeout with the pseudotime synchronization timeout. That is, the rekey acts as both a TEK or KEK rekey and a pseudotime synchronization timeout rekey. See the “Time-Based Antireplay” section for more information on pseudotime synchronization.

Retransmitting a Rekey

Multicast rekeys are retransmitted by default. For unicast rekeys, if the key server does not receive the ACK, it retransmits the rekey. In either case, before retransmitting a rekey, the key server checks if there is a TEK or KEK rekey scheduled in the next 120 seconds. If so, it stops the current retransmission and waits for the scheduled rekey to happen.

Group Member Access Control List

For GET VPN, the traffic that has to be protected is defined statically on the key server using the ACL. The group member gets information about what has to be protected from the key server. This structure allows the key server to choose and change the policy dynamically as needed. In Secure Multicast, the key server ACL is defined inclusively. The ACL includes only the exact traffic that should be encrypted, with an implicit deny causing all other traffic to be allowed in the clear (that is, if there is no permit, all other traffic is allowed).

GET VPN employs a different philosophy: The definition of which packets should be encrypted is delivered independently. GET VPN supports only statically defined traffic selectors. Policy can be defined by using both deny and permit ACLs on the key server. Only the deny ACL is allowed to be manually configured on a group member. The policies that are downloaded from the key server and configured on the group member

are merged. Any ACL that is configured on the group member has predominance over what is downloaded from the key server.

After the group member gets the ACL from the key server, the group member creates a temporary ACL and inserts it into the database. This ACL will be deleted if the group member is removed from the GDOI group for any reason. The packets that are going out of the interface are dropped by the group member if a packet matches the ACL but no IPsec SA exists for that packet.

The key server can send a set of traffic selectors, which may not exactly match the group member ACL on the group member. If such differences occur, the differences have to be merged and resolved. Because the group member is more aware of its topology than the key server, the downloaded ACLs are appended to the group member ACL. The group member ACL (except the implicit deny) is inserted into the database first, followed by the downloaded key server ACL. The database is prioritized, and the database search stops whenever a matched entry is found.

For information about configuring a group member ACL, see the “Configuring Group Member ACLs” section.

Behavior of a Group Member When Security Policy Changes

The behavior of a group member changes when ACL changes or any other policy changes are made in the key server. The effect of different policy changes on the behavior of the group members is explained in the following three scenarios.

Scenario 1

In the following example, the ACL has been initially configured to permit host A and host B.

```
ip access-list extended get-acl
permit ip host A host B
permit ip host B host A
```

Then the ACL is changed to permit host C and host D in the key server:

```
ip access-list extended get-acl
permit ip host C host D
permit ip host D host C
```

ACL changes affect the behavior of the group member in the following ways:

- Key server sends out a rekey to all group members immediately.
- Group member sends traffic between host A and host B in clear text immediately after rekey.
- Group member sends traffic between host C and host D in encrypted text immediately after rekey.

Note GETVPN group members of Cisco ASR 1000 Series Aggregation Services Routers and Cisco ISR G2 routers behave differently after a rekey (either triggered or periodic) that follows a ACL change or any other policy change in the key server. The group members of Cisco ISR G2 routers install the new policy without a full reregistration, while the group members of Cisco ASR 1000 Series Aggregation Services Routers will reregister to get the updated policy.

Scenario 2

The behavior of a group member changes when policy updates and transform set and time-based antireplay (TBAR) changes are made to the key server.

In this scenario, it is assumed that:

- The transform set has been changed from ESP-3DES to ESP-AES.
- The policy change occurs at 1000 seconds before the current TEK lifetime expires.

These policy changes affect the behavior of the group member in the following ways:

- The key server sends out a rekey of both old SAs (3DES) and new SAs (AES).
- Group member continues to use the old SA (3DES) for 1000 seconds until it expires.
- After the old SA expires, the group member automatically switches over to new SAs (AES).

Scenario 3

The behavior of a group member changes when other policy updates in the key server involve both ACL changes and other changes like the transform set or TBAR.

In this scenario it is assumed that:

- The ACL has been updated as specified in Scenario 1.
- The transform set was changed from ESP-3DES to ESP-AES.
- The policy change occurs 1000 seconds before the current TEK lifetime expires.

ACL changes and other policy updates affect the behavior of the group member in the following ways:

- The key server sends out a rekey that consists of both old SAs (3DES) and new SAs (AES).
- The group member sends traffic between host A and host B in clear text immediately after rekey.
- The group member sends encrypted traffic between host C and host D using old SAs (3DES) for 1000 seconds until its TEK lifetime expires.
- When old SAs (3DES) expire, the group member automatically switches to new SAs to encrypt traffic between host C and host D in AES.

Time-Based Antireplay

Antireplay is an important feature in a data encryption protocol such as IPsec (RFC 2401). Antireplay prevents a third party from eavesdropping on an IPsec conversation, stealing packets, and injecting those packets into a session at a later time. The time-based antireplay mechanism helps ensure that invalid packets are discarded by detecting the replayed packets that have already arrived at an earlier time.

GET VPN uses the Synchronous Antireplay (SAR) mechanism to provide antireplay protection for multisender traffic. SAR is independent of real-world Network Time Protocol (NTP) clock or sequential-counter mechanisms (which guarantee packets are received and processed in order). A SAR clock advances regularly. The time tracked by this clock is called pseudotime. The pseudotime is maintained on the key server and is sent periodically to the group members within a rekey message as a time-stamp field called pseudoTimeStamp. GET VPN uses a Cisco proprietary protocol called Metadata to encapsulate the pseudoTimeStamp. Group members have to be resynchronized to the pseudotime of the key server periodically. The pseudotime of the key server starts ticking from when the first group member registers. Initially, the key server sends the current pseudotime value of the key server and window size to group members during the registration process. New attributes, such as time-based replay-enabled information, window size, and the pseudotime of the key server, is sent under the SA payload (TEK).

The group members use the pseudotime to prevent replay as follows: the pseudoTimeStamp contains the pseudotime value at which a sender created a packet. A receiver compares the pseudotime value of senders with its own pseudotime value to determine whether a packet is a replayed packet. The receiver uses a time-based antireplay “window” to accept packets that contain a time-stamp value within that window. The window size is configured on the key server and is sent to all group members.

Note You should not configure time-based antireplay if you are using a Cisco VSA as a group member.

The figure below illustrates an antireplay window in which the value PT_r denotes the local pseudotime of the receiver, and W is the window size.

Figure 137: Antireplay Window

Clock Synchronization

Clocks of the group members can slip and lose synchronization with the key server. To keep the clocks synchronized, a rekey message (multicast or unicast, as appropriate), including the current pseudotime value of the key server, is sent periodically, either in a rekey message or at a minimum of every 30 minutes to the group member. If a packet fails this antireplay check, the pseudotime of both the sender and receiver is printed, an error message is generated, and a count is increased.

To display antireplay statistics, use the **show crypto gdoi group *group-name* gm replay** command on both the sender and receiver devices. If the configuration is changed by the administrator to affect the replay method of the size configuration, the key server initiates a rekey message.

Interval Duration

A tick is the interval duration of the SAR clock. Packets sent in this duration have the same pseudoTimeStamp. The tick is also downloaded to group members, along with the pseudotime from the key server. For example, as shown in the figure below, packets sent between T_0 and T_1 would have the same pseudoTimeStamp T_0 . SAR provides loose antireplay protection. The replayed packets are accepted if they are replayed during the window. The default window size is 100 seconds. It is recommended that you keep the window size small to minimize packet replay.

Figure 138: SAR Clock Interval Duration

Antireplay Configurations

The Antireplay feature can be enabled under IPsec SA on a key server by using the following commands:

- **replay time window-size**—Enables the replay time option, which supports the nonsequential, or time-based, mode. The window size is in seconds. Use this mode only if you have more than two group members in a group.
- **replay counter window-size**—Enables sequential mode. This mode is useful if only two group members are in a group.
- **no replay counter window-size**—Disables antireplay.

Control-Plane Time-Based Antireplay

Rekey Pseudotime Check

The rekey pseudotime check between key servers and group members is conducted as follows:

- The group member calculates the allowable pseudotime difference between the key server and its own as the lesser of the configured TBAR window size, that is, the value that was configured for it in the data plane, or 30 seconds.
- The group member accepts any rekey with a pseudotime larger than its own and updates its own pseudotime to the larger value. If the difference is larger than the calculated allowable pseudotime difference, it also generates the following syslog message:

```
*Jul 28 22:56:37.503: %GDOI-3-PSEUDO_TIME_LARGE: Pseudotime difference between key server
(20008 sec) and GM (10057 sec) is larger than expected in group GET. Adjust to new pseudotime
```

- If the group member receives a rekey with a pseudotime smaller than its own but within the allowable difference, the group member accepts the rekey and updates its pseudotime value to the rekey pseudotime value.
- If the group member receives a rekey with a pseudotime smaller than its own but exceeding the allowable difference, the group member drops the rekey message and generates the following syslog message:

```
*Jul 28 23:37:59.699: %GDOI-3-PSEUDO_TIME_TOO_OLD: Rekey received in group GET is too old
and fail PST check: my_pst is 22490 sec, peer_pst is 10026 sec, allowable_skew is 30 sec
```

ANN Message Pseudotime Handling in the Secondary Key Server

Cooperative key server announcement (ANN) messages are used to synchronize policy and group-member information between cooperative key servers.

The secondary key server handles ANN messages as follows:

- The secondary key server calculates the allowable ANN message pseudotime as the lesser of the configured TBAR window size, that is, the value that was configured for it in the data plane, or 30 seconds.
- If the secondary key server receives an ANN message from the primary key server with a larger pseudotime, it does the following:
 - It updates its pseudotime to the primary key server's value.
 - If the pseudotime difference is larger than allowable, it generates the following syslog message:

```
*Jul 28 23:48:56.871: %GDOI-4-GDOI_ANN_TIMESTAMP_LARGE: COOP_KS ANN received from KS 10.0.8.1
in group GET has pseudotime bigger than myself. Adjust to new pseudotime:
my_old_pst is 23147 sec, peer_pst is 30005 sec
```

- If the secondary key server receives an ANN message from the primary key server with a smaller pseudotime, it behaves as follows:
 - If the difference is within the allowable range, the secondary key server accepts it and updates its pseudotime to the primary key server's value.
 - If the difference exceeds the allowable range, it generates the following syslog message:

```
*Jul 28 23:42:12.603: %GDOI-4-GDOI_ANN_TIMESTAMP_TOO_OLD: COOP_KS ANN from KS 10.0.8.1 in
group GET is too old and fail PST check:
my_pst is 22743 sec, peer_pst is 103 sec, allowable_skew is 10 sec
```

If, after three retransmit requests, the secondary key server has still not received any ANN message with a valid pseudotime, it starts blocking new group-member registrations, as follows:

```
*Jul 28 23:38:57.859: %GDOI-5-COOP_KS_VALID_ANN_TIMER_EXPIRED: This sec-KS has NOT received
an ANN with valid pseudotime for an extended period in group GET. It will block new group
members registration temporarily until a valid ANN is received
*Jul 29 00:08:47.775: %GDOI-5-COOP_KS_BLOCK_NEW_GM_REGISTER: This key server temporarily
blocks group member with ip-addr 10.0.0.2 from registering in group GET as it has not
received an ANN with valid pseudotime for prolonged period
```

The secondary key server resumes its group member registration functionality if any of the following happens:

- It receives an ANN with a valid pseudotime from the primary key server.
- It becomes a primary key server itself.
- The **clear crypto gdoi group** command is executed on the secondary key server.

ANN Message Pseudotime Handling in the Primary Key Server

The primary key server handles ANN messages as follows:

- It calculates the allowable ANN message pseudotime as the lesser of the configured TBAR window size, that is, the value that was configured for it in the data plane, or 30 seconds.
- It accepts from the secondary key server ANN messages that have a smaller pseudotime but are within the allowable difference.
- It rejects ANN messages that have a smaller pseudotime but exceed the allowable difference.

During a network merge, the following conditions apply:

- The new primary key server always picks the larger pseudotime between the two key servers.
- If the difference is larger than the calculated allowable pseudotime difference, the new primary key server sends out rekeys to all group members to update their pseudotime. It also generates the following syslog messages:

```
*Jul 28 23:42:41.311: %GDOI-5-COOP_KS_ELECTION: KS entering election mode in group GET
(Previous Primary = NONE)
*Jul 28 23:42:41.311: %GDOI-4-GDOI_ANN_TIMESTAMP_LARGE: COOP_KS ANN received from KS 10.0.9.1
in group GET has PST bigger than myself. Adjust to new pseudotime:
my_old_pst is 0 sec, peer_pst is 22772 sec
*Jul 28 23:43:16.335: %GDOI-5-COOP_KS_TRANS_TO_PRI: KS 10.0.8.1 in group GET transitioned
to Primary (Previous Primary = NONE)
*Jul 28 23:43:16.347: %GDOI-5-KS_SEND_UNICAST_REKEY: Sending Unicast Rekey for group GET
from address 10.0.8.1 with seq # 1
```

Cooperative Key Server

The figure below illustrates cooperative key server key distribution. The text following the illustration explains the Cooperative Key Server feature.

Figure 139: Cooperative Key Server Key Distribution

Cooperative key servers provide redundancy to GET VPN. Multiple key servers are supported by GET VPN to ensure redundancy, high availability, and fast recovery if the primary key server fails. Cooperating GDOI key servers jointly manage the GDOI registrations for the group. Each key server is an active key server, handling GDOI registration requests from group members. Because the key servers are cooperating, each key server distributes the same state to the group members that register with it. Load balancing is achieved because each of the GDOI key servers can service a portion of the GDOI registrations.

The primary key server is responsible for creating and distributing group policy. When cooperative key server key distribution occurs, one key server declares itself as primary, creates a policy, and sends the policy to the other secondary key server. The secondary key server declares the primary key server as primary key server when it gets the policy and ends the election mode. The secondary key server now also blocks GM registration while the cooperative key server key distribution is in progress. This change allows the cooperative key server distribution to become more efficient because it saves time. For example, the syslog warning message similar to the following is displayed during distribution:

```
00:00:16: %GDOI-5-COOP_KS_BLOCK_NEW_GM_REGISTER_ELECTION: This KS temporarily blocks GM
with ip-addr 10.0.4.1 from registering in group diffint as the KS election is underway
```

The primary key server periodically sends out (or broadcasts) group information updates to all other key servers to keep those servers in synchronization. If the secondary key servers somehow miss the updates, they contact the primary key server to directly request information updates. The secondary key servers mark the primary key server as unreachable (that is, "dead") if the updates are not received for an extended period.

When a new policy is created on a primary key server, regardless of which key server a group member may be registered with, it is the responsibility of the primary key server to distribute rekey messages to GDOI group members.

In a cooperative-key-server setting, the rekey sequence number is synchronized between the primary and secondary key servers.

In a network merge, the key servers pick the larger of the rekey sequence numbers that they have between them.

If you are supporting more than 300 group members in your cooperative key server setup, you should increase the buffer size by using the **buffers huge size** command.

If the registration interface that is used in the GETVPN Group Configuration on the key server is shutdown, a network split will occur. If the interface is not the forwarding interface, as in the loopback interface which is the recommended configuration, rekeys will still be sent to the GMs from all of the KSs in the group. You cannot turn off the key servers by shutting down the interface. To safely turn off the key servers, use the **no crypto gdoi group group name** command.

The following example shows the registration interface that is referenced in the GETVPN Group Configuration on the key server.

```
crypto gdoi group groupA
identity number 111
server local
  sa ipsec 10
  profile groupA
  match address ipv4 groupA-crypto-policy
  no replay
  no tag
  address ipv4 a.b.c.d
  redundancy
  local priority 250
  peer address ipv4 a.b.c.d
  peer address ipv4 a.b.c.d
```

Announcement Messages

Announcement messages are secured by IKE Phase 1 and are sent as IKE notify messages. Authentication and confidentiality that are provided by IKE is used to secure the messaging between the key servers. Antireplay protection is provided by the sequence numbers in the announcement messages. Announcement messages are periodically sent from primary to secondary key servers.

Announcement messages include the components, described in the following sections that help maintain the current state.

Sender Priority of a Key Server

This value describes the priority of the sender, which is configurable using the CLI. The key server with the highest priority becomes the primary key server. If the priority values are the same, the key server with the highest IP address becomes the primary key server.

Maintaining the Role of the Sender

During the synchronization period, if the key servers are at geographically dispersed locations, they may suffer a network-partitioning event. If a network-partitioning event occurs, more than one key server can become the primary key server for a period of time. When the network is operating normally again and all the key servers find each other, they need to be told the current role of the sender so the key servers can attain their proper roles.

Request for a Return Packet Flag

All messages are defined as one-way messages. When needed, a key server can request the current state from a peer to find out its role or request the current state of the group.

Group Policies

The group policies are the policies that are maintained for a group, such as group member information and IPsec SAs and keys.

Antireplay functionalities and incorporated Cooperative announcement messages are supported. The primary key server updates the pseudotime value, sending it to all secondary key servers in the group. The secondary key servers should synchronize their SAR clocks to this updated value.

ANN Message Sequence Number Check Between Cooperative Key Servers

The following describes the sequence number check between cooperative key servers:

- Cooperative key servers drop any ANN message with a sequence number smaller than or equal to that of the last received ANN message.
- The ANN message is accepted if the sequence number is larger than that of the last received rekey message, no matter how large the difference.
- If a key server is reloaded, a new IKE session is created between the peers, and the reloaded key server's ANN sequence number will start with zero. In this case, the other side will accept the ANN message with any sequence number.

Change Key Server Role

In a network of cooperative key servers, the primary server is elected based on its highest priority at the time of election. The other key servers have secondary status. If the primary key server is detected as being dead or if its role changes, the **clear crypto gdoi ks coop role** command allows you to reset the cooperative role of the primary key server.

If the **clear crypto gdoi ks coop role** command is executed on a secondary key server, the election is triggered on that secondary key server although that server would most likely remain a secondary key server because there has been an elected primary key server. However, if the **clear crypto gdoi ks coop role** command is executed on the primary key server, the primary key server is reassigned to a secondary role, and as a result, a new election that involves all the key servers is triggered. If the previous primary server has the highest priority (of all the key servers), it again becomes the primary server. If the previous primary server does not have the highest priority, the server having the highest priority is elected as the new primary server.

Receive Only SA

For multicast traffic using the GDOI protocol, bidirectional SAs are installed. The Receive Only feature enables an incremental deployment so that only a few sites can be verified before bringing up an entire network. To test the sites, one of the group members should send encrypted traffic to all the other group members and have them decrypt the traffic and forward the traffic “in the clear.” Receive Only SA mode allows encryption in only the inbound direction for a period of time. (See the steps for the Receive Only SA process.) If you configure the **sa receive-only** command on the key server, Steps 2 and 3 happen automatically.

1. Mark IPsec SAs as “receive-only” on the GDOI key server.

This action allows the group members to install SAs in the inbound direction only. Receive-only SAs can be configured under a crypto group. (See the “Configuring the Group ID Server Type and SA Type” section.)

1. Mark GDOI TEK payloads as “receive only.”

If the **sa receive-only** command is configured, all TEKs under this group are going to be marked “receive only” by the key server when they are sent to the group member.

1. Install one-way IPsec flows.

Every time a GDOI group member receives an IPsec SA from the key server that is marked as “receive only,” the group member installs this IPsec SA only in the inbound direction rather than in both incoming and outgoing directions.

1. Test individual group members using the following local-conversion commands:
2. **crypto gdoi gm ipsec direction inbound optional**
3. **crypto gdoi gm ipsec direction both**

First, individually convert each of the group members to passive mode (this change tells the outbound check that there is a valid SA) and then to bidirectional mode.

1. Globally convert from “receive only” to “receive and send.”

The following method can be used when the testing phase is over and “receive only” SAs have to be converted to bidirectional SAs.

Global Conversion

Remove the **sa receive-only** command under the group. Removing the **sa receive-only** command creates new IPsec SAs for this group and causes a rekey. On receipt, group members reinstall the SA in both directions and begin to use it in passive mode. Because the SA cannot remain in passive mode forever, the group members change those SAs to receive or send mode if there is no rekey in 5 minutes. The conversion from passive mode to bidirectional encryption mode is automatic and does not require the administrator to do anything.

Passive SA

The Passive SA feature allows you to configure a group member so that it is in passive mode permanently. By using the Passive SA feature, you will avoid having to use the **crypto gdoi gm ipsec direction inbound optional** privileged EXEC command, which is not persistent after a router reload and can be overridden by key server configuration from a rekey. Having the group member in passive mode benefits network testing and debugging during migration to GET VPN, and it provides complete encryption protection during the migration. The group-member passive-mode configuration has higher priority over a key server configuration. The **crypto gdoi gm ipsec direction inbound optional** privileged EXEC command can override the configuration until the next rekey, which will bring back the group member and key server configuration.

To configure the Passive SA feature, see the “Configuring Passive SA” section.

Enhanced Solutions Manageability

Several **show** and **debug** commands are supported to help verify functionality. See the “Activating Fail-Close Mode” section for details.

Support with VRF-Lite Interfaces

The VRF-Lite application supports segmentation of traffic in the control and forwarding planes by keeping the routing tables separate for each user group (or VPN) and forwarding the traffic on the associated or dedicated interfaces of each user group.

There are some deployment scenarios in which remote sites that are connecting to an MPLS VPN network might be extending segmentation from a campus to the WAN. In such an extended segmentation case, a CE-PE interface on a CE (group member or key server) device “bounds” to its associated virtual routing and forwarding (VRF) instance. This VRF interface connects to an MPLS PE device where it is directly mapped to its associated Border Gateway Protocol (BGP) VRF process, in which case the crypto map is applied to a VRF interface. No other configuration changes are necessary.

Authentication Policy for GM Registration

GMs can authenticate to the key server at registration time using preshared keys or Public Key Infrastructure (PKI). Preshared keys are easy to deploy but must be managed proactively. We recommend that you deploy a peer-based preshared key instead of defining a default key (the key defined with an address of 0.0.0.0) for all the devices in the network. Preshared keys should be updated regularly (every few months).

Note A preshared key can be updated on a key server-group member (KS-GM) peer basis without affecting the crypto data plane or control plane because rekeys are secured using the KEK. It is important to ensure that a GM can re-register to each ordered set of key servers using the newly assigned preshared key.

PKI uses its infrastructure to overcome the key management difficulties encountered when preshared keys are used. The PKI infrastructure acts as a certificate authority (CA) where router certificates are issued and maintained. However, using PKI during IKE authentication is computationally intensive. In PKI deployments, key server capacity, design, and placement become important.

For added security, GET VPN also supports GM authorization using either preshared keys or PKI. For more information, see the “GET VPN Authorization” section.

GET VPN GM Authorization

GET VPN GM authorization can be done using preshared keys or PKI. It is a best practice to turn on GET VPN authorization. When a key server serves multiple GDOI groups, key server authorization is required to prevent a GM in one group from requesting keys and policies from another group. The ISAKMP authorization confirms that the GM is allowed to request GDOI attributes from the key server while the GDOI authorization confirms that the GM is allowed to request GDOI attributes from a specific group configured in the key server.

GDOI authorization is based on the ISAKMP identity sent by a GM. If a GM sends an IP address as an identity, then only an authorization address is used for authorization. If a GM sends a distinguished name (DN) or hostname, then an authorization identity is used. Using an IP address as an identity will bypass authorization matching a DN or hostname and vice versa. To ensure that only GMs with a specific DN can connect (and no GMs using another identity can connect), you must specify **deny any** in the authorization address.

GM Authorization Using Preshared Keys

GET VPN supports GM authorization using the IP address when preshared keys are used. An ACL matching the WAN addresses (or subnets) of the GM can be defined and applied to the GET VPN group configuration. Any GM whose IP addresses match the ACL authorizes successfully and can register to the key server. If a GM IP address does not match the ACL, the key server rejects the GM registration request.

In cases of unsuccessful authorization, the following syslog message is generated:

```
%GDOI-1-UNAUTHORIZED_IPADDR: Group getvpn received registration from
unauthorized ip address: 10.1.1.9
```

GM Authorization Using PKI

GET VPN supports GM authorization using the commonly used DN or fully qualified domain name (FQDN) when PKI is used. The **authorization identity** command is used to activate GM authorization. A crypto identity matching certain fields in the GM certificate (typically—organizational unit [OU]) can be defined and applied to the GET VPN group configuration. Use the **crypto identity** command to define a crypto identity.

Any GM whose certificate credentials match the ISAKMP identity is authorized and can register to the key server. For example, if all GM certificates are issued with OU=GETVPN, a key server can be configured to check (authorize) that all GMs present a certificate having OU=GETVPN. If the OU in the certificate presented by a GM is set to something else, the GM will not be authorized to register to the key server.

If authorization is unsuccessful, the following syslog message is generated:

```
%GDOI-1-UNAUTHORIZED_IDENTITY: Group getvpn received registration from
unauthorized identity: Dist.name: hostname=GroupMember-1, ou=TEST
```

Rekey Functionality in Protocol Independent Multicast-Sparse Mode

Multicast rekeying can be used with all modes of multicast. The **rekey retransmit** command should be used whenever the Protocol Independent Multicast-sparse mode (PIM-SM) is configured because the PIM-SM shortest path tree (SPT) can be torn down if it does not receive continuing traffic. When traffic resumes, PIM-SM must reestablish the SPT. Retransmitting rekey packets increases the chance that group members receive the rekeys when PIM-SM is setting up the SPT.

Fail-Close Mode

Until a group member registers with a key server, traffic passing through the group member is not encrypted. This state is called “fail open.” To prevent unencrypted traffic from passing through a group member before that member is registered, you can configure the Fail-Close feature. If the feature is configured, an implicit “permit ip any any” policy is installed, and all unencrypted traffic passing through the group member is dropped (this state is called fail-close mode).

The fail-close function can also be achieved by configuring an interface ACL. However, the Fail-Close feature is more manageable and is easier to implement than ACL lists.

If you configure the Fail-Close feature, you can still allow specific unencrypted traffic to pass through the group member by configuring the **match address** command (**match address** {*access-list-number* | *access-list-name*}). This explicit “deny” ACL is added before the implicit “permit ip any any” to allow denied (unencrypted) traffic to pass through the group member.

After the group member has successfully completed its registration, the fail-close policy, both explicit and implicit, is removed, and the group member behaves as it did before the Fail-Close feature was configured.

Guidelines for Using the Fail-Close Feature

When you are configuring a crypto map to work in fail-close mode, you must be careful. If the fail-close ACL is defined improperly, you may lock yourself out of the router. For example, if you use Secure Shell (SSH) to log in to the router through the interface with the crypto map applied, you have to include the **deny tcp any eq port host address** command line under the fail-close ACL. You may also need to include the routing protocol that the router is using (such as **deny ospf any any**) to find the path to the key server. It is suggested that you configure fail-close and its ACL first, and then verify the fail-close ACL using the **show crypto map gdoi fail-close map-name** command. After you have checked your fail-close ACL and are confident that it is

correct, you can make the crypto map work in the fail-close mode by configuring the **activate** command. Fail-close is not activated until you have configured the **activate** command.

The fail-close ACL is configured from the group-member perspective. The fail-close ACL is configured on group member as follows:

```
access-list 125 deny ip host host1-ip-addr host2-ip-addr
```

In fail-close mode, all IP traffic from host1 to host2 will be sent out by group member 1 in clear text. In addition, the inbound mirrored traffic (that is, IP traffic from host2 to host1) is also accepted by GM1 in clear text.

Note All IP traffic matching deny entries are sent out by the group member in clear text.

The inbound traffic is matched to the mirrored access list.

The fail-close access list follows the same rules as the group member access list. For more information, see the "Group Member Access Control List" section.

You need not configure the **deny udp any eq 848 any eq 848** command to make the GDOI registration go through. The code itself checks whether it is a GDOI packet for a particular group member from the key server to which it is configured. If it is a GDOI packet for this group member, the packet is processed. But for a scenario in which the key server is behind group member 1, if group member 1 cannot register successfully with the key server, other group members also will not be able to register unless an explicit **deny udp any eq 848 any eq 848** command line is configured for group member 1. However, if the Fail-Close feature is properly configured, even if a group member fails to register with a key server, you will be able to ensure that no unwanted traffic can go out "in the clear." But you can allow specified traffic to go out in the clear, in which case registration packets from other group members will be able to reach the key server through group member 1 even if it fails to get registered.

For information on configuring fail-close mode, see the "Activating Fail-Close Mode" section.

To verify whether fail-close mode is activated, use the **show crypto map gdoi fail-close** command.

Fail-close Revert

In the fail close mode, before registering in the fail close mode, group member applies its local fail close policy and manages the traffic accordingly. After registration, group member applies the policy downloaded from key server and handles traffic accordingly.

When there is no rekey or the group member is not able to re-register to the key server, the group member uses the same downloaded policy from the key server. It leads to packet drop as there is no key for encryption or decryption. Fail-close Revert enables group members to return to the fail close mode and to remove the downloaded key server policy. This happens only if fail-close revert is enabled on the group member.

This fail-close revert triggers when all active SAs expire and all the key servers are not reachable for re-registration. Clearing the IPsec SAs manually by using the command "clear crypto sa" does not provide the intended behavior of the feature. However "clear crypto gdoi" will revert to fail close mode in case of a key server unreachability.

To know about feature configuration steps, see the section, "Configuring Fail Close Revert".

Create MIB Object to Track a Successful GDOI Registration

The routing plane and crypto plane for GET VPN must be synchronized to avoid null routes. A GET VPN null route occurs during the following situations:

- GMs fail to register to a KS that has no active TEKs to encrypt or decrypt traffic.
- GMs TEK SAs have expired but do not receive new keys from KS through rekey or reregistration.
- GMs receive rekeys from KS, but errors occur when installing SAs to a crypto engine.

The Create MIB Object to Track a Successful GDOI Registration feature introduces a new MIB object in the GDOI MIB to indicate the number of active TEKs in a group.

GET VPN Routing Awareness for BGP

The routing plane and crypto plane for GET VPN must synchronize to avoid null routes. When a group member (GM) successfully registers to a key server (KS), no security policies or keys are installed on the GM. However, the GM may still advertise the routes of its protected network to other GMs.

The following diagram explains the creation of a null route.

Figure 140: Null Route Creation

1. Group Member1, Group Member2, Group Member3 boot up and establish a routing adjacency with the WAN.
2. Group Member1 and Group Member2 advertises the prefix for Network A into the WAN. The preferred path for traffic from Network B to Network A is through Group Member1.
3. Group Member3 advertises Network B into the WAN. The preferred path for traffic Network A to Network B is through Group Member1
4. KS defines the security to protect all traffic between Network A and Network B
5. Group Member1 and Group Member3 (as well as Group Member2) successfully obtain security keys from KS and protect all traffic between Network A <-> Network B.
6. Group Member1 fails to receive updated keys or policy and fails to reregister to a KS while Group Member2 and Group Member3 successfully obtain keys.
7. Routing protocols continue to prefer the path through Group Member1 for all Network A between Network B traffic.
8. Group Member1 drops all traffic flowing between Network A and Network B because the policy/keys are invalid.

When the host in Network B sends traffic to a host in Network A, the traffic will be encrypted by Group Member3 and sent to Network A via Group Member1 (the preferred path). However, Group Member1 will drop the packet because it has no policy or current keys to decrypt traffic. As a result, the traffic is dropped and a null route is created. Likewise, when a host in Network A sends traffic to a host in Network B, the traffic will be directed to Group Member1 (the preferred path) and dropped due to lack of policy or current keys in Group Member1. The appropriate behavior is for the traffic to be diverted and rerouted via Group Member2 while Group Member1 has no policy or keys.

The GET VPN Routing Awareness for BGP feature prevents routing absence by tracking the GETVPN GM crypto state and by applying the tracking information to perform bidirectional conditional route filtering on the GM.

Bidirectional Conditional Route Filtering

The bidirectional conditional route filtering supports different routing protocols, such as BGP, OSPF, EIGRP, RIPv2, etc. The EOT tracks the GET VPN GM crypto status and conditionally enables or disables specific route-map entries based on the EOT value. The following is a sample configuration to monitor the GET VPN GM crypto state.

```

route-map bgp-policy-out permit 10
  match ip address register-int-Only
route-map bgp-policy-out permit 20
  match track 99
  match ip address orig_route_map_acl_out
route-map bgp-policy-out deny 30

route-map bgp-policy-in permit 10
  match ip address noc
route-map bgp-policy-in permit 20
  match track 99
  match ip address orig_route_map_acl_in
route-map bgp-policy-in deny 30

ip access-list standard noc
  permit 1.1.1.0 <---- NOC subnet with Keyserver (KS)
ip access-list standard register-int-Only
  permit 2.2.2.2 <---- registration interface ip of the
GM itself
ip access-list standard orig_route_map_acl_in <---- original inbound route-map ACL
  permit a.b.c.d
  permit .....
ip access-list standard orig_route_map_acl_out <---- original outbound route-map ACL
  permit e.f.g.h
  permit .....

router bgp 64600
  no synchronization
  bgp router-id xxxxxxxx
  bgp log-neighbor-changes
  network xxxxxxxxxx mask 255.255.255.255
  network xxxxxxxxxx mask 255.255.255.252
  neighbor xxxxxxxxxx remote-as 65000
  neighbor xxxxxxxxxx description PE
  neighbor xxxxxxxxxx route-map bgp-policy-in in
  neighbor xxxxxxxxxx route-map bgp-policy-out out

```

In the above example, the **match track 99** command is specified to monitor the GET VPN GM crypto state. If GM works properly, the **match track 99** command returns a value *true* and the GM advertises or receives the following routes:

- Outbound—The routes to reach the GM registration interface and the routes permitted by inbound route map access control list (ACL) “orig_route_map_acl_out.”
- Inbound—The routes to reach the NOC and the routes permitted by outbound route map ACL “orig_route_map_acl_in” received from peers.

On the other hand, if GM does not work properly, the **match track 99** command returns a value *false* and the GM advertises or receives the following routes only:

- Outbound—The routes to reach the GM registration interface.
- Inbound—The routes to reach the NOC subnet.

Cisco Group Encrypted Transport VPN System Logging Messages

The table below lists GET VPN system logging (also called syslog) messages and explanations.

Table 313: GET VPN System Logging Messages

Message	Explanation
COOP_CONFIG_MISMATCH	The configuration between the primary KS and secondary KS are mismatched.
COOP_KS_ADD	A KS has been added to the list of cooperative KSs in a group.
COOP_KS_ELECTION	The local KS has entered the election process in a group.
COOP_KS_REACH	The reachability between the configured cooperative KSs is restored.
COOP_KS_REMOVE	A KS has been removed from the list of cooperative KSs in a group.
COOP_KS_TRANS_TO_PRI	The local KS transitioned to a primary role from being a secondary server in a group.
COOP_KS_UNAUTH	An unauthorized remote server tried to contact the local KS in a group. Could be considered a hostile event.
COOP_KS_UNREACH	The reachability between the configured cooperative KSs is lost. Could be considered a hostile event.
COOP_KS_VER_MISMATCH	KSs are running different versions of the Cisco IOS code.
COOP_PACKET_DROPPED	A hard limit set on the driver buffer size prevents the sending of packets this size or larger.
GDOI-3-GDOI_REKEY_SEQ_FAILURE	The rekey message is rejected because the sequence number antireplay check failed.

Message	Explanation
GDOI-3-GM_NO_CRYPTTO_ENGINE	No crypto engine is found due to a lack of resources or an unsupported feature requested.
GDOI-3-PSEUDO_TIME_LARGE	The rekey has a larger pseudotime that exceeds the calculated allowable pseudotime difference.
GDOI-3-PSEUDO_TIME_TOO_OLD	The rekey has a smaller pseudotime that exceeds the calculated allowable pseudotime difference.
GDOI-4-GDOI_ANN_TIMESTAMP_LARGE	The secondary KS receives from the primary KS an ANN that has a larger pseudotime that exceeds the calculated allowable pseudotime difference.
GDOI-4-GDOI_ANN_TIMESTAMP_TOO_OLD	The secondary KS receives from the primary KS an ANN that has a smaller pseudotime that exceeds the calculated allowable pseudotime difference.
GDOI-5-COOP_KS_BLOCK_NEW_GM_REGISTER	The secondary KS temporarily blocks a GM from registering in a group because it has not received a valid pseudotime from the primary KS.
GDOI-5-COOP_KS_VALID_ANN_TIMER_EXPIRED	The secondary KS keeps receiving ANNs with invalid pseudotimes after three retransmits. The secondary KS temporarily blocks new group-member registration until a valid ANN is received.
GDOI_ACL_NUM	The ACL has too many entries. GDOI will honor only the first 100 ACL entries specified.
GDOI_REKEY_FAILURE	During GDOI rekey the payload parsing failed on this GM from the KS.
GM_ACL_MERGE	The ACL differences between a GM and KS are resolved and a merge took place.
GM_ACL_PERMIT	The GM can support only an ACL for “deny.” Any traffic matching the “permit” entry will be dropped.
GM_CLEAR_REGISTER	The clear crypto gdoi command has been executed by the local GM.
GM_CM_ATTACH	A crypto map has been attached for the local GM.
GM_CM_DETACH	A crypto map has been detached for the local GM.
GM_CONV_SA_DUPLEX	IPsec SAs have been converted to bidirectional mode in a group on a GM.
GM_CONV_SA_DUPLEX_LOCAL	IPsec SAs have been converted to bidirectional mode in a group on a GM by a CLI command.
GM_DELETE	A GM has been deleted in a group from a KS.

Message	Explanation
GM_ENABLE_GDOI_CM	A GM has enabled ACL on a GDOI crypto map in a group with a KS.
GM_HASH_FAIL	During GDOI registration protocol, a message sent by the KS has bad or no hash.
GM_INCOMPLETE_CFG	Registration cannot be completed because the GDOI group configuration may be missing the group ID, server ID, or both.
GM_NO_IPSEC_FLOWS	The hardware limitation for IPsec flow limit reached. Cannot create any more IPsec SAs.
GM_RE_REGISTER	The IPsec SA created for one group may have been expired or cleared. Need to re-register to the KS.
GM_RECV_DELETE	A message sent by the KS to delete the GM has been received.
GM_RECV_REKEY	Rekey received.
GM_REGS_COMPL	Registration complete.
GM_REJECTING_SA_PAYLOAD	During GDOI registration protocol, a proposal sent by the KS was refused by the local GM.
GM_REKEY_NOT_REC'D	A GM has not received a rekey message from a KS in a group. Currently unimplemented.
GM_REKEY_TRANS_2_MULTI	A GM has transitioned from using a unicast rekey mechanism to using a multicast mechanism.
GM_REKEY_TRANS_2_UNI	A GM has transitioned from using a multicast rekey mechanism to using a unicast mechanism.
GM_SA_INGRESS	A received-only ACL has been received by a GM from a KS in a group.
GM_UNREGISTER	A GM has left the group.
KS_BAD_ID	A configuration mismatch exists between a local KS and a GM during GDOI registration protocol.
KS_BLACKHOLE_ACK	A KS has reached a condition of null route messages from a GM. Could be considered a hostile event.
KS_CLEAR_REGISTER	The clear crypto gdoi command has been executed by the local KS.
KS_CONV_SAS_DUPLEX	IPsec SAs have been converted to bidirectional mode in a group.

Message	Explanation
KS_CONV_SAS_INGRESS	IPsec SAs have been converted to receive-only mode in a group.
KS_FIRST_GM, GDOI, LOG_INFO	A local KS has received the first GM joining the group.
KS_GM_REJECTS_SA_PAYLOAD	During GDOI registration protocol, a proposal sent by the KS was refused by the GM.
KS_GM_REVOKED	During rekey protocol, an unauthorized member tried to join a group. Could be considered a hostile event.
KS_GROUP_ADD	A configuration command has been executed to add a KS in a group.
KS_GROUP_DELETE	A configuration command has been executed to remove a KS from a group.
KS_HASH_FAIL	During GDOI registration protocol, a message sent by the GM has a bad or no hash.
KS_LAST_GM	The last GM has left the group on the local KS.
KS_NACK_GM_EJECT	The KS has reached a condition of not receiving an ACK message from a GM and has been ejected.
KS_NO_RSA_KEYS	RSA keys were not created or they are missing.
KS_REGS_COMPL	The KS has successfully completed a registration in a group.
KS_REKEY_TRANS_2_MULTI	The group has transitioned from using a unicast rekey mechanism to a multicast mechanism.
KS_REKEY_TRANS_2_UNI	The group has transitioned from using a multicast rekey mechanism to using a unicast mechanism.
KS_SEND_MCAST_REKEY	Sending multicast rekey.
KS_SEND_UNICAST_REKEY	Sending unicast rekey.
KS_UNAUTHORIZED	During GDOI registration protocol, an unauthorized member tried to join a group. Could be considered a hostile event.
KS_UNSol_ACK	The KS has received an unsolicited ACK message from a past GM or is under a DOS attack. Could be considered a hostile event.
PSEUDO_TIME_LARGE	A GM has received a pseudotime with a value that is largely different from its own pseudotime.

Message	Explanation
REPLAY_FAILED	A GM or KS has failed an antireplay check.
UNAUTHORIZED_IDENTITY	The registration request was dropped because the requesting device was not authorized to join the group.
UNAUTHORIZED_IPADDR	The registration request was dropped because the requesting device was not authorized to join the group.
UNEXPECTED_SIGKEY	An unexpected signature key was found that frees the signature key.
UNREGISTERED_INTERFACE	Receiving registration from unregistered interface. Stop processing it.
UNSUPPORTED_TEK_PROTO	Unexpected TEK protocol.

How to Configure Cisco Group Encrypted Transport VPN

Configuring a Key Server

Prerequisites

Before creating the GDOI group, you must first configure IKE and the IPsec transform set, and you must create an IPsec profile. For information about how to configure IKE and the IPsec transform set and to create an IPsec profile, see the “Related Documents” subsection of the “Additional References” section.

Configuring RSA Keys to Sign Rekey Messages

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

To configure RSA keys that will be used to sign rekey messages, perform the following steps. Omit this subtask if rekey is not in use.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto key generate rsa general-keys label *name-of-key***

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto key generate rsa general-keys label name-of-key Example: <pre>Router(config)# crypto key generate rsa general-keys label mykeys</pre>	Generates RSA keys that will be used to sign rekey messages. You are prompted to confirm the length (in bits) of the keys to be generated. Length of less than 2048 is not recommended.

What to Do Next

Configure the group ID, server type, and SA type. (See the “Configuring the Group ID Server Type and SA Type” section.)

Configuring the Group ID Server Type and SA Type

For a large number of sites, it is better to take precautions and add functionality incrementally, especially when migrating from any other encryption solutions like Dual Multipoint VPN (DMVPN). For example, instead of setting up all the CPE devices to encrypt the traffic bidirectionally, it is possible to configure one-way encryption so that only one or fewer members of a group are allowed to send encrypted traffic. Others are allowed to receive only encrypted traffic. After the one-way encryption is validated for one or a few members, bidirectional encryption can be turned on for all the members. This “inbound only” traffic can be controlled using the **sa receive only** command under a crypto group.

To configure the group ID, server type, and SA type, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group group-name**
4. Enter one of the following commands:
 - **identity number number**
 - **identity address ipv4 address**
5. **server local**
6. **sa receive-only**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: <pre>Router(config)# crypto gdoi group gdoigroupname</pre>	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	Enter one of the following commands: <ul style="list-style-type: none"> • identity number <i>number</i> • identity address ipv4 <i>address</i> Example: <pre>Router(config-gdoi-group)# identity number 3333</pre> Example: <pre>Router(config-gdoi-group)# identity address ipv4 209.165.200.225</pre>	Identifies a GDOI group number or address.
Step 5	server local Example: <pre>Router(config-gdoi-group)# server local</pre>	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 6	sa receive-only Example: <pre>Router(config-local-server)# sa receive-only</pre>	Specifies that an IPsec SA is to be installed by a group member as “inbound only.”

What to Do Next

Remove the receive-only configuration on the key server so that the group members are now operating in bidirectional receive and send mode.

Configuring the Rekey

This section includes the following optional tasks:

Rekey is used in the control plane by the key server to periodically refresh the policy and IPsec SAs of the group. On the group-member side, instead of fully re-registering when timers expire for any other reasons, refreshing the registration with a rekey is more efficient. The initial registration is always a unicast registration.

The key server can be configured to send rekeys in unicast or multicast mode. The rekey transport mode is determined by whether the key server can use IP multicast to distribute the rekeys. If multicast capability is not present within the network of the customer, the key server will have to be configured to send rekeys using unicast messages.

Additional options for rekey use the **rekey authentication**, **rekey retransmit**, and **rekey address ipv4** commands. If unicast transport mode is configured, the **source address** command will have to be included to specify the source address of this unicast rekey message.

Multicast is the default transport type for rekey messages. The following bulleted items explain when to use rekey transport type multicast or unicast:

- If all members in a group are multicast capable, do not configure the **rekey transport unicast** command. The **no rekey transport unicast** command is not needed if the rekey transport type “unicast” was not configured previously under this group because multicast rekeys are on by default.
- If all members in a group are unicast, use the **rekey transport unicast** command.
- If you have mixed members in a group (that is, the majority are multicast, but a few are unicast), do not configure the **rekey transport unicast** command. The rekeys will be distributed using multicast to the majority of group members. The remainder of the group members that do not receive the multicast messages (unicast group members) will have to re-register to the key server when their policies expire. Mixed mode (that is, unicast and multicast rekey mode) is not supported.

If the **no rekey transport unicast** command is used, members in the GDOI group that are unable to receive the multicast rekey messages need to re-register with the key server to get the latest group policies. The re-registration forces the default transport type to multicast. If no transport type was configured previously, the multicast transport type will apply by default.

Prerequisites

Before configuring the **rekey authentication** command, you must have configured the router to have an RSA key generated using the **crypto key generate rsa** command and **general-keys** and **label** keywords (for example, “crypto key generate rsa general-key label my keys”).

Configuring a Unicast Rekey

In the configuration task table, the address “ipv4 10.0.5.2” specifies the interface on the key server by which the unicast or multicast rekey messages are sent. This address is required for unicast rekeys, but it is optional for multicast rekeys. For multicast rekeys, the source address of the key server can be retrieved from the rekey ACL.

To configure a unicast rekey, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. Enter one of the following commands:
 - **identity number** *number*

- **identity address ipv4** *address*
5. **server local**
 6. **rekey transport unicast**
 7. **rekey lifetime seconds** *number-of-seconds*
 8. **rekey retransmit** *number-of-seconds* **number** *number-of-retransmissions*
 9. **rekey authentication mypubkey rsa** *key-name*
 10. **address ipv4** *ipv4-address*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: <pre>Router(config)# crypto gdoi group gdoigroupname</pre>	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	Enter one of the following commands: <ul style="list-style-type: none"> • identity number <i>number</i> • identity address ipv4 <i>address</i> Example: <pre>Router(config-gdoi-group)# identity number 3333</pre> Example: <pre>Router(config-gdoi-group)# identity address ipv4 209.165.200.225</pre>	Identifies a GDOI group number or address.
Step 5	server local Example: <pre>Router(config-gdoi-group)# server local</pre>	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 6	rekey transport unicast Example: <pre>Router(config-local-server)# rekey transport unicast</pre>	Configures unicast delivery of rekey messages to group members.

	Command or Action	Purpose
Step 7	rekey lifetime <i>seconds number-of-seconds</i> Example: <pre>Router(gdoi-local-server)# rekey lifetime seconds 300</pre>	(Optional) Limits the number of seconds that any one encryption key should be used. <ul style="list-style-type: none"> • If this command is not configured, the default value of 86,400 seconds takes effect.
Step 8	rekey retransmit <i>number-of-seconds number number-of-retransmissions</i> Example: <pre>Router(gdoi-local-server)# rekey retransmit 10 number 3</pre>	(Optional) Specifies the number of times the rekey message is retransmitted. <ul style="list-style-type: none"> • If this command is not configured, there will be no retransmits.
Step 9	rekey authentication mypubkey rsa <i>key-name</i> Example: <pre>Router(gdoi-local-server)# rekey authentication mypubkey rsa mykeys</pre>	(Optional) Specifies the keys to be used for a rekey to GDOI group members. <ul style="list-style-type: none"> • This command is optional if rekeys are not required. If rekeys are required, this command is required.
Step 10	address ipv4 <i>ipv4-address</i> Example: <pre>Router(gdoi-local-server)# address ipv4 209.165.200.225</pre>	(Optional) Specifies the source information of the unicast rekey message. <ul style="list-style-type: none"> • If rekeys are not required, this command is optional. If rekeys are required, this command is required.

Configuring a Multicast Rekey

To configure a multicast rekey, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. Enter one of the following commands:
 - **identity number** *number*
 - **identity address ipv4** *address*
5. **server local**
6. **rekey address ipv4** *{access-list-name | access-list-number}*
7. **rekey lifetime** *seconds number-of-seconds*
8. **rekey retransmit** *number-of-seconds number number-of-retransmissions*
9. **rekey authentication** *{mypubkey | pubkey} rsa key-name*
10. **exit**
11. **exit**
12. **access-list** *access-list-number {deny | permit} udp host source [operator[port]] host source [operator[port]]*

13. `interface type slot/port`
14. `ip igmp join-group group-address [source source-address]`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group group-name Example: Router(config)# crypto gdoi group gdoigroupname	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	Enter one of the following commands: <ul style="list-style-type: none"> • identity number number • identity address ipv4 address Example: Router(config-gdoi-group)# identity number 3333 Example: Router(config-gdoi-group)# identity address ipv4 209.165.200.225	Identifies a GDOI group number or address.
Step 5	server local Example: Router(config-gdoi-group)# server local	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 6	rekey address ipv4 {access-list-name access-list-number} Example: Router(gdoi-local-server)# rekey address ipv4 121	Defines to which multicast subaddress range group members will register.
Step 7	rekey lifetime seconds number-of-seconds Example: Router(gdoi-local-server)# rekey lifetime seconds 300	(Optional) Limits the number of seconds that any one encryption key should be used. <ul style="list-style-type: none"> • If this command is not configured, the default value of 86,400 seconds takes effect.

	Command or Action	Purpose
Step 8	<p>rekey retransmit <i>number-of-seconds</i> number <i>number-of-retransmissions</i></p> <p>Example:</p> <pre>Router(gdoi-local-server)# rekey retransmit 10 number 3</pre>	<p>(Optional) Specifies the number of times the rekey message is retransmitted.</p> <ul style="list-style-type: none"> If this command is not configured, there will be no retransmits.
Step 9	<p>rekey authentication {mypubkey pubkey} rsa <i>key-name</i></p> <p>Example:</p> <pre>Router(gdoi-local-server)# rekey authentication mypubkey rsa mykeys</pre>	<p>(Optional) Specifies the keys to be used for a rekey to GDOI group members.</p> <ul style="list-style-type: none"> This command is optional if rekeys are not required. If rekeys are required, this command is required.
Step 10	<p>exit</p> <p>Example:</p> <pre>Router(gdoi-local-server)# exit</pre>	Exits GDOI server local configuration mode.
Step 11	<p>exit</p> <p>Example:</p> <pre>Router(config-gdoi-group)# exit</pre>	Exits GDOI group configuration mode.
Step 12	<p>access-list <i>access-list-number</i> {deny permit} udp host <i>source [operator[port]] host source [operator[port]]</i></p> <p>Example:</p> <pre>Router(config)# access-list 121 permit udp host 10.0.5.2 eq 848 host 239.0.1.2 eq 848</pre>	Defines an extended IP access list.
Step 13	<p>interface <i>type slot/ port</i></p> <p>Example:</p> <pre>Router(config)# interface gigabitethernet 0/0</pre>	Configures an interface type and enters interface configuration mode.
Step 14	<p>ip igmp join-group <i>group-address</i> [source <i>source-address</i>]</p> <p>Example:</p> <pre>Router(config-if)# ip igmp join-group 232.2.2.2 source 10.1.1.1</pre>	<p>Configures an interface on the router to join the specified group or channel.</p> <p>Note Use this command to manually join the stream when the key server is not reachable via the same interface as the one configured with the crypto map.</p>

Configuring Group Member ACLs

All IP traffic matching deny entries are sent out by the group member in clear text. The inbound traffic is matched to the mirrored access list.

Note The recommended method to add or delete an entry in the Group Member ACL is to first create a copy of the existing Group Member ACL with a different name and then add or delete the entry in this new ACL, after which, you should replace the existing group member ACL under the GDOI crypto map with the newly created Group Member ACL. If you do not follow this recommended method, it might lead to an unexpected behavior.

To configure group member ACLs, perform this task (note that a group member access list can contain only deny statements).

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **access-list** *access-list-number* **deny ip host** *source* **host** *source*
4. **access-list** *access-list-number* **permit ip** *source*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	access-list <i>access-list-number</i> deny ip host <i>source</i> host <i>source</i> Example: Router(config)# access-list 101 deny ip host 10.0.0.1 host 10.0.0.2	Defines a denied IP access list.
Step 4	access-list <i>access-list-number</i> permit ip <i>source</i> Example: Router(config)# access-list 103 permit ip 209.165.200.225 0.255.255.255 10.20.0.0 0.255.255.255	Defines an allowed IP access list.

What to Do Next

The access list defined in Step 4 is the same one that should be used to configure the SA. See the “Configuring the IPsec SA” section.

Configuring an IPsec Lifetime Timer

To configure an IPsec lifetime timer for a profile, perform the following steps. If this configuration task is not performed, the default is the maximum IPsec SA lifetime of 3600 seconds. The TEK lifetime value should be more than 900 seconds.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec profile** *name*
4. **set security-association lifetime** **seconds** *seconds*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto ipsec profile <i>name</i> Example: Router(config)# crypto ipsec profile profile1	Defines the IPsec parameters that are to be used for IPsec encryption between two IPsec routers and enters crypto ipsec profile configuration mode.
Step 4	set security-association lifetime seconds <i>seconds</i> Example: Router(ipsec-profile)# set security-association lifetime seconds 2700	Overrides (for a particular crypto map entry) the global lifetime value, which is used when negotiating IPsec SAs.

What to Do Next

Configure the IPsec SA. See the “Configuring IPsec SA” section.

Configuring an ISAKMP Lifetime Timer

To configure an ISAKMP lifetime timer, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp policy** *priority*

4. `lifetime seconds`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <code>Router> enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: <code>Router# configure terminal</code>	Enters global configuration mode.
Step 3	crypto isakmp policy <i>priority</i> Example: <code>Router(config)# crypto isakmp policy 1</code>	Defines an IKE policy and enters ISAKMP policy configuration mode.
Step 4	lifetime <i>seconds</i> Example: <code>Router(config-isakmp-policy)# lifetime 86400</code>	Specifies the lifetime of an IKE SA.

Configuring the IPsec SA

If time-based antireplay is configured on the key server but the group member is not capable of supporting it, the GDOI-3-GM_NO_CRYPTENGINE syslog message is logged to the group member. See the “Cisco Group Encrypted Transport VPN System Logging Messages” section for a list of system error messages.

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

To configure the IPsec SA, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto ipsec transform-set transform-set-name transform [transform2...transform4]`
4. `crypto ipsec profile ipsec-profile-name`
5. `set transform-set transform-set-name`
6. `exit`
7. `crypto gdoi group group-name`
8. Enter one of the following commands:

- **identity number** *number*
 - **identity address ipv4** *address*
9. **server local**
 10. **sa ipsec** *sequence-number*
 11. **profile** *ipsec-profile-name*
 12. **match address ipv4** {*access-list-number* | *access-list-name*}
 13. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto ipsec transform-set <i>transform-set-name</i> <i>transform</i> [<i>transform2...transform4</i>] Example: <pre>Router(config)# crypto ipsec transform-set gdoi-trans esp-aes esp-sha-hmac</pre>	Defines a transform set--an acceptable combination of security protocols and algorithms.
Step 4	crypto ipsec profile <i>ipsec-profile-name</i> Example: <pre>Router(config)# crypto ipsec profile profile1</pre>	Defines an IPsec profile and enters crypto ipsec profile configuration mode.
Step 5	set transform-set <i>transform-set-name</i> Example: <pre>Router(ipsec-profile)# set transform-set transformset1</pre>	Specifies which transform sets can be used with the crypto map entry.
Step 6	exit Example: <pre>Router(ipsec-profile)# exit</pre>	Exits IPsec profile configuration mode.
Step 7	crypto gdoi group <i>group-name</i> Example: <pre>Router(config)# crypto gdoi group gdoigroupname</pre>	Identifies a GDOI group and enters GDOI group configuration mode.

	Command or Action	Purpose
Step 8	Enter one of the following commands: <ul style="list-style-type: none"> • identity number <i>number</i> • identity address ipv4 <i>address</i> Example: <pre>Router(config-gdoi-group)# identity number 3333</pre> Example: <pre>Router(config-gdoi-group)# identity address ipv4 209.165.200.225</pre>	Identifies a GDOI group number or address.
Step 9	server local Example: <pre>Router(config-gdoi-group)# server local</pre>	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 10	sa ipsec <i>sequence-number</i> Example: <pre>Router(gdoi-local-server)# sa ipsec 1</pre>	Specifies the IPsec SA policy information to be used for a GDOI group and enters GDOI SA IPsec configuration mode.
Step 11	profile <i>ipsec-profile-name</i> Example: <pre>Router(gdoi-sa-ipsec)# profile gdoi-p</pre>	Defines the IPsec SA policy for a GDOI group.
Step 12	match address ipv4 { <i>access-list-number</i> <i>access-list-name</i> } Example: <pre>Router(gdoi-sa-ipsec)# match address ipv4 102</pre>	Specifies an IP extended access list for a GDOI registration.
Step 13	end Example: <pre>Router(gdoi-sa-ipsec)# end</pre>	Exits GDOI SA IPsec configuration mode and returns to privileged EXEC mode.

What to Do Next

Replay should be configured. If replay is not configured, the default is counter mode.

Configuring Time-Based Antireplay for a GDOI Group

To configure time-based antireplay for a GDOI group, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. **identity number** *policy-name*
5. **server local**
6. **address** *ip-address*
7. **sa ipsec** *sequence-number*
8. **profile** *ipsec-profile-name*
9. **match address** {**ipv4** *access-list-number* | *access-list-name*}
10. **replay counter window-size** *seconds*
11. **replay time window-size** *seconds*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Router(config)# crypto gdoi group gdoigroup1	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	identity number <i>policy-name</i> Example: Router(config-gdoi-group)# identity number 1234	Identifies a GDOI group number.
Step 5	server local Example: Router(config-gdoi-group)# server local	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 6	address <i>ip-address</i> Example: Router(config-server-local)# address 209.165.200.225	Sets the source address, which is used as the source for packets originated by the local key server.

	Command or Action	Purpose
Step 7	sa ipsec <i>sequence-number</i> Example: <pre>Router(config-server-local)# sa ipsec 1</pre>	Specifies the IPsec SA and enters GDOI SA IPsec configuration mode.
Step 8	profile <i>ipsec-profile-name</i> Example: <pre>Router(gdoi-sa-ipsec)# profile test1</pre>	Defines the IPsec SA policy for a GDOI group.
Step 9	match address { ipv4 <i>access-list-number</i> <i>access-list-name</i> } Example: <pre>Router(gdoi-sa-ipsec)# match address ipv4 101</pre>	Specifies an IP extended access list for a GDOI registration.
Step 10	replay counter window-size <i>seconds</i> Example: <pre>Router(gdoi-sa-ipsec)# replay counter window-size 512</pre>	Turns on counter-based antireplay protection for traffic defined inside an access list using GDOI if there are only two group members in a group. Note The behavior caused by this command and that caused by the replay time window-size command are mutually exclusive. You can configure either one without configuring the other.
Step 11	replay time window-size <i>seconds</i> Example: <pre>Router(gdoi-sa-ipsec)# replay time window-size 1</pre>	Sets the window size for antireplay protection using GDOI if there are more than two group members in a group. Note The behavior caused by this command and that caused by the replay counter window-size command are mutually exclusive. You can configure either one without configuring the other.

Configuring Passive SA

To configure passive SA (to put the group member in passive mode), perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. **identity** *name*
5. **passive**
6. **server address ipv4** {*address* | *hostname*}

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Router(config)# crypto gdoi group group1	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	identity <i>name</i> Example: Router(config-gdoi-group)# identity 2345	Sets the identity to the crypto map.
Step 5	passive Example: Router(config-gdoi-group)# passive	Puts the group member into passive mode.
Step 6	server address ipv4 { <i>address</i> <i>hostname</i> } Example: Router(config-gdoi-group)# server address ipv4 209.165.200.225	Specifies the address of the server that a GDOI group is trying to reach.

Resetting the Role of the Key Server

To reset the cooperative role of the primary key server, perform the following steps.

SUMMARY STEPS

1. enable
2. clear crypto gdoi ks coop role

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
	Router> enable	
Step 2	clear crypto gdoi ks coop role Example: Router# clear crypto gdoi ks coop role	Resets the cooperative role of the key server.

Configuring a Group Member

To configure a group member, perform the following subtasks:

Configuring the Group Name ID Key Server IP Address and Group Member Registration

To configure the group name, ID, key server IP address, and group member registration, perform the following steps. You can configure up to eight key server addresses.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. Do one of the following:
 - **identity number** *number*
 - **identity address ipv4** *address*
5. **server address ipv4** *address*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Router(config)# crypto gdoi group gdoigroupone	Identifies a GDOI group and enters GDOI group configuration mode.

	Command or Action	Purpose
Step 4	Do one of the following: <ul style="list-style-type: none"> • identity number <i>number</i> • identity address ipv4 <i>address</i> Example: <pre>Router(config-gdoi-group)# identity number 3333</pre> Example: <pre>Router(config-gdoi-group)# identity address ipv4 209.165.200.225</pre>	Identifies a GDOI group number or address.
Step 5	server address ipv4 <i>address</i> Example: <pre>Router(config-gdoi-group)# server address ipv4 209.165.200.225</pre>	Specifies the address of the server a GDOI group is trying to reach. <ul style="list-style-type: none"> • To disable the address, use the no form of the command.

What to Do Next

Configure a crypto map. See the “Creating a Crypto Map Entry” section.

Creating a Crypto Map Entry

To create a crypto map entry and associate a GDOI group to it, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name seq-num* **gdoi**
4. **set group** *group-name*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.

What to Do Next

	Command or Action	Purpose
Step 3	crypto map <i>map-name seq-num gdoi</i> Example: Router(config)# crypto map mymap 10 gdoi	Enters crypto map configuration mode and creates or modifies a crypto map entry.
Step 4	set group <i>group-name</i> Example: Router(config-crypto-map)# set group group1	Associates the GDOI group to the crypto map.

What to Do Next

Apply the crypto map to an interface to which the traffic has to be encrypted. See the “Applying the Crypto Map to an Interface to Which the Traffic Must Be Encrypted” section.

Applying the Crypto Map to an Interface to Which the Traffic Must Be Encrypted

To apply the crypto map to an interface to which the traffic must be encrypted, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **interface** *type slot / port*
4. **crypto map** *map-name redundancy standby-group-name stateful*

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	interface <i>type slot / port</i> Example: Router(config)# interface gigabitethernet 0/0	Configures an interface type and enters interface configuration mode.
Step 4	crypto map <i>map-name redundancy standby-group-name stateful</i> Example:	Applies the crypto map to the interface.

	Command or Action	Purpose
	Router(config-if)# crypto map map1	

Activating Fail-Close Mode

Fail-close mode prevents unencrypted traffic from passing through a group member before that member is registered with a key server.

To configure a crypto map to work in fail-close mode, perform the following steps:

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto map** *map-name* **gdoi fail-close**
4. **match address** {*access-list-number* | *access-list-name*}
5. **activate**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto map <i>map-name</i> gdoi fail-close Example: Router(config)# crypto map map1 gdoi fail-close	Specifies that the crypto map is to work in fail-close mode and enters crypto map fail-close configuration mode.
Step 4	match address { <i>access-list-number</i> <i>access-list-name</i> } Example: Router(crypto-map-fail-close)# match address 133	(Optional) Specifies an ACL for a GDOI registration.
Step 5	activate Example: Router(crypto-map-fail-close)# activate	Activates fail-close mode.

Configure Fail Close Revert

Note Activating fail close mode is mandatory for the Fail Close Revert feature.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. Enter one of the following commands:
 - **identity number** *number*
 - **identity address ipv4** *address*
5. **server address ipv4** *address*
6. **client fail-close revert**
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Router(config)# crypto gdoi group gdoigroupone	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	Enter one of the following commands: <ul style="list-style-type: none"> • identity number <i>number</i> • identity address ipv4 <i>address</i> Example: Router(config-gdoi-group)# identity number 3333 Example: Router(config-gdoi-group)# identity address ipv4 10.2.2.2	Identifies a GDOI group number or address.

	Command or Action	Purpose
Step 5	server address ipv4 <i>address</i> Example: <pre>Router(config-gdoi-group)# server address ipv4 10.0.5.2</pre>	Specifies the address of the server a GDOI group is trying to reach. <ul style="list-style-type: none"> To disable the address, use the no form of the command.
Step 6	client fail-close revert Example: <pre>Router(config-gdoi-group)# client fail-close revert</pre>	Enables the client fail close revert feature
Step 7	end Example: <pre>Router(config-gdoi-group)# end</pre>	Exits GDOI group configuration mode and returns to privileged EXEC mode.

Configuring Acceptable Ciphers or Hash Algorithms for KEK

Note Security threats, as well as the cryptographic technologies to help protect against them, are constantly changing. For more information about the latest Cisco cryptographic recommendations, see the [Next Generation Encryption \(NGE\)](#) white paper.

To configure the ciphers and hash algorithms for KEK to be allowed by the GM, perform the following steps.

SUMMARY STEPS

- enable**
- configure terminal**
- crypto gdoi group** *group-name*
- Enter one of the following commands:
 - identity number** *number*
 - identity address ipv4** *address*
- server address ipv4** *address*
- client rekey encryption** *cipher* [... [*cipher*]]
- client rekey hash** *hash*
- end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.

	Command or Action	Purpose
	Router> enable	
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Router(config)# crypto gdoi group gdoigroupone	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	Enter one of the following commands: <ul style="list-style-type: none"> • identity number <i>number</i> • identity address ipv4 <i>address</i> Example: Router(config-gdoi-group)# identity number 3333 Example: Router(config-gdoi-group)# identity address ipv4 10.2.2.2	Identifies a GDOI group number or address.
Step 5	server address ipv4 <i>address</i> Example: Router(config-gdoi-group)# server address ipv4 10.0.5.2	Specifies the address of the server a GDOI group is trying to reach. <ul style="list-style-type: none"> • To disable the address, use the no form of the command.
Step 6	client rekey encryption <i>cipher</i> [... [<i>cipher</i>]] Example: Router(config-gdoi-group)# client rekey encryption aes 128 aes 192 aes 256	Sets the client acceptable rekey ciphers for the KEK.
Step 7	client rekey hash <i>hash</i> Example: Router(config-gdoi-group)# client rekey hash sha	Sets the client acceptable hash algorithm for KEK.
Step 8	end Example: Router(config-gdoi-group)# end	Exits GDOI group configuration mode and returns to privileged EXEC mode.

Configuring Acceptable Transform Sets for TEK

To configure the transform sets used by TEKs for data encryption or authentication to be allowed by the GM, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec transform-set** *transform-set-name transform* [*transform2...transform4*]
4. **exit**
5. **crypto gdoi group** *group-name*
6. **client transform-sets** *transform-set-name1* [... [*transform-set-name6*]]
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto ipsec transform-set <i>transform-set-name transform</i> [<i>transform2...transform4</i>] Example: <pre>Router(config)# crypto ipsec transform-set gl esp-aes 192 esp-sha-hmac</pre>	Defines a transform set—an acceptable combination of security protocols and algorithms—and enters crypto transform configuration mode.
Step 4	exit Example: <pre>Router(cfg-crypto-trans)# exit</pre>	Exits crypto transform configuration mode.
Step 5	crypto gdoi group <i>group-name</i> Example: <pre>Router(config)# crypto gdoi group gdoigroupone</pre>	Identifies a GDOI group and enters GDOI group configuration mode.
Step 6	client transform-sets <i>transform-set-name1</i> [... [<i>transform-set-name6</i>]] Example:	Specifies the acceptable transform-set tags used by TEK for data encryption and authentication. <ul style="list-style-type: none"> • You can specify up to six transform-set tags.

	Command or Action	Purpose
	Router(config-gdoi-group)# client transform-sets g1	
Step 7	end Example: Router(config-gdoi-group)# end	Exits GDOI group configuration mode and returns to privileged EXEC mode.

Tracking the Group Member Crypto State

Perform this task to track the crypto state of the group member (GM) using the configured Enhanced Object Tracker (EOT) stub-object ID.

Before you begin

You must configure an Enhanced Object Tracking (EOT) by creating a stub-object and assign the object with a tracking ID to monitor the GDOI MIB. The following is a sample configuration in which, tracking ID 99 is assigned to the stub-object.

```
event manager applet test1
  event snmp oid <new GDOI MIB object> .....
  action 2.0 track set 99 state up

track 99 stub-object
  delay up 60
```

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. **client status active-sa track** *tracking-number*
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Device(config)# crypto gdoi group gdoigroupone	Identifies a GDOI group and enters GDOI group configuration mode.

	Command or Action	Purpose
Step 4	client status active-sa track <i>tracking-number</i> Example: <pre>Device(config-gdoi-group)# client status active-sa track 99</pre>	Enables the tracking for the stub-object. In this example, a GM will set the stub-object 99 to state “UP” when it receives valid traffic encryption key (TEK) from the key server (KS). On the other hand, the GM will set the stub-object 99 to state “DOWN” if it has no valid TEK because of errors, such as registration failure or TEK expiration before rekey.
Step 5	exit Example: <pre>Device(config-gdoi-group)# exit</pre>	Exits GDOI group configuration mode and returns to privileged EXEC mode.

Configuring GET VPN GM Authorization

GET VPN GM authorization can be done using preshared keys or PKI. It is a best practice to turn on GET VPN authorization. When a key server serves multiple GDOI groups, key server authorization is required to prevent a GM in one group from requesting keys and policies from another group. The ISAKMP authorization confirms that the GM is allowed to request GDOI attributes from the key server while the GDOI authorization confirms the GM is allowed to request GDOI attributes from a specific group configured in the key server.

To configure GET VPN GM authorization, perform either of the following tasks:

Configuring GM Authorization Using Preshared Keys

To configure GM authorization using preshared keys, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. **server local**
5. **authorization address ipv4** { *access-list-name* | *access-list-number* }
6. **exit**
7. **exit**
8. **access-list** *access-list-number* [**dynamic** *dynamic-name* [**timeout** *minutes*]] {**deny** | **permit**} *protocol source source-wildcard destination destination-wildcard* [**precedence** *precedence*] [**tos** *tos*] [**time-range** *time-range-name*] [**fragments**] [**log** [*word*] | **log-input** [*word*]]
9. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Router# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Router(config)# crypto gdoi group getvpn	Identifies a GDOI and enters GDOI group configuration mode.
Step 4	server local Example: Router(config-gdoi-group)# server local	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 5	authorization address ipv4 { <i>access-list-name</i> <i>access-list-number</i> } Example: Router(gdoi-local-server)# authorization address ipv4 50	Specifies a list of addresses for a GDOI.
Step 6	exit Example: Router(gdoi-local-server)# exit	Exits GDOI local configuration mode and returns to GDOI group configuration mode.
Step 7	exit Example: Router(config-gdoi-group)# exit	Exits GDOI group configuration mode and returns to global configuration mode.
Step 8	access-list <i>access-list-number</i> [dynamic <i>dynamic-name</i> [timeout <i>minutes</i>]] { deny permit } <i>protocol source source-wildcard destination destination-wildcard</i> [precedence <i>precedence</i>] [tos <i>tos</i>] [time-range <i>time-range-name</i>] [fragments] [log [<i>word</i>] log-input [<i>word</i>]] Example: Router(config)# access-list 50 permit ip 209.165.200.225 0.0.0.0 209.165.200.254 0.0.0.0	Defines an allowed IP access list. <ul style="list-style-type: none"> In the example, an access list with access list number 50 is defined, and packets sent from source IP address 209.165.200.225 to destination IP address 209.165.200.254 are permitted.
Step 9	exit Example: Router(config)# exit	Exits global configuration mode and returns to privileged EXEC mode.

Configuring GM Authorization Using PKI

To configure GM authorization using PKI, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto isakmp identity {address | dn | hostname}**
4. **crypto pki trustpoint name**
5. **subject-name [x.500-name]**
6. **exit**
7. **crypto gdoi group group-name**
8. **server local**
9. **authorization identity name**
10. **exit**
11. **exit**
12. **crypto identity name**
13. **dn name=string [, name=string]**
14. **exit**
15. **crypto isakmp identity {address | dn | hostname }**
16. **crypto pki trustpoint name**
17. **subject-name [x.500-name]**
18. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Router> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Router# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto isakmp identity {address dn hostname} Example: <pre>Router(config)# crypto isakmp identity dn</pre>	Defines the identity used by the router when the router is participating in the Internet Key Exchange (IKE) protocol.
Step 4	crypto pki trustpoint name Example: <pre>Router(config)# crypto pki trustpoint GETVPN</pre>	Declares the trustpoint that your router should use and enters ca-trustpoint configuration mode.

	Command or Action	Purpose
Step 5	subject-name [<i>x.500-name</i>] Example: Router(ca-trustpoint)# subject-name OU=GETVPN	Specifies the subject name in the certificate request.
Step 6	exit Example: Router(ca-trustpoint)# exit	Exits ca-trustpoint configuration mode and returns to global configuration mode.
Step 7	crypto gdoi group <i>group-name</i> Example: Router(config)# crypto gdoi group getvpn	Identifies a GDOI group and enters GDOI group configuration mode.
Step 8	server local Example: Router(config-gdoi-group)# server local	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 9	authorization identity <i>name</i> Example: Router(gdoi-local-server)# authorization identity GETVPN_FILTER	Specifies an identity for a GDOI group.
Step 10	exit Example: Router(gdoi-local-server)# exit	Exits GDOI local server configuration mode and returns to GDOI group configuration mode.
Step 11	exit Example: Router(config-gdoi-group)# exit	Exits GDOI group configuration mode and returns to global configuration mode.
Step 12	crypto identity <i>name</i> Example: Router(config)# crypto identity GETVPN_FILTER	Configures the identity of the router with a given list of DNs in the certificate of the router and enters crypto identity configuration mode.
Step 13	dn <i>name=string</i> [, <i>name=string</i>] Example: Router(config-crypto-identity)# dn ou=GETVPN	Associates the identity of a router with the DN in the certificate of the router.

	Command or Action	Purpose
Step 14	exit Example: <pre>Router(config-crypto-identity)# exit</pre>	Exits GDOI group configuration mode and returns to global configuration mode.
Step 15	crypto isakmp identity {address dn hostname } Example: <pre>Router(config)# crypto isakmp identity dn</pre>	Defines the identity used by the router when the router is participating in the IKE protocol.
Step 16	crypto pki trustpoint name Example: <pre>Router(config)# crypto pki trustpoint GETVPN</pre>	Declares the trustpoint that your router should use and enters ca-trustpoint configuration mode.
Step 17	subject-name [x.500-name] Example: <pre>Router(ca-trustpoint)# subject-name ou=getvpn</pre>	Specifies the subject name in the certificate request.
Step 18	end Example: <pre>Router(ca-trustpoint)# exit</pre>	Exits GDOI group configuration mode, saves the configuration, and returns to privileged EXEC mode.

Verifying and Troubleshooting Cisco Group Encrypted Transport VPN Configurations

The following tasks can be used to verify and troubleshoot your GET VPN configurations. These tasks are optional and are used to gather information during troubleshooting.

Note With CSCsi82594, if Time-based Anti-Replay (TBAR) is enabled, the rekey time period is set to 2 hours (7200 seconds). In this scenario, the Key Server periodically sends a rekey to the Group Members every 2 hours (7200 seconds). In the below example, even though the Traffic Encryption Key (TEK) lifetime is set to 28800 seconds (8 hours), the rekey timer is still 2 hours. For show outputs displaying TBAR information, use the **show crypto gdoi gm replay** and **show crypto gdoi ks replay** commands.

```
crypto ipsec profile atm-profile
set security-association lifetime seconds 28800
!
crypto gdoi group ATM-DSL
server local
  sa ipsec 1
  !
  replay time window-size 100
```

Verifying Active Group Members on a Key Server

To verify active group members on a key server, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **show crypto gdoi ks members**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto gdoi ks members Example: Router# show crypto gdoi ks members	Displays information about key server members.

Verifying Rekey-Related Statistics

To verify rekey-related statistics, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **show crypto gdoi ks rekey**
3. **show crypto gdoi [gm]**

DETAILED STEPS

Step 1 **enable**

Example:

```
Device> enable
```

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 **show crypto gdoi ks rekey**

Example:

```
Device# show crypto gdoi ks rekey
```

```
For group diffint (handle: 2147483650) server 10.0.8.1 (handle: 2147483650):
```

```
# of teks : 1 Seq num : 0
KEK POLICY (transport type : Unicast)
spi : 0xA8110DE7CC8B0FB201F2A8BFAA0F2D90
management alg : disabled encrypt alg : 3DES
crypto iv length : 8 key size : 24
orig life(sec) : 300 remaining life(sec) : 296 <----- ticking down
sig hash algorithm : enabled sig key length : 94
sig size : 64
sig key name : mykeys
```

On the key server, this command displays information about the rekeys that are being sent from the key server. The output displays the ticking down of the KEK remaining lifetime.

Step 3 show crypto gdoi [gm]

Example:

```
Device# show crypto gdoi
GROUP INFORMATION

Group Name : diffint
Group Identity : 3333
Rekeys received : 0
IPSec SA Direction : Both

Group Server list : 10.0.8.1

Group member : 10.0.3.1 vrf: None
Version : 1.0.2
Registration status : Registered
Registered with : 10.0.8.1
Re-registers in : 93 sec <-----re-registration time for TEK or KEK
Succeeded registration: 1
Attempted registration: 1
Last rekey from : 0.0.0.0
Last rekey seq num : 0
Unicast rekey received: 0
Rekey ACKs sent : 0
Rekey Received : never
allowable rekey cipher: any
allowable rekey hash : any
allowable transformtag: any ESP

Rekeys cumulative
Total received : 0
After latest register : 0
Rekey Acks sents : 0

ACL Downloaded From KS 10.0.8.1:
access-list permit ip host 10.0.1.1 host 239.0.1.1
access-list permit ip host 10.0.100.2 host 238.0.1.1

KEK POLICY:
Rekey Transport Type : Unicast
Lifetime (secs) : 255 <-----lifetime ticking
Encrypt Algorithm : 3DES
Key Size : 192
Sig Hash Algorithm : HMAC_AUTH_SHA
Sig Key Length (bits) : 512
```

On the group member, this command displays information about the rekeys that are being sent from the key server. The "re-registers in" field of the output displays the duration after which the group member re-registers for a TEK or a KEK, whichever time is smaller

Verifying IPsec SAs That Were Created by GDOI on a Group Member

To verify IPsec SAs that were created by GDOI on a group member, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `show crypto gdoi group group-name ipsec sa`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Router> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p><code>show crypto gdoi group group-name ipsec sa</code></p> <p>Example:</p> <pre>Router# show crypto gdoi group diffint ipsec sa</pre>	<p>Displays information about IPsec SAs that were created by GDOI on a group member.</p> <ul style="list-style-type: none"> • In this case, information will be displayed only for group "diffint." • For information about IPsec SAs for all groups, omit the group keyword and <i>group-name</i> argument.

Verifying IPsec SAs That Were Created by GDOI on a Key Server

To verify IPsec SAs that were created by GDOI on a key server, perform the following steps.

SUMMARY STEPS

1. `enable`
2. `show crypto ipsec sa`

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p><code>enable</code></p> <p>Example:</p> <pre>Device> enable</pre>	<p>Enables privileged EXEC mode.</p> <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	show crypto ipsec sa Example: Device# show crypto ipsec sa	Displays the settings used by current SAs.

Verifying the TEKs that a Group Member Last Received from the Key Server

To verify the TEKs that a GM last received from the KS, perform the following steps on the GM:

SUMMARY STEPS

1. enable
2. show crypto gdoi

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto gdoi Example: Router# show crypto gdoi	Displays the current GDOI configuration and the policy that is downloaded from the KS. The TEKs are listed in the TEK POLICY section. Without enabling debugging, you can use this command to compare the TEKs that a GM actually last received with the TEKs downloaded from the KS to the IPsec control plane (which you can view using the show crypto ipsec sa command).

Verifying Cooperative Key Server States and Statistics

To verify cooperative key server states and statistics, perform the following steps, using one or both of the **debug** and **show** commands shown.

SUMMARY STEPS

1. enable
2. debug crypto gdoi ks coop
3. show crypto gdoi group *group-name* ks coop [version]

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
	Router> enable	
Step 2	debug crypto gdoi ks coop Example: Router# debug crypto gdoi ks coop	Displays information about a cooperative key server.
Step 3	show crypto gdoi group group-name ks coop [version] Example: Router# show crypto gdoi group diffint ks coop version	Displays information for the group “diffint” and version information about the cooperative key server.

Verifying Antireplay Pseudotime-Related Statistics

To verify antireplay pseudotime-related statistics, perform the following steps using one or all of the **clear**, **debug**, and **show** commands.

SUMMARY STEPS

1. enable
2. clear crypto gdoi group group-name replay
3. debug crypto gdoi replay
4. show crypto gdoi group group-name
5. show crypto gdoi group group-name ks replay

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	clear crypto gdoi group group-name replay Example: Router# clear crypto gdoi group diffint replay	Clears the replay counters.
Step 3	debug crypto gdoi replay Example: Router# debug crypto gdoi replay	Displays information about the pseudotime stamp that is contained in a packet.
Step 4	show crypto gdoi group group-name Example:	Displays information about the current pseudotime of the group member.

	Command or Action	Purpose
	Router# show crypto gdoi group diffint	<ul style="list-style-type: none"> It also displays the different counts that are related to the antireplay for this group.
Step 5	show crypto gdoi group <i>group-name</i> ks replay Example: Router# show crypto gdoi group diffint ks replay	Displays information about the current pseudotime of the key server.

Verifying the Fail-Close Mode Status of a Crypto Map

To verify the fail-close mode status of a crypto map, perform the following steps.

SUMMARY STEPS

- enable
- show crypto map gdoi fail-close

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Router> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> Enter your password if prompted.
Step 2	show crypto map gdoi fail-close Example: Router# show crypto map gdoi fail-close	Displays information about the status of the fail-close mode.

Configuration Examples for Cisco Group Encrypted Transport VPN

Example: Key Server and Group Member Case Study

The following case study includes encrypting traffic CE-CE in an MPLS VPN environment.

The MPLS VPN core interconnects VPN sites as is shown in the figure below. VPN site CPEs, Group Member 1 through Group Member 4, are grouped into a single GDOI group that correlates with a VPN with which these sites are a part. This scenario is an intranet VPN scenario. All the key servers and Group Members are part of the same VPN. Key Server 1 and Key Server 2 are the cooperative key servers that support VPN members Group Member 1 through Group Member 4. Key Server 1 is the primary key server and Key Server 2 is the secondary key server.

Figure 141: Key Server and Group Member Scenario

The following configuration examples are based on the case study in the figure above.

Example Key Server 1

Key server 1 is the primary key server.

```

service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
service internal
!
hostname KS1
!
logging buffered 100000 debugging

ip subnet-zero
no ip domain lookup
ip domain name cisco
!
crypto isakmp policy 1
  encr 3des
  authentication pre-share
  group 2
  lifetime 400
crypto isakmp key cisco address 10.1.1.9
crypto isakmp key cisco address 10.1.1.1
crypto isakmp key cisco address 10.1.1.5
crypto isakmp key cisco address 10.1.1.17

```

Example: Configuring Group Member 1

```

crypto isakmp key cisco address 10.1.1.13
!
crypto ipsec transform-set gdoi-trans-group1 esp-3des esp-sha-hmac
!
crypto ipsec profile gdoi-profile-group1
 set security-association lifetime seconds 1800
 set transform-set gdoi-trans-group1
!
crypto gdoi group group1
 identity number 1
 server local

 rekey lifetime seconds 86400
 rekey retransmit 10 number 2
 rekey authentication mypubkey rsa group1-export-general
 rekey transport unicast
 sa ipsec 1
  profile gdoi-profile-group1
  match address ipv4 101
  replay counter window-size 64
 address ipv4 10.1.1.21
 redundancy
  local priority 1
  peer address ipv4 10.1.1.17
!
interface Ethernet0/0
 ip address 209.165.200.225 255.255.255.252
!
ip classless
ip route 0.0.0.0 0.0.0.0 10.1.1.22
!
access-list 101 permit ip 10.1.0.0 0.0.255.255 10.1.0.0 0.0.255.255
!
end

```

Example: Configuring Group Member 1

Group member 1 is part of a GDOI group that correlates with a VPN with which these sites are a part.

```

service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname GM1
!
resource policy
!
clock timezone EST 0
ip subnet-zero
!
crypto isakmp policy 1
 encr aes
 authentication pre-share
 group 14
 lifetime 3600
crypto isakmp key cisco address 209.165.200.225
crypto isakmp key cisco address 209.165.201.1
!
crypto gdoi group group1
 identity number 1
 server address ipv4 209.165.200.225
 server address ipv4 209.165.201.1

```

```

!
crypto map map-group1 10 gdoi
  set group group1
!
interface Ethernet0/0
  ip address 209.165.200.225 255.255.255.252
  crypto map map-group1
!
router bgp 1000
  no synchronization
  bgp log-neighbor-changes
  network 10.1.1.0 mask 255.255.255.0
  neighbor 10.1.1.2 remote-as 5000
  no auto-summary
!
ip classless
!
End

```

The same GDOI group cannot be applied to multiple interfaces. The following examples show unsupported cases:

Example 1

```

crypto map map-group1
  group g1
  interface ethernet 1/0
    crypto map map-group1
  interface ethernet 2/0
    crypto map map-group1

```

Example 2

```

crypto map map-group1 10 gdoi
  set group group1
crypto map map-group2 10 gdoi
  set group group1
  interface ethernet 1/0
    crypto map map-group1
  interface ethernet 2/0

```

Example: Configuring Group Member 2

Group member 2 is part of a GDOI group that correlates with a VPN with which these sites are a part.

```

service timestamps debug datetime msec
service timestamps log datetime msec
!
hostname GM2
!
resource policy
!
clock timezone EST 0
ip subnet-zero
!
crypto isakmp policy 1
  encr aes
  authentication pre-share
  group 14
  lifetime 3600

```

```

crypto isakmp key cisco address 209.165.200.225
crypto isakmp key cisco address 209.165.201.1
!
crypto gdoi group group1
  identity number 1
  server address ipv4 209.165.201.1
  server address ipv4 209.165.200.225
!
crypto map map-group1 10 gdoi
  set group group1
!
interface Ethernet0/0
  ip address 209.165.200.225 255.255.255.252
  crypto map map-group1
!
router bgp 2000
  no synchronization
  bgp log-neighbor-changes
  network 10.1.2.0 mask 255.255.255.0
  neighbor 10.1.1.6 remote-as 5000
  no auto-summary
!
ip classless
!
end

```

Example: Configuring Group Member 3

Group member 3 is part of a GDOI group that correlates with a VPN with which these sites are a part.

```

service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname GM3
!
resource policy
!
clock timezone EST 0
ip subnet-zero
!
crypto isakmp policy 1
  encr aes
  authentication pre-share
  group 14
  lifetime 3600
crypto isakmp key cisco address 209.165.200.225
crypto isakmp key cisco address 209.165.201.1
!
crypto ipsec transform-set gdoi-trans-group1 esp-aes esp-sha-hmac
crypto gdoi group group1
  identity number 1
  server address ipv4 209.165.200.225
  server address ipv4 209.165.201.1
!
crypto map map-group1 10 gdoi
  set group group1
!
interface Ethernet0/0
  ip address 209.165.201.1 255.255.255.252
  crypto map map-group1
!

```

```

router bgp 3000
  no synchronization
  bgp log-neighbor-changes
  network 10.1.3.0 mask 255.255.255.0
  neighbor 10.1.1.10 remote-as 5000
  no auto-summary
!
ip classless
!
end

```

Example: Configuring Group Member 4

Group member 4 is part of a GDOI group that correlates with a VPN with which these sites are a part.

```

service timestamps debug datetime msec
service timestamps log datetime msec
no service password-encryption
!
hostname GM4
!
clock timezone EST 0
ip subnet-zero
!
crypto isakmp policy 1
  encr aes
  authentication pre-share
  group 14
  lifetime 3600
crypto isakmp key cisco address 209.165.200.225
crypto isakmp key cisco address 209.165.201.1
!
crypto gdoi group group1
  identity number 1
  server address ipv4 209.165.200.225
  server address ipv4 209.165.201.1
!
crypto map map-group1 10 gdoi
  set group group1
!
interface Ethernet0/0
  ip address 209.165.201.1 255.255.255.252
  crypto map map-group1
!
router bgp 4000
  no synchronization
  bgp log-neighbor-changes
  network 10.1.4.0 mask 255.255.255.0
  neighbor 10.1.1.14 remote-as 5000
  no auto-summary
!
ip classless
!
end

```

Example: Configuring Group Member 5

If a group member has multiple interfaces that are part of the same GDOI group, you should use a loopback interface to source the crypto. If a loopback interface is not used, each interface that handles encrypted traffic must register individually with the key server.

The key server sees these as separate requests and must keep multiple records for the same group member, which also means sending multiple rekeys. If crypto is sourced from the loopback interface instead, the group member registers only once with the key server.

The following configuration shows how the group member registers once with the key server:

```
!
interface GigabitEthernet0/1
  description *** To AGG-1 ***
  crypto map dgvpn
!
interface GigabitEthernet0/2
  description *** To AGG-2 ***
  crypto map dgvpn
!
interface Loopback0
  ip address 209.165.201.1 255.255.255.255
!
  crypto map dgvpn local-address Loopback0
!
```

Example: Verifying the TEKs That a Group Member Last Received from the Key Server

The following example shows how to display the current GDOI configuration and the policy that is downloaded from the KS:

```
Device# show crypto gdoi

GROUP INFORMATION

    Group Name           : GETV6
    .
    .
    .
    KEK POLICY:
    .
    .
    .
    TEK POLICY for the current KS-Policy ACEs Downloaded:
    Ethernet2/0:
    IPsec SA:
        spi: 0x627E4B84(1652444036)
        transform: esp-aes
        sa timing:remaining key lifetime (sec): (3214)
        Anti-Replay(Time Based) : 10 sec interval
        tag method : cts sgt
        alg key size: 24 (bytes)
        sig key size: 20 (bytes)
        encaps: ENCAPS_TUNNEL

GROUP INFORMATION

    Group Name           : GETV4
    .
    .
```

```

.
KEK POLICY:
.
.
.
TEK POLICY for the current KS-Policy ACEs Downloaded:
 Ethernet2/0:
   IPsec SA:
     spi: 0xF6E6B597(4142314903)
     transform: esp-aes
     sa timing:remaining key lifetime (sec): (3214)
     Anti-Replay : Disabled
     tag method : cts sgt
     alg key size: 24 (bytes)
     sig key size: 20 (bytes)
     encaps: ENCAPS_TUNNEL

```

The TEKs are listed in the TEK POLICY section. Without enabling debugging, you can use this command to compare the TEKs that a GM actually last received with the TEKs downloaded from the KS to the IPsec control plane (which you can view using the **show crypto ipsec sa** command).

The tag method field shows the method used for GET VPN inline tagging; the possible values are either cts sgt (for Cisco TrustSec security group tags) or disabled. The alg key size field shows the key length for the encryption algorithm that is configured in the TEK policy. The sig key size field shows the key length for the signature that is configured in the TEK policy. The encaps field shows the type of IPsec encapsulation (either tunnel or transport) that is configured in the TEK policy.

The output from this command might show that a TEK has expired since the time it was received from the KS.

Example Passive SA

The following example displays information about crypto rules on outgoing packets:

```

Router# show crypto ruleset
Ethernet0/0:
  59 ANY ANY DENY
  11 ANY/848 ANY/848 DENY
  IP ANY ANY IPSec SA Passive
  IP ANY ANY IPSec Cryptomap

```

The following example displays the directional mode of the IPsec SA:

```

Router# show crypto ruleset detail
Ethernet0/0:
  20000001000019 59 ANY ANY DENY -> 20000001999999
  20000001000029 11 ANY/848 ANY/848 DENY -> 20000001999999
  20000001000035 IP ANY ANY IPSec SA Passive
  20000001000039 IP ANY ANY IPSec Cryptomap

```

Example Fail-Close Mode

The following example shows that fail-close mode has been activated, and unencrypted traffic from access list 102 is allowed before the group member is registered:

Example: Verifying Fail-Close Revert

```
crypto map map1 gdoi fail-close
  match address 102
  activate
crypto map map1 10 gdoi
  set group ks1_group
  match address 101
!
access-list 101 deny ip 10.0.1.0 0.0.0.255 10.0.1.0 0.0.0.255
access-list 102 deny tcp any eq telnet any
```

The following **show crypto map gdoi fail-close** command output shows that fail-close has been activated:

```
Router# show crypto map gdoi fail-close

Crypto Map: "svn"
  Activate: yes
  Fail-Close Access-List: (Deny = Forward In Clear, Permit = Drop)
    access-list 105 deny tcp any port = 23 any
    access-list 105 deny ospf any any
```

Example: Verifying Fail-Close Revert

```
Device#show cry gdoi group GDOI_GROUP_1 | i Fail|Policy
Fail-Close Revert : Enabled
KS Policy Removal in : 697 sec
```

Feature Information for Cisco Group Encrypted Transport VPN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 314: Feature Information for Cisco Group Encrypted Transport VPN

Feature Name	Releases	Feature Information
Cisco Group Encrypted Transport VPN	Cisco IOS XE Release 2.3	Cisco Group Encrypted Transport VPN is an optimal encryption solution for large-scale IP or MPLS sites that require any-to-any connectivity with minimum convergence time, low processing, provisioning, managing, and troubleshooting overhead. The following commands were introduced or modified: address ipv4 (GDOI) , clear crypto gdoi , crypto gdoi gm , debug crypto gdoi , local priority , peer address ipv4 , redundancy , rekey address ipv4 , rekey transport unicast , replay counter window-size , replay time window-size , sa receive-only , show crypto gdoi .
Create MIB Object to Track a Successful GDOI Registration	Cisco IOS XE Release 3.12S	The Create MIB Object to track a successful GDOI Registration feature introduces a new MIB object in the GDOI MIB to indicate the number of active TEKs in a group.

Feature Name	Releases	Feature Information
GET VPN Hardening	Cisco IOS XE Release 3.9S	<p>This feature improves GET VPN resiliency. The improvements in resiliency prevent or minimize data-traffic disruption by using one of the following methods:</p> <ul style="list-style-type: none"> • Making corrections when conditions that could cause a traffic disruption are detected. • Rapidly executing a recovery mechanism when a disruption is detected. <p>The following commands were modified: show crypto gdoi, show crypto ipsec sa, show tech-support.</p>
GET VPN IKEv1 Separation	Cisco IOS XE Release 3.11S	<p>This feature eases maintenance and troubleshooting.</p> <p>The following commands were modified: show tech-support, show crypto gdoi and show crypto ipsec sa.</p>
GET VPN Phase 1.2	Cisco IOS XE Release 2.3	<p>These enhancements include the following features:</p> <ul style="list-style-type: none"> • Change Key Server Role <p>This feature enables you to change the role of the key server from primary to secondary.</p> <p>The following commands were added or modified for this feature: clear crypto gdoi ks coop role</p> • Fail-Close Mode <p>This feature prevents unencrypted traffic from passing through the group member before that member is registered.</p> <p>The following commands were added or modified for this feature: activate, crypto map, match address, and show crypto map.</p> • Passive SA <p>This feature allows a group member to be configured into passive mode permanently.</p> <p>The following command was introduced: passive.</p>
GETVPN Routing Awareness for BGP	Cisco IOS XE Release 3.13S	<p>The following commands were introduced or modified: client status active-sa track.</p>

Feature Name	Releases	Feature Information
GET VPN Resiliency	Cisco IOS XE Release 3.9S	<p>This feature improves the resiliency of GET VPN, so that data traffic disruption is prevented or minimized when errors occur.</p> <p>This feature introduces long SA lifetime functionality, which extends the maximum for which you can configure the lifetime of the key encryption key and traffic encryption keys from 24 hours to 30 days. This feature also lets you configure key servers to continue to send periodic reminder rekeys to group members that did not respond with an acknowledgment in the last scheduled rekey.</p> <p>By using a long SA lifetime in combination with periodic reminder rekeys, a key server can effectively synchronize group members if they miss a scheduled rekey before the keys roll over.</p> <p>The following commands were modified: rekey lifetime, rekey retransmit, set security-association lifetime, show crypto gdoi.</p>
GET VPN Support of IPsec Inline Tagging for Cisco TrustSec	Cisco IOS XE Release 3.9S	<p>Cisco TrustSec (CTS) uses the user and device identification information acquired during authentication to classify packets as they enter the network. CTS maintains classification of each packet by tagging packets with security group tags (SGTs) on ingress to the CTS network so that they can be identified for applying security and other policy criteria along the data path. The tags allow network intermediaries such as switches and firewalls to enforce the access control policy based on the classification. The GET VPN Support of IPsec Inline Tagging for Cisco TrustSec feature uses GET VPN inline tagging to carry the SGT information across the private WAN.</p> <p>The following commands were introduced or modified: show crypto gdoi, show crypto ipsec sa, tag cts sgt.</p>
GET VPN Time-Based Anti-Replay	Cisco IOS XE Release 2.3	Support for time-based antireplay was added to the Cisco VSA.
GET VPN Troubleshooting	Cisco IOS XE Release 3.8S	<p>This feature provides improved debugging levels (so debug messages can be enabled per feature), event logging, exit trace capabilities to save a log of error conditions and their tracebacks, and conditional debugging (which provides the ability to debug individual group members from the key server). The conditional debugging feature provides the ability to perform conditional debugging on the key server so that it can filter based on GM or other cooperative key servers. The event logging feature provides the ability to log the last set of events.</p> <p>The following commands were introduced or modified: clear crypto gdoi, debug crypto condition unmatched, debug crypto gdoi, debug crypto gdoi condition, monitor event-trace gdoi, show crypto gdoi, and show monitor event-trace gdoi.</p>

Feature Name	Releases	Feature Information
Group Encrypted Transport VPN Key Server	Cisco IOS XE Release 3.6S	Support was added for configuring a device running Cisco IOS XE as a key server. In Cisco IOS XE Release 3.6S, this feature was introduced on the Cisco ASR 1000 Series Aggregation Services Routers. In Cisco IOS XE Release 3.13S, support was added for the Cisco Cloud Services Router (CSR) 1000V Series.
VSA Support for GET VPN	Cisco IOS XE Release 2.3	Cisco VSA (high-performance crypto engine) support was added for GDOI and GET VPN.

Glossary

DOI—Domain of Interpretation. For Internet Security Association Key Management Protocol (ISAKMP), a value in the security association (SA) payload that describes in which context the key management message is being sent (IPsec or Group Domain of Interpretation).

GDOI—Group Domain of Interpretation. For ISAKMP, a means of distributing and managing keys for groups of mutually trusted systems.

group member—Device (Cisco IOS router) that registers with a group that is controlled by the key server for purposes of communicating with other group members.

group security association—SA that is shared by all group members in a group.

IPsec—IP security. Data encryption protocol for IP packets that are defined in a set of RFCs (see IETF RFC 2401).

ISAKMP—Internet Security Association and Key Management Protocol. Protocol that provides a framework for cryptographic key management protocols.

KEK—key encryption key. Key used to protect the rekey between the key server and group members.

key server—Device (Cisco IOS router) that distributes keys and policies to group members.

MTU—maximum transmission unit. Size (in bytes) of the largest packet or frame that a given layer of a communications protocol can pass onward.

SA—security association. SA that is shared by all group members in a group.

Simple Network Management Protocol (SNMP)—An interoperable standards-based protocol that allows for external monitoring of a managed device through an SNMP agent.

TEK—traffic encryption key. Key that is used to protect the rekey between group members.

CHAPTER 237

GET VPN GM Removal and Policy Trigger

The GET VPN GM Removal and Policy Trigger feature lets you easily remove unwanted group members (GMs) from the group encrypted transport (GET) VPN network, provides a rekey triggering method to install new security associations (SAs) and remove obsolete SAs, and lets you check whether devices are running versions of GET VPN software that support these capabilities.

Note Overlapping ACLs in GETVPN groups are prohibited. It is essential to clearly state and enforce this policy to avoid configuration issues that can lead to security vulnerabilities or operational problems within the VPN network.

Information About GM Removal and Policy Trigger

GET VPN Software Versioning

GET VPN software versions are of the form

major-version.minor-version.mini-version

where

- *major-version* defines compatibility for all GET VPN devices.
- *minor-version* defines compatibility for key server (KS)-to-KS (cooperative key server) associations and for GM-to-GM interoperability.
- *mini-version* tracks feature changes that have no compatibility impact.

For example, the base version (for all prior GET VPN features) is 1.0.1. Also, for example, the version that contains the GM removal feature and the policy replacement feature is 1.0.2, which means that these features

are fully backward compatible with the base version (despite the introduction of behavior in these features for triggered rekeys).

GMs send the GET VPN software version to the KS in the vendor-ID payload during Internet Key Exchange (IKE) phase 1 negotiation (which is defined in RFC 2408, *Internet Security Association and Key Management Protocol [ISAKMP]*). KSs send the software version to other cooperative KSs in the version field of the cooperative KS announcement (ANN) messages. Cooperative KSs also synchronize their lists of versions that each GM is using.

The GM removal feature and the policy replacement feature each provide a command that you run on the KS (or primary KS) to find devices in the group that do not support that feature.

GM Removal

Without the GM removal and policy replacement features, you would need to complete the following steps to remove unwanted GMs from a group:

1. Revoke the phase 1 credential (for example, the preshared key or one or more PKI certificates).
2. Clear the traffic encryption key (TEK) and key encryption key (KEK) database on the KS.
3. Clear the TEK and KEK database on each GM individually and force each GM to re-register.

The third step is time-consuming when a GET VPN group serves thousands of GMs. Also, clearing the entire group in a production network might cause a network disruption. The GET VPN GM Removal and Policy Trigger feature automates this process by introducing a command that you enter on the KS (or primary KS) to create a new set of TEK and KEK keys and propagate them to the GMs.

GM Removal Compatibility with Other GET VPN Software Versions

You should use the GET VPN GM Removal and Policy Trigger feature only after all devices in the GET VPN network are upgraded to GET VPN software versions that support this feature. Otherwise, secondary KSs or GMs running older software will ignore the GM removal message and continue to encrypt and decrypt traffic using the old SAs. This behavior causes network traffic disruption.

This feature provides a command that you use on the KS (or primary KS) to check whether all devices in the network are running versions that support GM removal. When the primary KS tries to remove GMs in a network containing devices that do not support GM removal, a warning message appears. For more information, see the “Ensuring That GMs Are Running Software Versions That Support GM Removal” section.

GM Removal with Transient IPsec SAs

The GET VPN GM Removal and Policy Trigger feature provides a command that you use on the KS (or primary KS) to trigger GM removal with transient IPsec SAs. This behavior shortens key lifetimes for all GMs and causes them to re-register before keys expire. During GM removal, no network disruption is expected, because traffic continues to be encrypted and decrypted using the transient IPsec SA until its lifetime expires. For more information, see the “Removing GMs with Transient IPsec SAs” section.

GM Removal with Immediate IPsec SA Deletion

The GET VPN GM Removal and Policy Trigger feature provides an optional keyword that you can use on the KS (or primary KS) to force GMs to delete old TEKs and KEKs immediately (without using transient SAs) and re-register. However, this behavior can cause a disruption to the data plane, so you should use this

method only for important security reasons. For more information, see the “Removing GMs and Deleting IPsec SAs Immediately” section.

Policy Replacement and Rekey Triggering

The GET VPN GM Removal and Policy Trigger feature provides a new rekey triggering method to remove obsolete SAs and install new SAs.

Inconsistencies Regarding Which TEK and KEK Policy Changes Will Trigger Rekeys

Without this feature, there are inconsistencies regarding which TEK and KEK policy changes will trigger rekeys:

- Multiple rekeys could be sent during the course of security policy updates.
- Some policy changes (for example, transform set, profile, lifetime, and anti-replay) will install new SAs on GMs; however, the SAs from the existing policies remain active until their lifetimes expire.
- Some policy changes (for example, a TEK’s access control entry/access control list (ACE/ACL) changes) will install new SAs on GMs and take effect immediately. However, the obsolete SAs are kept in each GM’s database (and can be displayed using the **show crypto ipsec sa** command until their lifetimes expire).

For example, if the KS changes the policy from Data Encryption Standard (DES) to Advanced Encryption Standard (AES), when the GM receives this triggered rekey, it installs the new SAs (for example, for AES) and shortens the lifetimes of the old SAs (for example, for DES). The GM continues to encrypt and decrypt traffic using the old SAs until their shortened lifetimes expire.

Following is the formula to calculate the shortened lifetime:

$$\text{TEK_SLT} = \text{MIN}(\text{TEK_RLT}, \text{MAX}(90\text{s}, \text{MIN}(5\%(\text{TEK_CLT}), 3600\text{s})))$$

where

- TEK_SLT is the TEK shortened lifetime
- TEK_RLT is the TEK remaining lifetime
- TEK_CLT is the TEK configured lifetime

The following table summarizes the inconsistencies regarding rekeys.

Table 315: Rekey Behavior After Security Policy Changes

Policy Changes	Rekey Sent?	Rekey Behavior After Policy Changes
TEK: SA lifetime	No	The old SA remains active until its lifetime expires. The new lifetime will be effective after the next scheduled rekey. Even if you enter the clear crypto sa command, it will re-register and download the old SA with the old lifetime again.
TEK: IPSEC transform set	Yes	The SA of the old transform set remains active until its lifetime expires.

Policy Changes	Rekey Sent?	Rekey Behavior After Policy Changes
TEK: IPSEC profile	Yes	The SA of the old profile remains active until its lifetime expires.
TEK: Matching ACL	Yes	Outbound packet classification immediately uses the ACL. But the old SAs remain in the SA database (you can view them by using the show crypto ipsec sa command).
TEK: Enable replay counter	Yes	But the old SA without counter replay remains active until its lifetime expires.
TEK: Change replay counter value	No	The SA with a new replay counter is sent out in the next scheduled rekey.
TEK: Disable replay counter	Yes	But the old SA with counter replay enabled remains active until its lifetime expires.
TEK: Enable TBAR	Yes	But the old SA with time-based anti-replay (TBAR) disabled remains active until its lifetime expires.
TEK: Change TBAR window	No	The SA with a new TBAR window will be sent out in the next scheduled rekey.
TEK: Disable TBAR	Yes	But the old SA with TBAR enabled remains active until its lifetime expires.
TEK: Enable receive-only	Yes	Receive-only mode is activated right after the rekey.
TEK: Disable receive-only	Yes	Receive-only mode is deactivated right after the rekey.
KEK: SA lifetime behavior	No	The change is applied with the next rekey.
KEK: Change authentication key	Yes	The change is applied immediately.
KEK: Change crypto algorithm	Yes	The change is applied immediately.

This feature solves these problems by ensuring consistency. With this feature, GET VPN policy changes alone will no longer trigger a rekey. When you change the policy (and exit from global configuration mode), a syslog message appears on the primary KS indicating that the policy has changed and a rekey is needed. This feature provides a new command that you then enter on the KS (or primary KS) to send a rekey (that is based on the latest security policy in the running configuration).

This feature also provides an extra keyword to the new command to force a GM receiving the rekey to remove the old TEKs and KEK immediately and install the new TEKs and KEK. Therefore, the new policy takes effect immediately without waiting for old policy SAs to expire. (However, using this keyword could cause a temporary traffic discontinuity, because all GMs might not receive the rekey message at the same time.)

Policy Replacement and Rekey Triggering Compatibility with Other GET VPN Software Versions

You should use rekey triggering only after all devices in the GET VPN network are upgraded to GET VPN software versions that support this feature. For GMs running older versions that do not yet support the **crypto gdoi ks** command, the primary KS uses the software versioning feature to detect those versions and only triggers a rekey without sending instruction for policy replacement. Therefore, when a GM receives the rekey,

it installs the new SAs but does not shorten the lifetimes of the old SAs. (This behavior is the same as the prior rekey method and ensures backward compatibility for devices that cannot support policy replacement.)

This feature provides a command that you use on the KS (or primary KS) to check whether all the devices in the network are running versions that support policy replacement. For more information, see the “Ensuring That GMs Are Running Software Versions That Support Policy Replacement” section.

How to Configure GET VPN GM Removal and Policy Trigger

Ensuring That GMs Are Running Software Versions That Support GM Removal

You should use the GET VPN GM Removal and Policy Trigger feature only after all devices in the GET VPN network are upgraded to GET VPN software versions that support this feature. Otherwise, secondary KSs or GMs that are running older software will ignore the GM removal message and continue to encrypt and decrypt traffic using the old SAs. This behavior causes network traffic disruption.

Perform this task on the KS (or primary KS) to ensure that all devices in the network support GM removal.

SUMMARY STEPS

1. **enable**
2. **show crypto gdoi feature gm-removal**
3. **show crypto gdoi feature gm-removal | include No**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto gdoi feature gm-removal Example: Device# show crypto gdoi feature gm-removal	Displays the version of the GET VPN software running on each KS and GM in the GET VPN network and displays whether that device supports GM removal.
Step 3	show crypto gdoi feature gm-removal include No Example: Device# show crypto gdoi feature gm-removal include No	(Optional) Displays only those devices that do not support GM removal.

Removing GMs with Transient IPsec SAs

Perform this task on the KS (or primary KS) to trigger removal of GMs with transient IPsec SAs.

SUMMARY STEPS

1. **enable**
2. **clear crypto gdoi [group *group-name*] ks members**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	clear crypto gdoi [group <i>group-name</i>] ks members Example: Device# clear crypto gdoi ks members	Creates a new set of TEK and KEK keys. This command also sends out GM removal messages to all GMs to clean up their old TEK and KEK databases.

Examples

A message appears on the KS as follows:

```
Device# clear crypto gdoi ks members
```

```
% This GM-Removal message will shorten all GMs' key lifetimes and cause them to re-register before keys expiry.
```

```
Are you sure you want to proceed? ? [yes/no]: yes
```

```
Sending GM-Removal message to group GET...
```

After each GM receives the GM removal message, the following syslog message appears on each GM:

```
*Jan 28 08:37:03.103: %GDOI-4-GM_RECV_DELETE: GM received delete-msg from KS in group GET.
```

```
TEKs lifetime are reduced and re-registration will start before SA expiry
```

Each GM removes the KEK immediately and shortens the lifetimes of the old TEKs as follows:

```
TEK_SLT = MIN(TEK_RLT, MAX(90s, MIN(5%(TEK_CLT), 3600s)))
```

```
TEK_SLT: TEK shortened lifetime
```

```
TEK_RLT: TEK Remaining LifeTime
```

```
TEK_CLT: TEK Configured LifeTime
```

Also, the GMs start re-registering to the KS to obtain the new TEKs and KEK according to the conventional re-registration timer and with jitter (random delay) applied. Jitter prevents all GMs from reregistering at the same time and overloading the key server CPU. Only GMs that pass the authentication based on the new credential installed on the KS will receive the new TEKs and KEK.

GM removal should not cause a network disruption, because traffic continues to be encrypted and decrypted using the transient IPsec SA until its lifetime expires.

If you try to use this command on the secondary KS, it is rejected as follows:

```
Device# clear crypto gdoi ks members
```

```
ERROR for group GET: can only execute this command on Primary KS
```

Removing GMs and Deleting IPsec SAs Immediately

Perform this task on the KS (or primary KS) to force GMs to delete old TEKs and KEKs immediately and re-register.

SUMMARY STEPS

1. **enable**
2. **clear crypto gdoi [group *group-name*] ks members now**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	clear crypto gdoi [group <i>group-name</i>] ks members now Example: Device# clear crypto gdoi ks members now	Creates a new set of TEK and KEK keys. This command also sends out GM removal messages to all GMs to clean up their old TEK and KEK databases. <p>Note Using the now keyword can cause a network disruption to the data plane. Proceed with the GM removal only if a security concern is more important than a disruption.</p>

Examples

A message appears on the KS as follows:

```
Device# clear crypto gdoi ks members now

% This GM-Removal immediate message will cleanup all GMs downloaded policies
% This will cause all GMs to re-register.
Are you sure you want to proceed? ? [yes/no]: yes
Sending GM-Removal message to group GET...
```

After you enter the above command, the KS sends a “remove now” message to each GM to trigger the following actions on each GM:

1. Immediately cleans up its downloaded TEKs and KEK and its policy and returns to fail-open mode (unless fail-close mode is explicitly configured).
2. Sets up a timer with a randomly chosen period within 2 percent of the configured TEK lifetime.
3. When the timer in Step 2 expires, the GM starts re-registering to the KS to download the new TEKs and KEK.

On each GM, the following syslog message is displayed to indicate that the GM will re-register in a random time period:

```
*Jan 28 08:27:05.627: %GDOI-4-GM_RECV_DELETE_IMMEDIATE: GM receive REMOVAL-NOW in group
GET to cleanup downloaded policy now. Re-registration will start in a randomly chosen
period of 34 sec
```

If you try to remove GMs in a network containing devices that do not support GM removal, a warning message appears:

```
Device# clear crypto gdoi ks members now

% This GM-Removal immediate message will cleanup all GMs downloaded policies
% This will cause all GMs to re-register.
Are you sure you want to proceed? ? [yes/no]: yes
WARNING for group GET: some devices cannot support GM-REMOVAL and can cause network
disruption. Please check 'show crypto gdoi feature'.
Are you sure you want to proceed ? [yes/no]: no
```

Ensuring that GMs Are Running Software Versions That Support Policy Replacement

Perform this task on the KS (or primary KS) to check whether all devices in the network support policy replacement.

SUMMARY STEPS

1. enable
2. show crypto gdoi feature policy-replace
3. show crypto gdoi feature policy-replace | include No

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto gdoi feature policy-replace Example: Device# show crypto gdoi feature policy-replace	Displays the version of the GET VPN software running on each KS and GM in the GET VPN network and displays whether that device supports policy replacement.
Step 3	show crypto gdoi feature policy-replace include No Example: Device# show crypto gdoi feature policy-replace include No	(Optional) Finds only those devices that do not support policy replacement. For these devices, the primary KS sends only the triggered rekey without instructions for policy replacement. Therefore, when a GM receives the rekey, it installs the new SAs but does not shorten the lifetimes of the old SAs. This behavior is the same as the existing rekey method and ensures backward compatibility.

Triggering a Rekey

If you change the security policy (for example, from DES to AES) on the KS (or primary KS) and exit from global configuration mode, a syslog message appears on the KS indicating that the policy has changed and a rekey is needed. You enter the rekey triggering command as described below to send a rekey based on the latest policy in the running configuration.

Perform this task on the KS (or primary KS) to trigger a rekey.

SUMMARY STEPS

1. **enable**
2. **crypto gdoi ks [group *group-name*] rekey [replace-now]**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	crypto gdoi ks [group <i>group-name</i>] rekey [replace-now] Example: Device# crypto gdoi ks group mygroup rekey	Triggers a rekey on all GMs. The optional replace-now keyword immediately replaces the old TEKs and KEK on each GM to enable the new policy before the SAs expire. Note Using the replace-now keyword could cause a temporary traffic discontinuity.

Examples

A message appears on the KS as follows:

```
Device# crypto gdoi ks rekey
Device#
*Jan 28 09:17:44.363: %GDOI-5-KS_SEND_UNICAST_REKEY: Sending Unicast Rekey with
policy-replace for group GET from address 10.0.8.1 with seq # 2
```

After the policy change, when each GM receives this triggered rekey, it installs the new SAs (for example, for AES) and shortens the lifetimes of the old SAs (for example, for DES). Each GM continues to encrypt and decrypt traffic using the old SA until its shortened lifetime expires.

If you try to trigger a rekey on the secondary KS, it rejects the command as shown below:

```
Device# crypto gdoi ks rekey
ERROR for group GET: This command must be executed on Pri-KS
```

Configuration Examples for GET VPN GM Removal and Policy Trigger

Example: Removing GMs from the GET VPN Network

Ensuring That GMs Are Running Software Versions That Support GM Removal

The following example shows how to use the GET VPN software versioning command on the KS (or primary KS) to check whether all the devices in the network support the GM removal feature:

```
Device# show crypto gdoi feature gm-removal

Group Name: GET
Key Server ID      Version  Feature Supported
-----
10.0.8.1           1.0.2   Yes
10.0.9.1           1.0.2   Yes
10.0.10.1          1.0.2   Yes
10.0.11.1          1.0.2   Yes
Group Member ID   Version  Feature Supported
-----
10.0.0.2           1.0.2   Yes
10.0.0.3           1.0.1   No
```

The following example shows how to find only those devices that do not support GM removal:

```
Device# show crypto gdoi feature gm-removal | include No

10.0.0.3           1.0.1   No
```

The above example shows that the GM with IP address 10.0.0.3 is running older software version 1.0.1 (which does not support GM removal) and should be upgraded.

Removing GMs with Transient IPsec SAs

The following example shows how to trigger GM removal with transient IPsec SAs. You use this command on the KS (or primary KS).

```
Device# clear crypto gdoi ks members

% This GM-Removal message will shorten all GMs' key lifetimes and cause them to
re-register before keys expiry.
Are you sure you want to proceed? ? [yes/no]: yes
Sending GM-Removal message to group GET...
```

Removing GMs and Deleting IPsec SAs Immediately

The following example shows how to force GMs to delete old TEKs and KEKs immediately and re-register. You use this command on the KS (or primary KS).

```
Device# clear crypto gdoi ks members now

% This GM-Removal immediate message will cleanup all GMs downloaded policies
% This will cause all GMs to re-register.
Are you sure you want to proceed? ? [yes/no]: yes
Sending GM-Removal message to group GET...
```

Example: Triggering Rekeys on Group Members

Ensuring That GMs Are Running Software Versions That Support Rekey Triggering

The following example shows how to use the GET VPN software versioning command on the KS (or primary KS) to display the version of software on devices in the GET VPN network and display whether they support rekey triggering after a policy change:

```
Device# show crypto gdoi feature policy-replace

Key Server ID      Version  Feature Supported
10.0.8.1           1.0.2   Yes
10.0.9.1           1.0.2   Yes
10.0.10.1          1.0.2   Yes
10.0.11.1          1.0.2   Yes
Group Member ID    Version  Feature Supported
5.0.0.2            1.0.2   Yes
9.0.0.2            1.0.1   No
```

The following example shows how to find only those devices that do not support rekey triggering after policy replacement:

```
Device# show crypto gdoi feature policy-replace | include No

          9.0.0.2          1.0.1          No
```

For these devices, the primary KS sends only the triggered rekey without instructions for policy replacement. Therefore, when a GM receives the rekey, it installs the new SAs but does not shorten the lifetimes of the old SAs.

Triggering a Rekey

The following example shows how to trigger a rekey after you have performed a policy change. In this example, an IPsec policy change (for example, DES to AES) occurs with the **profile gdoi-p2** command:

```
Device# configure terminal
Device(config)# crypto gdoi group GET
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# sa ipsec 1
Device(gdoi-sa-ipsec)# no profile gdoi-p
Device(gdoi-sa-ipsec)# profile gdoi-p2
Device(gdoi-sa-ipsec)# end
```

```

Device#

*Jan 28 09:15:15.527: %SYS-5-CONFIG_I: Configured from console by console
*Jan 28 09:15:15.527: %GDOI-5-POLICY_CHANGE: GDOI group GET policy has changed. Use
'crypto gdoi ks rekey' to send a rekey, or the changes will be send in the next scheduled
rekey
Device# crypto gdoi ks rekey
Device#
*Jan 28 09:17:44.363: %GDOI-5-KS_SEND_UNICAST_REKEY: Sending Unicast Rekey with
policy-replace for group GET from address 10.0.8.1 with seq # 2

```

The following example shows the error message that appears if you try to trigger a rekey on the secondary KS:

```

Device# crypto gdoi ks rekey

ERROR for group GET: This command must be executed on Pri-KS

```

Note If time-based antireplay (TBAR) is set, the key server periodically sends a rekey to the group members every 2 hours (7200 sec). In the following example, even though the lifetime is set to 8 hours (28800 sec), the rekey timer is set to 2 hours.

```

Device(config)# crypto ipsec profile atm-profile
Device(ipsec-profile)# set security-association lifetime seconds 28800
!
Device(ipsec-profile)# exit
Device(config)# crypto gdoi group ATM-DSL
Device(config-gdoi-group)# server local
Device(gdoi-sa-ipsec)# sa ipsec 1
!
Device(gdoi-sa-ipsec)# replay time window-size 100

```

The commands **show crypto gdoi gm replay** and **show crypto gdoi ks replay** displays TBAR information.

Feature Information for GET VPN GM Removal and Policy Trigger

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 316: Feature Information for GET VPN GM Removal and Policy Trigger

Feature Name	Releases	Feature Information
GET VPN GM Removal and Policy Trigger		<p>This feature provides a command that lets you efficiently eliminate unwanted GMs from the GET VPN network, provides a rekey triggering command to install new SAs and remove obsolete SAs, and provides commands that display whether devices on the network are running versions of GET VPN software that support these features.</p> <p>The following commands were introduced or modified: clear crypto gdoi, crypto gdoi ks, show crypto gdoi.</p>

CHAPTER 238

GDOI MIB Support for GET VPN

The existing MIBs in crypto are the Internet Key Exchange (IKE) and IP security (IPsec) MIBs, which are not sufficient for Group Domain of Interpretation (GDOI). The GDOI MIB Support for GET VPN feature adds MIB support for RFC 6407, [The Group Domain of Interpretation](#) ; it supports only the objects related to the GDOI MIB IETF standard. You can import the GDOI MIB .my file into an SNMP management station and parse it to retrieve the table objects and hierarchy information.

The GDOI MIB consists of objects and notifications (formerly called traps) that include information about GDOI groups, group member (GM) and key server (KS) peers, and the policies that are created or downloaded. Only “get” operations are supported for GDOI.

To configure GDOI MIB support for GET VPN, see the “Configuring GDOI MIB Support for GET VPN” section.

- [Information About GDOI MIB Support for GET VPN, on page 3245](#)

Information About GDOI MIB Support for GET VPN

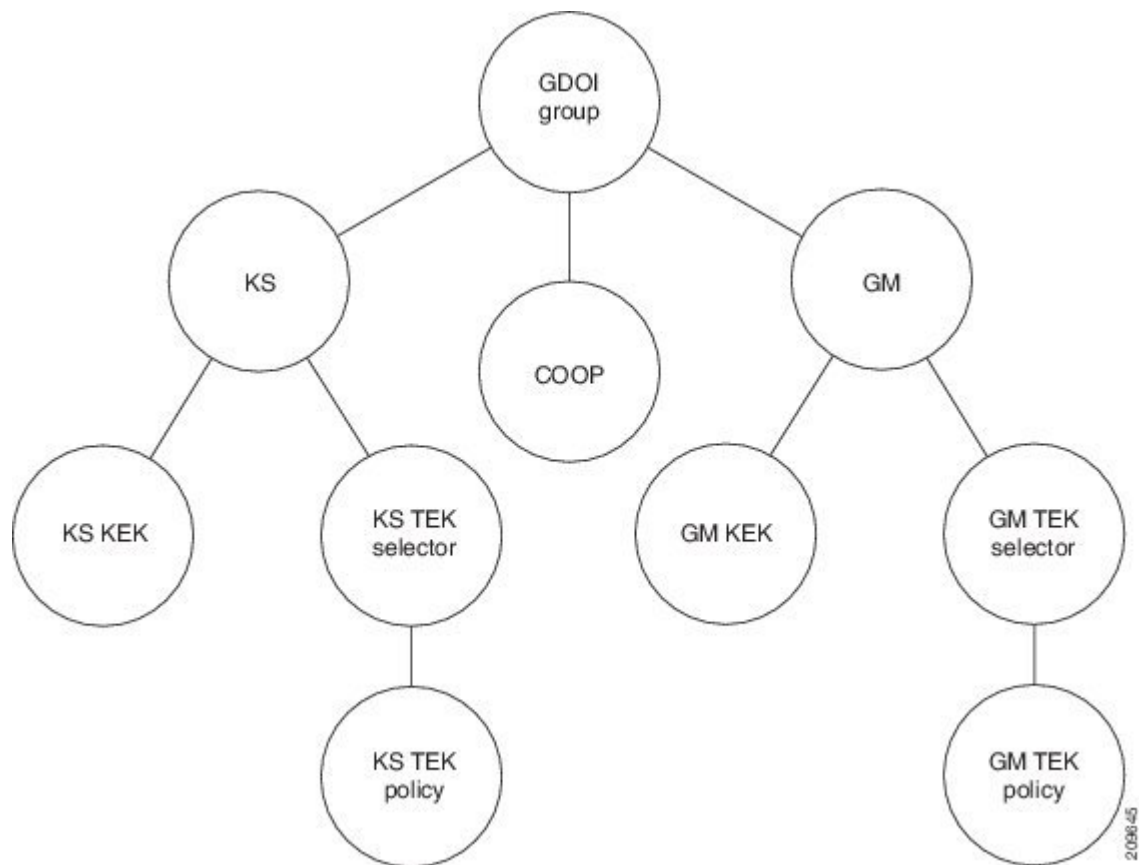

GDOI MIB Compatibility with Other GET VPN Software Versions

The GDOI MIB Support for GET VPN feature provides a command that you use on the KS (or primary KS) to check whether all the devices in the network are running versions that support the GDOI MIB. For more information, see the “Ensuring that GMs Are Running Software Versions That Support the GDOI MIB” section.

GDOI MIB Table Hierarchy

The GDOI MIB objects are organized into the following GDOI MIB tables. Following is the relationship (hierarchy) among the tables:

Figure 142: GDOI MIB Table Hierarchy

GDOI MIB Table Objects

Following is a list of the MIB table objects (listed per group).

Group table objects:

- Group ID type—Specifies whether the group ID is an IP address, group number, hostname, and so on.
- Group ID length—Number of octets in the group ID value.
- Group ID value—Group number, IP address, or hostname.
- Group name—String value.
- Group member count -- Specifies the number of registered KSs to this group.
- Group active peer KS count -- Specifies the number of active KSs to this group.
- Group last rekey retransmits -- Specifies the cumulative count of number of rekey messages and retransmit messages sent as a part of last rekey operation.
- Group last rekey time taken -- Specifies the time taken by the KS to complete the last rekey operation.

KS table objects:

- KS ID type
- KS ID length
- KS ID value
- Active KEK—SPI of the key encryption key (KEK) that is currently used by the KS to encrypt the rekey message.
- Last rekey sequence number—Last rekey number that was sent by the KS to the group.
- KS Role -- Primary or secondary.
- Number of registered GMs -- count of GMs registered to this KS.

COOP table objects:

- COOP peer ID type
- COOP peer ID length
- COOP peer ID value
- COOP peer ID role -- Primary or secondary
- COOP peer status -- Alive, dead or unknown
- Number of registered GMs -- count of GMs registered to the COOP peer

GM table:

- GM ID type
- GM ID length
- GM ID value
- Registered KS ID type—ID type of the KS to which the GM is registered.
- Registered KS ID length
- Registered KS ID value
- Active KEK—SPI of the KEK currently used by the GM to decrypt rekey messages.
- Last rekey seq number—Last rekey number received by the GM.
- Count of active TEKs -- number of active TEKs used by the GM to encrypt/decrypt/authenticate dataplane traffic.

KS KEK table:

- KEK index
- KEK SPI
- KEK source ID information—Source ID type, ID length, and ID value.
- KEK source ID port—Port associated with the source ID.
- KEK destination ID information—Destination ID type, ID length, and ID value.

- KEK destination ID port—Port associated with the destination ID.
- IP protocol ID—UDP or TCP.
- Key management algorithm (unused).
- Encryption algorithm and key length (bits)
- SIG payload hash algorithm, SIG payload signature algorithm, and SIG payload key length (bits).
- Hash algorithm (will be reused from the IPsec MIB)
- Diffie-Hellman group
- KEK original lifetime (seconds)—Maximum time for which a KEK is valid.
- KEK remaining lifetime (seconds)

KS TEK selector table (corresponds to the ACLs that are configured as part of the IPsec SA in the GDOI group configuration on the KS):

- TEK selector index—An integer index for traffic encryption keys (TEK).
- TEK source ID information—Source ID type, ID length, and ID value.
- TEK source ID port—Port associated with the source ID.
- TEK destination ID information—Destination ID type, ID length, and ID value.
- TEK destination ID port—Port associated with the destination ID.
- TEK Security protocol—GDOI_PROTO_IPSEC_ESP protocol ID value in the SA TEK payload (see RFC 6407).

KS TEK policy table:

- TEK policy index—An integer index.
- TEK SPI—Four octets
- Encapsulation mode—Tunnel or transport.
- Encryption algorithm and key length (bits)
- Integrity and authentication algorithm and key length (bits)
- TBAR window size (seconds)
- TEK original lifetime (seconds)—Maximum time for which a TEK is valid.
- TEK remaining lifetime (seconds)
- TEK Status—Inbound, outbound, or not in use.

GM KEK table:

- KEK index—An integer index.
- KEK SPI
- KEK source ID information—Source ID type, ID length, and ID value.

- KEK source ID port—Port associated with the source ID.
- KEK destination ID information—Destination ID type, ID length, and ID value.
- KEK destination ID port—Port associated with the destination ID.
- IP protocol ID—UDP or TCP.
- Key management algorithm (unused)
- Encryption algorithm and key length (bits)
- SIG payload hash algorithm, SIG payload signature algorithm, and SIG payload key length (bits)
- Hash algorithm
- Diffie-Hellman group
- KEK original lifetime (seconds)—Maximum time for which a KEK is valid.
- KEK remaining lifetime (seconds)

GM TEK selector table (corresponds to the ACLs that are downloaded to the GM as part of the TEK policy from the KS):

- TEK selector index—An integer index.
- TEK source ID information—Source ID type, ID length, and ID value.
- TEK source ID port—Port associated with the source ID.
- TEK destination ID information—Destination ID type, ID length, and ID value.
- TEK destination ID port—Port associated with the destination ID.
- TEK Security protocol—GDOI_PROTO_IPSEC_ESP protocol ID value in the SA TEK payload (see RFC 6407).

GM TEK policy table:

- TEK policy index—An integer index.
- TEK SPI—Four octets.
- Encapsulation mode—Tunnel or transport.
- Encryption algorithm and key length (bits)
- Integrity and authentication algorithm and key length (bits)
- TBAR window size (seconds)
- TEK original lifetime (seconds)—Maximum time for which a TEK is valid.
- TEK remaining lifetime (seconds)
- TEK Status—Inbound, outbound, or not in use.

GDOI MIB Notifications

The GDOI MIB supports the Simple Network Management Protocol (SNMP) notifications in the following table. The GDOI MIB contains two kinds of notifications: those generated by the KS and those generated by each GM. You can enable any combination of notifications (or all notifications).

Table 317: SNMP Notifications Supported by the GDOI MIB

Notification	Description
KS New Registration	A KS first received a registration request from a GM.
KS Registration Complete	A GM completed registration to the KS.
KS Rekey Pushed	A rekey message was sent by the KS.
KS No RSA Keys	An error notification was received from the KS because of missing RSA keys.
GM Register	A GM first sent a registration request to a KS.
GM Registration Complete	A GM completed registration to a KS.
GM Re-Register	A GM began the reregistration process with a KS.
GM Rekey Received	A rekey message was received by a GM.
GM Incomplete Config	A GM sent an error notification because of a missing configuration.
GM Rekey Failure	A GM sent an error notification because it cannot process and install a rekey.
KS Role Change	A KS switches between primary and secondary role.
KS GM Deleted	Generated when a GM is deleted from the KS.
KS Peer Reachable	Generated by a KS when unreachable COOP peer becomes reachable.
KS Peer Unreachable	Generated by a KS when reachable COOP peer becomes unreachable.

For more information, see the “Enabling GDOI MIB Notifications” section.

GDOI MIB Limitations

The GDOI MIB contains only objects that are listed in RFC 6407 and does not contain objects for functionality specific to the Cisco implementation of GDOI. This functionality includes:

- Cooperative key servers
- GM ACLs
- Receive-only SAs
- Fail-close/fail-open
- Crypto map objects
- Other Cisco GET VPN-specific features

How to Configure GDOI MIB Support for GET VPN

Ensuring that GMs Are Running Software Versions That Support the GDOI MIB

Perform this task on the KS (or primary KS) to ensure that all devices in the GET VPN network support the GDOI MIB.

SUMMARY STEPS

1. **enable**
2. **show crypto gdoi feature gdoi-mib**
3. **show crypto gdoi feature gdoi-mib | include No**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto gdoi feature gdoi-mib Example: Device# show crypto gdoi feature gdoi-mib	Displays the version of the GET VPN software running on each KS and GM in the network and displays whether that device supports the GDOI MIB.
Step 3	show crypto gdoi feature gdoi-mib include No Example: Device# show crypto gdoi feature gdoi-mib include No	(Optional) Finds only those devices that do not support the GDOI MIB.

Creating Access Control for an SNMP Community

You specify an SNMP community access string to define the relationship between the SNMP manager and the SNMP agent on the KS or GM in order to permit access to SNMP. Your community access string acts like a password to regulate access to the agent on the device.

Perform this task to specify the community access string.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **snmp-server community *community-string* [view *view-name*] [ro | rw] [ipv6 *nacl*] [*access-list-number* | *extended-access-list-number*] [*access-list-name*]**

4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	snmp-server community <i>community-string</i> [view <i>view-name</i>] [ro rw] [ipv6 nacl] [<i>access-list-number</i> <i>extended-access-list-number</i> <i>access-list-name</i>] Example: Device(config)# snmp-server community mycommunity	Specifies the community access string.
Step 4	end Example: Device(config)# end	Exits global configuration mode, saves the configuration, and returns to privileged EXEC mode.

For more information about specifying a community access string, refer to the “Configuring SNMP Support” module in the *SNMP Configuration Guide*. For more information about the **snmp-server community** command (including syntax and usage guidelines), refer to the [Cisco IOS SNMP Support Command Reference](#).

Enabling Communication with the SNMP Manager

Perform this task to enable communication between the SNMP agent on the KS or GM and the SNMP manager.

SUMMARY STEPS

1. enable
2. configure terminal
3. snmp-server host {hostname | ip-address} version {1 | 2c | 3} community-string
4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	snmp-server host {hostname ip-address} version {1 2c 3} <i>community-string</i> Example: Device(config)# snmp-server host 209.165.200.225 version 2c mycommunity	Specifies the host to receive SNMP notifications. <ul style="list-style-type: none"> • 2c is usually used as the SNMP version.
Step 4	end Example: Device(config)# end	Exits global configuration mode, saves the configuration, and returns to privileged EXEC mode.

For more information about enabling communication with the SNMP manager, refer to the “Configuring SNMP Support” module in the *SNMP Configuration Guide*. For more information about the **snmp-server host** command (including syntax and usage guidelines), refer to the [Cisco IOS SNMP Support Command Reference](#).

Enabling GDOI MIB Notifications

Perform this task to enable GDOI MIB notifications on the KS or GM.

SUMMARY STEPS

1. enable
2. configure terminal
3. snmp-server enable traps gdoi [*notification-type*]
4. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example:	Enters global configuration mode.

	Command or Action	Purpose
	Device# configure terminal	
Step 3	<p>snmp-server enable traps gdoi [<i>notification-type</i>]</p> <p>Example:</p> <pre>Device(config)# snmp-server enable traps gdoi gm-registration-complete gm-rekey-rcvd ks-new-registration ks-reg-complete</pre>	<p>Specifies the particular SNMP notifications to be enabled. You can specify any combination of the following types in any order. If you enter the command without any of the following keywords, all GDOI MIB notifications are enabled.</p> <ul style="list-style-type: none"> • gm-incomplete-cfg—A GM sent an error notification because of a missing configuration. • gm-re-register—A GM began the reregistration process with a KS. • gm-registration-complete—A GM completed registration to a KS. • gm-rekey-fail—A GM sent an error notification because it cannot successfully process and install a rekey. • gm-rekey-rcvd—A rekey message was received by a GM. • gm-start-registration—A GM first sent a registration request to a KS. • ks-new-registration—A KS first received a registration request from a GM. • ks-no-rsa-keys—An error notification was received from the KS because of missing RSA keys. • ks-reg-complete—A GM completed registration to the KS. • ks-rekey-pushed—A rekey message was sent by the KS. • ks-gm-deleted—A GM is deleted by the KS. • ks-peer-reachable—An unreachable COOP peer becomes reachable. • ks-peer-unreachable—A reachable COOP peer becomes unreachable. • ks-role-change—A KS changes its role from primary to secondary or vice-versa.
Step 4	<p>end</p> <p>Example:</p> <pre>Device(config)# end</pre>	<p>Exits global configuration mode, saves the configuration, and returns to privileged EXEC mode.</p>

Configuration Examples for GDOI MIB Support for GET VPN

Example: Ensuring That GMs Are Running Software Versions That Support the GDOI MIB

The following example shows how to use the GET VPN software versioning command on the KS (or primary KS) to check whether all the devices in the network support the GDOI MIB:

```
Device# show crypto gdoi feature gdoi-mib

Group Name: GET
Key Server ID      Version  Feature Supported
-----
10.0.8.1           1.0.2   Yes
10.0.9.1           1.0.2   Yes
10.0.10.1          1.0.2   Yes
10.0.11.1          1.0.2   Yes
Group Member ID    Version  Feature Supported
-----
10.0.11.2           1.0.2   Yes
10.0.11.3           1.0.1   No
```

The following example shows how to find only those devices that do not support the GDOI MIB:

```
Device# show crypto gdoi feature gdoi-mib | include No

10.0.11.3          1.0.1   No
```

Example: Creating Access Control for an SNMP Community

The following example shows how to specify an SNMP community string named mycommunity to define the relationship between the SNMP manager and the SNMP agent on the KS or GM in order to permit access to SNMP:

```
Device> enable
Device# configure terminal
Device(config)# snmp-server community mycommunity
Device(config)# end
```

Example: Enabling Communication with the SNMP Manager

The following example shows how to enable communication with the SNMP manager. This example uses a community string named mycommunity that has already been created:

```
Device> enable
Device# configure terminal
```

```
Device(config)# snmp-server host 209.165.200.225 version 2c mycommunity
Device(config)# end
```

Example: Enabling GDOI MIB Notifications

The following example shows how to enable GDOI MIB notifications:

```
Device> enable
Device# configure terminal
Device(config)# snmp-server enable traps gdoi gm-registration-complete gm-rekey-rcvd
ks-new-registration ks-reg-complete
Device(config)# end
```

CHAPTER 239

GET VPN Resiliency

The GET VPN Resiliency feature improves the resiliency of Cisco Group Encrypted Transport (GET) VPN so that data traffic disruption is prevented or minimized when errors occur.

- [Prerequisites for GET VPN Resiliency, on page 3259](#)
- [Restrictions for GET VPN Resiliency, on page 3259](#)
- [Information About GET VPN Resiliency, on page 3259](#)
- [How to Configure GET VPN Resiliency, on page 3261](#)
- [Configuration Examples for GET VPN Resiliency, on page 3266](#)
- [Additional References for GET VPN Resiliency, on page 3267](#)
- [Feature Information for GET VPN Resiliency, on page 3268](#)

Prerequisites for GET VPN Resiliency

All key servers (KSs) and group members (GMs) on which you want to enable this feature must be running GET VPN software version 1.0.4 or higher. You should use this feature only after all devices in the GET VPN network are upgraded to GET VPN software versions that support this feature. This feature provides a command that you use on the KS (or primary KS) to check whether all devices in the network are running versions that support this feature. For more information, see the “*Ensuring That GMs Are Running Software Versions That Support Long SA Lifetime*” section.

Restrictions for GET VPN Resiliency

- All key servers (KSs) and group members (GMs) must be upgraded for Long SA Lifetime.

Information About GET VPN Resiliency

Long SA Lifetime

The long security association (SA) lifetime functionality extends the maximum lifetime of the key encryption key (KEK) and traffic encryption key (TEK) from 24 hours to 30 days. This functionality also lets you configure key servers (KSs) to continue to send periodic reminder rekeys to group members (GMs) that do not respond with an acknowledgment in the last scheduled rekey.

By using a long SA lifetime in combination with periodic reminder rekeys, a KS can effectively synchronize GMs if they miss a scheduled rekey before the keys roll over.

Note For a lifetime longer than 24 hours, the encryption algorithm must be Advanced Encryption Standard-cipher block chaining (AES-CBC) or Advanced Encryption Standard-Galois/Counter Mode (AES-GCM) with an AES key of 128 bits or stronger.

You can use the long SA lifetime functionality along with the GETVPN Suite-B feature to use AES-GSM and Galois Message Authentication Code-Advanced Encryption Standard (GMAC-AES) as traffic encryption key (TEK) policy transforms in a group for packets encapsulated with GCM-AES and GMAC-AES.

Migrating to Long SA Lifetime

When migrating to the long SA lifetime functionality (greater than or equal to one day), the following rules apply:

- When a long SA lifetime is configured on a crypto IPsec profile, GETVPN displays a warning message to not use the IPsec profile for a non- Group Domain of Interpretation (GDOI) group.
- If group members are registered to a key server with short SA lifetime and the key server changes the policy to long SA lifetime, GETVPN checks the software version of all the GMs when the **crypto gdoi ks rekey** command is configured to initiate the policy change. If the GMs registered with the KS do not support long SA lifetime, a message is displayed to discourage the policy change until all GMs are upgraded.
- When the Long SA feature is enabled in KS, it will block registration from GMs running older Cisco IOS releases, which does not support this feature.

Clock Skew Mitigation

Sometimes with longer security association (SA) lifetimes, a group member (GM) may not receive updates from a key server for a longer duration. This may result in group members experiencing clock skew for key encryption key (KEK) lifetime, traffic encryption key (TEK) lifetime, and Time-Based Anti-Replay (TBAR) pseudotime. The refresh rekey and rollover to new outbound IPsec SA helps GMs in mitigating clock skew issues.

Refresh Rekey

If the traffic encryption key (TEK) lifetime is set for a duration greater than two days and Time-Based Anti-Replay (TBAR) is disabled, a key server sends a refresh rekey every 24 hours which updates the key encryption key (KEK) lifetime, TEK lifetime, and TBAR pseudotime on all group members (GMs). In simple terms, a refresh rekey is a retransmission of the current KEK policy, TEK policy, and TBAR pseudotime (if enabled) to all GMs, regardless of the status of receiving a unicast acknowledgment (ACK) for the last rekey. If TBAR is enabled, the refresh rekey is sent every two hours to synchronize the pseudotime, so that an additional refresh rekey is not required.

Rollover to New Outbound IPsec SA

When a long SA lifetime (greater than one day) is configured, the rollover happens when the remaining lifetime of the traffic encryption key (TEK) reaches 1% of the old TEK configured lifetime that has a lower limit of 30 seconds and not 30 seconds of the old TEK's remaining lifetime. This allows a greater clock skew between the group members (GMs) before discarding traffic from one GM rolling over to the new TEK late (after the

other GM has already deleted the old TEK). This mitigates the GM from being “offline” (disconnected from the KS) for a long duration and from being unable to receive the refresh rekeys to mitigate the clock skew.

Periodic Reminder Sync-Up Rekey

The periodic reminder sync-up rekey functionality in the key server (KS) lets you to send periodic reminder rekeys to group members (GMs) who do not respond with an acknowledgment (ACK) in the last scheduled rekey. This functionality in combination with the long SA lifetime functionality is effective for a KS to synchronize with GMs when they miss a scheduled rekey before the keys rollover. In a KS group configuration, a new keyword **periodic** is added to the **rekey retransmit** command when configuring the rekey retransmission.

Each periodic rekey increments the sequence number, similar to rekey retransmissions. The GM is removed from the database on the KS after 3 scheduled rekeys (not retransmissions) for which the GM does not send an ACK.

Pre-Positioned Rekey

The pre-positioned rekey functionality allows the key server (KS) to send a rekey earlier than half the duration of the SA lifetime, when a longer SA lifetime (greater than one day) is configured. The normal behavior of sending the rekey is used for a short SA lifetime. When group members (GMs) receive this early rekey, they continue to use the old TEK as outbound until rolled over to the new TEK as outbound. The pre-positioned rekey feature along with the Long SA Lifetime feature improves key rollover stability. This functionality allows the (KS) sufficient time to recover rekey errors, such as periodic reminder rekeys and synchronize rekeys.

How to Configure GET VPN Resiliency

Ensuring That GMs Are Running Software Versions That Support Long SA Lifetime

You should use the Long SA Lifetime feature only after all devices in the GET VPN network are upgraded to GET VPN software versions that support this feature.

Perform this task on the key server (or primary key server) to ensure that all devices in the network support long SA lifetime.

SUMMARY STEPS

1. **enable**
2. **show crypto gdoi feature long-sa-lifetime**
3. **show crypto gdoi feature long-sa-lifetime | include No**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example:	Enables privileged EXEC mode. • Enter your password if prompted.

	Command or Action	Purpose
	Device> enable	
Step 2	show crypto gdoi feature long-sa-lifetime Example: Device# show crypto gdoi feature long-sa-lifetime	Displays the version of the GET VPN software running on each KS and GM in the GET VPN network and displays whether that device supports long SA lifetime.
Step 3	show crypto gdoi feature long-sa-lifetime include No Example: Device# show crypto gdoi feature long-sa-lifetime include No	(Optional) Displays only those devices that do not support long SA lifetime.

Configuring Long SA Lifetime

Configuring Long SA Lifetime for TEK

To configure long SA lifetime for traffic encryption key (TEK), perform the following steps.

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto ipsec profile *name*
4. set security-association lifetime days *days*
5. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto ipsec profile <i>name</i> Example: Device(config)# crypto ipsec profile gdoi-p	Defines the IPsec parameters that are to be used for IPsec encryption between two IPsec devices and enters crypto IPsec profile configuration mode.
Step 4	set security-association lifetime days <i>days</i> Example: Device(ipsec-profile)# set security-association lifetime days 15	Configures the security association (SA) lifetime to over one day. <ul style="list-style-type: none"> • The maximum number of days is 30.

	Command or Action	Purpose
Step 5	end Example: Device(ipsec-profile)# end	Exits crypto IPsec profile configuration mode and returns to privileged EXEC mode.

Configuring Long SA Lifetime for KEK

To configure long SA lifetime for key encryption key (TEK), perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. **identity number** *number*
5. **server local**
6. **rekey lifetime days** *days*
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Device(config)# crypto gdoi group GET	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	identity number <i>number</i> Example: Device(config-gdoi-group)# identity number 3333	Identifies a GDOI group number.
Step 5	server local Example: Device(config-gdoi-group)# server local	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 6	rekey lifetime days <i>days</i> Example: Device(gdoi-local-server)# rekey lifetime days 20	Limits the number of days or seconds for a KEK.

	Command or Action	Purpose
Step 7	end Example: Device(gdoi-local-server) # end	Exits GDOI local server configuration mode and returns to privileged EXEC mode.

Configuring the Periodic Reminder Sync-Up Rekey

To configure the periodic reminder sync-up rekey, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. **identity number** *number*
5. **server local**
6. **rekey retransmit** *number-of-seconds* **periodic**
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Device(config)# crypto gdoi group group1	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	identity number <i>number</i> Example: Device(config-gdoi-group)# identity number 3333	Identifies a GDOI group number.
Step 5	server local Example: Device(config-gdoi-group)# server local	Designates a device as a GDOI key server and enters GDOI local server configuration mode.

	Command or Action	Purpose
Step 6	rekey retransmit <i>number-of-seconds</i> periodic Example: Device(gdoi-local-server)# rekey retransmit 10 periodic	Specifies the number of times the rekey message is periodically retransmitted. <ul style="list-style-type: none"> • If this command is not configured, there will be no retransmits.
Step 7	end Example: Device(gdoi-local-server)# end	Exits GDOI local server configuration mode and returns to privileged EXEC mode.

Verifying and Troubleshooting GET VPN Resiliency

Verifying and Troubleshooting GET VPN Resiliency on a Key Server

To view the configuration that is running on a key server (KS), use the **show running-config** command and the following commands.

SUMMARY STEPS

1. **enable**
2. **show crypto gdoi**
3. **show crypto gdoi ks rekey**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto gdoi Example: Device# show crypto gdoi	Displays the current GDOI configuration and the policy that is downloaded from the KS.
Step 3	show crypto gdoi ks rekey Example: Device# show crypto gdoi ks rekey	Displays information about the rekeys that are sent from the KS.

Verifying and Troubleshooting GET VPN Resiliency on a Group Member

To view the configuration that is running on a group member (GM), use the **show running-config** command and the following commands.

SUMMARY STEPS

1. **enable**

2. `show crypto gdoi ks rekey`
3. `show crypto gdoi ks policy`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device# <code>enable</code>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto gdoi ks rekey Example: Device# <code>show crypto gdoi ks rekey</code>	Displays information about the rekeys that are sent from the KS.
Step 3	show crypto gdoi ks policy Example: Device# <code>show crypto gdoi ks policy</code>	Displays the time until the next rekey.

Configuration Examples for GET VPN Resiliency

Example: Ensuring That GMs Are Running Software Versions That Support Long SA Lifetime

The following example shows how to use the GET VPN software versioning command on the KS (or primary KS) to check whether all the devices in each group support long SA lifetimes:

```
Device# show crypto gdoi feature long-sa-lifetime

Group Name: GETVPN
  Key Server ID      Version  Feature Supported
  10.0.5.2           1.0.4   Yes
  10.0.6.2           1.0.4   Yes
  10.0.7.2           1.0.3   No
  10.0.8.2           1.0.2   No

  Group Member ID    Version  Feature Supported
  10.0.1.2           1.0.2   No
  10.0.2.5           1.0.3   No
  10.0.3.1           1.0.4   Yes
  10.0.3.2           1.0.4   Yes
```

You can also enter the above command on a GM (which will display the information for the GM but not for the KS or other GMs).

The following example shows how to enter the command on the KS (or primary KS) find only those devices in the GET VPN network that do *not* support long SA lifetimes:

```
Device# show crypto gdoi feature long-sa-lifetime | include No

10.0.7.2          1.0.3          No
10.0.8.2          1.0.2          No
10.0.1.2          1.0.2          No
10.0.2.5          1.0.3          No
```

Example: Configuring Long SA Lifetime

Example: Configuring Long SA Lifetime for TEK

The following example shows how to configure the long SA lifetime for traffic encryption key (TEK):

```
Device> enable
Device# configure terminal
Device(config)# crypto ipsec profile gdoi-p
Device(ipsec-profile)# set security-association lifetime days 15
Device(ipsec-profile)# end
```

Example: Configuring Long SA Lifetime for KEK

The following example shows how to configure the long SA lifetime for key encryption key (KEK):

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group GET
Device(config-gdoi-group)# identity number 3333
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# rekey lifetime days 20
Device(gdoi-local-server)# end
```

Example: Configuring the Periodic Reminder Sync-Up Rekey

The following example shows how to configure the periodic reminder sync-up rekey:

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group group1
Device(config-gdoi-group)# identity number 3333
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# rekey retransmit 10 periodic
Device(gdoi-local-server)# end
```

CHAPTER 240

GETVPN Resiliency GM - Error Detection

The GETVPN Resiliency - GM Error Detection feature detects erroneous packets in the data plane for each Group Domain of Interpretation (GDOI) group such as invalid stateful packet inspections (SPIs) or Time-Based Anti-Replay (TBAR) errors. These errors are tracked, and the outer source IP address of the packet is recorded.

- [Information About GETVPN Resiliency - GM Error Detection, on page 3271](#)

Information About GETVPN Resiliency - GM Error Detection

Error Handling

The GETVPN Resiliency - GM Error Detection feature should be enabled on both the GM and KS for error handling to work. The KS encodes the group information in the SPI (Security Parameter Index) and then it downloads it via the TEK policy to the GM.

When a failure is detected by the GETVPN Resiliency - GM Error Detection feature, a syslog message is generated to show the source IP address of the erroneous packet:

```
*Feb 10 21:01:56.043:
%GDOI-4-TIMEBASED_REPLAY_FAILED: An anti replay check has failed in
group GETVPN from sourceip-address
100.0.0.9.
  my_pseudotime is 600006.78 secs,
  peer_pseudotime is 500033.34 secs, replay_window is 100
(second)
*Feb 10 21:01:56.043:
%CRYPTO-4-PKT_REPLAY_ERR: decrypt: replay check failed
connection id=29, sequence
number=11
```

The **show crypto gdoi gm** command displays the history of the last 50 Time-Based Anti-Replay (TBAR) errors. You can use these source IP address records to track down the sender group members (GMs) and investigate any existing hardware or software problems. The following statistical information is also available in the command:

- GM recovery feature ON/OFF

- Interval between recoveries
- Number of GM recovery reregistration enforced

When errors occur, the GM reregisters to the next available key server (KS) to retrieve the latest policy and keys and maintains all previously downloaded group policies and keys until the registration is complete.

For instance, when a cooperative key server (COOP KS) split occurs, each promoted KS generates its own Key Encryption Key (KEK) and Traffic Encryption Key (TEK). When a GM receives invalid SPI packets, it will decode it (the KS encodes the group information in the SPI and then it downloads it via the TEK policy to the GM) and if it finds that it belongs to the current getvpn group then it will start the recovery registration.

An invalid SPIs can belong to one of the following two categories:

- Positive invalid SPI: An invalid SPI that belong to the current group and require GM recovery registration.
- Negative invalid SPI: An invalid SPI that does not require recovery registration.

In the case of a positive invalid SPI, a recovery registration to the next key server (KS) on its list is performed. This recovery registration is repeated for each invalid stateful packet inspection (SPI) packet or TBAR error in each client recovery interval to the next KS on the list. When all the KSs in the list are recovered and no longer contain the invalid SPI, that SPI is marked as a false positive and no more recovery registrations are performed. The KSs will always do the recovery registration for TBAR errors. However, once the GM recovers to all the KSs in the list because of an invalid SPI and none of the KSs has that SPI, it will mark that SPI as a false positive and will not do more recovery registrations due to that SPI.

A syslog message is generated to notify you that this GM recovery reregistration feature is triggered. For instance, if you configure the GM to monitor for control-plane errors every 300 seconds, when the recovery registration occurs the following syslog is generated:

```
*Feb 23 19:06:28.600: %GDOI-5-GM_RECOVERY_REGISTER: received invalid GDOI packets; register to KS to refresh policy, keys, and PST.
```

How to Configure GETVPN Resiliency - GM Error Detection

Configuring GETVPN Resiliency - GM Error Detection

SUMMARY STEPS

1. **crypto gdoi group** *group-name*
2. **identity number** *number*
3. **server address ipv4** *address*
4. **client recovery-check interval** *interval*
5. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	crypto gdoi group <i>group-name</i> Example:	Creates a Group Domain of Interpretation (GDOI) group and enters GDOI group configuration mode.

	Command or Action	Purpose
	Device(config)# crypto gdoi group GETVPN	
Step 2	identity number <i>number</i> Example: Device(config-gdoi-group)# identity number 1111	Identifies a GDOI group number.
Step 3	server address ipv4 <i>address</i> Example: Device(config-gdoi-group)# server address ipv4 1.0.0.2	Specifies the IP address of the server that the GDOI group is trying to reach.
Step 4	client recovery-check interval <i>interval</i> Example: Device(config-gdoi-group)# client recovery-check interval 300	Sets the interval of time for the client group member (GM) to monitor for control-plane errors.
Step 5	exit Example: Device(config-gdoi-group)# exit	Exits GDOI group configuration mode and returns to global configuration mode.

Configuration Examples for GETVPN Resiliency - GM Error Detection

Example: Configuring GETVPN Resiliency - GM Error Detection

The following example shows how to enable the group member (GM) to monitor for control-plane errors every 300 seconds.

```
crypto gdoi group GETVPN
 identity number 1111
 server address ipv4 1.0.0.2
 client recovery-check interval 300
```

Feature Information for GETVPN Resiliency - GM Error Detection

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 320: Feature Information for GETVPN Resiliency - GM Error Detection

Feature Name	Releases	Feature Information
GETVPN Resiliency - GM Error Detection		Detects erroneous packets in the data plane for each GDOI group. The following command was introduced: client recovery-check interval.

CHAPTER 241

GETVPN CRL Checking

During the Group Encrypted Transport VPN (GET VPN) process, certificates are received from a certificate authority (CA) and used as a proof of identity. Certificates may be revoked for a number of reasons, such as key compromise or certificate loss. Revoked certificates are placed on a certificate revocation list (CRL) that is published periodically to a repository. This list is stored on the repository for the length of time specified by a configured CRL lifetime, and can be anything from a few hours to several days.

- [Information About GETVPN CRL Checking, on page 3277](#)
- [How to Configure GETVPN CRL Checking, on page 3278](#)
- [Configuration Examples for GETVPN CRL Checking, on page 3283](#)
- [Additional References for GETVPN CRL Checking, on page 3284](#)
- [Feature Information for GETVPN CRL Checking, on page 3285](#)

Information About GETVPN CRL Checking

In Internet Key Exchange (IKE), certificates are validated when a session is established between two peers. Current sessions are not affected by certificate revocation. However, new sessions will fail to establish and certificates are not validated again unless group members reregister to the key server (KS).

The GETVPN CRL Checking feature enables public key infrastructure (PKI) to notify Group Domain of Interpretation (GDOI) KSs when a new CRL is available for a configured trustpoint. The KS then creates a new Key Encryption Key (KEK) and sends a reauthentication message to the group member devices, which print a syslog message, delete the current KEKs, and reregister to the KS.

Cooperative Key Server Protocol Integration

Cooperative Key Server Protocol (COOP) is a feature of GET VPN that allows you to configure multiple key servers (KSs) in a VPN network. It is used for KS redundancy.

GETVPN CRL checking integrates with COOP by enabling group member (GM) reauthentication on all KSs. However there is always a possibility that a COOP split may occur, where connectivity is temporarily lost among cooperative KSs.

No COOP Split when Reauthentication is Triggered

If no COOP split occurs the primary GM device deletes the Key Encryption Key (KEK) to secondary KSs and sends a reauthentication message to GMs. The secondary KSs then have the current policies synchronized

with the primary policies before the GMs start to reregister. All GMs reregister and reauthenticate to an available KS and receive the new KEK.

COOP Split when Reauthentication is Triggered

If a COOP split occurs before reauthentication is triggered and there are only two primary KSs, they both send out the reauthentication message. Each primary KS creates a new and different KEK. The GM only understands the first reauthentication message it receives as it deletes all the existing KEKs immediately after receiving the message. The GM then reregisters to an available KS and a CRL check takes place. When reregistering, the GM receives either the KEK of the first primary or the KEK of the second primary, depending on which KS the GM reregistered. The GM then installs that KEK and receives further rekeys only from that primary KS. When the COOP merge occurs, the KSs sync up the policies and send rekeys so that all GMs have the current KEK and traffic encryption keys (TEKs).

Avoiding the Creation of Different KEKs

Reauthentication and CRL checking still occurs if reauthentication is triggered during a COOP split. However, triggering the creation of different KEKs in the KSs is avoided by delaying reauthentication. A primary KS only starts the reauthentication if all COOP KSs are reachable (not split). If one COOP KS is not reachable, the primary KS delays sending the reauthentication message until all COOP KSs are reachable.

How to Configure GETVPN CRL Checking

You need to configure several components prior to enabling the GETVPN CRL Checking feature. These include:

- A defined public key infrastructure (PKI) certificate authority (CA) so that group members and key servers are PKI clients and, therefore must enroll to get certificates.
- Key servers (KSs) configured to have certificate revocation list (CRL) checking enabled in PKI.
- KSs configured to download the CRL when it is available on the CA and on a first-needed basis. This means that the KSs download the CRL following the first group member (GM) registration after the new CRL is available. See the “Configuring Key Servers for GETVPN CRL Checking” section.
- CRL checking disabled on the group member devices for PKI. See the “Disabling CRL Checking on Group Members” section.
- Internet Key Exchange (IKE) authentication set to certificates. See the “Setting IKE Authentication to Certificates” section

Configuring Key Servers for GETVPN CRL Checking

To configure key servers (KSs) to download the certificate revocation list (CRL) when the first group member (GM) registration occurs after a new CRL is available on the certificate authority (CA), perform the following steps:

SUMMARY STEPS

1. **ip domain name** *name*
2. **ip http server**

3. **crypto pki trustpoint** *name*
4. **enrollment url** *url*
5. **revocation-check** *method*
6. **exit**
7. **crypto identity** *method*
8. **fqdn** *domain*
9. **fqdn** *domain*
10. **exit**
11. **crypto gdoi group** *group-name*
12. **server local**
13. **authorization identity** *name*
14. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	ip domain name <i>name</i> Example: Device(config)# ip domain name cisco.com	Defines a default domain name that the Cisco IOS software uses to complete unqualified hostnames (names without a dotted-decimal domain name).
Step 2	ip http server Example: Device(config)# ip http server	Enables the HTTP server on an IP or IPv6 system.
Step 3	crypto pki trustpoint <i>name</i> Example: Device(config)# crypto pki trustpoint mycert	Defines the trustpoint that your device should use and enters CA trustpoint configuration mode.
Step 4	enrollment url <i>url</i> Example: Device(config-ca-trustpoint)# enrollment url http://10.1.3.1:80	Specifies the enrollment URL of the CA.
Step 5	revocation-check <i>method</i> Example: Device(config-ca-trustpoint)# revocation-check crl	Ensures certificate checking is performed by a CRL.
Step 6	exit Example: Device(config-ca-trustpoint)# exit	Exits CA trustpoint configuration mode and returns to global configuration mode.

	Command or Action	Purpose
Step 7	crypto identity <i>method</i> Example: <pre>Device(config)# crypto identity abcd</pre>	Configures the identity of the device with a given list of distinguished names (DNs) in the certificate of the device and enters crypto identity configuration mode. Note You can set restrictions in the device configuration that prevent peers with specific certificates, especially certificates with particular DN, from having access to selected encrypted interfaces.
Step 8	fqdn <i>domain</i> Example: <pre>Device(config-crypto-identity)# fqdn ut01-unix5.cisco.com</pre>	Derives the name mangler from the remote identity of the fully qualified domain name (FQDN) for a GM.
Step 9	fqdn <i>domain</i> Example: <pre>Device(config-crypto-identity)# fqdn ut01-unix6.cisco.com</pre>	Derives the name mangler from the remote identity of the FQDN for the next GM.
Step 10	exit Example: <pre>Device(config-crypto-identity)# exit</pre>	Exits crypto identity configuration mode and returns to global configuration mode.
Step 11	crypto gdoi group <i>group-name</i> Example: <pre>Device(config)# crypto gdoi group gdoi-group1</pre>	Creates a Group Domain of Interpretation (GDOI) group and enters GDOI group configuration mode.
Step 12	server local Example: <pre>Device(config-gdoi-group)# server local</pre>	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 13	authorization identity <i>name</i> Example: <pre>Device(config-gdoi-local-server)# authorization identity abcd</pre>	Specifies an authorization identity for a GDOI group based on a distinguished name (DN) or FQDN,
Step 14	end Example: <pre>Device(config-gdoi-local-server)# end</pre>	Exits GDOI local server configuration mode and returns to privileged EXEC mode.

Disabling CRL Checking on Group Members

To disable certificate revocation list (CRL) checking on group members (GMs) for public key infrastructure (PKI), perform the following steps:

SUMMARY STEPS

1. **ip domain name** *name*
2. **ip http server**
3. **crypto pki trustpoint** *name*
4. **enrollment url** *url*
5. **revocation-check** *method*
6. **exit**

DETAILED STEPS

	Command or Action	Purpose
Step 1	ip domain name <i>name</i> Example: Device(config)# ip domain name cisco.com	Defines a default domain name that the Cisco IOS software uses to complete unqualified hostnames (names without a dotted-decimal domain name).
Step 2	ip http server Example: Device(config)# ip http server	Enables the HTTP server on an IP or IPv6 system.
Step 3	crypto pki trustpoint <i>name</i> Example: Device(config)# crypto pki trustpoint mycert	Defines the trustpoint that your device should use and enters CA trustpoint configuration mode.
Step 4	enrollment url <i>url</i> Example: Device(config-ca-trustpoint)# enrollment url http://10.1.3.1:80	Specifies the enrollment URL of the certificate authority (CA).
Step 5	revocation-check <i>method</i> Example: Device(config-ca-trustpoint)# revocation-check none	Disables certificate checking on the GMs.
Step 6	exit Example: Device(config-ca-trustpoint)# exit	Exits CA trustpoint mode and returns to global configuration mode.

Setting IKE Authentication to Certificates

SUMMARY STEPS

1. **crypto isakmp policy** *priority*
2. **no authentication pre-share**
3. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	crypto isakmp policy <i>priority</i> Example: Router(config)# crypto isakmp policy 1	Defines an internet key exchange (IKE) policy and enters ISAKMP policy configuration mode.
Step 2	no authentication pre-share Example: Router(config-isakmp)# no authentication pre-share	Resets the authentication method within the IKE policy to the default value.
Step 3	end Example: Router(config)# end	Returns to privileged EXEC mode.

Enabling GETVPN CRL Checking on Key Servers

To configure public key infrastructure (PKI) to notify the Group Domain of Interpretation (GDOI) key server (KS) when a new certificate revocation list (CRL) is available for the configured trustpoint certificate authority (CA), perform the following steps:

SUMMARY STEPS

1. **crypto gdoi group** *group-name*
2. **server local**
3. **registration periodic crl trustpoint** *trustpoint-name*
4. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	crypto gdoi group <i>group-name</i> Example: Device(config)# crypto gdoi group gdoi_group1	Creates a GDOI group and enters GDOI group configuration mode.

	Command or Action	Purpose
Step 2	server local Example: <pre>Device(config-gdoi-group)# server local</pre>	Designates a device as a GDOI key server and enters GDOI local server configuration mode.
Step 3	registration periodic crl trustpoint <i>trustpoint-name</i> Example: <pre>Device(config-gdoi-local-server)# registration periodic crl trustpoint mycert</pre>	Enables periodic registrations for the GDOI Ks when new CRLs become available for the configured PKI trustpoint certificate authority.
Step 4	end Example: <pre>Device(config-gdoi-local-server)# end</pre>	Exits GDOI local server mode and returns to privileged EXEC mode.

Configuration Examples for GETVPN CRL Checking

Example: Enabling GETVPN CRL Checking

The following examples show how the GETVPN CRL checking feature is enabled, including all required preconfigurations.

Example: Configuring Key Servers for GETVPN CRL Checking

In the following example, the key servers (Ks) are configured to download the certificate revocation list (CRL) when the first group member registration occurs after a new CRL is available on the trustpoint certificate authority (CA) named mycert:

```
ip domain name cisco.com
ip http server
crypto pki trustpoint mycert
  enrollment url http://10.1.3.1:80
  revocation-check crl

crypto identity abcd
  fqdn ut01-unix5.cisco.com
  fqdn ut01-unix6.cisco.com

crypto gdoi group gdoi-group1
  server local
  authorization identity abcd
```

Example: Disabling CRL Checking on Group Members

In the following example, CRL checking on Group Members (GM) for public key infrastructure (PKI) is disabled:

```
ip domain name cisco.com
ip http server
crypto pki trustpoint mycert
  enrollment url http://10.1.3.1:80
  revocation-check none
```

Example: Setting IKE Authentication to Certificates

```
crypto isakmp policy 1
  no authentication pre-share
```

Example: Enabling GETVPN CRL Checking on Key Servers

In the following example, PKI is configured to notify the GDOI KS named group1 when a new CRL is available for the trustpoint CA named mycert:

```
Crypto gdoi group gdoi_group1
  Server local
  registration periodic crl trustpoint mycert
```

CHAPTER 242

GET VPN Support with Suite B

The GET VPN Support with Suite B feature adds support of the Suite B set of ciphers to Cisco Group Encrypted Transport (GET) VPN. Suite B is a set of cryptographic algorithms that includes Galois Counter Mode Advanced Encryption Standard (GCM-AES) as well as algorithms for hashing, digital signatures, and key exchange.

Suite B for IP security (IPsec) VPNs is a standard whose usage is defined in RFC 4869, [Suite B Cryptographic Suites for IPsec](#). Suite B provides a comprehensive security enhancement for Cisco IPsec VPNs, and it allows additional security for large-scale deployments. Suite B is the recommended solution for organizations requiring advanced encryption security for the wide-area network (WAN) between remote sites.

- [Prerequisites for GET VPN Support with Suite B, on page 3287](#)
- [Restrictions for GET VPN Support with Suite B, on page 3287](#)
- [Supported Platforms for GET VPN Support with Suite B, on page 3288](#)
- [Information About GET VPN Support with Suite B, on page 3289](#)
- [How to Configure GET VPN Support with Suite B, on page 3297](#)
- [Configuration Examples for GET VPN Support with Suite B, on page 3313](#)
- [Additional References, on page 3316](#)
- [Feature Information for GET VPN Support with Suite B, on page 3317](#)

Prerequisites for GET VPN Support with Suite B

All key servers (KSs) and group members (GMs) on which you want to enable this feature must be running GET VPN software version 1.0.4 or higher. You should use this feature only after all devices in the GET VPN network are upgraded to GET VPN software versions that support this feature. This feature provides a command that you use on the KS (or primary KS) to check whether all devices in the network are running versions that support Suite B. For more information, see the "Ensuring That GMs Are Running Software Versions That Support Suite B" section.

Restrictions for GET VPN Support with Suite B

When they are using a GCM policy or a Galois Message Authentication Code (GMAC) traffic encryption key (TEK) policy, all cooperative KSs for a group must use an access control list (ACL) that has identical ACL entries (ACEs) in the identical order. If not, GMs that register to separate KSs cannot encrypt and decrypt correctly after downloading the policy. This is because with Suite B, an SPI (security parameter index ID that is associated with the TEK) is generated for *each* ACL entry and is unique to each ACL entry.

You cannot reorder entries in an existing ACL. So if you are using a GCM or GMAC TEK policy and must update the ACL on each KS so that it has identical entries in the identical order on each KS, you must remove the ACL from each secondary KS, then create a new ACL on the primary KS, then copy it to the secondary KSs, and then enter the **crypto gdoi ks rekey** command on the primary KS to trigger a rekey across the GET VPN network.

You remove an ACL by using the **no** form of the **ip access-list** command (or if you are using IPv6, the **no** form of the **ipv6 access-list** command).

Supported Platforms for GET VPN Support with Suite B

The following table details the platforms and their corresponding models, each supporting Suite B for GET VPN, organized by release:

Table 322: From Cisco IOS XE Release 16.9.1

Information About GET VPN Support with Suite B

Suite B

Suite B is standardized by the National Security Agency (NSA) and the National Institute of Standards and Technology (NIST). The GET VPN Support with Suite B feature allows these cryptographic algorithms to be used with GDOI and GET VPN in various ways, including the use of SHA-2/HMAC-SHA-2 and AEC-GCM/AES-GMAC.

Secure Hash Algorithm 2 (SHA-2) is a set of cryptographic hash functions (SHA-224, SHA-256, SHA-384, and SHA-512) designed by the NSA and published by the NIST as a U.S. Federal Information Processing Standard (FIPS). SHA-2 includes many changes from its predecessor, SHA-1. SHA-2 comprises a set of four hash functions with digests that are 224, 256, 384, or 512 bits.

HMAC is a mechanism for message authentication using iterative cryptographic hash functions. HMAC-SHA-2 is HMAC used in combination with the SHA-2 version (SHA-224, SHA-256, SHA-384, and SHA-512) iterative cryptographic hash functions in combination with a secret shared key in IPsec. These combinations are called HMAC-SHA-224, HMAC-SHA-256, HMAC-SHA-384, and HMAC-SHA-512. These algorithms can be used as the basis for data origin authentication and integrity verification mechanisms for the authentication header (AH) (although not supported by GET VPN), encapsulating security payload (ESP), IKE, and IKEv2 protocols, and also as pseudo-random functions (PRFs) for IKE and IKEv2.

AES using GCM (AES-GCM) is an encryption algorithm for IPsec. AES using Galois Message Authentication Code (AES-GMAC) is a message integrity algorithm also used for IPsec.

SHA-2 and HMAC-SHA-2

The GET VPN Support with Suite B feature lets you use SHA-2 and HMAC-SHA-2 (HMAC-SHA-256, 384, and 512) as the hash and signature algorithms. SHA-2 and HMAC-SHA-2 with 256, 384, & 512-bit keys are used in

- GDOI registration using IKEv1 as the hash algorithm as described in [Section 3.2](#) (authentication between KSs and GMs) of RFC 6407, [The Group Domain of Interpretation](#).
- The key encryption key (KEK) rekey policy to hash the rekey message for authentication of the rekey message from the KS as well as authentication of the acknowledgment message from the GM.
- The TEK IPsec policy as HMAC-SHA-2 for IPsec SA integrity checking.

AES-GCM and AEC-GMAC

AES-GCM (AES-GCM-128, 192, and 256) and AES-GMAC (AES-GMAC-128, 192, and 256) cryptographic algorithms with 256, 384, and 512-bit keys are used in TEK IPsec policies as IPsec SA encryption and integrity algorithms. GCM is used for encryption and integrity, while GMAC is used for integrity only.

Sets of Cryptographic Algorithms that Comply with Suite B

RFC 4869 describes four sets of cryptographic algorithms for use with IKE and IPsec. When configured, any of these sets will comply with Suite B. Each set consists of an encryption algorithm, a digital signature algorithm, a key agreement algorithm, and a hash or message digest algorithm:

- Suite-B-GCM-128: Provides ESP integrity protection and confidentiality using 128-bit AES-GCM (see RFC 4106, [The Use of Galois/Counter Mode \(GCM\) in IPsec Encapsulating Security Payload \(ESP\)](#)). Use this suite or Suite-B-GCM-256 when ESP integrity protection and encryption are both needed.
- Suite-B-GCM-256: Provides ESP integrity protection and confidentiality using 256-bit AES-GCM (see RFC 4106, [The Use of Galois/Counter Mode \(GCM\) in IPsec Encapsulating Security Payload \(ESP\)](#)). Use this suite or Suite-B-GCM-128 when ESP integrity protection and encryption are both needed.
- Suite-B-GMAC-128: Provides ESP integrity protection using 128-bit AES-GMAC (see RFC 4543, [The Use of Galois Message Authentication Code \(GMAC\) in IPsec ESP and AH](#)) but does not provide confidentiality. Use this suite or Suite-B-GMAC-256 only when there is no need for ESP encryption.
- Suite-B-GMAC-256: Provides ESP integrity protection using 256-bit AES-GMAC (see RFC 4543, [The Use of Galois Message Authentication Code \(GMAC\) in IPsec ESP and AH](#)) but does not provide confidentiality. Use this suite or Suite-B-GMAC-128 only when there is no need for ESP encryption.

Cisco software contains the ability to configure any of these algorithms. The GET VPN Support with Suite B feature allows GET VPN to use these algorithms.

SID Management

In GET VPN, a counter-based mode of operation (for example, ESP-GCM-AES) requires that an initialization vector (IV) is never reused with a group key. Therefore, this feature provides a method to allow a KS to allocate to each GM (for each interface) a unique sender identifier (SID) for IV construction.

In Suite B, TEK IPsec policies that are used as IPsec SA encryption and integrity algorithms require management of unique pools of SID values on KSs to distribute those unique SID values (GMSIDs) to GMs.

Each cooperative KS must have a distinct pool of GMSIDs to allocate. Each KS configures unique KS SIDs (KSSIDs) to configure these SID pools.

A SID space is divided into two parts: a KSSID part and a GMSID part. Therefore, a SID is a concatenation of a KSSID and a GMSID, where the KSSID is the KS portion of a SID, and the GMSID is the GM portion of the SID. A SID is formed by the following bits:

```

0           1           2
0 1 2 3 4 5 6 7 8 9 0 1 2 3 4 5 6 7 8 9 0 1 2 3 (bits)
+-----+-----+-----+-----+-----+-----+
|   KSSID   |           GMSID           |
+-----+-----+-----+-----+-----+

```

In this example, each KSSID (0 to 127) has 2^{17} (131,072) GMSIDs, which are dynamically assigned to each registering GM.

A GM uses GMSIDs to form a unique 64-bit IV for each packet sent with a given key when using AES-GCM or AES-GMAC. An IV is formed by the following bytes:

```

0 1 2 3 4 5 6 7 (bytes)
+-----+-----+-----+-----+-----+
|   SID   |           SSIV           |
+-----+-----+-----+-----+

```

The sender specific IV (SSIV) is a packet counter.

Group Size

The group size is the length of the SID space allocation for KSSIDs as well as GMSIDs that are reserved to a KS for distribution to GMs. Available group sizes are small (8, 12, or 16 bits), medium (24 bits, which is the default), and large (32 bits). Medium is sufficient for nearly all networks.

You should use a large group size only if you must strictly adhere to the requirement in section A.5, “Key/IV Pair Uniqueness Requirements from SP 800-38D” of the publication [Implementation Guidance for FIPS PUB 140-2 and the Cryptographic Module Validation Program](#) in which GET VPN used in conjunction with Suite B must have at least 2^{32} unique possible “module names” (SIDs). This publication is issued and maintained by the NIST and the Communications Security Establishment Canada (CSEC).

For example, in a large group size with one KS, the SID is 32 bits, there are 512 KSSID values (in the range of 0 to 511), and each has 8,388,607 GMSIDs to distribute to registering GMs. With a large group size, use the following KSSID assignment guidelines to configure KSSID ranges:

Table 325: Recommended KSSID Ranges for Group Size Large

KS	1 KS (no cooperative KSs)	2 cooperative KSs	3 cooperative KSs	4 cooperative KSs
KS1	0 - 511	0 - 255	0 - 127	0 - 63
KS2	—	256 - 511	128 - 255	64 - 127
KS3	—	—	256 - 383	128 - 191
KS4	—	—	384 - 511	192 - 255
KS5	—	—	—	256 - 319

KS	1 KS (no cooperative KSs)	2 cooperative KSs	3 cooperative KSs	4 cooperative KSs
KS6	—	—	—	320 - 383
KS7	—	—	—	384 - 447
KS8	—	—	—	448 - 511

If you plan to expand the cooperative KS network to include more KSs, while you are initially configuring the original KS or KSs, use the column in the above table with the *anticipated* number of KSs in the network so that you can add the new KS or KSs later.

You should use a small (8-, 12-, or 16-bit) group size only in well-understood cases where strict interoperability with SID lengths of 8, 12, and 16 bits is required according to RFC 6054, [Using Counter Modes with Encapsulating Security Payload \(ESP\) and Authentication Header \(AH\) to Protect Group Traffic](#). If such interoperability is needed, you must be careful when designing the network, because the number of SIDs per group is severely limited (and therefore, the number of KSs and GMs in a group is severely limited). Following are the limitations for a small group size:

Table 326: Limitations for Group Size Small

SID length	KSSIDs (total KSs)	GMSIDs per KSSID	GMSIDs (total GMs)	Possible number of GM registrations for one KS (after assigning KSSIDs to all KSs evenly)			
				1 KS	2 KSs	4 KSs	8 KSs
—	—	—	—	1 KS	2 KSs	4 KSs	8 KSs
8 bits	2	128	255	320	96	—	—
12 bits	4	1,024	4,095	3,840	1,792	768	—
16 bits	16	4,096	65,535	64,512	31,744	15,360	7,168

KSSID Assignment with Cooperative Key Servers

You should plan ahead to assign a certain number of initial GDOI KS identifiers (KSSIDs) to each KS based on the configured group size, number of KSs, number of GMs, number of GMs per KS, and any future expansion of KSs or GMs (or both).

When there are multiple cooperative KSs in a GDOI group, each KS must have a unique set of KSSID values to ensure that a registering GM never receives the same SID as another registering GM in the group. Therefore, you should plan how you will assign KSSIDs across cooperative KSs in advance, while considering the number of cooperative KSs and if cooperative KSs will be added later. If none will be added, you can assign all available KSSIDs across all KSs. If cooperative KSs will be added, you should reserve some KSSIDs to assign to those KSs when you add them to the network.

You can reassign KSSIDs; however, if KSSIDs that are already used by a KS to distribute GMSIDs are removed from the KS, the group will reinitialize (meaning that all GMs will be forced to re-register, and TEK IPsec SAs will be rekeyed to reset the used KSSIDs) without traffic loss. To avoid this group reinitialization, use the guidelines in the following table (which uses the default group size of medium):

Table 327: Recommended KSSID Assignment Ranges for Cooperative KSs (Group Size Medium)

	1 KS (no cooperative KSs)	2 cooperative KSs	3 cooperative KSs	4 cooperative KSs
KS1	0 - 127	0 - 63	0 - 31	0 - 15
KS2	—	64 - 127	32 - 63	16 - 31
KS3	—	—	64 - 95	32 - 47
KS4	—	—	96 - 127	48 - 64
KS5	—	—	—	65 - 80
KS6	—	—	—	81 - 95
KS7	—	—	—	96 - 112
KS8	—	—	—	113 - 127

If you plan to expand the cooperative KS network to include more KSs, when initially configuring the original KS (or KSs), use the column in the above table with the planned number of KSs in the *expanded* network so that the new KS or KSs can be added later.

Following are additional guidelines for assigning KSSIDs to KSs:

- Configure only contiguous blocks of KSSIDs across KSs (for example, KS1 = 0-9 + 40-49, KS2 = 10-19 + 50-59, KS3 = 20-29, KS4 = 30-39, and so on).
- Any one KS should have enough KSSID space to receive all GM registrations from the group (in case the other KSs fail all of their GM registrations).
- To avoid reinitialization of the group, only add new KSSID values or ranges; do not remove them unless necessary.
- During a network split (a connectivity loss among cooperative KSs), do not change the KSSID assignment; this prevents overlapping KSSIDs, which would cause reinitialization on a merge (when connectivity has been restored among cooperative KSs).
- If the group begins in an *n*-way split (meaning that secondary KSs are planned but not yet configured), configure all of the KSSIDs as if the group was not split.

The number of KSSIDs available depends on the group size configuration as in the following table:

Table 328: Ranges of Available KSSIDs Based on Group Size

Configured Group Size	Number of Available KSSIDs
Small (8-bit)	0 to 1
Small (12-bit)	0 to 3
Small (16-bit)	0 to 15
Medium	0 to 127

Configured Group Size	Number of Available KSSIDs
Large	0 to 511

Group Reinitialization

Group reinitialization is the process of retiring KSSIDs. Group reinitialization occurs across all KSs (primary and secondary). Any KS can trigger a group reinitialization, and it occurs whenever

- You change the TEK policy from non-GCM to GCM.
- You change the group size.
- You remove a previously used KSSID.
- A KS in the group runs out of both KSSIDs and GMSIDs.
- A KSSID overlap that was detected by a cooperative KS is resolved.

During reinitialization, all KSs move their used KSSIDs to old (used) KSSIDs (and they are thus retired). Then, reinitialization creates a new KEK and new TEKs, lowers the existing TEK lifetime, and deletes the existing TEKs to cause all GMs to re-register (within the window determined by the **clear crypto gdoi ks members** command). This window is five percent of the remaining lifetime, between 90 seconds and one hour. When the lifetime of the existing TEKs has expired, each KS resets its old (used) KSSIDs, then all KSSIDs are available for use once again.

Reinitialization does not cause traffic disruption on the GMs. All GMs receive new GMSIDs with new TEKs when re-registering.

Cisco GET VPN System Logging Messages for Suite B

The tables below explain the GET VPN system logging (also called syslog) messages that are related to Suite B.

Table 329: KS and Cooperative KS Messages

Message	Explanation
%GDOI-5-KS_REINIT_GROUP: <i>reason</i> for group <i>group-name</i> and will re-initialize the group.	<p>The KS will reinitialize the group. The possible <i>reason</i> strings are as follows:</p> <ul style="list-style-type: none"> • KS configured Suite-B transform requiring SIDs • KS configured Suite-B transform requiring SIDs during scheduled rekey • KS is running out of SIDs • KS changed Group Size • KS removed used KSSIDs • KS issued 'clear crypto gdoi ks members' • KS issued re-init test cmd • KSSID overlap was resolved • Pri KS peer changed used Group Size • Pri KS peer sent re-init request • Sec KS peer sent re-init request
%GDOI-5-KS_REINIT_FINISH: Re-initialization of group <i>group-name</i> completed.	<p>Reinitialization for the group is complete. It is useful to know when a reinitialization has completed, because some operations are blocked during a reinitialization (such as when the group size is changed and used KSSIDs are removed). A reinitialization does not finish until the old (used) TEK is cleared, which might not occur until a reinitialization is checked again (for example while a show command is executing, while a group size or KSSIDs are being configured, or when a cooperative KS is being updated) or until the next GM registers.</p>
%GDOI-3-KS_NO_SID_AVAILABLE: GMs for group <i>group-name</i> need SIDs but this KS has no KS SIDs configured or no more SIDs available.	<p>(When using GCM and after a GM begins registration) GMs for the group need SIDs, but either the KS has no KSSIDs configured or has no more SIDs available.</p>

Message	Explanation
%GDOI-3-COOP_KS_KSSID_OVERLAP: Overlapping KS Sender Identifier(s) (KSSID) { <i>KSSID</i> <i>KSSID-Range</i> } with COOP-KS peer <i>ip-address</i> in group <i>group-name</i> blocking GM registration (MISCONFIG).	A KSSID or KSSID range that overlaps with a cooperative KS peer in another group is blocking GM registration. An overlapping KSSID configuration is blocked on cooperative KSs by the CLI, but it might occur in a GET VPN network split scenario (in which one or more cooperative KSs were temporarily unavailable but have come back online) or with saved configurations.
%GDOI-5-COOP_KS_KSSID_OVERLAP_RESOLVED: Resolved overlapping KS Sender Identifier(s) (KSSID) with COOP-KS peer allowing GM registrations once again.	A KSSID that overlaps with a cooperative KS peer was resolved (which allows GM registrations to resume).

Table 330: GM Messages

Message	Explanation
%GDOI-5-GM_IV_EXHAUSTED: GM for group <i>group-name</i> exhausted its IV space for interface <i>interface-name</i> and will re-register.	The GM for the group exhausted its IV space (meaning its set of unique IVs) for a particular SA and will re-register.
%GDOI-5-GM_REJECTING_SA_PAYLOAD: Registration: Policy in SA payload sent by KS <i>ip-address</i> rejected by GM in the group <i>group-name</i> reason: client rekey hash algorithm (<i>kek-policy</i>) is unacceptable by this GM.	The client rekey hash algorithm (the specified KEK policy) was not accepted by a GM in the specified group. At registration, the GM rejected the KEK policy.
%GDOI-5-GM_REJECTING_SA_PAYLOAD: Registration: Policy in SA payload sent by KS <i>ip-address</i> rejected by GM in the group <i>group-name</i> reason : client rekey transform-sets (<i>tek-policy</i>) for data-protection are unacceptable by this GM.	The client rekey transform sets (the specified TEK policy) for data protection was not accepted by the GM. At registration, the GM rejected the TEK policy.
%GDOI-5-GM_REKEY_TRANSFORMSET_CHECK_FAIL: The transform set (<i>transform-set</i>) for data protection in group <i>group-name</i> is unacceptable by this client.	The transform set for data protection in the group was not accepted by the client. The GM received a rekey and rejected the TEK policy.
%GDOI-3-KS_REKEY_AUTH_KEY_LENGTH_INSUFFICIENT: Rejected rekey sig-hash algorithm change: using sig-hash algorithm HMAC_AUTH_SHAbits requires an authentication key length of at least <i>number-of-bits</i> bits (<i>number-of-blocks</i> blocks in bytes) - current RSA key "360-bit" is only 45 blocks in bytes.	Configuration of the rekey signature hash algorithm was rejected, because the RSA key did not have a long enough modulus. HMAC-SHA-384 requires a modulus of at least 465 bits (59 blocks in bytes), and HMAC-SHA-512 requires a modulus of 593 bits (75 blocks in bytes).

How to Configure GET VPN Support with Suite B

Each feature in the GET VPN Support with Suite B feature set is independently configurable. But to be compliant with the Suite B standard, you must configure certain combinations of these features. For more information about these combinations, see RFC 4869, [Suite B Cryptographic Suites for IPsec](#).

Ensuring that GMs Are Running Software Versions That Support Suite B

Because GET VPN is a technology that is based on groups, all devices in the same group (including the primary KS, cooperative KSs, and GMs) must support the Suite B feature before you can enable the feature. If you want to enable the feature for a group, you must ensure that all devices in the group are running compatible versions of the GET VPN software.

To ensure that all devices in the GET VPN network support Suite B, perform the following steps on the KS (or primary KS).

SUMMARY STEPS

1. `enable`
2. `show crypto gdoi feature suite-b`
3. `show crypto gdoi feature suite-b | include No`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto gdoi feature suite-b Example: Device# show crypto gdoi feature suite-b	Displays the version of the GET VPN software running on each KS and GM in the network and displays whether that device supports Suite B.
Step 3	show crypto gdoi feature suite-b include No Example: Device# show crypto gdoi feature suite-b include No	(Optional) Finds only those devices that do not support Suite B.

Configuring a Key Server for GET VPN Suite B

Configuring the Signature Hash Algorithm for the KEK

Perform this task to configure the signature hash algorithm for the KEK.

Before you begin

This task has the following prerequisites:

- Make sure that rekey authentication that is using an RSA key pair associated with the device is enabled. To do so, use the **rekey authentication** command with the **mypubkey rsa** *key-name* keywords and argument.
- Make sure that the RSA key pair has a modulus of sufficient length. HMAC-SHA-384 requires a modulus of at least 465 bits (59 blocks in bytes), and HMAC-SHA-512 requires a modulus of 593 bits (75 blocks in bytes). If the rekey signature hash algorithm is changed to SHA-384 or SHA-512 with a key pair of insufficient modulus length, a configuration rejection message appears on the console, and system logging messages are generated. Similarly, if the rekey signature hash algorithm is already SHA-384 or SHA-512 and the key pair is modified to one of insufficient modulus length, a similar message appears on the console, and the same system logging messages are generated.
- To use SHA-2/HMAC-SHA-2 for authentication of the *acknowledgment* from GMs to KSs after receiving a rekey message, you must enable unicast distribution of rekey messages to GMs. To do so, use the **rekey transport unicast** command.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group [ipv6] group-name**
4. **server local**
5. **rekey sig-hash algorithm algorithm**
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group [ipv6] group-name Example: Device(config)# crypto gdoi group mygroup	Identifies a GDOI group and enters GDOI group configuration mode. • If you are using GET VPN over IPv6 in the data plane, you must use the ipv6 keyword.
Step 4	server local Example:	Designates a device as a GDOI KS and enters GDOI local server configuration mode.

	Command or Action	Purpose
	<code>Device(config-gdoi-group)# server local</code>	
Step 5	<p>rekey sig-hash algorithm <i>algorithm</i></p> <p>Example:</p> <pre>Device(gdoi-local-server)# rekey sig-hash algorithm sha512</pre>	Configures the signature hash algorithm for the KEK. For Suite B, you must specify sha256 , sha384 , or sha512 .
Step 6	<p>end</p> <p>Example:</p> <pre>Device(gdoi-local-server)# end</pre>	Exits GDOI local server configuration mode and returns to privileged EXEC mode.

Configuring the Group Size

This task is optional. For nearly all deployments, the default group size (sender identifier length) of medium is recommended. Perform this task to configure the group size for Suite B.

When you change the group size in a group with cooperative KSs after Suite B (meaning ESP-GCM or ESP-GMAC) is configured and after the Suite B policy has been generated, you must change the group size on all secondary KSs before changing it on the primary KS.

Changing the group size causes the group to reinitialize (so that the new SID length can be used). Conflicting group size configurations across KSs will block GM registration.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group [ipv6] group-name**
4. **server local**
5. **group size {small {8 | 12 | 16} | medium | large}**
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	<p>enable</p> <p>Example:</p> <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	<p>configure terminal</p> <p>Example:</p> <pre>Device# configure terminal</pre>	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto gdoi group [ipv6] group-name Example: Device(config)# crypto gdoi group mygroup	Identifies a GDOI group and enters GDOI group configuration mode. <ul style="list-style-type: none"> If you are using GET VPN over IPv6 in the data plane, you must use the ipv6 keyword.
Step 4	server local Example: Device(config-gdoi-group)# server local	Designates a device as a GDOI KS and enters GDOI local server configuration mode.
Step 5	group size {small {8 12 16} medium large} Example: Device(gdoi-local-server)# group size small 16	Configures the group size.
Step 6	end Example: Device(gdoi-local-server)# end	Exits GDOI local server configuration mode and returns to privileged EXEC mode.

Configuring Key Server Identifiers

Suite B requires the assignment of unique GMSIDs to each GM, which means that a GM cannot reuse a previously used SID (either from itself or another GM) for the same key. Therefore, although GET VPN is designed to disallow overlapping SID values, you should correctly configure KSSID values among KSs so that each KS has a unique set. (KSSID overlap among KSs will cause a reinitialization.)

You must configure at least one unique KSSID to allot a pool of SIDs to the KS. You do so on the KS before configuring GCM or GMAC as the TEK IPsec policy.

Perform this task to assign a KSSID or a range of KSSIDs to a KS. Each KS must be assigned at least one KSSID when using GCM or GMAC. You can configure a single KSSID, a range of KSSIDs, or both. For the default group size of medium, there are 128 possible KSSID values in the range from 0 to 127.

KSSID values are not assigned to (and usable by) the KS until you exit GDOI local server ID configuration mode.

SUMMARY STEPS

- enable**
- configure terminal**
- crypto gdoi group [ipv6] group-name**
- server local**
- identifier**
- range lowest-kssid - highest-kssid**
- value kssid**
- end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group [ipv6] group-name Example: Device(config)# crypto gdoi group mygroup	Identifies a GDOI group and enters GDOI group configuration mode. <ul style="list-style-type: none"> • If you are using GET VPN over IPv6 in the data plane, you must use the ipv6 keyword.
Step 4	server local Example: Device(config-gdoi-group)# server local	Designates a device as a GDOI KS and enters GDOI local server configuration mode.
Step 5	identifier Example: Device(gdoi-local-server)# identifier	Enters GDOI local server ID configuration mode.
Step 6	range lowest-kssid - highest-kssid Example: Device(gdoi-local-server-id)# range 10 - 20	Assigns a range of KSSIDs. <ul style="list-style-type: none"> • This range must be unique in the entire group.
Step 7	value kssid Example: Device(gdoi-local-server-id)# value 0	Assigns a KSSID. <ul style="list-style-type: none"> • This KSSID must be unique in the entire group. • The value 0 command allots the pool of SIDs to the KS that begin with KSSID value 0 (meaning that it is allotted the pool of SID values beginning with 0x0 and ending with 0x1FFFF).
Step 8	end Example: Device(gdoi-local-server-id)# end	Exits GDOI local server ID configuration mode and returns to privileged EXEC mode.

If you try to configure one or more KSSIDs on a KS that are already assigned to another KS (and the cooperative KS network is not split), the configuration is denied, and the following message appears when you exit GDOI local server ID configuration mode:

```
% Key Server SID Configuration Denied:
% The following Key Server SIDs being added overlap:
% 2, 200-250 (COOP-KS Peer: 10.0.9.1)
```

If the cooperative KS network *is* split, you should not configure overlapping KSSIDs. If overlapping KSSIDs are detected on a network merge, GM registration is blocked until the overlap is resolved. The following system logging message appears on both KSs:

```
%GDOI-3-COOP_KSSID_OVERLAP: Overlapping KS Sender Identifier(s) (KSSID) {2, 200-250} with
COOP-KS peer 10.0.9.1 in group diffint blocking GM registration (MISCONFIG)
```

When a KS unconfigures the overlapping KSSIDs, the group reinitializes (meaning that all GMs are forced to re-register, and TEK IPsec SAs are rekeyed to reset the used KSSIDs) without traffic loss. The following system logging messages appear on the KS:

```
%SYS-5-CONFIG_I: Configured from console by console
%GDOI-5-COOP_KSSID_OVERLAP_RESOLVED: Resolved overlapping KS Sender Identifier(s) (KSSID)
with COOP-KS peer allowing GM registrations once again
%GDOI-5-KS_REINIT_GROUP: KSSID overlap was resolved for group diffint and will re-initialize
the group.
%GDOI-5-KS_SEND_UNICAST_REKEY: Sending Unicast Rekey for group diffint from address 10.0.8.1
with seq # 11
%GDOI-4-GM_DELETE: GM 10.0.3.1 deleted from group diffint.
%GDOI-4-GM_DELETE: GM 10.65.9.2 deleted from group diffint.
```

The %GDOI-5-KS_SEND_UNICAST_REKEY system logging message appears only if this is the primary KS. The peer KS that had overlapping KSSIDs also displays the %GDOI-5-COOP_KSSID_OVERLAP_RESOLVED system logging message.

Configuring the IPsec SA for Suite B

To configure the IPsec SA for Suite B, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec transform-set** *transform-set-name* {**esp-gcm** | **esp-gmac**} [**128** | **192** | **256**]
4. **crypto ipsec profile** *ipsec-profile-name*
5. **set transform-set** *transform-set-name*
6. **exit**
7. **crypto gdoi group** [**ipv6**] *group-name*
8. Enter one of the following commands:
 - **identity number** *number*
 - **identity address ipv4** *address*
9. **server local**
10. **sa ipsec** *sequence-number*
11. **profile** *ipsec-profile-name*

12. **match address** {**ipv4** | **ipv6**} {*access-list-number* | *access-list-name*}
13. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto ipsec transform-set <i>transform-set-name</i> { esp-gcm esp-gmac } [128 192 256] Example: <pre>Device(config)# crypto ipsec transform-set gl esp-gcm 192</pre>	Defines a transform set—an acceptable combination of security protocols and algorithms—and enters crypto transform configuration mode. <ul style="list-style-type: none"> • For Suite B, you must specify a transform set using ESP-GCM or ESP-GMAC. (You can define multiple transform sets by entering the command again on separate command lines.) • You can optionally specify a key size of 128, 192, or 256. The default key size is 128.
Step 4	crypto ipsec profile <i>ipsec-profile-name</i> Example: <pre>Device(config)# crypto ipsec profile profile1</pre>	Defines the IPsec profile (the parameters to be used for IPsec encryption between two IPsec routers) and enters IPsec profile configuration mode.
Step 5	set transform-set <i>transform-set-name</i> Example: <pre>Device(ipsec-profile)# set transform-set transformset1</pre>	Specifies which transform sets can be used with the crypto map entry.
Step 6	exit Example: <pre>Device(ipsec-profile)# exit</pre>	Exits IPsec profile configuration mode.
Step 7	crypto gdoi group [ipv6] <i>group-name</i> Example: <pre>Device(config)# crypto gdoi group gdoigroupname</pre>	Identifies a GDOI group and enters GDOI group configuration mode. <ul style="list-style-type: none"> • If you are using GET VPN over IPv6 in the data plane, you must use the ipv6 keyword.

	Command or Action	Purpose
Step 8	Enter one of the following commands: <ul style="list-style-type: none"> • identity number <i>number</i> • identity address ipv4 <i>address</i> Example: Device(config-gdoi-group)# identity number 3333 Example: Device(config-gdoi-group)# identity address ipv4 209.165.200.225	Identifies a GDOI group number or address. <ul style="list-style-type: none"> • The identity number <i>number</i> command applies to IPv4 and IPv6 configurations. • The identity address ipv4 <i>address</i> command applies only to IPv4 configurations.
Step 9	server local Example: Device(config-gdoi-group)# server local	Designates a device as a GDOI KS and enters GDOI local server configuration mode.
Step 10	sa ipsec <i>sequence-number</i> Example: Device(gdoi-local-server)# sa ipsec 1	Specifies the IPsec SA policy information to be used for a GDOI group and enters GDOI SA IPsec configuration mode.
Step 11	profile <i>ipsec-profile-name</i> Example: Device(gdoi-sa-ipsec)# profile gdoi-p	Defines the IPsec SA policy for a GDOI group.
Step 12	match address { ipv4 ipv6 } { <i>access-list-number</i> <i>access-list-name</i> } Example: Device(gdoi-sa-ipsec)# match address ipv4 102	Selects an IP extended access list (ACL) for a GDOI registration. <ul style="list-style-type: none"> • You must use the ipv4 keyword for IPv4 groups and the ipv6 keyword for IPv6 groups. • You must use a named (not numbered) access list for IPv6 configurations. <p>Note Make sure that you select an ACL that has identical entries in the identical order among all the cooperative KSs for the group. If not, GMs that register to separate KSs cannot encrypt and decrypt correctly after downloading the policy.</p> <p>Note If you attempt to assign an IPv6 group with IPv4 policies, an error message appears indicating that the access list name is invalid, or the list already exists but is the wrong type:</p> <pre>Access-list type conflicts with prior definition % ERROR: access-list-name is either an invalid name or the list already exists but is the wrong type.</pre>

	Command or Action	Purpose
Step 13	end Example: <pre>Device(gdoi-sa-ipsec)# end</pre>	Exits GDOI SA IPsec configuration mode and returns to privileged EXEC mode.

Configuring a Group Member for GET VPN Suite B

Configuring Acceptable Ciphers or Hash Algorithms for KEK for Suite B

To configure the Suite B ciphers and hash algorithms for KEK to be allowed by the GM, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group [ipv6] *group-name***
4. Enter one of the following commands:
 - **identity number *number***
 - **identity address ipv4 *address***
5. **server address ipv4 *address***
6. **client rekey encryption *cipher* [... [*cipher*]]**
7. **client rekey hash *hash***
8. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto gdoi group [ipv6] <i>group-name</i> Example: <pre>Device(config)# crypto gdoi group gdoigroupone</pre>	Identifies a GDOI group and enters GDOI group configuration mode. <ul style="list-style-type: none"> • If you are using GET VPN over IPv6 in the data plane, you must use the ipv6 keyword.

	Command or Action	Purpose
Step 4	Enter one of the following commands: <ul style="list-style-type: none"> • identity number <i>number</i> • identity address ipv4 <i>address</i> Example: <pre>Device(config-gdoi-group)# identity number 3333</pre> Example: <pre>Device(config-gdoi-group)# identity address ipv4 10.2.2.2</pre>	Identifies a GDOI group number or address.
Step 5	server address ipv4 <i>address</i> Example: <pre>Device(config-gdoi-group)# server address ipv4 10.0.5.2</pre>	Specifies the address of the server that a GDOI group is trying to reach. <ul style="list-style-type: none"> • To disable the address, use the no form of the command.
Step 6	client rekey encryption <i>cipher</i> [... [<i>cipher</i>]] Example: <pre>Device(config-gdoi-group)# client rekey encryption 3des-cbc aes 192 aes 256</pre>	Sets the client acceptable rekey ciphers for the KEK.
Step 7	client rekey hash <i>hash</i> Example: <pre>Device(config-gdoi-group)# client rekey hash sha384</pre>	Sets the client acceptable hash algorithm for KEK. <ul style="list-style-type: none"> • For Suite B, you must specify either sha256, sha384, or sha512.
Step 8	end Example: <pre>Device(config-gdoi-group)# end</pre>	Exits GDOI group configuration mode and returns to privileged EXEC mode.

Configuring Acceptable Transform Sets for TEKs for Suite B

To configure the transform sets used by TEKs for data encryption or authentication to be allowed by the GM, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ipsec transform-set** *transform-set-name* {**esp-gcm** | **esp-gmac**} [**128** | **192** | **256**]
4. **exit**
5. **crypto gdoi group** [**ipv6**] *group-name*
6. **client transform-sets** *transform-set-name1* [... [*transform-set-name6*]]
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: <pre>Device> enable</pre>	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: <pre>Device# configure terminal</pre>	Enters global configuration mode.
Step 3	crypto ipsec transform-set <i>transform-set-name</i> { esp-gcm esp-gmac } [128 192 256] Example: <pre>Device(config)# crypto ipsec transform-set g1 esp-gcm 192</pre>	Defines a transform set—an acceptable combination of security protocols and algorithms—and enters crypto transform configuration mode. <ul style="list-style-type: none"> • For Suite B, you must specify a transform set using ESP-GCM or ESP-GMAC. • You can define multiple transform sets by entering the command again on separate command lines. • You can optionally specify a key size of 128, 192, or 256. The default key size is 128.
Step 4	exit Example: <pre>Device(cfg-crypto-trans)# exit</pre>	Exits crypto transform configuration mode.
Step 5	crypto gdoi group [ipv6] <i>group-name</i> Example: <pre>Device(config)# crypto gdoi group gdoigroupone</pre>	Identifies a GDOI group and enters GDOI group configuration mode. <ul style="list-style-type: none"> • If you are using GET VPN over IPv6 in the data plane, you must use the ipv6 keyword.
Step 6	client transform-sets <i>transform-set-name1</i> [... [<i>transform-set-name6</i>]] Example: <pre>Device(config-gdoi-group)# client transform-sets g1</pre>	Specifies the acceptable transform-set tags used by TEKs for data encryption and authentication. <ul style="list-style-type: none"> • You can specify up to six transform-set tags.
Step 7	end Example: <pre>Device(config-gdoi-group)# end</pre>	Exits GDOI group configuration mode and returns to privileged EXEC mode.

Verifying and Troubleshooting GET VPN Support with Suite B

Verifying and Troubleshooting GET VPN Support with Suite B on a Key Server

To view the configuration that is running on a KS, use the **show running-config** command.

SUMMARY STEPS

1. **show crypto gdoi ks identifier [detail]**
2. **show crypto gdoi ks coop identifier [detail]**
3. **show crypto gdoi feature suite-b**
4. **show crypto gdoi ks policy**

DETAILED STEPS

Step 1 **show crypto gdoi ks identifier [detail]**

Example:

```
Device# show crypto gdoi ks identifier detail

KS Sender ID (KSSID) Information for Group diffint:

Transform Mode           : Counter (Suite B)
reinitializing           : No
SID Length (Group Size) : 24 bits (medium)
Current KSSID In-Use     : 0
Last GMSID Used         : 1

KSSID (or SIDS)Assigned  : 0-15
KSSID (or SIDS)Used      : 0
KSSID (or SIDS) Used (Old) : none
Available KSSID (or SIDS): 1-15

REMAINING SIDs:
KSSID to reinitialize at : 15
GMSID to reinitialize at  : 6291456
# of SIDs Remaining for Cur KSSID : 8388606
# of SIDs Remaining until Re-init : 132120575
```

This command displays the status of SID management for Suite B. The Transform Mode field can be either Non-Counter (Non-Suite B) or Counter (Suite B) to check if SID management and a Suite B policy is currently used in the group. If the group is currently reinitializing (meaning that all GMs will be forced to re-register, and TEK IPsec SAs will be rekeyed to reset the used KSSIDs), then the reinitializing field displays Yes. The SID Length (Group Size) field determines the group size currently used in the group, which defaults to 24 bits (medium).

The Current KSSID In-Use and Last GMSID Used fields correspond to the SID (or SIDS) to be distributed to the next registering GM. The KSSID (or SIDS) Assigned field corresponds to the locally configured KSSIDs that have been synced with cooperative KSs, and the Available KSSID (or SIDS) field corresponds to those KSSIDs that have not been used yet since the last reinitialization. Each time a new KSSID is used, it is added to the KSSID (or SIDS) Used field, and during a reinitialization, those used KSSIDs are transferred to the KSSID (or SIDS) Used (Old) field. At the end of a reinitialization period, the old used KSSIDs are cleared and put in the Available KSSIDs pool again.

Note When the value in the # of SIDs Remaining until Re-init field approaches 0, a reinitialization will occur soon if GMs are continuing to re-register. Although a reinitialization should not cause traffic disruption or network problems, it will cause all GMs to re-register.

Step 2 show crypto gdoi ks coop identifier [detail]

Example:

```
Device# show crypto gdoi ks coop identifier detail

COOP-KS Sender ID (SID) Information for Group diffint:

  Local KS Role: Primary , Local KS Status: Alive
  Local Address      : 10.0.8.1
  Next SID Client Operation : NOTIFY
  reinitializing    : No
  KSSID Overlap     : No
  SID Length (Group Size) Cfg : 24 bits (medium)
  SID Length (Group Size) Used : 24 bits (medium)
  Current KSSID In-Use : 0
  KSSID (or SIDS)Assigned : 0-15
  KSSID (or SIDS)Used : 0
  Old KSSID (or SIDS)Used : none

  Peer KS Role: Secondary , Peer KS Status: Alive
  Peer Address   : 10.0.9.1
  Next SID Client Operation : NOTIFY
  reinitializing : No
  KSSID Overlap  : No
  SID Length (Group Size) Cfg : 24 bits (medium)
  SID Length (Group Size) Used : 24 bits (medium)
  Current KSSID In-Use : 16
  KSSID (or SIDS)Assigned : 16-31
  KSSID (or SIDS)Used : 16
  Old KSSID (or SIDS)Used : none
```

This command displays the status of SID information that is synchronized across cooperative KSs.

When the KSSID Overlap field displays Yes, GM registration is blocked until the overlap of KSSIDs (which could have happened during a network split) is resolved. You must unconfigure the overlapping KSSIDs from one cooperative KS or the other before GM registration can resume. When the overlapping KSSIDs are resolved, a reinitialization occurs.

When you change the group size (not recommended for most deployments), all secondary KSs must first configure the new group size. Then on the primary KS, the SID Length (Group Size) Cfg field displays the new group size on all cooperative KS peers. Only when the primary KS configures the new group size will all KSs start to use the new group size and update the SID Length (Group Size) Used field to display the new group size.

Step 3 show crypto gdoi feature suite-b

Example:

```
Device# show crypto gdoi feature suite-b

Group Name: diffint
  Key Server ID   Version   Feature Supported
  10.0.8.1        1.0.4    Yes
  10.0.9.1        1.0.4    Yes

  Group Member ID   Version   Feature Supported
```

10.0.3.1	1.0.4	Yes
10.0.4.1	1.0.4	Yes

This command displays whether KSs and GMs can use the Suite B feature set (meaning AES-GCM, AES-GMAC, SHA-2, and HMAC-SHA2). The Version field must display 1.0.4 or higher, and the Feature Supported field must display Yes for all KSs in the cooperative KS group and for the registered GMs.

Step 4 show crypto gdoi ks policy

Example:

```
Device# show crypto gdoi ks policy
```

```
Key Server Policy:
```

```
For group diffint (handle: 2147483650) server 10.0.8.1 (handle: 2147483650):
```

```
# of teks : 4  Seq num : 0
KEK POLICY (transport type : Unicast)
 spi : 0x80474E999FE8F60364B7F51809E28C84
 management alg : disabled  encrypt alg : 3DES
 crypto iv length : 8  key size : 24
 orig life(sec): 86400  remaining life(sec): 85586
 sig hash algorithm : enabled  sig key length : 162
 sig size : 128
 sig key name : mykeys

TEK POLICY (encaps : ENCAPS_TUNNEL)
 spi : 0x9C666FA7
 access-list : gcm-acl
 Selector : permit ip host 10.0.1.1 host 239.0.1.1
 transform : esp-gcm

TEK POLICY (encaps : ENCAPS_TUNNEL)
 spi : 0xC8B4DE6D
 access-list : gcm-acl
 Selector : permit ip host 10.0.1.1 host 10.0.100.2
 transform : esp-gcm
 alg key size : 20  sig key size : 0
 orig life(sec) : 900  remaining life(sec) : 87
 tek life(sec) : 900  elapsed time(sec) : 813
 override life (sec): 0  antireplay window size: 64
```

```
TEK POLICY (encaps : ENCAPS_TUNNEL)
```

```

spi                : 0x1C908AF3
access-list        : gcm-acl
Selector           : permit ip host 10.0.100.2 host 10.0.1.1
transform          : esp-gcm
alg key size       : 20             sig key size       : 0
orig life(sec)     : 900           remaining life(sec) : 87
tek life(sec)      : 900           elapsed time(sec)   : 813

```

This command displays whether a TEK and IPsec SA were generated per ACE (displayed in the Selector field) from the ACL in the access-list field for the ESP-GCM or ESP-GMAC TEK policy. This command also displays whether the KEK policy is using SHA-2/HMAC-SHA-2 as the signature hash algorithm.

Verifying and Troubleshooting GET VPN Support with Suite B on a GM

To view the configuration that is running on a GM, use the **show running-config** command.

SUMMARY STEPS

1. **show crypto gdoi gm identifier [detail]**
2. **show crypto gdoi feature suite-b**
3. **show crypto gdoi**

DETAILED STEPS

Step 1 **show crypto gdoi gm identifier [detail]**

Example:

```

Device# show crypto gdoi gm identifier detail

GM Sender ID (SID) Information for Group diffint:

Group Member: 10.65.9.2          vrf: None
Transform Mode                   : Counter (Suite B)
# of SIDs Last Requested        : 3

CURRENT SIDs:
  Shared Across Interfaces?      : Yes
  SID Length (Group Size)        : 24 bits (medium)
  # of SIDs Downloaded           : 3
  First SID Downloaded           : 0x08000007
  Last SID Downloaded            : 0x08000009

CM Interface  B/W (Kbps)  MTU (B)  # Req # Rx  Installed SID Range
=====
Et2/0         10000         1500    1   3   0x08000007 - 0x08000009
Et3/0         10000         1500    1   3   0x08000007 - 0x08000009
Et4/0         10000         1500    1   3   0x08000007 - 0x08000009

NEXT SID REQUEST:
  TEK Lifetime                   : 900 sec
  SID Length (Group Size)        : 32 bits (LARGE)

```

This command displays the status of received and installed SIDs on a GM when it is using GCM-AES or GMAC-AES as the TEK IPsec SA policy. The Transform Mode field can display Non-Counter (Non-Suite B) or Counter (Suite B) to check whether SIDs are being downloaded and installed and whether a Suite B policy is used in the group. The # of SIDs Last Requested field mainly depends on the number of interfaces to which the crypto map is applied for this registered GM (meaning using the local-address or client registration interface). The SIDs are Shared Across Interfaces field when using local-address and each CM Interface's Installed SID Range field will be the same. You use this command mainly to verify that each CM interface has SIDs installed.

Step 2 show crypto gdoi feature suite-b

Example:

```
Device# show crypto gdoi feature Suite B

      Version      Feature Supported
      1.0.4         Yes
```

This command displays whether this GM can use the Suite B feature set (meaning GCM-AES, GMAC-AES, SHA-2, and HMAC-SHA-2). The Version field must display 1.0.4 or higher, and the Feature Supported field must display Yes.

Step 3 show crypto gdoi

Example:

```
Device# show crypto gdoi

GROUP INFORMATION

  Group Name           : diffint
  Group Identity       : 1234
  Crypto Path          : ipv4
  Key Management Path  : ipv4
  Rekeys received      : 0
  IPSec SA Direction  : Both

  Group Server list    : 10.0.8.1

  Group member         : 10.0.3.1      vrf: None
    Version             : 1.0.4
    Registration status : Registered
    Registered with     : 10.0.8.1
  .
  .
  .
ACL Downloaded From KS 10.0.8.1:
  access-list permit ip host 10.0.1.1 host 239.0.1.1
  access-list permit ip host 10.0.100.2 host 238.0.1.1
  access-list permit ip host 10.0.1.1 host 10.0.100.2
  access-list permit ip host 10.0.100.2 host 10.0.1.1

KEK POLICY:
  Rekey Transport Type : Unicast
  Lifetime (secs)      : 85740
  Encrypt Algorithm     : 3DES
  Key Size              : 192
  Sig Hash Algorithm    : HMAC_AUTH_SHA256
  Sig Key Length (bits) : 1024

TEK POLICY for the current KS-Policy ACEs Downloaded:
```

```

Ethernet3/0:
  IPsec SA:
    spi: 0x318846DE(831014622)
    transform: esp-gcm
    sa timing:remaining key lifetime (sec): (86350)
    Anti-Replay(Counter Based) : 64

  IPsec SA:
    spi: 0xF367AEA0(4083658400)
    transform: esp-gcm
    sa timing:remaining key lifetime (sec): (86350)
    Anti-Replay(Counter Based) : 64

  IPsec SA:
    spi: 0xE583A3F5(3850609653)
    transform: esp-gcm
    sa timing:remaining key lifetime (sec): (86350)
    Anti-Replay(Counter Based) : 64

  IPsec SA:
    spi: 0xE9AC04C(245022796)
    transform: esp-gcm
    sa timing:remaining key lifetime (sec): (86350)
    Anti-Replay(Counter Based) : 64

```

The presence of multiple IPsec SAs shows that GCM or GMAC is configured (note that each IPsec SA has a unique SPI for each ACE that was downloaded). For each ACE listed in the TEK POLICY for the current KS-Policy ACEs Downloaded section, this command displays whether a TEK policy and IPsec SA were downloaded (and installed) from the ACLs that are listed in the ACL Downloaded From KS section. This command also displays whether the KEK policy is using SHA-2/HMAC-SHA-2 for the signature hash algorithm (for example, HMAC_AUTH_SHA256).

Configuration Examples for GET VPN Support with Suite B

Example: Ensuring that GMs Are Running Software Versions That Support Suite B

The following example shows how to use the GET VPN software versioning command on the KS (or primary KS) to check whether all the devices in each group support Suite B cryptography:

```

Device# show crypto gdoi feature suite-b

Group Name: GETVPN
  Key Server ID      Version  Feature Supported
  10.0.5.2            1.0.4   Yes
  10.0.6.2            1.0.4   Yes
  10.0.7.2            1.0.3   No
  10.0.8.2            1.0.2   No

  Group Member ID    Version  Feature Supported
  10.0.1.2            1.0.2   No
  10.0.2.5            1.0.3   No
  10.0.3.1            1.0.4   Yes

```

Example: Configuring a Key Server for GET VPN Suite B

```
10.0.3.2      1.0.4      Yes
```

You can also enter the above command on a GM (which will display the information for the GM but not for the KS or other GMs).

The following example shows how to enter the command on the KS (or primary KS) find only those devices in the GET VPN network that do *not* support Suite B:

```
Device# show crypto gdoi feature suite-b | include No
10.0.7.2      1.0.3      No
10.0.8.2      1.0.2      No
10.0.1.2      1.0.2      No
10.0.2.5      1.0.3      No
```

Example: Configuring a Key Server for GET VPN Suite B

Configuring the Signature Hash Algorithm for the KEK

The following example shows how to configure the signature hash algorithm for the KEK:

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group mygroup
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# rekey sig-hash algorithm sha512
Device(gdoi-local-server)# end
```

Configuring the Group Size for Suite B

Configuring the group size for Suite B is optional, because the default group size of medium is sufficient for most deployments. The following example shows how to configure the group size for Suite B:

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group mygroup
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# group size small 16
Device(gdoi-local-server)# end
```

Configuring Key Server Identifiers

The following example shows how to assign a KSSID as well as a range of KSSIDs to a KS:

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group mygroup
```

```
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# identifier
Device(gdoi-local-server-id)# range 10 - 20
Device(gdoi-local-server-id)# value 0
Device(gdoi-local-server-id)# end
```

Configuring the IPsec SA for Suite B

The following example shows how to configure the IPsec SA for Suite B. This example uses an identity number instead of an identity address:

```
Device> enable
Device# configure terminal
Device(config)# crypto ipsec transform-set g1 esp-gcm 192
Device(config)# crypto ipsec profile profile1
Device(ipsec-profile)# set transform-set transformset1
Device(ipsec-profile)# exit
Device(config)# crypto gdoi group gdoigroupname
Device(config-gdoi-group)# identity number 3333
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# sa ipsec 1
Device(gdoi-sa-ipsec)# profile gdoi-p
Device(gdoi-sa-ipsec)# match address ipv4 102
Device(gdoi-sa-ipsec)# end
```

Example: Configuring a Group Member for GET VPN Suite B

Configuring Ciphers or Hash Algorithms for the KEK for Suite B

The following example shows how to configure the Suite B ciphers and hash algorithms for the KEK to be allowed by the GM. This example uses an identity address (compatible only with IPv4 data plane configurations). You could instead use an identity number (which would be compatible with IPv4 and IPv6 data plane configurations).

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group gdoigroupone
Device(config-gdoi-group)# identity address ipv4 10.2.2.2
Device(config-gdoi-group)# server address ipv4 10.0.5.2
Device(config-gdoi-group)# client rekey encryption 3des-cbc aes 192 aes 256
Device(config-gdoi-group)# client rekey hash sha384
Device(config-gdoi-group)# end
```

Configuring Acceptable Transform Sets for TEKs for Suite B

The following example shows how to configure the acceptable transform sets used by TEKs for data encryption or authentication.

```
Device> enable
```

```

Device# configure terminal
Device(config)# crypto ipsec transform-set g1 esp-gcm 192
Device(cfg-crypto-trans)# exit
Device(config)# crypto gdoi group gdoigroupone
Device(config-gdoi-group)# client transform-sets g1
Device(config-gdoi-group)# end

```

Feature Information for GET VPN Support with Suite B

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 331: Feature Information for GET VPN Support with Suite B

Feature Name	Releases	Feature Information
GET VPN Support with Suite B		<p>The GET VPN Support with Suite B feature adds support of the Suite B set of ciphers to Cisco Group Encrypted Transport (GET) VPN. Suite B is a set of cryptographic algorithms that includes Galois Counter Mode Advanced Encryption Standard (GCM-AES) as well as algorithms for hashing, digital signatures, and key exchange. Suite B for IP security (IPsec) VPNs is a standard whose usage is defined in RFC 4869. Suite B provides a comprehensive security enhancement for Cisco IPsec VPNs, and it allows additional security for large-scale deployments. Suite B is the recommended solution for organizations requiring advanced encryption security for the wide-area network (WAN) between remote sites.</p> <p>The following commands were introduced or modified: client rekey hash, crypto key export ec, crypto key generate ec keysize, crypto key import ec, group size, identifier, rekey sig-hash algorithm, show crypto gdoi.</p>

Feature Name	Releases	Feature Information
GET VPN Support with Suite B	Cisco IOS XE Release 17.13.1a	<p>This enhancement introduces support for GET VPN Support with Suite B on the following routers models:</p> <ul style="list-style-type: none">• Cisco ASR 1000 Series Aggregation Services Routers<ul style="list-style-type: none">• ASR1009-X + ESP200-X)• Cisco Catalyst 8000V Edge Software• Cisco Catalyst 8200 Series Edge Platforms<ul style="list-style-type: none">• C8200-1N-4T• Cisco Catalyst 8300 Series Edge Platforms<ul style="list-style-type: none">• C8300-2N2S-4T2X• C8300-1N1S-6T• Cisco Catalyst 8500 Series Edge Platforms<ul style="list-style-type: none">• C8500-12X• C8500-20X6C

GET VPN Support with Suite B	Cisco IOS XE Release 17.14.1a	<p>From Cisco IOS XE 17.14.1a, this enhancement introduces support for Suite B ciphers with GET VPN on the following platforms and its corresponding models:</p> <ul style="list-style-type: none"> • Cisco ASR 1000 Series Aggregation Services Routers: <ul style="list-style-type: none"> • ASR 1000 with ESP100-X • Cisco Catalyst 8300 Series Edge Platforms: <ul style="list-style-type: none"> • C8300-1N1S-4T2X • Cisco Catalyst 8200 Series Edge Platforms: <ul style="list-style-type: none"> • C8200L-1N-4T • Cisco Catalyst 8500 Series Edge Platforms: <ul style="list-style-type: none"> • 8500-12X4QC • C8500L-8S4X • Cisco 1000 Series Integrated Services Routers: <ul style="list-style-type: none"> • C1131 • C112X • C116X • C111X

CHAPTER 243

GET VPN Support of IPsec Inline Tagging for Cisco TrustSec

The Cisco TrustSec (CTS) architecture secures networks by establishing domains of trusted network devices. Once a network device authenticates with the network, the communication on the links between devices in the cloud is secured with a combination of encryption, message integrity checks, and replay protection mechanisms.

CTS uses the user and device identification information acquired during the authentication phase to classify packets as they enter the network. CTS maintains classification of each packet or frame by tagging it with a security group tag (SGT) on ingress to the network so that it can be identified for applying security and other policy criteria along the data path. The tags allow network intermediaries such as switches and firewalls to enforce access control policy based on the classification.

The GET VPN Support of IPsec Inline Tagging for Cisco TrustSec feature uses GET VPN inline tagging to carry the SGT information across the private WAN.

- [Prerequisites for GET VPN Support of IPsec Inline Tagging for Cisco TrustSec, on page 3321](#)
- [Restrictions for GET VPN Support of IPsec Inline Tagging for Cisco TrustSec, on page 3322](#)
- [Information About GET VPN Support of IPsec Inline Tagging for Cisco TrustSec, on page 3322](#)
- [How to Configure GET VPN Support of IPsec Inline Tagging for Cisco TrustSec, on page 3324](#)
- [Configuration Examples for GET VPN Support of IPsec Inline Tagging for Cisco TrustSec, on page 3328](#)
- [Additional References for GET VPN Support of IPsec Inline Tagging for Cisco TrustSec, on page 3331](#)
- [Feature Information for GET VPN Support of IPsec Inline Tagging for Cisco TrustSec, on page 3332](#)

Prerequisites for GET VPN Support of IPsec Inline Tagging for Cisco TrustSec

All key servers (KSs) and group members (GMs) on which you want to enable this feature must be running GET VPN software version 1.0.5 or higher. You should use this feature only after all devices in the GET VPN network are upgraded to GET VPN software versions that support it.

This feature provides a command that you use on the KS (or primary KS) to check whether all devices in the network are running versions that support IPsec inline tagging for Cisco TrustSec. For more information, see the "Ensuring That GMs Are Running Software Versions That Support IPsec Inline Tagging for Cisco TrustSec" section.

Restrictions for GET VPN Support of IPsec Inline Tagging for Cisco TrustSec

- This feature does not support IPv6 traffic.
- This feature does not support transport mode on the Cisco ASR 1000 Series Aggregation Services Routers or on the Cisco VPN Internal Service Module for Cisco Integrated Services Routers Generation 2 (ISR G2).

Information About GET VPN Support of IPsec Inline Tagging for Cisco TrustSec

Group Member Registration of Security Group Tagging Capability

When a KS receives a security association (SA) registration request from a group member (GM) or receives a connection establishment request from a cooperative KS, it checks whether any group SA has SGT inline tagging enabled. If so, all GMs and cooperative KSs must register using GET VPN software version 1.0.5 or higher to be accepted. Otherwise, the registration request or establishment request is rejected, and the KS generates a syslog message to notify the network administrator.

Creation of SAs with Security Group Tagging Enabled

After you enable GET VPN support of IPsec inline tagging (using the `tag cts sgt` command) in a group SA and then trigger a rekey (using the `crypto gdoi ks rekey` command), the KS checks for GMs and cooperative KSs in the group not using a compatible software version. If found, a warning message appears:

```
WARNING for group GETVPN: some devices cannot support SGT inline tagging. Rekey can cause
traffic disruption and GM registration failures. Please check 'show crypto gdoi feature
sgt'.
Are you sure you want to proceed ? [yes/no]:
```

Handling of Security Group Tags in the Group Member Data Plane

Egress traffic is traffic sent out from a GDOI-protected interface of a GM. The following table specifies GM behavior for the egress path:

Table 332: Egress Handling of Security Group Tags

Security group tagging is enabled on SA	CTS provides SGTs	GM data plane behavior
Yes	Yes	Adds SGTs to Cisco metadata and encrypts
Yes	No	Encrypts without SGTs

Security group tagging is enabled on SA	CTS provides SGTs	GM data plane behavior
No	Yes	Encrypts without SGTs
No	No	Encrypts without SGTs

Ingress traffic is traffic received by a GDOI-protected interface of a GM. The table below specifies GM behavior for the ingress path:

Table 333: Ingress Handling of Security Group Tags

Security group tagging is enabled on SA	CTS provides SGTs	GM data plane behavior
Yes	Yes	Decrypts and extracts SGTs for CTS
Yes	No	Decrypts without SGT processing
No	Yes	Decrypts and ignores SGTs
No	No	Decrypts without SGT processing

Packet Overhead and Fragmentation When Using Security Group Tagging

Because it adds Cisco metadata containing the SGT information to each GDOI packet, SGT inline tagging increases packet overhead by eight bytes (or 16 bytes with time-based antireplay enabled).

If a packet is fragmented before GDOI encryption, each fragment is inline tagged with SGT information accordingly. If packet is fragmented after GDOI encryption, only the first fragment is inline tagged with SGT information.

You can use two methods to handle fragmentation. The first method is to use the **ip mtu** command on the interface that is handling encryption to accommodate the extra bytes used to carry the SGT information via Cisco metadata. The second method is to use the **ip tcp adjust-mss 1352** command on the GM's LAN interface. This command ensures that the resulting IP packet on the LAN segment is less than 1392 bytes, thereby providing 108 bytes for any overhead plus the Cisco metadata to carry the SGTs.

For more information about designing around MTU issues, refer to the “Designing Around MTU Issues” section of the [Group Encrypted Transport VPN \(GETVPN\) Design and Implementation Guide](#)

How to Configure GET VPN Support of IPsec Inline Tagging for Cisco TrustSec

Ensuring That GMs Are Running Software Versions That Support IPsec Inline Tagging for Cisco TrustSec

You should use the IPsec Inline Tagging for Cisco TrustSec feature only after all devices in the GET VPN network are upgraded to GET VPN software versions that support this feature.

Perform this task on the KS (or primary KS) to ensure that all devices in the network support IPsec inline tagging for Cisco TrustSec.

SUMMARY STEPS

1. **enable**
2. **show crypto gdoi feature cts-sgt**
3. **show crypto gdoi feature cts-sgt | include No**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	show crypto gdoi feature cts-sgt Example: Device# show crypto gdoi feature cts-sgt	Displays the version of the GET VPN software running on each KS and GM in the GET VPN network and displays whether that device supports IPsec inline tagging for Cisco TrustSec.
Step 3	show crypto gdoi feature cts-sgt include No Example: Device# show crypto gdoi feature cts-sgt include No	(Optional) Displays only those devices that do not support IPsec inline tagging for Cisco TrustSec.

Configuring IPsec Inline Tagging for Cisco TrustSec

To configure IPsec inline tagging for Cisco TrustSec, perform the following steps.

SUMMARY STEPS

1. **enable**
2. **configure terminal**

3. **crypto gdoi group** *group-name*
4. Enter one of the following commands:
 - **identity number** *number*
 - **identity address ipv4** *address*
5. **server local**
6. **sa ipsec** *sequence-number*
7. **tag cts sgt**
8. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Device(config)# crypto gdoi group GET-SGT	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	Enter one of the following commands: <ul style="list-style-type: none"> • identity number <i>number</i> • identity address ipv4 <i>address</i> Example: Device(config-gdoi-group)# identity number 3333 Example: Device(config-gdoi-group)# identity address ipv4 10.2.2.2	Identifies a GDOI group number or address.
Step 5	server local Example: Device(config-gdoi-group)# server local	Designates a device as a GDOI KS and enters GDOI local server configuration mode.

	Command or Action	Purpose
Step 6	sa ipsec <i>sequence-number</i> Example: Device(gdoi-local-server) # sa ipsec 1	Specifies the IPsec SA policy information to be used for a GDOI group and enters GDOI SA IPsec configuration mode.
Step 7	tag cts sgt Example: Device(gdoi-sa-ipsec) # tag cts sgt	Enables IPsec inline tagging for Cisco TrustSec.
Step 8	end Example: Device(gdoi-sa-ipsec) # end	Exits GDOI SA IPsec configuration mode and returns to privileged EXEC mode.

After enabling IPsec inline tagging, you must trigger a rekey. For more information, see the "Triggering a Rekey" section.

Triggering a Rekey

If you change the security policy (for example, from DES to AES) on the KS (or primary KS) and exit from global configuration mode, a syslog message appears on the KS indicating that the policy has changed and a rekey is needed. You enter the rekey triggering command as described below to send a rekey based on the latest policy in the running configuration.

Perform this task on the KS (or primary KS) to trigger a rekey.

SUMMARY STEPS

1. **enable**
2. **crypto gdoi ks [group *group-name*] rekey [replace-now]**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	crypto gdoi ks [group <i>group-name</i>] rekey [replace-now] Example: Device# crypto gdoi ks group mygroup rekey	Triggers a rekey on all GMs. The optional replace-now keyword immediately replaces the old TEKs and KEK on each GM to enable the new policy before the SAs expire. Note Using the replace-now keyword could cause a temporary traffic discontinuity.

Examples

A message appears on the KS as follows:

```
Device# crypto gdoi ks rekey
Device#
*Jan 28 09:17:44.363: %GDOI-5-KS_SEND_UNICAST_REKEY: Sending Unicast Rekey with
policy-replace for group GET from address 10.0.8.1 with seq # 2
```

After the policy change, when each GM receives this triggered rekey, it installs the new SAs (for example, for AES) and shortens the lifetimes of the old SAs (for example, for DES). Each GM continues to encrypt and decrypt traffic using the old SA until its shortened lifetime expires.

If you try to trigger a rekey on the secondary KS, it rejects the command as shown below:

```
Device# crypto gdoi ks rekey
ERROR for group GET: This command must be executed on Pri-KS
```

Verifying and Troubleshooting GET VPN Support of IPsec Inline Tagging for Cisco TrustSec

To view the configuration that is running on a GM, use the **show running-config** command.

To display the number of packets that are tagged with SGTs, enter the following command.

```
Device# show crypto ipsec sa detail

interface: Ethernet0/0
  Crypto map tag: GET, local addr 5.0.0.2
  protected vrf: (none)
  local ident (addr/mask/prot/port): (0.0.0.0/0.0.0.0/0/0)
  remote ident (addr/mask/prot/port): (0.0.0.0/0.0.0.0/0/0)
  Group: GET-SGT
.
.
.
#pkts tagged (send): 0, #pkts untagged (rcv): 5
```

The pkts tagged (send) field displays packets tagged with an SGT in the outbound direction. The pkts untagged (rcv) field displays packets not tagged with an SGT in the inbound direction.

Configuration Examples for GET VPN Support of IPsec Inline Tagging for Cisco TrustSec

Example: Ensuring That GMs Are Running Software Versions That Support IPsec Inline Tagging for Cisco TrustSec

The following example shows how to use the GET VPN software versioning command on the KS (or primary KS) to check whether all the devices in each group support IPsec inline tagging for Cisco TrustSec:

```
Device# show crypto gdoi feature cts-sgt

Group Name: GETVPN
  Key Server ID      Version  Feature Supported
  10.0.5.2            1.0.5   Yes
  10.0.6.2            1.0.5   Yes
  10.0.7.2            1.0.3   No
  10.0.8.2            1.0.2   No

  Group Member ID    Version  Feature Supported
  10.0.1.2            1.0.2   No
  10.0.2.5            1.0.3   No
  10.0.3.1            1.0.5   Yes
  10.0.3.2            1.0.5   Yes
```

You can also enter the above command on a GM (which will display the information for the GM but not for the KS or other GMs).

The following example shows how to enter the command on the KS (or primary KS) find only those devices in the GET VPN network that do *not* support IPsec inline tagging for Cisco TrustSec:

```
Device# show crypto gdoi feature cts-sgt | include No

  10.0.7.2            1.0.3   No
  10.0.8.2            1.0.2   No
  10.0.1.2            1.0.2   No
  10.0.2.5            1.0.3   No
```

Example: Configuring IPsec Inline Tagging for Cisco TrustSec

The following example shows how to configure CTS SGT inline tagging in an IPsec SA for a KS serving a single GDOI group:

```
Device> enable
Device# configure terminal
Device(config)# ip access-list extended ACL-SGT
Device(config-ext-nacl)# permit ip any any
Device(config-ext-nacl)# exit
Device(config)# crypto gdoi group GET-SGT
```

```

Device(config-gdoi-group)# identity number 1
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# sa ipsec 1
Device(gdoi-sa-ipsec)# tag cts sgt
Device(gdoi-sa-ipsec)# profile gdoi-p2
Device(gdoi-sa-ipsec)# match address ipv4 ACL-SGT
Device(gdoi-sa-ipsec)# replay time window-size 100
Device(gdoi-sa-ipsec)# end

```

The following example shows how to configure two groups: A group with GMs that are upgraded to GET VPN version 1.0.5 or higher (and therefore supports CTS SGT inline tagging) and a group with GMs that are not yet upgraded. The upgraded GMs will register to group number 1111 (a lower crypto map sequence number) and with group number 2222 (a higher crypto-map sequence number). Non-upgraded GMs will register only to group number 2222.

This example configures SGT tagging for traffic between two sites. The **permit ip** commands add access control entries (ACEs) to the access control list (ACL) that permit communication between the two sites:

```

Device> enable
Device# configure terminal
Device(config)# ip access-list extended ACL_NET_AB
Device(config-ext-nacl)# permit ip 10.1.0.0 0.0.255.255 10.2.0.0 0.0.255.255
Device(config-ext-nacl)# permit ip 10.2.0.0 0.0.255.255 10.1.0.0 0.0.255.255
Device(config-ext-nacl)# exit
Device(config)# ip access-list extended ACL_ALL
Device(config-ext-nacl)# permit ip any any
Device(config-ext-nacl)# exit
Device(config)# crypto gdoi group GET1
Device(config-gdoi-group)# identity number 1111
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# rekey authentication mypubkey rsa mykey
Device(gdoi-local-server)# rekey transport unicast
Device(gdoi-local-server)# sa ipsec 1
Device(gdoi-sa-ipsec)# tag cts sgt
Device(gdoi-sa-ipsec)# profile gdoi-p2
Device(gdoi-sa-ipsec)# match address ipv4 ACL_NET_AB
Device(gdoi-sa-ipsec)# replay time window-size 100
Device(gdoi-sa-ipsec)# exit
Device(gdoi-local-server)# exit
Device(config-gdoi-group)# exit
Device(config)# crypto gdoi group GET2
Device(config-gdoi-group)# crypto gdoi group GET2
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# rekey authentication mypubkey rsa mykey
Device(gdoi-local-server)# rekey transport unicast
Device(gdoi-local-server)# sa ipsec 1
Device(gdoi-sa-ipsec)# profile gdoi-p2
Device(gdoi-sa-ipsec)# match address ipv4 ACL_ALL
Device(gdoi-sa-ipsec)# replay time window-size 100
Device(gdoi-sa-ipsec)# end

```

Note GET VPN supports a maximum of 100 ACEs per ACL.

Example: Triggering Rekeys on Group Members

Ensuring That GMs Are Running Software Versions That Support Rekey Triggering

The following example shows how to use the GET VPN software versioning command on the KS (or primary KS) to display the version of software on devices in the GET VPN network and display whether they support rekey triggering after a policy change:

```
Device# show crypto gdoi feature policy-replace

Key Server ID      Version  Feature Supported
10.0.8.1           1.0.2   Yes
10.0.9.1           1.0.2   Yes
10.0.10.1          1.0.2   Yes
10.0.11.1          1.0.2   Yes
Group Member ID    Version  Feature Supported
5.0.0.2            1.0.2   Yes
9.0.0.2            1.0.1   No
```

The following example shows how to find only those devices that do not support rekey triggering after policy replacement:

```
Device# show crypto gdoi feature policy-replace | include No

          9.0.0.2           1.0.1           No
```

For these devices, the primary KS sends only the triggered rekey without instructions for policy replacement. Therefore, when a GM receives the rekey, it installs the new SAs but does not shorten the lifetimes of the old SAs.

Triggering a Rekey

The following example shows how to trigger a rekey after you have performed a policy change. In this example, an IPsec policy change (for example, DES to AES) occurs with the **profile gdoi-p2** command:

```
Device# configure terminal
Device(config)# crypto gdoi group GET
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# sa ipsec 1
Device(gdoi-sa-ipsec)# no profile gdoi-p
Device(gdoi-sa-ipsec)# profile gdoi-p2
Device(gdoi-sa-ipsec)# end
Device#

*Jan 28 09:15:15.527: %SYS-5-CONFIG_I: Configured from console by console
*Jan 28 09:15:15.527: %GDOI-5-POLICY_CHANGE: GDOI group GET policy has changed. Use
'crypto gdoi ks rekey' to send a rekey, or the changes will be send in the next scheduled
rekey
Device# crypto gdoi ks rekey
Device#
*Jan 28 09:17:44.363: %GDOI-5-KS_SEND_UNICAST_REKEY: Sending Unicast Rekey with
policy-replace for group GET from address 10.0.8.1 with seq # 2
```

The following example shows the error message that appears if you try to trigger a rekey on the secondary KS:

```
Device# crypto gdoi ks rekey
```

```
ERROR for group GET: This command must be executed on Pri-KS
```

Note If time-based antireplay (TBAR) is set, the key server periodically sends a rekey to the group members every 2 hours (7200 sec). In the following example, even though the lifetime is set to 8 hours (28800 sec), the rekey timer is set to 2 hours.

```
Device(config)# crypto ipsec profile atm-profile
Device(ipsec-profile)# set security-association lifetime seconds 28800
!
Device(ipsec-profile)# exit
Device(config)# crypto gdoi group ATM-DSL
Device(config-gdoi-group)# server local
Device(gdoi-sa-ipsec)# sa ipsec 1
!
Device(gdoi-sa-ipsec)# replay time window-size 100
```

The commands **show crypto gdoi gm replay** and **show crypto gdoi ks replay** displays TBAR information.

CHAPTER 244

GETVPN GDOI Bypass

The GETVPN GDOI Bypass feature supports enabling and disabling the default Group Domain of Interpretation (GDOI) bypass crypto policy. It also supports hardening of the default GDOI bypass crypto policy once it is enabled.

- [Restrictions for GETVPN GDOI Bypass, on page 3335](#)
- [Information About GETVPN GDOI Bypass, on page 3335](#)

- [Additional References for GETVPN GDOI Bypass, on page 3340](#)
- [Feature Information for GETVPN GDOI Bypass, on page 3340](#)

Restrictions for GETVPN GDOI Bypass

When a key server (KS) is placed behind a group member (GM), the local deny Access Control List (ACL) must be configured explicitly to allow traffic using UDP as the transport protocol and port 848 as either the source or destination (UDP 848 traffic) to pass through.

Information About GETVPN GDOI Bypass

GDOI Bypass Crypto Policy

The Cisco IOS Group Encrypted Transport VPN (GETVPN) uses Group Domain of Interpretation (GDOI) as the key management protocol.

A group member (GM) is a device responsible for encryption and decryption, that is, a device responsible for handling the GET VPN data plane.

A key server (KS) is a device responsible for creating and maintaining the GET VPN control plane. All encryption policies, such as traffic, encryption protocols, security association, rekey timers, and so on, are centrally defined on the KS and are pushed down to all GMs at registration time.

Enabling and Disabling the Default GDOI Bypass Crypto Policy

A new group member (GM) configuration allows users to disable the Group Domain of Interpretation (GDOI) bypass crypto policy and to control traffic exceptions by explicitly configuring the GM local access control list (ACL).

Hardening of the Default GDOI Bypass Crypto Policy

To improve security, the following changes have been enforced while applying the default Group Domain of Interpretation (GDOI) bypass crypto policy:

- The default GDOI bypass crypto policy is installed only on Group Encrypted Transport VPN (GETVPN)-protected interfaces (interfaces at which GDOI crypto map is applied). Only UDP848 traffic that is destined for the group member's (GM) address used for registration or rekey is allowed.
- If the GM VRF-aware feature is used to specify that the GDOI data plane and control plane are in different VRFs, auto-insertion of the default GDOI bypass crypto policy is not applied to the GDOI-protected interface.
- If traffic using UDP as the transport protocol and port 848 as either the source or destination (UDP 848 traffic) is expected to arrive at other non-GDOI-protected interfaces (but with other crypto maps applied), exceptions for the non-GDOI crypto map must be explicitly configured.
- If a crypto map set with multiple groups is configured, the overall GDOI bypass crypto policy installed is the union of all the GDOI bypass crypto policies for each group within the security association database (SADB).

Any of the conditions mentioned below triggers a recompute of the default GDOI bypass crypto policy applied to a GETVPN-protected interface:

- Removing **client bypass-policy** configuration using the **no client bypass-policy** command.
- Applying or removing the GDOI bypass crypto map from an interface.
- Applying or removing the GDOI bypass crypto map from crypto map sets.
- Changing the IP address of the GDOI-protected interface (if **no client registration interface** is used)
 - If **client registration interface** is used, the following cases trigger a recompute of the default GDOI bypass crypto policy applied to a GETVPN-protected interface:
 - Changes from **no client registration interface** to **client registration interface**
 - Changes to the client registration interface (for example, from loopback 0 to loopback 1)
 - Changes to the client registration interface address

How to Configure GETVPN GDOI Bypass

Enabling the Default GDOI Bypass Crypto Policy

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto gdoi group group-name`
4. `client bypass-policy`
5. `end`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Device(config)# crypto gdoi group GETVPN	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	client bypass-policy Example: Device(config-gdoi-group)# client bypass-policy	Enables the default GDOI bypass crypto policy.
Step 5	end Example: Device(config-gdoi-group)# end	Exits GDOI group configuration mode and returns to privileged EXEC mode.

Disabling the Default GDOI Bypass Crypto Policy

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto gdoi group group-name`
4. `no client bypass-policy`

5. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Device(config)# crypto gdoi group GETVPN	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	no client bypass-policy Example: Device(config-gdoi-group)# no client bypass-policy	Disables the default GDOI bypass crypto policy.
Step 5	end Example: Device(config-gdoi-group)# end	Exits GDOI group configuration mode and returns to privileged EXEC mode.

Verifying Enablement and Disablement of the Default GDOI Bypass Crypto Policy

SUMMARY STEPS

1. enable
2. show crypto gdoi gm acl
3. show crypto gdoi gm acl

DETAILED STEPS

Step 1	enable Enables privileged EXEC mode. • Enter your password if prompted. Example: Device> enable
---------------	---

Step 2 **show crypto gdoi gm acl**

Verifies the enablement of the default GDOI bypass crypto policy.

Note VRF will be displayed only if it is non-global.

Example:

```
Device# show crypto gdoi gm acl

Group Name: GETVPN
ACL Downloaded From KS 10.0.0.2:
  access-list  deny eigrp any any
  access-list  permit ip any any
ACL Configured Locally:
ACL of default GDOI bypass policy:
  Ethernet1/0: deny udp host 10.0.0.9 eq 848 any eq 848 vrf RED*
```

Step 3 **show crypto gdoi gm acl**

Verifies the disablement of the default GDOI bypass crypto policy.

Example:

```
Device# show crypto gdoi gm acl

Group Name: GETVPN
ACL Downloaded From KS 10.0.0.2:
  access-list  deny eigrp any any
  access-list  permit ip any any
ACL Configured Locally:
ACL of default GDOI bypass policy: Disabled
```

Configuration Examples for GETVPN GDOI Bypass

Example: Enabling the Default GDOI Bypass Crypto Policy

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group getvpn
Device(config-gdoi-group)# client bypass-policy
Device(config-gdoi-group)# end
```

Example: Disabling the Default GDOI Bypass Crypto Policy

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group getvpn
Device(config-gdoi-group)# no client bypass-policy
Device(config-gdoi-group)# end
```

Feature Information for GETVPN GDOI Bypass

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 335: Feature Information for GETVPN GDOI Bypass

Feature Name	Releases	Feature Information
GETVPN GDOI Bypass		The following commands were introduced: client bypass-policy and show crypto gdoi gm acl .

CHAPTER 245

GETVPN G-IKEv2

Cisco Group Encrypted Transport VPN (GET VPN) includes a set of features that are necessary to secure IP multicast group traffic or unicast traffic over an enterprise private WAN that originates on or flows through a Cisco device. The GETVPN G-IKEv2 feature implements Internet Key Exchange version 2 (IKEv2) protocol on GETVPN thereby allowing GETVPN to derive the benefits of IKEv2.

- [Restrictions for GETVPN G-IKEv2, on page 3343](#)
- [Information About GETVPN G-IKEv2, on page 3343](#)
- [How to Configure GETVPN G-IKEv2, on page 3350](#)
- [Additional References for GETVPN G-IKEv2, on page 3354](#)
- [Feature Information for GETVPN G-IKEv2, on page 3355](#)

Restrictions for GETVPN G-IKEv2

- You can configure either Group Key Management (GKM) or Group Domain of Interpretation (GDOI) for a group member (GM), whereas you can configure both GKM and GDOI for a key server (KS).
- IKEv2 for COOP is not supported. Use IKEv1 for COOP between the key servers in the G-IKEv2 setup.
- EAP is not currently supported with G-IKEv2.
- GETVPN G-IKEv2 does not support IP-D3P. IP-D3P with G-IKEv2 is yet to be supported on GETVPN Group Members (GMs).

Information About GETVPN G-IKEv2

Overview of GETVPN G-IKEv2

Cisco Group Encrypted Transport Virtual Private Network (GETVPN) architecture is based on the Group Domain of Interpretation (GDOI) protocol. GETVPN uses Internet Security Exchange and Key Management Protocol (ISAKMP) to authenticate new group members, download cryptographic policy, and distribute traffic encryption key (TEK) and key encryption key (KEK) to group members. However, Internet Key Exchange Version 2 (IKEv2) has replaced. IKEv2 reduces network latency, reduces complexity in message exchanges, improves interoperability and reliability, and fixes cryptographic issue in HASH authentication. GET VPN combines IKEv2 protocol with IPsec to provide an efficient method to secure IP multicast traffic or unicast

traffic through the GETVPN G-IKEv2 feature. This feature provides a complete IKEv2 solution across all of Cisco's VPN technologies.

The G-IKEv2 protocol provides a mechanism for a group member (GM) to download policy and keys from a key server (KS). These policy and keys are used to secure communication among GMs in a group. G-IKEv2 is a new model to secure group communication between remote locations in an enterprise private WAN. The following figure depicts the basic system architecture of GETVPN using G-IKEv2 to register GM's with a KS and download keys and policy to GM's from a KS.

Figure 143: GETVPN Architecture through G-IKEv2 Protocol

Internet Key Exchange Version 2 (IKEv2)

Internet Key Exchange Version 2 (IKEv2), a next-generation key management protocol based on RFC 4306, is an enhancement of the IKE Protocol. IKEv2 is used for performing mutual authentication and establishing and maintaining security associations (SAs). For more information on IKEv2, see *FlexVPN and Internet Key Exchange Version 2 Configuration Guide*.

The following table compares the tunnel performance between IKE and IKEv2.

Protocol	Tunnels per Second	Maximum Simultaneous Tunnels
IKE	45	60
IKEv2	89	200

The benefits of IKEv2 are as follows:

Dead Peer Detection and Network Address Translation-Traversal

Internet Key Exchange Version 2 (IKEv2) provides built-in support for Dead Peer Detection (DPD) and Network Address Translation-Traversal (NAT-T).

Certificate URLs

Certificates can be referenced through a URL and hash, instead of being sent within IKEv2 packets, to avoid fragmentation.

Denial of Service Attack Resilience

IKEv2 does not process a request until it determines the requester, which addresses to some extent the Denial of Service (DoS) problems in IKEv1, which can be spoofed into performing substantial cryptographic (expensive) processing from false locations.

EAP Support

IKEv2 allows the use of Extensible Authentication Protocol (EAP) for authentication.

Multiple Crypto Engines

If your network has both IPv4 and IPv6 traffic and you have multiple crypto engines, choose one of the following configuration options:

- One engine handles IPv4 traffic and the other engine handles IPv6 traffic.
- One engine handles both IPv4 and IPv6 traffic.

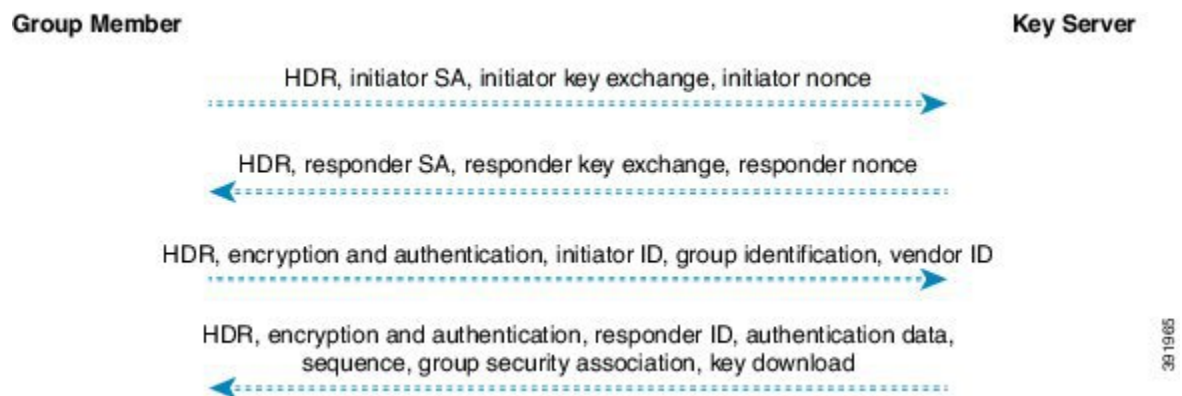

Reliability and State Management (Windowing)

IKEv2 uses sequence numbers and acknowledgments to provide reliability, and mandates some error-processing logistics and shared state management.

GETVPN G-IKEv2 Exchanges

The message exchanges between GM and KS conforms to the Internet Engineering Task Force (IETF) Group Key Management using IKEv2 Standards draft.

Figure 144: G-IKEv2 Message Exchanges

1. Group member initiates a registration request to key server by sending preferred cryptographic algorithms (in SA_i payload), Diffie–Hellman public number, in initiator’s key exchange (KE) phase 1 payload, and nonce, which is a random number for guaranteeing liveness in Initiator’s nonce payload.
2. Key server responds with the negotiated cryptographic algorithm (in responder’s SA phase 1 payload), Diffie–Hellman public number (in responder’s KE payload), nonce (in responder’s nonce payload). Optionally, if key server is configured to use Rivest, Shamir, and Adleman (RSA) digital signature as an authentication method, key server also sends a certificate request.

3. On receiving key server's response to the registration request, the group member uses the cryptographic algorithm in the SAr1 payload and Diffie–Hellman value to create keys and to encrypt the message sent to the key server. The encrypted message includes the initiator's ID and, optionally, certificate and certificate request, if RSA digital signature is used as authentication method. In case of Suite B implementations, a notify payload is sent for requesting sender IDs used with Galois/Counter Mode (GCM)–Advanced Encryption Standard (AES) or Galois Message Authentication Code (GMAC)–Advanced Encryption Standard (AES) transforms.

Note Group member requests a set of sender IDs applicable for interfaces for a lifetime of one day. After receiving the lifetime in a registration (for Long SA Lifetime) or a rekey (for Short SA Lifetime) message, group member stores the lifetime for calculating the number of sender IDs for future registrations.

4. After authenticating group manager, key server authorizes group member before registering group manager. After registration, key server sends the group's policy (in the GSA payload) and the group's keying material (in the KD payload) to group manager. The SEQ payload is optional and is sent when the key server wants to inform group manager of the current sequence number of the rekey message. These payloads are included in the GSA_AUTH response message.

Group Member Communication

Group members do not establish IPsec tunnels with one another, but use the IPsec policy and keys to secure communication between group members in a group.

Future Registrations

When a secure registration channel is established between group manager and key server, additional group member registrations for additional groups occurs through the established secure registration channel. In such scenario, group member uses the GSA_CLIENT_SERVER exchange that includes the group ID (IDg) to request either key encryption keys (KEK) or traffic encryption keys (TEKs) or both from key server.

Key Server Rekey

Key server distributes new group keys to group members using the G-IKEv2 group maintenance channel via unicast or multicast communication. Rekey is optional in G-IKEv2. When rekey is used, the KS sends a rekey message to group member. This message could be unicast or multicast depending on the key server configuration. Key server uses the KEK that is sent to the group member during registration to encrypt the rekey message. On receiving a rekey message, group member must ensure that the SEQ number in the rekey message is larger than the last received SEQ number. Group member could have received the SEQ number either via a registration message or a rekey message, whichever is later. If key server group is configured as both GDOI (IKEv1) and G-IKEv2 group, two rekey messages are sent—one over GDOI and another over G-IKEv2—for multicast rekey. In case of unicast rekey, key server only sends a GDOI or G-IKEv2 rekey depending on the group member's mode or type.

Note If the rekey is unicast, the group member must send an acknowledgment to key server.

Supported Features and GKM Version

The GETVPN G-IKEv2 feature supports the existing GETVPN features, which are as follows:

- Rekey and retransmission
- GM access control list (ACL)
- Fail-close mode
- Receive-only mode
- Anti-replay
- Authentication policy for group member registration
- GDOI MIBS
- VRF-Aware group member
- Group member removal and policy replacement
- Cooperative key server
- GETVPN IPv6 dataplane
- IPsec inline tagging support
- GETVPN resiliency phase 1 and phase 2
- Cooperative announcement message optimization

The GETVPN G-IKEv2 feature is supported in GKM version 1.0.12 and later releases. The supported GKM versions for a key server is 1.0.13 and a group member is 1.0.12. The difference between versions on a key server and a group member is because the IP D3P support on GETVPN Key Server and Internet-Draft ACK for Cisco GETVPN Key Server features are available on the key server from 1.0.13 only.

GDOI to G-IKEv2 Migration

Over a period of time, you may want to upgrade and migrate your key servers and group members to G-IKEv2. Migration from GDOI to G-IKEv2 for an entire GETVPN group requires careful planning. You cannot migrate all your group members at the same time. The migration entails allowing GDOI group members and G-IKEv2 group members to communicate using the same traffic encryption key (TEK) while using different control plane protocols—GDOI and G-IKEv2. A GDOI to G-IKEv2 migration sequence includes the following:

- Backward compatibility—The new Cisco IOS software image containing the GETVPN G-IKEv2 feature must support existing GDOI features and must be consistent with for earlier releases of GDOI features for Cisco IOS software.
- Service upgrade—The recommended sequence for changing the Cisco IOS software image is secondary key server, primary key server, and group member.
- Service downgrade—The recommended sequence for changing the Cisco IOS software image is group member, secondary key server, and primary key server.

Service Upgrade Procedure

1. Save the existing key server and group member GDOI configurations. For more information, see the “Configuration Replace and Configuration Rollback” feature module in the *Managing Configuration Files Configuration Guide*.
2. Configure a key encryption key (KEK) and a traffic encryption key (TEK) lifetime on all key servers to avoid network split and merge during the migration of the key servers. Use the `crypto gdoi ks rekey` command to configure the new lifetimes.
3. Upgrade key server to the new Cisco IOS software images. Follow the sequence mentioned above—start with the secondary key server followed by the primary key server. All existing configurations that use the keyword `gdoi` will be converted to the keyword `gkm`. For example, the global configuration command `crypto gdoi group` will be converted to `crypto gkm group` command. However, the groups continue to use GDOI for registration and rekey.
4. On key server, execute the `gikev2` command in the server local command for groups that support GDOI and G-IKEv2 group members.
5. Upgrade group members to the new Cisco IOS software image. All existing configurations that use the keyword “`gdoi`” will be converted to the keyword `gkm`. For example, the global configuration commands `crypto gdoi group` and `crypto map gdoi` will be converted to “`crypto gkm group`” and `crypto map gkm` respectively. These groups continue to use GDOI for registration and rekey and include the `client protocol gdoi` command.
6. Configure the `client protocol gikev2` command to use G-IKEv2 on group member.
7. Configure the `no gdoi` command in the server local command, to stop servicing GDOI group members.

For a group member to use GDOI after upgrading to G-IKEv2, configure the `client protocol gdoi` command in the group member group configuration. Group member registers again with key server using GDOI instead of G-IKEv2.

Note Before you convert group member, ensure that key server to which group member is registered is configured with the `gdoi` command in GDOI local server configuration mode.

Service Downgrade Procedure

Use the previously saved GDOI configurations (saved before upgrade procedure) and downgrade the Cisco IOS software for each group member. Next, downgrade the key server; beginning with the secondary key server followed by primary key server. For more information, see the “Configuration Replace and Configuration Rollback” feature module in the *Managing Configuration Files Configuration Guide*.

Migration Examples

This section provides examples on GDOI to G-IKEv2 migration. The following examples show how the GDOI group `g1` is converted to a GKM group after upgrading to a G-IKEv2 Cisco IOS software image. The following is a sample key server configuration before Cisco IOS software upgrade.

```
crypto gdoi group g1
  identity 1111
  server local
```

```

.
.
sa ipsec 1
  profile getvpn_profile
  match address getvpn_acl
.
.
.
  redundancy
.
.
.

```

The following is a sample key server configuration after Cisco IOS software upgrade. In this example, the commands **gdoi**, **no gikev2**, and **gikev2** are automatically added. The **gikev2** command starts accepting G-IKEv2 registrations.

```

crypto gkm group g1
  identity 1111
  server local
  gdoi
  no gikev2
  gikev2 ikev2_profile1
.
.
.
sa ipsec 1
  profile getvpn_profile
  match address getvpn_acl
.
.
.
  redundancy
.
.
.

```

The following is a sample group member configuration before Cisco IOS software upgrade.

```

crypto gdoi group g1
  identity 1111
  server address ipv4 ks1
  server address ipv4 ks2

crypto map GETVPN_CM 10 gdoi
  set group g1

interface g0/0/0
  crypto map GETVPN_CM

```

The following is a sample group member configuration after Cisco IOS software upgrade. In this example, the commands **client protocol gdoi** and **client protocol gikev2** are automatically added. The **client protocol gikev2** command starts using G-IKEv2.

```

crypto gkm group g1
  identity 1111
  server address ipv4 ks1
  server address ipv4 ks2
  client protocol gdoi
  client protocol gikev2 ikev2_profile1 ] - Configure this to start using G-IKEv2

crypto map GETVPN_CM 10 gdoi
  set group g1

```

```
interface g0/0/0
  crypto map GETVPN_CM
```

GETVPN G-IKEv2 Configuration

All GETVPN commands—EXEC and global configuration commands—include the keyword **gdoi**. G-IKEv2 does not include the Domain of Interpretation, therefore, a generic abbreviation **gkm** referring to Group Key Management is used for a group that can use either GDOI or G-IKEv2 protocols for registration and rekey. As of now, both commands **crypto gdoi** and **crypto gkm** are available. However, the **GDOI** keyword will be deprecated and replaced by the **gkm** keyword in future. For example, to configure a key server group, the GDOI command is **crypto gdoi group group-name**, whereas the GKM command would be **crypto gkm group group-name**.

How to Configure GETVPN G-IKEv2

Configuring an IKEv2 Profile

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto ikev2 profile profile-name**
4. **authentication** {local {rsa-sig | pre-share [key {0 | 6} password]} | ecdsa-sig | eap [gtc | md5 | ms-chapv2] [username username] [password {0 | 6} password]} | remote {eap [query-identity | timeout seconds] | rsa-sig | pre-share [key {0 | 6} password]} | ecdsa-sig }
5. **identity local** {address {ipv4-address | ipv6-address} | dn | email email-string | fqdn fqdn-string | key-id opaque-string }
6. **keyring** {local keyring-name | aaa list-name [name-mangler mangler-name | password password] }
7. **match** {address local {ipv4-address | ipv6-address | interface name} | certificate certificate-map | fvrf {fvrf-name | any} | identity remote address {ipv4-address [mask] | ipv6-address prefix} | {email [domain string] | fqdn [domain string]} string | key-id opaque-string }
8. **pki trustpoint trustpoint-label** [sign | verify]
9. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.

	Command or Action	Purpose
Step 3	crypto ikev2 profile <i>profile-name</i> Example: Device(config)# crypto ikev2 profile gkm-gikev2	Defines an IKEv2 profile and enters IKEv2 profile configuration mode.
Step 4	authentication { local { rsa-sig pre-share [key { 0 6 } <i>password</i>]} ecdsa-sig eap [gtc md5 ms-chapv2] [username <i>username</i>] [password { 0 6 } <i>password</i>]} remote { eap [query-identity timeout <i>seconds</i>] rsa-sig pre-share [key { 0 6 } <i>password</i>]} ecdsa-sig }} Example: Device(config-ikev2-profile)# authentication local ecdsa-sig	Specifies the local or remote authentication method. <ul style="list-style-type: none"> • rsa-sig—Specifies RSA-sig as the authentication method. • pre-share—Specifies the preshared key as the authentication method. • ecdsa-sig—Specifies ECDSA-sig as the authentication method. • eap—Specifies EAP as the remote authentication method. • query-identity—Queries the EAP identity from the peer. • timeout <i>seconds</i>—Specifies the duration, in seconds, to wait for the next IKE_AUTH request after sending the first IKE_AUTH response. <p>Note You can specify only one local authentication method but multiple remote authentication methods.</p>
Step 5	identity local { address { <i>ipv4-address</i> <i>ipv6-address</i> } dn email <i>email-string</i> fqdn <i>fqdn-string</i> key-id <i>opaque-string</i> } Example: Device(config-ikev2-profile)# identity local email abc@example.com	This is an optional step. Specifies the local IKEv2 identity type. <p>Note If the local authentication method is a preshared key, the default local identity is the IP address. If the local authentication method is a Rivest, Shamir, and Adleman (RSA) signature, the default local identity is a Distinguished Name.</p>
Step 6	keyring { local <i>keyring-name</i> aaa <i>list-name</i> [name-mangler <i>mangler-name</i> password <i>password</i>] } Example: Device(config-ikev2-profile)# keyring aaa keyring1 name-mangler mangler1	Specifies the local or AAA-based key ring that must be used with the local and remote preshared key authentication method. <p>Note You can specify only one key ring. Local AAA is not supported for AAA-based preshared keys.</p> <p>Note Depending on your release, the local keyword and the name-mangler <i>mangler-name</i> keyword-argument pair should be used.</p> <p>Note When using AAA, the default password for a Radius access request is "cisco". You can use the password keyword within the keyring command to change the password.</p>

	Command or Action	Purpose
Step 7	match { address local { <i>ipv4-address</i> <i>ipv6-address</i> interface <i>name</i> } certificate <i>certificate-map</i> fvr { <i>fvr-name</i> any } identity remote address { <i>ipv4-address</i> [<i>mask</i>] <i>ipv6-address prefix</i> } { email [<i>domain string</i>] fqdn [<i>domain string</i>]} <i>string</i> key-id <i>opaque-string</i> } Example: Device(config-ikev2-profile)# match address local interface Ethernet 2/0	Uses match statements to select an IKEv2 profile for a peer.
Step 8	pki trustpoint <i>trustpoint-label</i> [sign verify] Example: Device(config-ikev2-profile)# pki trustpoint tsp1 sign	Specifies Public Key Infrastructure (PKI) trustpoints for use with the RSA signature authentication method. Note If the sign or verify keyword is not specified, the trustpoint is used for signing and verification. Note In contrast to IKEv1, a trustpoint must be configured in an IKEv2 profile for certificate-based authentication to succeed. There is no fallback for globally configured trustpoints if this command is not present in the configuration. The trustpoint configuration applies to the IKEv2 initiator and responder.
Step 9	end Example: Device(config-ikev2-profile)# end	Exits the IKEv2 profile configuration mode and returns to the privileged EXEC mode.

Configuring GKM Policy on a Key Server

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gkm group** [**ipv6**] *group-name*
4. **server local**
5. **gikev2** *IKEv2-profile-name*
6. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.

	Command or Action	Purpose
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gkm group [ipv6] group-name Example: Device(config)# crypto gkm group gkm-grp1	Configures a GKM policy and enters GKM group configuration mode.
Step 4	server local Example: Device(config-gkm-group)# server local	Designates a device as a GKM key server and enters GKM local server configuration mode.
Step 5	gikev2 IKEv2-profile-name Example: Device(gkm-local-server)# gikev2 gkm-gikev2	Enables G-IKEv2 profile for registration and rekey on a key server.
Step 6	end Example: Device(gkm-local-server)# end	Exits GKM local server configuration mode and returns to privileged EXEC mode.

Configuring GKM Policy on Group Member

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto gkm group [ipv6] group-name
4. client protocol gikev2 gkm-gikev2
5. end

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gkm group [ipv6] group-name Example:	Configures a GKM policy and enters GKM group configuration mode.

	Command or Action	Purpose
	<code>Device(config)# crypto gkm group gkm-grp2</code>	
Step 4	client protocol gikev2 <i>gkm-gikev2</i> Example: <code>Device(config-gkm-group)# client protocol gikev2 gkm-gikev2</code>	Enables G-IKEv2 profile for registration and rekey on a group member.
Step 5	end Example: <code>Device(config-gkm-group)# end</code>	Exits GKM group configuration mode and returns to privileged EXEC mode.

Feature Information for GETVPN G-IKEv2

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 336: Feature Information for GETVPN G-IKEv2

Feature Name	Releases	Feature Information
GETVPN G-IKEv2		The following commands were introduced or modified: client protocol , crypto gkm group , gikev2 , show crypto gkm .

CHAPTER 246

8K GM Scale Improvement

The 8K GM Scale Improvement feature supports optimization of the Cooperative Protocol (COOP) announcement messages by increasing the number of Group Members (GM) to 8000.

- [Prerequisites for 8K GM Scale Improvement, on page 3357](#)
- [Information About 8K GM Scale Improvement, on page 3357](#)
- [How to Configure 8K GM Scale Improvement, on page 3358](#)
- [Configuration Examples for 8K GM Scale Improvement, on page 3359](#)
- [IPSEC Encryption and Decryption in GETVPN, on page 3359](#)
- [Additional References for 8K GM Scale Improvement, on page 3360](#)
- [Feature Information, on page 3361](#)

Prerequisites for 8K GM Scale Improvement

To upgrade or downgrade a particular protocol version, maintain the same policies, keys, and group member (GM) database to ensure uninterrupted communication between GMs.

Information About 8K GM Scale Improvement

8K GM Scale Improvement

A Cooperative Protocol Announcement (COOP ANN) message has several clients and each client is associated with a protocol version. The COOP ANN message has been optimized to hold up to 8000 Group Members (GM), subsequently increasing the protocol version of the GM header.

This feature also supports upgrade and downgrade of a GM header protocol version.

How to Configure 8K GM Scale Improvement

Upgrading and Downgrading the Group Member Header Protocol Version

Before you begin

- Ensure that all Key Servers (KS) are upgraded to the “optimize” protocol version before scaling the network to more than 4000 GMs
- Ensure that all upgraded KSs must be downgraded to the “base” protocol version before scaling down to a network that supports only up to 4000 GMs.

SUMMARY STEPS

1. **enable**
2. **configure terminal**
3. **crypto gdoi group** *group-name*
4. **server local**
5. **redundancy**
6. **protocol version** {base | optimize}
7. **end**

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gdoi group <i>group-name</i> Example: Device(config)# crypto gdoi group GETVPN	Identifies a GDOI group and enters GDOI group configuration mode.
Step 4	server local Example: Device(config-gdoi-group)# server local	Identifies a group server defined locally and enters GDOI local server configuration mode.
Step 5	redundancy Example: Device(gdoi-local-server)# redundancy	Enters GDOI COOP KS configuration mode. Note Ensure that the local server source address is defined.

	Command or Action	Purpose
Step 6	protocol version {base optimize} Example: Device(gdoi-coop-ks-config)# protocol version optimize	Upgrades or downgrades the protocol version of the GM header. <ul style="list-style-type: none"> • base—COOP ANN message supports up to 4000 GMs. • optimize—COOP ANN message supports up to 8000 GMs.
Step 7	end Example: Device(gdoi-coop-ks-config)# end	Exits COOP KS configuration mode and returns to privileged EXEC mode.

Configuration Examples for 8K GM Scale Improvement

Example: Upgrading the Group Member Header Protocol Version

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group getvpn
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# redundancy
Device(gdoi-coop-ks-config)# protocol version optimize
Device(gdoi-coop-ks-config)# end
```

Example: Downgrading the Group Member Header Protocol Version

```
Device> enable
Device# configure terminal
Device(config)# crypto gdoi group getvpn
Device(config-gdoi-group)# server local
Device(gdoi-local-server)# redundancy
Device(gdoi-coop-ks-config)# protocol version base
Device(gdoi-coop-ks-config)# end
```

IPSEC Encryption and Decryption in GETVPN

In GETVPN IPsec flow, inbound traffic decryption might not happen in the expected IPsec flow recorder. The decrypted traffic can be recorded in any IPsec SA, if available. The decryption might happen in a random IPsec flow recorder. The following is an example:

```
Device# ping vrf cust1 48.1.1.1 so 38.1.1.1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 48.1.1.1, timeout is 2 seconds:
Packet sent with a source address of 38.1.1.1
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/1/1 ms
```

```

Device# show crypto session ivrf cust1 detail | sec permit ip 38.0.0.0
IPSEC FLOW: permit ip 38.0.0.0/255.0.0.0 48.0.0.0/255.0.0.0
Active SAs: 2, origin: crypto map
Inbound:  #pkts dec'ed 0 drop 0 life (KB/Sec) KB Vol Rekey Disabled/1 hours, 16
mins
Outbound: #pkts enc'ed 5 drop 0 life (KB/Sec) KB Vol Rekey Disabled/1 hours, 16
mins

Device# show crypto session ivrf cust1 detail | sec permit ip 48.0.0.0
IPSEC FLOW: permit ip 48.0.0.0/255.0.0.0 38.0.0.0/255.0.0.0
Active SAs: 2, origin: crypto map
Inbound:  #pkts dec'ed 0 drop 0 life (KB/Sec) KB Vol Rekey Disabled/1 hours, 16
mins
Outbound: #pkts enc'ed 0 drop 0 life (KB/Sec) KB Vol Rekey Disabled/1 hours, 16
mins

Device# show crypto session ivrf cust1 detail | sec permit ip 45.0.0.0
IPSEC FLOW: permit ip 45.0.0.0/255.0.0.0 35.0.0.0/255.0.0.0
Active SAs: 2, origin: crypto map
Inbound:  #pkts dec'ed 5 drop 0 life (KB/Sec) KB Vol Rekey Disabled/1 hours, 15
mins
Outbound: #pkts enc'ed 0 drop 0 life (KB/Sec) KB Vol Rekey Disabled/1 hours, 15
mins

```

In the above example, flow inbound traffic is not decrypted in the expected IPsec flow.

To overcome this issue and view the number of encrypted and decrypted packets, you can use the following **show** command. Here's a sample output of the **show** command.

```

Device# show crypto gdoi group v6-cust-gdoi1 gm dataplane counters

Data-plane statistics for group v6-cust-gdoi1:
#pkts encrypt      : 1912  #pkts decrypt      : 1914
#pkts tagged (send) : 1841  #pkts untagged (rcv) : 1834
#pkts no sa (send)  : 0      #pkts invalid sa (rcv) : 0
#pkts encaps fail (send) : 0     #pkts decap fail (rcv) : 0
#pkts invalid prot (rcv) : 0     #pkts verify fail (rcv) : 0
#pkts not tagged (send) : 0     #pkts not untagged (rcv) : 0
#pkts internal err (send) : 0     #pkts internal err (rcv) : 0

```

CHAPTER 247

GET VPN Interoperability

The D3P Support on GETVPN Key Server, Activation Time Delay, and GDOI Interop ACK for Cisco GETVPN Key Server features enhance interoperability between key servers and group members.

- [Prerequisites for GET VPN Interoperability, on page 3363](#)
- [Restrictions for GET VPN Interoperability, on page 3363](#)
- [Information About GET VPN Interoperability, on page 3364](#)
- [How to Configure GET VPN Interoperability, on page 3368](#)
- [Configuration Examples for GET VPN Interoperability, on page 3374](#)
- [Additional References for GET VPN Interoperability, on page 3375](#)
- [Feature Information for GET VPN Interoperability, on page 3376](#)

Prerequisites for GET VPN Interoperability

- To enable the feature for a group, ensure that all the devices in a group are running compatible Cisco IOS software and Group Domain of Interpretation (GDOI) versions.
- Enable the Unicast Rekey functionality on a GDOI group before configuring the Internet-Draft ACK for Cisco GETVPN Key Server and Activation Time Delay features.

Restrictions for GET VPN Interoperability

- The IP-D3P support on GETVPN Key Server feature cannot coexist with the GETVPN Resiliency - GM Error Detection and GET VPN Support of IPsec Inline Tagging for Cisco TrustSec features. The latter features must be disabled before enabling IP-D3P support on a GET VPN key server and the IP-D3P must be disabled before enabling GETVPN Resiliency support on GETVPN Key Server.
- The Activation Time Delay feature supports only on IPsec security association. Multiple IPsec SA must not be configured.
- Cisco-Metdata and IP-D3P cannot coexist. When switching between CMD-feature and IP-D3P, the keyserver must perform **crypto gdoi ks rekey replace** to all the GMs to make sure these two features are not enabled simultaneously.
- ASR1K supports IP-D3P only in GETVPN IPv4 tunnel mode.

Information About GET VPN Interoperability

Overview of IP-Delivery Delay Detection Protocol (IP-D3P)

IP datagrams can be subject to a delivery delay attack, where a host or gateway receives datagrams that are not fresh. A fresh datagram is defined as a “Recently generated; not replayed from some earlier interaction of the protocol.” An IP-D3P datagram consists of a header and an IP payload. The IP-D3P header includes a timestamp that is used by the receivers of the packet to determine if the packet has been recently generated. Receivers compare the timestamp delivered in the IP packet to their local time and thus determine whether the packet should be accepted.

IP-D3P uses the system clock of group members to create and verify the IP-D3P datagram’s timestamp. In most cases, the system clock is set from an external protocol, such as Network Time Protocol (NTP) to synchronize the system clocks of the sender and receiver.

The D3P support on GETVPN Key Server feature enables support for IP-D3P on GET VPN.

IP-D3P Support for Key Server

A new configuration command, **d3p**, in the GDOI local server configuration mode allows you to enable IP-D3P on a key server. After you enable the D3P command, the primary key server issues a rekey to all the group members having a Group Associated Policy (GAP) payload with D3P attributes. The GAP payload includes the following attributes in the rekey message:

- D3P-TYPE—Portable Operating System Interface (POSIX) time, in milliseconds.
- D3P-WINDOWSIZE—IP-D3P window size, in milliseconds.

The **show crypto gkm ks** command displays the IP-D3P parameters that are enabled on a key server.

IP-D3P Support for Cooperative Key Server

If a GET VPN group has more than one key server, IP-D3P must be enabled on all the key servers. The primary key server sends the GAP payload containing the IP-D3P attributes to the secondary key servers through an announcement message, which notifies all cooperative key servers that IP-D3P is now enforced in the group.

On receiving the GAP payload, cooperative key servers check the IP-D3P attributes against their group configuration. If there is a mismatch, cooperative key servers generate a syslog message, warning the network administrator of a misconfiguration or incorrect configuration, as:

```
%GDOI-3-COOP_CONFIG_MISMATCH: WARNING: IP-D3P configuration between Primary KS and Secondary KS are mismatched
```

IP-D3P Support for Group Member

Group members receive the IP-D3P parameters present in the rekey messages. Group members process the new GAP payload attributes—D3P-TYPE and D3P-WINDOWSIZE. The window-size, which must be used in IP-D3P for a group member, can be overwritten by using the **client d3p** command in the GDOI group configuration. For example, if a key server configuration is **d3p window msec 1000** and a group member configuration is **client d3p window sec 50**, the group member can enable IP-D3P using the following parameters and overriding the parameters received from the key server:

```
D3P-TYPE = POSIX-TIME-MSEC
D3P-WINDOWSIZE = 50000
```

Use the **show crypto gdoi gm** command to display the IP-D3P configuration of a group member and the IP-D3P errors, if any, that were encountered.

Note IP-D3P cannot be enabled on Cisco ASR 9000 Series Aggregation Services Routers, which use the parameters sent by a key server. Use the **show crypto gdoi group** command to view the parameters sent by the key server on Cisco ASR 9000 Series Aggregation Services Routers.

Activation Time Delay

GET VPN supports the Activation Time Delay (ATD) feature, in which a key server instructs group members to delay the use of new security associations (SAs) for traffic encryption. A key server includes the ATD value in the Group Associated Policy (GAP) payload when sending unicast rekey messages to group members. The time delay value is not user configurable; it is fixed as 30 seconds before SA expiry. The formula for calculating the ATD value is as follows:

$$\text{ATD} = \text{Max}((\text{Max}(\text{old-SA-remaining-lifetime_sec}, 30\text{sec}) - 30\text{sec}), 1\text{sec})$$

Note ATD support is limited to group members that are configured on Cisco ASR 9000 Series Aggregation Services Routers and on non-Cisco devices. Therefore, a key server does not send ATD information to devices other than Cisco ASR 9000 Series Aggregation Services Routers and non-Cisco devices.

Rekey Acknowledgment

When a key server sends a rekey message to group members for updating the keys and policies of a group, it is useful for a key server to know if all group members have received the rekey message and have successfully processed, installed, and responded to the new keys and policies.

Cisco Unicast Rekey Acknowledgment Message

If a unicast rekey is configured, a key server sends rekey messages, for which group members reciprocate by sending an acknowledgment rekey message.

Note There is no acknowledgment message if multicast rekey is configured.

If a key server sends three consecutive unacknowledged unicast rekeys to a group member, and if the unicast rekeys are unacknowledged by that group member, the group member is removed from the group member database in the key server and no further unicast rekeys are sent to that group member.

GDOI I-D Rekey Acknowledgement Message

The GDOI Interop ACK for Cisco Key Server feature implements the standards for rekey acknowledgment messages between non-Cisco group members and a key server, as defined in the RFC-8263, GROUPKEY-PUSH Acknowledgment message.

The GDOI GROUPKEY-PUSH Acknowledgment message, which is referred to as GDOI I-D Rekey ACK, differs from the Cisco unicast rekey acknowledgment message by defining an interoperable method for a group member to send a rekey acknowledgment to any key server in a group.

GDOI I-D Rekey ACK Support for a Key Server

The **rekey acknowledgement** command enables the key server to request group members to acknowledge rekeys depending on the keywords chosen with the command:

- **cisco**—Accepts Cisco-proprietary rekey ACK (encrypted) message.
- **interoperable**—Requests and accepts rekey ACK (unencrypted) message as per the corresponding Internet Draft.
- **any**—Accepts any supported ACK message based on the group key member version.

After enabling the **rekey acknowledgement** command, the key server sends a new policy attribute, **KEK_ACK_REQUESTED**. The new policy attribute in the key encryption key (KEK) SA payload for registration and rekey.

GDOI I-D Rekey ACK Support for Cooperative Key Server

The **rekey acknowledgement** command must be configured on all the key servers if a GET VPN group has multiple key servers. When a primary key server sends an announcement message to a secondary key server, the primary key server also includes the **KEK SA** payload carrying the **KEK_ACK_REQUESTED** attribute. This notifies all the cooperative key servers to send the **KEK_ACK_REQUESTED** attribute to the group members registered under them.

Upon receiving the **KEK SA** payload with the **KEK_ACK_REQUESTED** attribute, cooperative key servers check their group configuration. If there is a mismatch, cooperative key servers generate a message, warning the network administrator of a misconfiguration or incorrect configuration, as shown here:

```
%GDOI-3-COOP_CONFIG_MISMATCH: WARNING: Interoperable Rekey ACK configuration between Primary
KS and Secondary KS are mismatched
```

Note Rekey acknowledgments are sent only to a primary key server because it is the primary key server that sends rekey messages. A rekey acknowledgment is sent to a cooperative server only when a cooperative key server is promoted as a primary key server, and if the old primary key server did not create a key encryption key (KEK) or traffic encryption key (TEK) policy.

GDOI I-D Rekey Support for Group Member

A group member is said to support the Internet-Draft ACK for Cisco GETVPN Key Server feature if the group member receives the rekey message containing the **KEK_ACK_REQUESTED** attribute in the **KEK SA** payload and sends the GDOI I-D Rekey ACK to the key server through an acknowledgment message.

Key Server and Group Member Communication

When a key server sends the **KEK_ACK_REQUESTED** attribute in the **KEK SA** payload, a group member must respond to subsequent rekey messages with the GDOI I-D Rekey ACK unless notified otherwise by the corresponding key server. The communication between a key server and group members are as follows:

1. For every GROUPKEY-PUSH message sent by a key server, the group member must respond with the GROUP-PUSH-KEY ACK message.
2. The key server verifies and validates the message for format and payload. If validation fails, the message is dropped.
3. If validation is successful, the key server processes the SEQ and ID payloads to record the latest acknowledged sequence number for the group member associated with the ID. The sequence number must be the same as the last sent sequence number; otherwise, the SEQ and ID payload will not be recorded.

Note In case of a Cisco key server, a group member is removed from the database if a group member does not send an acknowledgment for three consecutive rekey messages. If a group member is configured with the unicast rekey feature and the KEK_ACK_REQUESTED attribute is not sent for a given KEK Security Parameter Index (SPI), the group members must send the Cisco Unicast Rekey ACK message to the key server.

The following table explains the attributes sent in the KEK SA payload along with the values sent for each acknowledgment option configured on a key server:

Table 338: KEK SA Payload for Each Acknowledgment Option

Acknowledgement Option	New Cisco Group Member	Cisco ASR 9000 Group Member	Non-Cisco Group Member
Cisco	No Attribute	No Attribute	No Attribute
Interoperable	KEK_ACK_REQ REKEY_ACK_KEK_SHA256	KEK_ACK_REQ REKEY_ACK_KEK_SHA256	KEK_ACK_REQ REKEY_ACK_KEK_SHA256
Any	No Attribute	KEK_ACK_REQ REKEY_ACK_KEK_SHA256	KEK_ACK_REQ REKEY_ACK_KEK_SHA256

Note When the **no rekey acknowledgement** command is used to set the rekey acknowledgment to the default value 'Cisco', the key server does not include the KEK_ACK_REQUESTED attribute in the KEK SA payload.

The following table explains the acknowledgment methodology for each acknowledgment type configured via the keywords in the **rekey acknowledgement** command on a key server:

Table 339: Acknowledgment Methodology

Acknowledgement Option	Key Server Accepts I-D ACK	Key Server Accepts Cisco ACK
Cisco	No (results in error)	Yes
Interoperable	Yes	No (results in error)
Any	Yes	Yes

How to Configure GET VPN Interoperability

Ensuring the Correct GDOI Version on a Key Server

SUMMARY STEPS

1. **enable**
2. **show crypto gkm feature *feature name***
3. **show crypto gkm feature *feature-name* | include no**

DETAILED STEPS

Step 1 **enable**

Enables privileged EXEC mode.

- Enter your password if prompted.

```
Device> enable
```

Step 2 **show crypto gkm feature *feature name***

Displays the GDOI version running on each key server and group member in the network and information about whether the device supports GET VPN interoperability features, namely, D3P support on GETVPN Key Server and Internet-Draft ACK for Cisco GETVPN Key Server.

Example:

```
Device# show crypto gkm feature ip-d3p
Group Name: GET VPN1
  Key Server ID      Version  Feature Supported
  10.0.8.1           1.0.11  Yes
  10.0.9.1           1.0.10  No
  Group Member ID   Version  Feature Supported
  10.0.3.1           1.0.11  Yes
  10.65.9.2         1.0.10  No
```

Example:

```
Device# show crypto gkm feature gdoi-interop-ack
Group Name: GET VPN2
  Key Server ID      Version  Feature Supported
  10.0.8.1           1.0.11  Yes
  10.0.9.1           1.0.10  No
  Group Member ID   Version  Feature Supported
  10.0.3.1           1.0.11  Yes
  10.65.9.2         1.0.10  No
```

Step 3 **show crypto gkm feature *feature-name* | include no**

(Optional) Finds devices that do not support a feature.

Example:

```
Device# show crypto gkm feature gdoi-interop-ack | include no
```

Ensuring the Correct GDOI Version on a Group Member

SUMMARY STEPS

1. `enable`
2. `show crypto gkm feature feature name`

DETAILED STEPS

Step 1 `enable`

Enables privileged EXEC mode.

- Enter your password if prompted.

Step 2 `show crypto gkm feature feature name`

Displays the GDOI version running on a group member in the network and information about whether the device supports GET VPN interoperability features, namely, D3P support on GETVPN Key Server and Internet-Draft ACK for Cisco GETVPN Key Server.

Example:

```
Device# show crypto gkm feature ip-d3p
      Version      Feature Supported
      1.0.11       Yes
```

Example:

```
Device# show crypto gkm feature gdoi-interop-ack
      Version      Feature Supported
      1.0.10       No
```

Enabling IP-D3P on a Key Server

SUMMARY STEPS

1. `enable`
2. `configure terminal`
3. `crypto gkm group GETVPN`
4. `server local`
5. `sa d3p window {sec seconds | msec milliseconds}`
6. `exit`
7. `show crypto gkm ks replay`

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gkm group GETVPN Example: Device(config)# crypto gkm group GETVPN	Configures a group key management (GKM) group and enters GKM group configuration mode.
Step 4	server local Example: Device(config-gkm-group)# server local	Designates the device as a key server and enters GDOI local server configuration mode.
Step 5	sa d3p window {sec seconds msec milliseconds} Example: Device(gdoi-local-server)# sa d3p window msec 5000	Enables IP delivery delay detection protocol (IP-D3P) on all security associations in the group. <ul style="list-style-type: none"> • sec seconds—Window size, in seconds. The range is from 1 to 100. • msec milliseconds—Window size, in milliseconds. The range is from 100 to 10000.
Step 6	exit Example: Device(gdoi-local-server)# exit	Exits GDOI local server configuration mode and returns to privileged EXEC mode.
Step 7	show crypto gkm ks replay Example: Device# show crypto gkm ks replay	Displays key server group information for time-based anti-replay.

Example

The following is a sample output from the **show crypto gkm ks replay** command:

```
Device# show crypto gkm ks replay
Anti-replay Information For Group GETVPN:
  IP-D3P: Type = POSIX-TIME-MSEC, Window-size = 5000 msec
```

Enabling IP-D3P on a Group Member

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto gkm group GET
4. client d3p window {sec seconds | msec milliseconds}
5. exit
6. show crypto gkm gm replay

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none"> • Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gkm group GET Example: Device(config)# crypto gkm group GETVPN	Configures a group key management (GKM) group and enters GKM group configuration mode.
Step 4	client d3p window {sec seconds msec milliseconds} Example: Device(config-gkm-group)# client d3p window sec 50	Enables client-acceptable IP delivery delay detection protocol (IP-D3P). <ul style="list-style-type: none"> • sec seconds—Window size, in seconds. The range is from 1 to 100. • msec milliseconds—Window size, in milliseconds. The range is from 100 to 10000.
Step 5	exit Example: Device(gdoi-local-server)# exit	Exits GDOI local server configuration mode and returns to privileged EXEC mode.
Step 6	show crypto gkm gm replay Example: Device# show crypto gkm gm replay	Displays group member information for time-based anti-replay.

Example

The following is a sample output from the **show crypto gkm gm replay** command:

```

Device# show crypto gkm gm replay
Anti-replay Information For Group GET:
IP-D3P:
  Posix-time-msec           : 502764.17
  Input Packets              : 5           Output Packets           : 5
  Input Error Packets        : 5           Output Error Packets      : 0

IP-D3P Error History (sampled at 10pak/min):
  xx:xx:xx.xxx PST Tue Feb 25 2014: src=5.0.0.2; my_time=502729.95; peer_time=33.46;
win=10
  yy:yy:yy.yyy PST Tue Feb 25 2014: src=5.0.0.2; my_time=502723.95; peer_time=27.45;
win=10

```

Enabling Rekey Acknowledgment

SUMMARY STEPS

1. enable
2. configure terminal
3. crypto gkm group GET
4. server local
5. rekey acknowledgement {cisco | interoperable | any}
6. exit
7. show crypto gkm ks replay

DETAILED STEPS

	Command or Action	Purpose
Step 1	enable Example: Device> enable	Enables privileged EXEC mode. <ul style="list-style-type: none">• Enter your password if prompted.
Step 2	configure terminal Example: Device# configure terminal	Enters global configuration mode.
Step 3	crypto gkm group GET Example: Device(config)# crypto gkm group GET	Configures a group key management (GKM) group and enters GKM group configuration mode.
Step 4	server local Example: Device(config-gkm-group)# server local	Designates the device as a key server and enters GDOI local server configuration mode.
Step 5	rekey acknowledgement {cisco interoperable any} Example: Device(gdoi-local-server)# rekey acknowledgment interoperable	Enables group members to acknowledge rekeys. <ul style="list-style-type: none">• cisco—Accepts Cisco Rekey ACK (encrypted) message.

	Command or Action	Purpose
		<ul style="list-style-type: none"> • interoperable—Requests and accepts interoperable rekey ACK (unencrypted) message. • any—Accepts a supported ACK message based on group key member version.
Step 6	exit Example: Device(gdoi-local-server)# exit	Exits GDOI local server configuration mode and returns to privileged EXEC mode.
Step 7	show crypto gkm ks replay Example: Device# show crypto gkm ks replay	Displays rekey acknowledgment configuration on the key server.

Example

The following is a sample output from **show** commands displaying the rekey acknowledgment configuration:

```
Device# show crypto gkm

Configuration Examples for GET VPN Interoperability

Example: Enabling IP-D3P on a Key Server

```

Device> enable
Device# configure terminal
Device(config)# crypto gkm group GETVPN
Device(config-gkm-group)# server local
Device(gdoi-local-server)# sa d3p window msec 5000
Device(gdoi-local-server)# exit

```

Example: Enabling IP-D3P on a Group Member

```
Device> enable
Device# configure terminal
Device(config-gkm-group)# client d3p window sec 50
Device(gdoi-local-server)# exit
```

Example: Enabling Rekey Acknowledgement

```
Device> enable
Device# configure terminal
Device(config)# crypto gkm group GET
Device(config-gkm-group)# server local
Device(gdoi-local-server)# rekey acknowledgment interoperable
Device(gdoi-local-server)# exit
```

The Cisco Support and Documentation website provides online resources to download documentation, software, and tools. Use these resources to install and configure the software and to troubleshoot and resolve technical issues with Cisco products and technologies. Access to most tools on the Cisco Support and Documentation website requires a Cisco.com user ID and password.	http://www.cisco.com/cisco/web/support/index.html

Feature Information for GET VPN Interoperability

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 340: Feature Information for GET VPN Interoperability

Feature Name	Releases	Feature Information
D3P support on GETVPN Key Server		<p>The D3P support on GETVPN Key Server feature enables support for IP-D3P on a GET VPN network.</p> <p>The following commands were introduced or modified: client d3p, sa d3p, show crypto gkm gm replay, show crypto gkm ks replay.</p>
Internet-Draft ACK for Cisco GETVPN Key Server		<p>The Internet-Draft ACK for Cisco GETVPN Key Server implements the standard for rekey acknowledgment message between non-Cisco group members and key server as defined in the GDOI GROUPKEY-PUSH Acknowledgment Message draft.</p> <p>The following commands were introduced or modified: rekey acknowledgement, show crypto gkm.</p>
RFC 8263 ID Ack implementation		<p>The Group Domain of Interpretation (GDOI) includes the ability of key server to provide a set of current devices with additional security associations. For example, to rekey expiring security associations. This feature adds the ability of a key server to request that the group devices return an acknowledgement of receipt of its rekey message and specifies the acknowledgement method.</p>

CHAPTER 248

Perfect Forward Secrecy for GETVPN

If a Group Member (GM) is compromised, an attacker may access saved long-term keys and messages. With Perfect Forward Secrecy (PFS) for GETVPN, the attacker cannot use the keys and messages to obtain the keys of past or future sessions. Thus, the attacker may use the compromised Traffic Encryption Key (TEK) to decrypt the communication of the current session, but cannot decrypt recorded or future communication.

- [Feature Information for PFS for GETVPN, on page 3377](#)
- [Information About PFS for GETVPN, on page 3377](#)

Feature Information for PFS for GETVPN

The following table provides release information about the feature or features described in this module. This table lists only the software release that introduced support for a given feature in a given software release train. Unless noted otherwise, subsequent releases of that software release train also support that feature.

Use Cisco Feature Navigator to find information about platform support and Cisco software image support. To access Cisco Feature Navigator, go to www.cisco.com/go/cfn. An account on Cisco.com is not required.

Table 341: Feature Information for PFS for GETVPN

Feature Name	Releases	Feature Information
Perfect Forward Secrecy for GETVPN	Cisco IOS XE Gibraltar 16.12.1	The following commands are introduced or modified: show crypto gkm feature pfs , pfs , show crypto gdoi , and client pfs .

Information About PFS for GETVPN

Overview of PFS for GETVPN

Suppose a device is compromised and an attacker accesses the long-term keys saved on it. For Perfect Forward Secrecy (PFS), the attacker must not be able to use the long-term keys to obtain keys and decrypt recorded communication of past sessions. A related security measure is called Perfect Backward Secrecy (PBS). For PBS, the attacker must not be able to use the long-term keys to obtain keys and decrypt communication of future sessions.

If a GM is compromised, an attacker may access saved long-term keys and messages. The attacker may so obtain the Diffie Hellman (DH) result and the registration message or the Key Encryption Key (KEK) and past rekey messages. With PFS for GETVPN, the attacker cannot use the keys and messages to obtain TEKs of past sessions. In addition, the attacker cannot use the KEK to decrypt future rekey messages, and so, cannot obtain TEKs of future sessions. Thus, the attacker has access only to the TEK of the current session. Despite the compromised keys, any recorded or future communication remains secure.

PFS for GETVPN comprises the following changes:

- A modified rekey process; the GM registration mechanism is unchanged.
- If you enable PFS for GETVPN, the default lifetime of the GM-KS IKEv2 channel changes from 1 day to 600 seconds.

However, if you have configured customized lifetime, the lifetime does not change after you enable PFS for GETVPN.

- Key Servers (KSs) and Group Members (GMs) that support PFS for GETVPN have new version numbers. The version numbers support backward compatibility and interactions with third-party GMs.

Restrictions for PFS for GETVPN

- A Key Server (KS) and a Group Member (GM) must communicate using the IKEv2 protocol. PFS for GETVPN is not supported when KS and GM communicate using the IKEv1 protocol.
- Enable PFS on all the KSs in a COOP. On a GM, PFS is enabled by default.
- Both scheduled rekey and manually triggered rekey cause a GM to reregister with a KS. The reregistration may cause a noticeable overhead at the KS, especially at scale.
- Force rekey can cause traffic loss because of a key mismatch between GMs.
- When the RSA key size is 4096, because of the large size of the key, the Crypto Engine takes considerable time for a rekey signing. During a rekey signing, if too many registration requests are received, the Crypto Engine may be overloaded. An overloaded Crypto Engine logs the following error message:

```
%ACE-3-TRANSERR: IOSXE-ESG(9): IKEA trans 0x11A8; opcode 0x23; param 0x0; error 0xC;
retry cnt 0
```

You may see this error message more frequently in a GETVPN deployment that uses an RSA key size of 4096, has more than 100 GMs, and has PFS enabled. The increased frequency is because when PFS is enabled, every rekey triggers a re-registration, and with more than a 100 GMs, the Crypto Engine is more likely to receive several registration requests during a rekey signing and may be overloaded.

Similarly, you may see this error message more frequently in such a deployment if you run the **crypto gdoi ks rekey replace-now** command repeatedly due to the registration requests triggered by this command.

In a GETVPN deployment with PFS enabled, we recommend that you use an RSA key size of 2048. Using an RSA key size of 4096 is not necessary because the rekey message does not contain TEK/KEK keys.

Modified Rekey Process

PFS for GETVPN ensures that an attacker cannot use the KEK from a compromised GM to decrypt past or future rekey messages. Thus, the attacker cannot obtain past or future KEKs or TEKs. For this purpose, PFS for GETVPN modifies the rekey mechanism so that rekey messages do not include KEKs or TEKs. The contents of the rekey message depend on the type of rekey.

Scheduled Rekey

1. When the rekey timer for KEK or TEK expires, KS generates a new KEK or TEK, respectively.
2. KS sets a private attribute in the GSA payload of the rekey message and encrypts the message with the current KEK. The rekey message does not include the new KEK or TEK. KS sends the rekey message to the GM.
3. GM receives the rekey message and decrypts the message using the current KEK. GM identifies the scheduled rekey and starts a reregistration timer for a random time interval in the 0–6 seconds range.
4. When the reregistration timer expires, GM initiates reregistration with the KS.
5. After reregistration, KS sends the KEK or TEK to the GM over the IKEv2 channel.
6. On receiving a new KEK, GM replaces the old KEK with the new KEK.
7. On receiving a new TEK, GM checks the Activation Time Delay (ATD) for the TEK. If the ATD is non-zero, GM starts a timer to enforce ATD before installing the TEK in the data plane.

ATD is calculated on the KS as follows:

- a. If Long SA lifetime is configured, the ATD timer is initialized to a value in seconds computed as follows:
$$\text{ATD} = (\text{remaining lifetime of old TEK}) - (1\% \text{ of remaining lifetime of old TEK}) - 75$$

The new TEK rolls over at (1% of remaining lifetime of old TEK).

- b. If Long SA lifetime is not configured, the ATD timer is initialized to a value in seconds computed as follows:
$$\text{ATD} = (\text{remaining lifetime of old TEK}) - 75$$

The new TEK rolls over 30 seconds before the expiry of the old TEK.

Sync-up Rekey

1. KS sends a GM a rekey message that includes only the pseudoTimeStamp (PST) value.
The message does not contain KEK or TEK.
2. On receiving the rekey message, GM updates its pseudotime value and does not trigger any reregistration. Depending on the pseudoTimeStamp value received from the KS and the TimeBased Anti Replay (TBAR) window configured on the GM, GM may generate syslog messages.

Manually Triggered Key

- When you trigger a rekey operation using **crypto gdoi ks** or **clear crypto gdoi ks members**, KS sends the GAP/DELETE payload based on the rekey type.
 - Rekey message without policy change

Table 342: GAP/DELETE Payload for a Rekey Message Without Policy Change

Type	KEK	TEK	Private Attribute for Rekey	KD	GAP	DELETE
crypto gdoi ks rekey	No	No	No	No	No	No
crypto gdoi ks rekey replace-now	No	No	Yes	No	ATD 1 sec	No
clear crypto gdoi ks members	No	No	No	No	ATD 5% of TEK	Yes
clear crypto gdoi ks members now	No	No	Yes	No	ATD 1 sec	Yes

- Rekey message with policy change

Table 343: GAP/DELETE Payload for a Rekey Message with Policy Change

Type	KEK	TEK	Private Attribute for Rekey	KD	GAP	DELETE
crypto gdoi ks rekey	No	No	Yes	No	ATD 5% of TEK	No
crypto gdoi ks rekey replace-now	No	No	Yes	No	ATD 1 sec	No
clear crypto gdoi ks members	No	No	No	No	ATD 5% of TEK	Yes
clear crypto gdoi ks members now	No	No	Yes	No	ATD 1 sec	Yes

- On receiving the rekey message, GM initiates reregistration with the KS.
- As part of GM reregistration, KS sends the KEK or TEK to the GM over the IKEv2 channel.
- GM sets the lifetime of the old key to the Activation Time Delay (ATD) value sent by the KS. After the ATD, GM deletes the old key and installs the new key.

Suite-B Support

During the first registration of a GM, KS assigns a unique Sender Identifier (SID) and Initialization Vector (IV) range to the GM. When a GM re-registers with a KS in response to a rekey message, the GM provides the SID that the KS assigned during registration. KS does not assign new a SID or Initialization Vector (IV) range to the GM.

KS and GM Versions for PFS for GETVPN

If Cisco IOS XE Gibraltar 16.12.1 or a later release is installed on a GM, PFS for GETVPN is enabled by default. You can disable PFS for GETVPN using the command-line interface. The GM version varies based on whether PFS is enabled or not as summarized in the following table.

	Without Suite-B Support	With Suite-B Support	ASR 1000 Series
PFS disabled	16	17	19
PFS enabled	21	22	20

If Cisco IOS XE Gibraltar 16.12.1 or a later release is installed on a KS, PFS for GETVPN is disabled by default and the KS version is 1.0.18. You can enable PFS for GETVPN via the CLI. With PFS for GETVPN enabled, the KS version is 1.0.23. Enable PFS for GETVPN on all the cooperative KSs.

KS sends rekey messages to GMs based on the GM version:

- To GMs that have PFS for GETVPN disabled and send a version number such as 1.0.17 or 1.0.19, KS sends rekey messages that have the KEK or TEK.

KS sends rekey messages that have the KEK or TEK to GMs that have PFS for GETVPN disabled and to non-Cisco GMs. GMs that have PFS for GETVPN disabled send a version number such as 1.0.17 or 1.0.19 to the KS. Non-Cisco GMs send an unknown version number to the KS.

- KS sends modified rekey messages that do not have KEK or TEK to GMs that have PFS for GETVPN enabled. GMs that have PFS for GETVPN enabled send a version number such as 1.0.20 or 1.0.22

Upgrading KS and GM for PFS for GETVPN

For PFS for GETVPN to be effective, enable PFS on every KS and GM in the network. If you do not enable PFS for GETVPN on a GM and the GM is breached, compromised keys can hamper the security of the entire network.

Upgrade the KSs in the network as follows:

Note We recommend that you upgrade KSs while there is sufficient time for the expiry of KEK and TEKS.

1. Upgrade a Secondary KS and wait for the COOP election to complete.
2. Repeat Step 1 for each Secondary KS in the COOP.

The Secondary KSs reboot and synchronize with the Primary KS and assume the role of Secondary KSs.

3. Upgrade the Primary KS.

One of the Secondary KSs is elected as the new Primary KS. The upgraded KS reboots and assumes the role of a Secondary KS.

4. Enable PFS on all the KSs.

After the upgrade, KS sends rekey messages based on the version number that GMs send. Based on the GM version number, KS sends rekey messages that contain KEK or TEK, or modified rekey messages without KEK or TEK.
