    - **Never**— Select to never send cookie challenges to peer devices.
  - **Number of SAs Allowed in Negotiation**—Limits the maximum number of SAs that can be in negotiation at any time. If used with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check. The default is 100 %.

- **Maximum number of SAs Allowed**—Limits the number of allowed IKEv2 connections.

**Step 6** Select the following for **IPsec Settings**:

- **Enable Fragmentation Before Encryption**—This option lets traffic travel across NAT devices that do not support IP fragmentation. It does not impede the operation of NAT devices that do support IP fragmentation.
- **Path Maximum Transmission Unit Aging**—Check to enable PMTU (Path Maximum Transmission Unit) Aging, the interval to Reset PMTU of an SA (Security Association).
- **Value Reset Interval**—Enter the number of minutes at which the PMTU value of an SA (Security Association) is reset to its original value. Valid range is 10 to 30 minutes, default is unlimited.

**Step 7** Select the following for **NAT Settings**:

- **Keepalive Messages Traversal**—Select whether to enable NAT keepalive message traversal. NAT traversal keepalive is used for the transmission of keepalive messages when there is a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPsec flow. If you select this option, configure the interval, in seconds, between the keepalive signals sent between the spoke and the middle device to indicate that the session is active. The value can be from 10 to 3600 seconds. The default is 20 seconds.
- **Interval**—Sets the NAT keepalive interval, from 10 to 3600 seconds. The default is 20 seconds.

**Step 8** Click **Save**.

## Customize Cisco Secure Client

You can configure the Secure Client customizations using the management center and deploy them to the VPN headend. The threat defense device distributes these customizations to the endpoint when a user connects from the Secure Client. Administrators can customize the following elements at the endpoint:

**Table 102: Secure Client Customizations Available in Management Center**

| Customization         | Description                                                                                    | More Info                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| GUI text and messages | Customize or localize Secure Client GUI text and informational/error messages.                 | <a href="#">Customize and Localize Secure Client GUI Text and Messages, on page 1732</a> |
| Icons and images      | Customize the logo, images, or icons of the Secure Client GUI.                                 | <a href="#">Customize Secure Client Icons and Images, on page 1733</a>                   |
| Scripts               | Deploy scripts on the endpoint devices when a client establishes or disconnects a VPN session. | <a href="#">Deploy Scripts on Endpoint Devices Using Secure Client, on page 1735</a>     |
| Binaries              | Deploy custom applications using Secure Client APIs.                                           | <a href="#">Deploy Custom Applications Using Cisco Secure Client APIs, on page 1736</a>  |

| Customization                  | Description                            | More Info                                                           |
|--------------------------------|----------------------------------------|---------------------------------------------------------------------|
| Custom Installer Transforms    | Customize the Secure Client installer. | <a href="#">Customize the Secure Client Installer, on page 1737</a> |
| Localized Installer Transforms | Localize the Secure Client installer.  | <a href="#">Localize the Client Installer, on page 1738</a>         |

## Guidelines and Limitations for Secure Client Customizations

### General Limitations

- If there are any customizations earlier than 7.4 configured directly on the threat defense using the CLI, the management center removes these customizations during deployment.
- No clustering support.

**Table 103: Limitations for Secure Client Customizations**

| Customization                       | Limitations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GUI Text and Message Customizations | <ul style="list-style-type: none"> <li>• You must restart Secure Client before you use this customization.</li> <li>• No support for right-to-left languages.</li> <li>• Some strings are truncated in the GUI due to hardcoded field lengths.</li> <li>• Some messages are hardcoded in the client. For example: <ul style="list-style-type: none"> <li>• Status messages (during an update)</li> <li>• Untrusted server messages</li> <li>• Deferred update messages</li> </ul> </li> <li>• Localization is version-specific.</li> </ul> <p>If an Administrator created a translation table based on a template of an old Secure Client version, the new messages do not appear to the remote users. The Administrator must merge the latest template with the translation table so that the table has the new messages. You can use third-party tools like Get text to perform the merge.</p> |

| Customization                                                        | Limitations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Icons and Images Customizations                                      | <ul style="list-style-type: none"> <li>You must restart Secure Client before you use this customization.</li> <li>The customization object names must match the Secure Client GUI filenames. | Deploy Custom Applications Using Cisco Secure Client APIs (Binaries) | <ul style="list-style-type: none"> <li>After you use this customization, if you deploy an updated version of the Secure Client on the management center, the client will download the update and replace your custom UI.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Customize the Client Installer                                       | <ul style="list-style-type: none"> <li>This customization is available only for Windows.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Customize and Localize Secure Client GUI Text and Messages

You can customize the Secure Client GUI text and the informational/error messages. You also can customize the GUI text and all messages to appear in a preferred language.

### Customize GUI Text and Messages

To customize the GUI text or messages, you can edit the messages in the message file. You can update the messages to include more details in the error messages. For example:

- Modify any label in the login dialog box such as **Password** to **Domain Password**.
- Add your support contact details in the error messages.

### Localize GUI Text and Messages

Threat defense devices use translation tables to translate the labels and user messages displayed in the Secure Client. When a user connects to the remote access VPN, the Secure Client identifies the locale set on the endpoint and downloads the translation file. Threat defense devices support 128 locales. By default, Secure Client is installed in English.

- For Cisco Secure Client 5.0, the default localization files for various languages are part of the application.
- For AnyConnect Clients 4.x, you can download the localization files for a few languages from Cisco.com and upload them to the management center.

### How to Customize Secure Client GUI Text and Messages

#### Before you begin

Configure one or more remote access VPN policies.

#### Procedure

- 
- Step 1** Get the base template or translation file either from the Secure Client package or from Cisco.com. For example, AnyConnect.po.
- Step 2** Use a text editor to add the translations or customize the labels or messages.
- Step 3** Update the **msgstr** string corresponding to each **msgid**.
- Step 4** Save the file.
- Step 5** Create a new Secure Client Customization object.
- Choose **Objects > Object Management > VPN > Secure Client Customization**.
  - Click **Add Secure Client Customization**.
  - Enter the name and description for the customization.
  - From the **Customization Type** drop-down list, choose **GUI Text and Messages**.
  - From the **Language** drop-down list, choose a language for which you are adding the translation.
  - Click **Browse** and select the translation file. The supported file extensions are .po, .mo, and .txt.
- Step 6** Add the customization to the remote access VPN policy.
- Choose **Devices > Remote Access**.
  - Click the edit icon of the remote access VPN policy.
  - Click **Advanced > Secure Client Customizations > Localization**.
  - Click + to select the translation file.
  - Click **Add**.
  - Click **OK**.
- Step 7** Click **Save**.
- Step 8** Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
- 

#### What to do next

Verify the Secure Client customizations. For more information, see [Verify Secure Client Customizations, on page 1739](#).

#### Customize Secure Client Icons and Images

You can customize the logo, images, and icons of the Secure Client GUI using the management center.

To customize the logo, images, and icons of the Secure Client GUI, you must create a Secure Client customization object in the management center. The name of this customization object must match the Secure Client GUI filename. File names are different for each operating system and are case-sensitive. For more information about the filenames, extensions, and sizes for each OS, see the [Cisco Secure Client Administrator Guide](#).

For example, if you want to replace the corporate logo for Windows clients, you must create a customization object with the name as `company_logo` and add this customization object to the remote access VPN policy. If you use a different name for the customization object, the Secure Client installer does not change the component. However, if you deploy your own executable to customize the GUI, the customization object can have any name.

Location of all images files:

- Windows: `%PROGRAMFILES%\Cisco\Cisco Secure Client\res\`
- Linux: `/opt/cisco/secure client/pixmaps`
- macOS: Not supported

### *How to Customize Secure Client Images and Icons*

#### **Before you begin**

Configure one or more remote access VPN policies.

#### **Procedure**

---

**Step 1** Create the icons or images using the correct extensions, and sizes.

Images do not appear properly if the image size is not correct. The management center or the threat defense device does not verify the image size.

For more information about the filenames, extensions, and sizes, see the [Cisco Secure Client Administrator Guide](#).

**Step 2** Create a new Secure Client Customization object.

- a) Choose **Objects > Object Management > VPN > Secure Client Customization**.
- b) Click **Add Secure Client Customization**.
- c) Enter the name and description for the customization object.

Ensure that the customization object name matches the Secure Client GUI filenames. For more information about the filenames, see the [Cisco Secure Client Administrator Guide](#).

- d) From the **Customization Type** drop-down list, choose **Icon and Images**.
- e) From the **Platform** drop-down list, choose a platform.
- f) Click **Browse** and select the file. The supported file extensions are `.png`, `.ico`, and `.jpeg`.
- g) Repeat the steps from 2a - f to add multiple icons and images.

**Step 3** Add the customization object to the remote access VPN policy.

- a) Choose **Devices > Remote Access**.
- b) Click the edit icon of the remote access VPN policy.
- c) Click **Advanced > Secure Client Customizations > Icons and Images**.

- d) Click + to select the file.
- e) Click **Add**.
- f) Click **OK**.

**Step 4** Click **Save**.

**Step 5** Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

### What to do next

Verify the Secure Client customizations. For more information, see [Verify Secure Client Customizations, on page 1739](#).

## Deploy Scripts on Endpoint Devices Using Secure Client

Secure Client lets you download and run scripts when the following events occur:

- Establishment of a new client VPN session with the threat defense. The script triggered by this event is an OnConnect script because it requires this filename prefix. Reconnection of the VPN session does not trigger this script.
- Disconnection of a client VPN session with the threat defense. The script triggered by this event is an OnDisconnect script because it requires this filename prefix.

These scripts run asynchronously and do not delay the connection establishment or disconnection. They can be of any extension and must be executable on the endpoint. Secure Client identifies the OnConnect and OnDisconnect scripts by the filename. It looks for a file whose name begins with OnConnect or OnDisconnect regardless of the file extension.

Some examples of this feature are:

- Refresh the group policy upon VPN connection.
- Mount a network drive upon a VPN connection.
- Unmount a network drive upon a VPN disconnection.

To enable scripts, check the **Enable Scripting** option in the VPN profile. By default, the client does not launch scripts. The client does not require the script to be written in a specific language. It requires an application that can run the script to be installed on the client computer. For the client to launch the script, the script must run from the command line.

Secure Client can only launch scripts after the user logs in and establishes a VPN session. You cannot launch the OnConnect script from the Start Before Logon (SBL) GUI. You must check the **Enable Post SBL On Connect Script** option in the VPN profile to trigger the scripts once the user logs in. Secure Client is a 32-bit application. When the scripts run on a 64-bit Windows version, they use the 32-bit version of cmd.exe.

### *How to Add Customized Scripts for Secure Client*

#### Before you begin

1. Configure a remote access VPN.
2. Enable scripting in the VPN profile.

3. Add the VPN profile to the remote access VPN group policy.

## Procedure

- 
- Step 1** Create OnConnect and OnDisconnect scripts for a platform.
- Step 2** Create a new Secure Client Customization object.
- a) Choose **Objects > Object Management > VPN > Secure Client Customization**.
  - b) Click **Add Secure Client Customization**.
  - c) Enter the name and description for the customization.
  - d) From the **Customization Type** drop-down list, choose **Scripts**.
  - e) From the **Platform** drop-down list, choose a platform.
  - f) Select one of the following:
    - **On Connect**: To select an OnConnect script.
    - **On Disconnect**: To select an OnDisconnect script.
  - g) Click **Browse** and select the script you want to execute on the endpoint.
- Step 3** Add the customization to the remote access VPN policy.
- a) Choose **Devices > Remote Access**.
  - b) Click the edit icon of the remote access VPN policy.
  - c) Click **Advanced > Secure Client Customizations > Localization**.
  - d) Click + to select the translation file.
  - e) Click **Add**.
  - f) Click **OK**.
- Step 4** Click **Save**.
- Step 5** Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
- 

### What to do next

Verify the Secure Client customizations. For more information, see [Verify Secure Client Customizations, on page 1739](#).

## Deploy Custom Applications Using Cisco Secure Client APIs

For Windows, Linux, or MacOS machines, you can create and deploy a custom client that uses the Secure Client APIs. You can use this client binary file to replace the Secure Client GUI or CLI binary files.

Your executable can call any resource files such as logo images that you import to the management center. When you deploy your own executable, you can use any filenames for your resource files.

The following table lists the filenames of the client executable files for the different operating systems:

Table 104: Filenames of the Secure Client Executable Files

| Client OS | Client GUI File                                                                                                                                                               | Client CLI File |
|-----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|
| Windows   | vpnui.exe                                                                                                                                                                     | vpncli.exe      |
| Linux     | vpnui                                                                                                                                                                         | vpn             |
| MacOS     | Not supported by the management center deployment. However, you can deploy an executable for the macOS that replaces the client GUI using other means, such as Altiris Agent. | vpn             |

### How to Deploy Custom Applications Using Cisco Secure Client API

#### Before you begin

Configure one or more remote access VPN policies.

#### Procedure

- 
- Step 1** Create the custom application using the Cisco Secure Client APIs.
- Step 2** Create a new Secure Client Customization object.
- Choose **Objects > Object Management > VPN > Secure Client Customization**.
  - Click **Add Secure Client Customization**.
  - Enter the name and description for the customization.
  - From the **Customization Type** drop-down list, choose **Binary**.
  - From the **Platform** drop-down list, choose a platform.
  - Click **Browse** and select the custom application.
- Step 3** Add the customization to the remote access VPN policy.
- Choose **Devices > Remote Access**.
  - Click the edit icon of the remote access VPN policy.
  - Click **Advanced > Secure Client Customizations > Binaries**.
  - Click + to select the translation file.
  - Click **Add**.
  - Click **OK**.
- Step 4** Click **Save**.
- Step 5** Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
- 

#### Customize the Secure Client Installer

You can customize the Secure Client GUI by creating a custom transform that deploys with the client installer program. You can import the transform to the management center and deploy it to the threat defense device. The threat defense deploys this transform to the endpoint using the client installer program.

---

**Note** This customization is available only for Windows.

---

## Localize the Client Installer

You can translate the messages displayed by the Cisco Secure Client installer. The management center uses a transform to translate the messages displayed by the installer. The transform alters the installation but leaves the original security-signed MSI intact. These transforms only translate the installer screens and do not translate the client GUI screens.

Every release of Cisco Secure Client includes a localized transform that administrators can upload to the management center whenever they upload Cisco Secure Client packages with new software. If you use our localization transform, ensure that you update them with the latest release from Cisco.com whenever you upload a new Cisco Secure Client package.

## How to Customize or Localize the Client Installer

### Before you begin

Configure one or more remote access VPN policies.

## Procedure

- 
- Step 1** Create a customized or localized transform.
- Step 2** Create a new Secure Client Customization object.
- Choose **Objects > Object Management > VPN > Secure Client Customization**.
  - Click **Add Secure Client Customization**.
  - Enter the name and description for the customization.
  - From the **Customization Type** drop-down list, choose **Customized Installer Transform** or **Localized Installer Transform**.
  - From the **Platform** drop-down list, choose a platform.
  - Click **Browse** and select the transform.
- Step 3** Add the customization to the remote access VPN policy.
- Choose **Devices > Remote Access**.
  - Click the edit icon of the remote access VPN policy.
  - Click **Advanced > Secure Client Customizations > Custom Installer Transforms** or **Localized Installer Transforms**.
  - Click **+** to select the transform.
  - Click **Add**.
  - Click **OK**.
- Step 4** Click **Save**.
- Step 5** Choose **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
-

## Verify Secure Client Customizations

### Validate the Deployment

After the deployment is complete, validate the deployment in the management center. Click the **Transcript Details** (📄) icon to verify the commands generated for the customizations.

### Examples

1. The example below shows the transcript details of a GUI text and messages customization: Secure Client en\_us localization with customized prompts.

```
import webvpn translation-table AnyConnect language en-us disk0:/AnyConnect_en-us.po
```

2. The example below shows the transcript details of customized icons and images: customization of the Secure Client logo to ABC logo.

```
import webvpn AnyConnect-customization type resource platform win name company_logo.png
disk0:/company_logo.png
```

3. The example below shows the transcript details of the customized OnConnect and OnDisconnect scripts. The On connect script mounts the network drive and the On disconnect script unmounts the network drive.

```
import webvpn AnyConnect-customization type binary platform win name
scripts_OnConnect_mount.bat disk0:/mount.bat
import webvpn AnyConnect-customization type binary platform win name
scripts_OnDisconnect_unmount.bat disk0:/unmount.bat
```

### Verify Customizations Using Threat Defense Commands

Use the following commands on the threat defense to verify the customizations:

- **show import webvpn translation-table detailed:** Shows the available translation tables.

```
HQ-FTD# show import webvpn translation-table detailed
Translation Tables' Templates:
  AnyConnect          ia4DaAXNSv15pZboQRGJcs9KMX=
  customization
Translation Tables:
  fr                  customization          BWWodsOt1PbvDvYOp8hLb3W7a64=
  ja                  customization          lNvUk1+qTLNZyNrBcApMQPHnm1M=
  ru                  customization          UqyKyUAcjR+xTGUtdiIFnoIiW5U=
```

- **show import webvpn AnyConnect-customization detailed:** Shows the details of the Secure Client customizations.

```
HQ-FTD# show import webvpn AnyConnect-customization detailed
OEM resources for AnyConnect client:
linux-64/binary/scripts_OnConnect_conn.sh          w6+n7z80D/8AR+u12f7DvTmcDTw=
linux-64/binary/scripts_OnDisconnect_discon.sh      jx5LJC2XBEmEkGeww59CAkszvnI=
linux-64/resource/company-logo.png                GsfBDroqGSQEewuBDS/3DJNVv88=
win/binary/scripts_OnConnect_mount.bat             dzjfsLYYft/XMLPlzskK1+Wv1bw=
win/binary/scripts_OnDisconnect_unmount.bat        k6x1KhF112IRyJu08+sdYXgKNgM=
win/resource/company_logo.png                     cmEvxwqvtaS+Pz/6sb9n3NZudS4=
```

### Verify Customizations in Secure Client

- In Secure Client, click the **Message History** tab to verify that the customizations are downloaded.

Use the DART tool to view the client-side diagnostics.

Table 105: Verifying the Customizations in Secure Client

| Customization                                 | Verification                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-----------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| GUI text and message customizations           | <ul style="list-style-type: none"> <li>• Verify if Secure Client has the language localization or customized files in the following locations: <ul style="list-style-type: none"> <li>• Windows: %ProgramData%\Cisco\Cisco AnyConnect Secure Mobility Client\110n\&lt;language-code&gt;\LC_MESSAGES (AnyConnect versions 4.9 and earlier)</li> <li>• Windows: %ProgramData%\Cisco\Cisco Secure Client\110n\&lt;language-code&gt;\LC_MESSAGES (Secure Client versions 5.0 and later)</li> <li>• For Mac OS and Linux: <ul style="list-style-type: none"> <li>/opt/cisco/anyconnect/110n/&lt;LANGUAGE-CODE&gt;\LC_MESSAGES</li> </ul> </li> </ul> </li> <li>• Verify the contents of the localized or customized file and confirm if they have the customized or localized strings. ## Configure Secure Client Management VPN Tunnel

A management VPN tunnel provides connectivity to the corporate network whenever a client system is powered up, without the VPN users having to connect to the VPN. This helps organizations keep their endpoints

up-to-date with software patches and updates. Management tunnel disconnects when the user-initiated VPN tunnel is established.

This section provides information about configuring Secure Client management VPN tunnel on threat defense. Configuring the Secure Client management tunnel on threat defense using the management center web interface requires the following settings:

- A **Connection profile** with certificate-based authentication and a group URL.
- **Secure Client management VPN profile file**, configured a server with group URL and backup servers if required.
- A **Group policy** with the management VPN profile, split tunneling with explicitly included networks, client bypass protocol, and no banner.

For detailed instructions on configuring the Secure Client Management VPN tunnel, see [Configuring Secure Client Management VPN Tunnel on Threat Defense, on page 1742](#).

## Requirements and Prerequisites for Secure Client Management VPN Tunnel

### Software and Configuration Requirements

Ensure that you have the following before you configure the Secure Client Management tunnel on using the threat defense using the management center web interface:

- Ensure that you are using threat defense and management center versions 6.7.0 or above.
- Download the Secure ClientSecure Client VPN Webdeploy package 4.7 or above and upload it to threat defense remote access VPN.
- Ensure that the certificate authentication is configured in the connection profile.
- Ensure that no banner is configured in the group policy.
- Check the split tunneling configuration in the management tunnel-group policy.

### Certificate Requirements

- Threat Defense must have a valid identity certificate for remote access VPN and the root certificate from the local certifying authority (CA) must be present on the threat defense.
- Endpoints connecting to the management VPN tunnel must have a valid identity certificate.
- CA certificate for threat defense's identity certificate must be installed on the endpoints and the CA certificate for the endpoints must be installed on the threat defense.
- The identity certificate issued by the same local CA must be present in the Machine store.  
Certificate Store (For Windows) and/or in System Keychain (For macOS).

## Limitations of Secure Client Management VPN Tunnel

- Secure Client Management VPN Tunnel supports only certificate authentication, it does not support AAA-based authentication.
- Public or private proxy settings are not supported.

- Secure Client upgrade and AnyConnect module download are not supported when the management VPN tunnel is connected.

## Configuring Secure Client Management VPN Tunnel on Threat Defense

### Procedure

---

#### Step 1 Create a remote access VPN policy configuration using the wizard:

For information about configuring a remote access VPN, see [Configuring a New Remote Access VPN Connection, on page 1685](#).

#### Step 2 Configure connection profile settings for management VPN tunnel:

**Note** It is advisable to create a new connection profile to be used only for Secure Client management VPN tunnel.

- Edit the remote access VPN policy you have created.
- Select and edit the connection profile that will be used for management VPN tunnel.
- Click **AAA > Authentication Method** and select **Client Certificate Only**. Configure the authorization and accounting settings as required.
- Click the **Aliases** tab of the connection profile.
- Click **Add (+)** under URL Aliases and **URL Alias** for the connection profile.
- Click **Enabled** to enable the URL.
- Click **OK** and then click **Save** to save the connection profile settings.

For more information about connection profile settings, see [Configure Connection Profile Settings, on page 1696](#).

#### Step 3 Create a management tunnel profile using the Secure Client profile editor:

- Download the Secure Client **VPN Management Tunnel Standalone Profile Editor** from [Cisco Software Download Center](#) if you have not done already.
- Create a management tunnel profile with the required settings for your VPN users and save the file.
- Configure a server in the Server List with the group URL you have configured in the connection profile.

For information about creating a management profile using the Profile Editor, see the [Cisco Secure Client \(including AnyConnect\) Administrator Guide](#).

#### Step 4 Create a management tunnel object:

- On your Secure Firewall Management Center web interface, navigate to **Object > Object Management > VPN > Secure Client File**.
- Click **Add Secure Client File**.
- Specify the **Name** for the Secure Client file.
- Click **Browse** and select the management tunnel profile file you have saved.
- Click the **File Type** drop-down and select **Secure Client Management VPN Profile**.
- Click **Save**.

**Note** You can also create the management tunnel object when you create or update Secure Client settings for a group policy. See [Group Policy Secure Client Options, on page 1563](#).

**Step 5 Associate a management profile with a group policy and configure group policy settings:**

You must add the management VPN profile to the group policy associated with the connection profile used for the management tunnel VPN connection. When the user connects, the management VPN profile is downloaded along with the user VPN profile already mapped to the group policy, enabling the management VPN tunnel feature.

**Caution**      **No Banner:** Check and ensure that no banner is configured in the group policy settings. You can check the banner settings under **Group Policy > General Settings > Banner**.

- a) Edit the connect profile you have created for management VPN tunnel.
- b) Click **Edit Group Policy > Secure Client > Management Profile**.
- c) Click the **Management VPN Profile** drop-down and select the management profile file object you have created.

**Note**      You can also click + and add a new Secure Client Management VPN Profile object.

- d) Click **Save**.

**Step 6 Configure split tunneling in group policy:**

- a) Click **Edit Group Policy > General > Split Tunneling**.
- b) From the IPv4 or IPv6 split tunneling drop-down, select **Tunnel networks specified below**.
- c) Select the Split Tunnel Network List Type: **Standard Access List** or **Extended Access List**, and then select the required access list to allow the traffic over the management VPN tunnel.
- d) Click **Save** to save the split tunnel settings.

**Secure Client Custom Attribute**

Secure Client Management VPN tunnel requires split include tunneling configuration by default. If you are configuring Secure Client custom attribute in the group policy to deploy the management VPN tunnel with split tunneling to tunnel all, you can do so using FlexConfig because management center 6.7 web interface does not support Secure Client custom attribute.

The following is an example command for Secure Client custom attribute:

```
webvpn
 anyconnect-custom-attr ManagementTunnelAllAllowed description ManagementTunnelAllAllowed
 anyconnect-custom-data ManagementTunnelAllAllowed true true
 group-policy MGMT_Tunnel attributes
  anyconnect-custom ManagementTunnelAllAllowed value true
```

**Step 7 Deploy, verify, and monitor the remote access VPN policy:**

- a) Deploy the management VPN tunnel configuration to threat defense.

**Note**      Client systems must connect to the threat defense remote access VPN once to download the management tunnel VPN profile to the client machines.

- b) You can verify the Secure Client management VPN tunnel at **Secure Mobility Client > VPN > Statistics**.

You can also check the management VPN session details on the threat defense command prompt using the **show vpn-sessiondb anyconnect** command.

- c) On your management center web interface, click **Analysis** to view the management tunnel session information.

## Multiple Certificate Authentication

Multiple certificate based authentication gives the ability to have the threat defense validate the machine or device certificate, to ensure the device is a corporate-issued device, in addition to authenticating the user's identity certificate to allow VPN access using the Secure Client during SSL or IKEv2 EAP phase.

The multiple certificates option allows certificate authentication of both the machine and user via certificates. Without this option, you could only do certificate authentication of either machine or the user, but not both.

### Guidelines and Limitations of Multiple Certificate Authentication

---

**Note** When you configure multiple certificate authentication, ensure that you set the value of **AutomaticCertSelection** to true in the Cisco Secure Client Profile settings.

---

- Multiple certificate authentication currently limits the number of certificates to two.
- Secure Client must indicate support for multiple certificate authentication. If that is not the case then the gateway uses one of the legacy authentication methods or fails the connection. Secure Client version 4.4.04030 or later supports Multi-Certificate based authentication.
- Secure Client supports only RSA-based certificates.
- Only SHA256, SHA384, and SHA512 based certificate are supported during the Secure Client aggregate authentication.
- Certificate authentication cannot be combined with SAML authentication.

### Configuring Multiple Certificate Authentication

**Before you begin**

Before you configure multiple certificate authentication, ensure that you have configured the certificate enrollment object that is used to obtain the identity certificate for each threat defense device. For more information, see [Certificate Map Objects, on page 1557](#).

**Procedure**

---

**Step 1** Choose **Devices > VPN > Remote Access**.

**Step 2** Select the remote access VPN policy and click **Edit**.

**Note** If you have not configured a remote access VPN, click **Add** to create a new remote access VPN policy.

- Step 3** Select and **Edit** a connection profile to configure multiple certificate authentication.
- Step 4** Click **AAA** settings and select **Authentication Method** > **Client Certificate Only** or **Client Certificate & AAA**.
- Note** Select the **Authentication Server** if you have selected the Client Certificate & AAA authentication method
- Step 5** Select the **Enable multiple certificate authentication** checkbox.
- Step 6** Choose one of the certificates to **Map username from client certificate**:
- **First Certificate**— Select this option to map the username from the machine certificate sent from the VPN client.
  - **Second Certificate**— Select this option to map the username from the user certificate sent from the client.
- The username sent from the client is used as the VPN session username when certificate only authentication is enabled. When AAA and certificate authentication is enabled, VPN session username will be based on prefill option.
- Note** If you select the **Map specific field** option, which includes the username from the client certificate, the **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively.
- If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields that can be used as the identifier when matching users to a connection profile DN rules are used for enhanced certificate authentication.
- If you have selected the Client Certificate & AAA authentication, select the **Prefill username from certificate on user login window** option to prefill the secondary username from the client certificate when the user connects via AnyConnect VPN module of Cisco Secure Client.
- **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.
- Step 7** Configure the required AAA settings and connection profile settings for the remote access VPN.
- Step 8** Save the connection profile and remote access VPN configuration and deploy it on your threat defense device.

## Customizing Remote Access VPN AAA Settings

This section provides information about customizing your AAA preferences for remote access VPNs. For more information, see [Configure AAA Settings for Remote Access VPN](#), on page 1698.

# Authenticate VPN Users via Client Certificates

You can configure remote access VPN authentication using client certificate when you create a new remote access VPN policy using the wizard or by editing the policy later.

## Before you begin

Configure the certificate enrollment object that is used to obtain the identity certificate for each threat defense device that acts as a VPN gateway.

## Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > VPN > Remote Access**.
- Step 2** Select a remote access policy and click **Edit**; or click **Add** to create a new remote access VPN policy.
- Step 3** For a new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.
- Step 4** Click **AAA > Authentication Method > Client Certificate Only**.

With this authentication method, the user is authenticated using a client certificate. You must configure the client certificate on VPN client endpoints. By default, the user name is derived from client certificate fields CN and OU respectively. If the user name is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.

If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display the following default values, respectively: **CN (Common Name)** and **OU (Organisational Unit)**. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields, that can be used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

- Primary and Secondary fields pertaining to the **Map specific field** option contain these common values:
  - C (Country)
  - CN (Common Name)
  - DNQ (DN Qualifier)
  - EA (Email Address)
  - GENQ (Generational Qualifier)
  - GN (Given Name)
  - I (Initial)
  - L (Locality)
  - N (Name)
  - O (Organisation)
  - OU (Organisational Unit)
  - SER (Serial Number)

- SN (Surname)
  - SP (State Province)
  - T (Title)
  - UID (User ID)
  - UPN (User Principal Name)
- Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

For more information, see [Configure AAA Settings for Remote Access VPN, on page 1698](#).

**Step 5** Save your changes.

---

[Adding Certificate Enrollment Objects](#), on page 1511

## Configure VPN User Authentication via Client Certificate and AAA Server

When you configure remote access VPN authentication to use both client certificate and authentication server, VPN client authentication is done using both the client certificate validation and AAA server.

#### Before you begin

- Configure the certificate enrollment object that you use to obtain the identity certificate for each threat defense device that acts as a VPN gateway.
- Configure the RADIUS server group object and any AD or LDAP realms to use in the remote access VPN policy configuration.
- Ensure that the AAA Server is reachable from the Secure Firewall Threat Defense device for the remote access VPN configuration to work.

#### Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > Remote Access**.
- Step 2** Click **Edit** on the remote access VPN policy for which you want to update the authentication or click **Add** to create new one.
- Step 3** If you choose to create new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.
- Step 4** Go to **AAA** and from the **Authentication Method** drop-down, choose **Client Certificate & AAA**.
- When you select the **Authentication Method** as:  
**Client Certificate & AAA**—Both types of authentication are done.

- **AAA**—If you select the **Authentication Server** as **RADIUS**, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select **AD** and **LDAP** from the Authentication Server drop-down list, you must manually select the **Authorization Server** and **Accounting Server** respectively.
- **Client Certificate**—Authenticates the user with client certificate. You must configure client certificate on the VPN client endpoints. By default, the username is derived from client certificate fields **CN** & **OU** respectively. If you use any other field in the client profile to specify the username, use **Primary Field** and **Secondary Field** to map appropriate fields.

If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields that can be used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

Primary and Secondary fields pertaining to the **Map specific field** option contains these common values:

- C (Country)
  - CN (Common Name)
  - DNQ (DN Qualifier)
  - EA (Email Address)
  - GENQ (Generational Qualifier)
  - GN (Given Name)
  - I (Initial)
  - L (Locality)
  - N (Name)
  - O (Organisation)
  - OU (Organisational Unit)
  - SER (Serial Number)
  - SN (Surname)
  - SP (State Province)
  - T (Title)
  - UID (User ID)
  - UPN (User Principal Name)
- Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

For more information, see [Configure AAA Settings for Remote Access VPN](#), on page 1698.

**Step 5** Save your changes.

## Manage Password Changes over VPN Sessions

Password management allows remote access VPN policy administrator to configure the notification settings for the remote access VPN users on their password expiry. Password management is available in AAA settings with authentication methods AAA Only and Client Certificate & AAA. For more information, see [Configure AAA Settings for Remote Access VPN](#), on page 1698.

### Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > Remote Access**.
- Step 2** Click **Edit** on the remote access VPN policy that you want to update.
- Step 3** Click **Edit** on the connection profile that includes AAA settings.
- Step 4** Choose **AAA > Advanced Settings >**.
- Step 5** Check the **Enable Password Management** check-box and select one of the following:
- Notify User - days ahead of password expiry and specify the number of days in the box.
  - Notify user on the day of password expiration.
- Step 6** Save your changes.

## Send Accounting Records to the RADIUS Server

Accounting records in remote access VPN help the VPN administrator track the services that users access and the amount of network resources that they consume. Accounting information includes when user session start and stop, username, the number of bytes that pass through the device for each session, the service used, and the duration of each session.

You can use accounting alone or together with authentication and authorization. When you activate AAA accounting, the network access server reports the user activity to the configured accounting server. You can configure a RADIUS server as the accounting server so that the management center sends all the user activity information to the RADIUS server.

---

**Note** You can use the same RADIUS server or separate RADIUS servers for authentication, authorization, and accounting in remote access VPN AAA settings.

---

### Before you begin

- Configure a RADIUS group object with RADIUS servers to receive authentication requests or accounting records. For more information, see [RADIUS Server Group Options, on page 1464](#).
- Ensure that the RADIUS server is reachable from the threat defense device. Configure routing on your Secure Firewall Management Center at **Devices > Device Management > Edit Device > Routing** to ensure connectivity to the RADIUS server.

### Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > Remote Access**.
  - Step 2** Click **Edit** on the remote access policy for which you want to configure RADIUS server, or create new remote access VPN policy.
  - Step 3** Click **Edit** on the connection profile that includes AAA settings and choose **AAA**.
  - Step 4** Select the RADIUS server from the **Accounting Server** drop-down.
  - Step 5** Save your changes.

---

## Delegating Group Policy Selection to Authorization Server

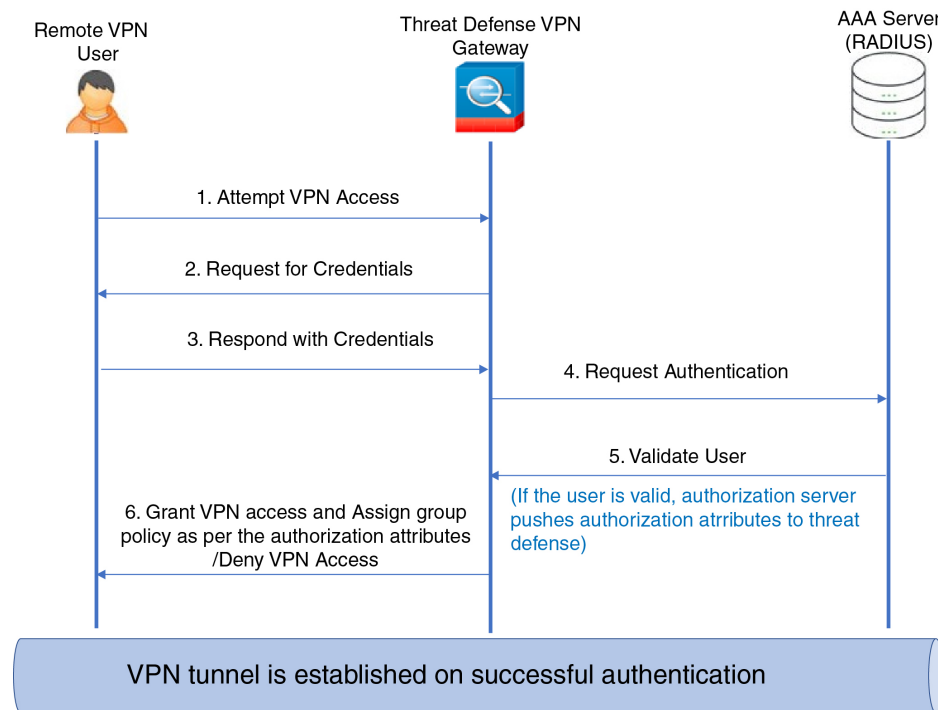

The group policy applied to a user is determined when the VPN tunnel is being established. You can select a group policy for a connection profile while creating a remote access VPN policy using the wizard or update the connection policy for connection profiles later. However, you can configure the AAA (RADIUS) server to assign the group policy or it is obtained from the current connection profile. If the threat defense device receives attributes from the external AAA server that conflicts with those configured on the connection profile, then attributes from the AAA server always take the precedence.

You can configure ISE or the RADIUS Server to set the Authorization Profile for a user or user-group by sending IETF RADIUS Attribute 25 and map to the corresponding group policy name. You can configure specific group policy to a user or user group to push a Downloadable ACL, set a banner, Restrict VLAN, and configure the advanced option of applying an SGT to the session. These attributes are applied to all users that are part of that group when the VPN connection is established.

For more information, see the Configure Standard Authorization Policies section of [Cisco Identity Services Engine Administrator Guide](#) and [RADIUS Server Attributes for Secure Firewall Threat Defense, on page 1704](#).

Figure 369: Remote Access VPN Group Policy Selection by AAA Server

[Configure Connection Profile Settings](#), on page 1696

**Override the Selection of Group Policy or Other Attributes by the Authorization Server**

When a remote access VPN user connects to the VPN, the group policy and other attributes configured in the connection profile are assigned to the user. However, the remote access VPN system administrator can delegate the selection of group policy and other attributes to the authorization server by configuring ISE or the RADIUS Server to set the Authorization Profile for a user or user-group. Once users are authenticated, these specific authorization attributes are pushed to the threat defense device.

**Before you begin**

Ensure that you configure a remote access VPN policy with RADIUS as the authentication server.

**Procedure**

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > VPN > Remote Access**.
  - Step 2** Select a remote access policy and click **Edit**.
  - Step 3** Select RADIUS or ISE as the authorization server if not configured already.
  - Step 4** Select **Advanced > Group Policies** and add the required group policy. For detailed information about a group policy object, see [Configure Group Policy Objects, on page 1561](#).

You can map only one group policy to a connection profile; but you can create multiple group policies in a remote access VPN policy. These group policies can be referenced in ISE or the RADIUS server and configured to override the group policy configured in the connection profile by assigning the authorization attributes in the authorization server.

- Step 5** Deploy the configuration on the target threat defense device.
- Step 6** On the authorization server, create an Authorization Profile with RADIUS attributes for IP address and downloadable ACLs.

When the group policy is configured in the authorization server selected for remote access VPN, the group policy overrides the group policy configured in the connection profile for the remote access VPN user after the user is authenticated.

## Deny VPN Access to a User Group

When you do not want an authenticated user or user group to be able to use VPN, you can configure a group policy to deny VPN access. You can configure a group policy in a remote access VPN policy and reference it in the ISE or RADIUS server configuration for authorization.

### Before you begin

Ensure that you have configured remote access VPN using the Remote Access Policy wizard and configured authentication settings for the remote access VPN policy.

### Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > VPN > Remote Access**.
  - Step 2** Select a remote access policy and click **Edit**.
  - Step 3** Select **Advanced > Group Policies**.
  - Step 4** Select a group policy and click **Edit** or add a new group policy.
  - Step 5** Select **Advanced > Session Settings** and set **Simultaneous Login Per User** to 0 (zero). This stops the user or user group from connecting to the VPN even once.
  - Step 6** Click **Save** to save the group policy and then save the remote access VPN configuration.
  - Step 7** Configure ISE or the RADIUS server to set the Authorization Profile for that user/user-group to send IETF RADIUS Attribute 25 and map to the corresponding group policy name.
  - Step 8** Configure the ISE or RADIUS server as the authorization server in the remote access VPN policy.
  - Step 9** Save and deploy the remote access VPN policy.

## Restrict Connection Profile Selection for a User Group

When you want to enforce a single connection profile on a user or user group, you can choose to disable the connection profile so that the group alias or URLs are not available for the users to select when they connect using the AnyConnect VPN module of Cisco Secure Client.

For example, if your organization wants to use specific configurations for different VPN user groups such as mobile users, corporate-issued laptop users, or personal laptop users, you can configure connection a profile specific to each of these user groups and apply the appropriate connection profile when the user connects to the VPN.

The AnyConnect VPN module of Cisco Secure Client, by default, shows a list of the connection profiles ( by connection profile name, alias, or alias URL) configured in management center and deployed on threat defense. If custom connection profiles are not configured, AnyConnect VPN module of Cisco Secure Client shows the *DefaultWEBVPNGroup* connection profile. Use the following procedure to enforce a single connection profile for a user group.

### Before you begin

- On your Secure Firewall Management Center web interface, configure remote access VPN using the remote access VPN policy wizard with Authentication Method as 'Client Certificate Only' or 'Client Certificate + AAA'. Choose the username fields from the certificate.
- Configure ISE or RADIUS server for authorization and associate the group policy with the authorization server.

### Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > VPN > Remote Access**.
  - Step 2** Select a remote access policy and click **Edit**.
  - Step 3** Select **Access Interfaces** and disable **Allow users to select connection profile while logging in**.
  - Step 4** Click **Advanced > Certificate Maps**.
  - Step 5** Select **Use the configured rules to match a certificate to a Connection Profile**.
  - Step 6** Select the **Certificate Map Name** or click the **Add** icon to add a certificate rule.
  - Step 7** Select the **Connection Profile**, and click **Ok**.
- With this configuration, when a user connects from the AnyConnect VPN module of Cisco Secure Client, the user will have the mapped connection profile and will be authenticated to use the VPN.

## Update the Secure Client Profile for Remote Access VPN Clients

Secure Client Profile is an XML file that contains an administrator-defined end user requirements and authentication policies to be deployed on a VPN client system as part of Secure Client. It makes the preconfigured network profiles available to end users.

You can use the GUI-based Secure Client Profile Editor, an independent configuration tool, to create them. The standalone profile editor can be used to create a new or modify existing Secure Client profile. You can download the profile editor from [Cisco Software Download Center](#).

See the Secure Client Profile Editor chapter in the appropriate release of the [Cisco Secure Client \(including AnyConnect\) Administrator Guide](#) for details.

### Before you begin

- Ensure that you have configured remote access VPN using the Remote Access Policy wizard and deployed the configuration on threat defense device. See [Create a New Remote Access VPN Policy, on page 1686](#).
- On your Secure Firewall Management Center web interface, go to **Objects > Object Management > VPN > Secure Client File** and add the new Secure Client image.

### Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > VPN > Remote Access**.
- Step 2** Select a remote access VPN policy and click **Edit**.
- Step 3** Select the connection profile that includes the client profile to be edited, and click **Edit**.
- Step 4** Click **Edit Group Policy > Secure Client > Profiles**.
- Step 5** Select the client profile XML file from the list or click **Add** to add a new client profile.
- Step 6** Save the group policy, connection profile, and then the remote access VPN policy.
- Step 7** Deploy the changes.
- Changes to the client profile will be updated on the VPN clients when they connect to the remote access VPN gateway.
-

## RADIUS Dynamic Authorization

Secure Firewall Threat Defense has the capability to use RADIUS servers for user authorization of VPN remote access and firewall cut-through-proxy sessions using dynamic access control lists (ACLs) or ACL names per user. To implement dynamic ACLs for dynamic authorization or RADIUS Change of Authorization (RADIUS CoA), you must configure the RADIUS server to support them. When the user tries to authenticate, the RADIUS server sends a downloadable ACL or ACL name to the threat defense. Access to a given service is either permitted or denied by the ACL. Secure Firewall Threat Defense deletes the ACL when the authentication session expires.

## Configuring RADIUS Dynamic Authorization

### Before you begin:

- Only one interface can be configured in the security zone or interface group if it is referred in a RADIUS Server.
- A dynamic authorization enabled RADIUS server requires Secure Firewall Threat Defense 6.3 or later for the dynamic authorization to work.
- Interface selection in RADIUS server is not supported on Secure Firewall Threat Defense 6.2.3 or earlier versions. The interface option will be ignored during deployment.
- Threat Defense posture VPN does not support group policy change through dynamic authorization or RADIUS change of authorization (CoA).

## Two-Factor Authentication

You can configure two-factor authentication for the remote access VPN. With two-factor authentication, the user must supply a username and static password, plus an additional item such as an RSA token or a passcode. Two-factor authentication differs from using a second authentication source in that two-factor is configured on a single authentication source, with the relationship to the RSA server tied to the primary authentication source.

Secure Firewall Threat Defense supports RSA tokens and Duo Push authentication requests to Duo Mobile for the second factor in conjunction with any RADIUS or AD server as the first factor in the two-factor authentication process.

### Configuring RSA Two-Factor Authentication

#### About this task:

You can configure the RADIUS or AD server as the authentication agent in the RSA server, and use the server in Secure Firewall Management Center as the primary authentication source in the remote access VPN.

When using this approach, the user must authenticate using a username that is configured in the RADIUS or AD server, and concatenate the password with the one-time temporary RSA token, separating the password and token with a comma: *password,token*.

In this configuration, it is typical to use a separate RADIUS server (such as one supplied in Cisco ISE) to provide authorization services. You would configure the second RADIUS server as the authorization and, optionally, accounting server.

#### Before you begin:

Ensure that the following configurations are complete before configuring RADIUS two-factor authentication on Secure Firewall Threat Defense:

#### On the RSA Server

- Configure RADIUS or Active Directory server as an authentication agent.
- Generate and download the configuration (*sdconf.rec*) file.
- Create a token profile, assign the token to the user, and distribute the token to the user. Download and install the token on the remote access VPN client system.

For more information, see [RSA SecureID Suite documentation](#).

#### On the ISE Server

- Import the configuration (*sdconf.rec*) file generated on the RSA server.
- Add the RSA server as the external identity source and specify the shared secret.

**Table 107: Procedure**

|        | Do This                                                         | More Info |
|--------|-----------------------------------------------------------------|-----------|
| Step 1 | Log on to your Secure Firewall Management Center web interface. |           |

|        | Do This                                                                                                                                          | More Info                                                                                                                                                                                                                                                                                                                               |
|--------|--------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 2 | Create a RADIUS server group.                                                                                                                    | <a href="#">RADIUS Server Group Options, on page 1464</a>                                                                                                                                                                                                                                                                               |
| Step 3 | Create a RADIUS Server object within the new RADIUS server group, with RADIUS or AD server as the host and with a timeout of 60 seconds or more. | <a href="#">RADIUS Server Group Options, on page 1464</a><br><b>Note</b> The RADIUS or AD server must be the same server that is configured as the authentication agent in RSA server.<br><br>For two-factor authentication, make sure that the timeout is updated to 60 seconds or more in the Secure Client Profile XML file as well. |
| Step 4 | Configure a new remote access VPN policy using the wizard or edit an existing remote access VPN policy.                                          | <a href="#">Create a New Remote Access VPN Policy, on page 1686</a>                                                                                                                                                                                                                                                                     |
| Step 5 | Select RADIUS as the authentication server and then select the newly-created RADIUS server group as the authentication server.                   | <a href="#">Configure AAA Settings for Remote Access VPN, on page 1698</a>                                                                                                                                                                                                                                                              |
| Step 7 | Deploy the configuration changes.                                                                                                                | <a href="#">Deploy Configuration Changes, on page 240</a>                                                                                                                                                                                                                                                                               |

## Configuring Duo Two-Factor Authentication

### About this task:

You can configure the Duo RADIUS server as the primary authentication source. This approach uses the Duo RADIUS Authentication Proxy. (You cannot use a direct connection with the Duo Cloud Service over LDAPS.)

For the detailed steps to configure Duo, see <https://duo.com/docs/cisco-firepower>.

You would then configure Duo to forward authentication requests directed to the proxy server to use another RADIUS server, or an AD server, as the first authentication factor, and the Duo Cloud Service as the second factor.

When using this approach, the user must authenticate using a username that is configured on both the Duo Cloud or web server, and the associated RADIUS server. The user must enter the password configured in the RADIUS server, followed by one of the following Duo codes:

- **Duo-passcode.** For example, *my-password,123456*.
- **push.** For example, *my-password,push*. Use **push** to tell Duo to send a push authentication to the Duo Mobile app, which the user must have already installed and registered.
- **sms.** For example, *my-password,sms*. Use **sms** to tell Duo to send an SMS message with a new batch of passcodes to the user's mobile device. The user's authentication attempt will fail when using **sms**. The user must then re-authenticate and enter the new passcode as the secondary factor.
- **phone.** For example, *my-password,phone*. Use **phone** to authenticate using phone callback.

For more information on login options with examples, see <https://guide.duo.com/anyconnect>.

**Before you begin:**

Before configuring two-factor authentication with Duo Authentication Proxy on threat defense, ensure that you complete the following configurations:

- Configure a working primary authentication (RADIUS or AD) for your remote access VPN users before you begin to deploy Duo.
- Install Duo proxy service on a Windows or Linux machine within your network to integrate Duo with Secure Firewall Threat Defense remote access VPN. This Duo proxy server also acts as a RADIUS server.

Download and install the most recent Duo authentication proxy from the following location:

- **Windows:** <https://dl.duosecurity.com/duoauthproxy-latest.exe>
- **Linux:** <https://dl.duosecurity.com/duoauthproxy-latest-src.tgz>
- Verify the checksum at <https://duo.com/docs/checksums#duo-authentication-proxy>.
- Configure Duo authentication file `authproxy.cfg`. Follow instructions on the <https://duo.com/docs/cisco-firepower#configure-the-proxy> page to configure the authentication configuration settings.  
The `authproxy.cfg` configuration file must contain the details for RADIUS or ISE server, threat defense device, Duo proxy server details, Integration Key, Secret key, and API host details.
- Ensure that you have the right API host information in the `authproxy.cfg` file.
- Configure other required settings such as secondary authentication factor in the newly installed Duo proxy server at **Duo Security Server > Duo Admin Panel > Applications > CISCO RADIUS VPN**.

**Table 108: Procedure**

|        | <b>Do This</b>                                                                                                                                     | <b>More Info</b>                                                                                                                                                                                             |
|--------|----------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Step 1 | Log on to your Secure Firewall Management Center web interface.                                                                                    |                                                                                                                                                                                                              |
| Step 2 | Create a RADIUS server group.                                                                                                                      | <a href="#">RADIUS Server Group Options, on page 1464</a>                                                                                                                                                    |
| Step 3 | Create a RADIUS Server object within the new RADIUS server group with Duo proxy server as the host with a timeout of 60 seconds or more.           | <a href="#">RADIUS Server Options, on page 1465</a><br><b>Note</b> For two-factor authentication, make sure that the timeout is updated to 60 seconds or more in the Secure Client Profile XML file as well. |
| Step 4 | Configure a new remote access VPN policy using the wizard or edit an existing remote access VPN policy.                                            | <a href="#">Create a New Remote Access VPN Policy, on page 1686</a>                                                                                                                                          |
| Step 5 | Select RADIUS as the authentication server and then select the RADIUS server group created with the Duo proxy server as the authentication server. | <a href="#">Configure AAA Settings for Remote Access VPN, on page 1698</a>                                                                                                                                   |

|        | Do This                           | More Info                                                 |
|--------|-----------------------------------|-----------------------------------------------------------|
| Step 7 | Deploy the configuration changes. | <a href="#">Deploy Configuration Changes, on page 240</a> |

## Secondary Authentication

Secondary authentication or double authentication in Secure Firewall Threat Defense adds an additional layer of security to remote access VPN connections by using two different authentication servers. With secondary authentication enabled, the Secure Client VPN users must provide two sets of credentials to login to the VPN gateway.

Secure Firewall Threat Defense remote access VPN supports secondary authentication in AAA Only and Client Certificate & AAA authentication methods.

**Figure 370: Remote Access VPN Secondary or Double Authentication**

### Related Topics

[Configure Remote Access VPN Secondary Authentication](#), on page 1759

## Configure Remote Access VPN Secondary Authentication

When remote access VPN authentication is configured to use both client certificate and authentication server, VPN client authentication is done using both the client certificate validation and AAA server.

### Before you begin

- Configure two authentication (AAA) servers— the primary and secondary authentication servers, and required identity certificates. The authentication servers can be RADIUS server, and AD or LDAP realms.
- Ensure that the AAA servers are reachable from the Secure Firewall Threat Defense device for the remote access VPN configuration to work. Configure routing (at **Devices > Device Management > Edit Device > Routing**) to ensure connectivity to the AAA servers.

### Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > VPN > Remote Access**.
- Step 2** Select a remote access policy and click **Edit**; or click **Add** to create a new remote access VPN policy.
- Step 3** For a new remote access VPN policy, configure the authentication while selecting connection profile settings. For an existing configuration, select the connection profile that includes the client profile, and click **Edit**.
- Step 4** Click **AAA > Authentication Method, AAA or Client Certificate & AAA**.

- When you select the **Authentication Method** as:

**Client Certificate & AAA**—Authentication is done using both client certificate and AAA server.

- **AAA**—If you select the **Authentication Server** as **RADIUS**, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select **AD** and **LDAP** from the Authentication Server drop-down list, you must manually select the **Authorization Server** and **Accounting Server** respectively.
- Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.
- **Use secondary authentication** — Secondary authentication is configured in addition to primary authentication to provide additional security for VPN sessions. Secondary authentication is applicable only to **AAA only** and **Client Certificate & AAA** authentication methods.

Secondary authentication is an optional feature that requires a VPN user to enter two sets of username and password on the Secure Client login screen. You can also configure to pre-fill the secondary username from the authentication server or client certificate. Remote access VPN authentication is granted only if both primary and secondary authentications are successful. VPN authentication is denied if any one of the authentication servers is not reachable or one authentication fails.

You must configure a secondary authentication server group (AAA server) for the second username and password before configuring secondary authentication. For example, you can set the primary authentication server to an LDAP or Active Directory realm and the secondary authentication to a RADIUS server.

**Note** By default, secondary authentication is not required.

**Authentication Server**— Secondary authentication server to provide secondary username and password for VPN users.

Select the following under **Username for secondary authentication**:

- **Prompt:** Prompts the users to enter the username and password while logging on to VPN gateway.
- **Use primary authentication username:** The username is taken from the primary authentication server for both primary and secondary authentication; you must enter two passwords.

- **Map username from client certificate:** Prefills the secondary username from the client certificate.
  - If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity.  
See **Authentication Method** descriptions for more information about primary and secondary field mapping.
- **Prefill username from certificate on user login window:** Prefills the secondary username from the client certificate when the user connects via Secure Client.
  - **Hide username in login window:** The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.
- **Use secondary username for VPN session:** The secondary username is used for reporting user activity during a VPN session.

For more information, see [Configure AAA Settings for Remote Access VPN, on page 1698](#).

## Single Sign-On Authentication with SAML 2.0

### About SAML Single Sign-On Authentication

Security Assertion Markup Language (SAML) is an open standard for logging users into applications using their sessions in another context. Organizations already know the identity of users when users log in to their Active Directory (AD) domain or the intranet. They use this identity information to log in users to other applications, such as web-based applications using SAML. Individual applications do not need to store credentials and users do not have to remember and manage different sets of credentials for individual applications. SAML single sign-on (SSO) works by transferring the user's identity from one place (the identity provider) to another (the service provider).

### SAML Single Sign-On with Secure Firewall Threat Defense

The Secure Firewall Threat Defense device supports SAML 2.0 single sign-on (SSO) authentication for remote access VPN connections using the Secure Client. You need the following to configure SAML 2.0 SSO on Secure Firewall Threat Defense:

- **Identity Provider (IdP)**—The Duo Access Gateway acts as the identity provider to perform user authentication and issues assertions.
- **Service Provider (SP)**—The threat defense device acts as the service provider and obtains the authentication assertion from the identity provider.
- **VPN Client**—The Secure Client performs SAML 2.0 authentication via the embedded browser.

## Guidelines and Limitations for SAML 2.0

- Threat Defense supports the following signatures for SAML authentication:
  - SHA1 with RSA and HMAC
  - SHA2 with RSA and HMAC
- Threat Defense supports SAML 2.0 Redirect-POST binding , which is supported by all SAML IdPs.
- The Threat Defense functions as a SAML SP only. It cannot act as an Identity Provider in gateway mode or peer mode.
- You can enforce an access policy on a SAML-authenticated user if you have an associated identity policy with an AD realm matching the SAML domain. However, it does not work for Azure AD SAML because it requires additional mapping from the tenant ID of the Azure AD to an associated realm ID on the threat defense device.
- Having SAML authentication attributes available in DAP evaluation (similar to RADIUS attributes sent in RADIUS auth response from AAA server) is not supported. Threat Defense supports SAML enabled group policy on DAP policy; however, you cannot check the username attribute while using SAML authentication, because the username attribute is masked by the SAML Identity provider.
- Threat Defense administrators need to ensure clock synchronization between the threat defense and the SAML IdP for proper handling of authentication assertions and proper timeout behavior.
- Threat Defense administrators have the responsibility to maintain a valid signing certificate on both threat defense and IdP considering the following:
  - The IdP signing certificate is mandatory when configuring an IdP on the threat defense.
  - The threat defense does not do a revocation check on the signing certificate received from the IdP.
- In SAML assertions, there are NotBefore and NotOnOrAfter conditions. The threat defense SAML configured timeout interacts with these conditions as follows:
  - Timeout overrides NotOnOrAfter if the sum of NotBefore and timeout is earlier than NotOnOrAfter.
  - If NotBefore + timeout is later than NotOnOrAfter, then NotOnOrAfter takes effect.
  - If the NotBefore attribute is absent, the threat defense denies the login request. If the NotOnOrAfter attribute is absent and SAML timeout is not set, threat defense denies the login request.
- Threat Defense does not work with Duo in a deployment using an internal SAML, which forces the threat defense to proxy for the client to authenticate, due to the FQDN change that occurs during challenge/response for Two-factor authentication (push, code, password).
- When using SAML with Secure Client, follow these guidelines:
  - Untrusted server certificates are not allowed in the embedded browser.
  - The embedded browser SAML integration is not supported in CLI or SBL modes.
  - SAML authentication established in a web browser is not shared with Secure Client and vice versa.
  - Depending on the configuration, various methods are used when connecting to the headend with the embedded browser. For example, while Secure Client might prefer an IPv4 connection over an IPv6 connection, the embedded browser might prefer IPv6, or vice versa. Similarly, Secure Client

may fall back to no proxy after trying proxy and getting a failure, while the embedded browser may stop navigation after trying proxy and getting a failure.

- You must synchronize your threat defense's Network Time Protocol (NTP) server with the IdP NTP server in order to use the SAML feature.
- You cannot access internal servers with SSO after logging in using an internal IdP.
- The SAML IdP NameID attribute determines the user's username and is used for authorization, accounting, and VPN session database.
- SAML does not support Start Before Logon (SBL).
- Multiple attributes received with a SAML assertion are not supported.

## Configuring a SAML Single Sign-On Authentication

### Before you begin

Ensure that you have done the following before you configure SAML single sign-on with threat defense remote access VPN:

- Create an account with Duo.
- Download and install the Duo Access Gateway.
- Obtain the following from your SAML identity provider (Duo).
  - Identity Provider Entity ID URL
  - Sign-in URL
  - Sign-out URL
  - Identity provider certificate
- Create a SAML single sign-on server object. For more information, see [Add a Single Sign-on Server, on page 1466](#).

---

**Note** You can create a single sign-on server object in the **Connection Profile** settings when you create a new policy using the Remote Access VPN policy Wizard.

---

### Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
  - Step 2** Click **Edit** next to the remote access VPN policy for which you want to configure SAML authentication. If you want to create a new policy, click **Add**.
  - Step 3** Click **Edit** on the connection profile that you want to modify.
  - Step 4** Choose **AAA** settings and select **SAML** from the **Authentication Method** drop-down.

- Step 5** Choose the required SAML single sign-on server as the **Authentication Server**.
- Step 6** Configure the required settings for the remote access VPN.
- Step 7** Save and deploy the remote access VPN policy on your threat defense device.

---

[Configure AAA Settings for Remote Access VPN](#), on page 1698

## Configuring SAML Authorization

### About SAML Authorization

SAML authorization supports user attributes delivered in SAML assertions within the AAA and Dynamic Access Policy (DAP) frameworks. You can configure the SAML assertion attributes on the Identity Provider as name-value pairs which then parses as strings. The attributes received are made available to DAP so that they can be used when defining selection criteria within a DAP record. The SAML assertion *cisco\_group\_policy* is used to determine the Group Policy to be applied to the VPN session.

### Dynamic Access Policy Attribute Representation

In the DAP table, the DAP attributes are represented in the following format:

```
aaa.saml.name = "value"
```

Example, *aaa.saml.department = "finance"*

This attribute can be used in DAP selection as follows:

```
<attr>
<name>aaa.saml.department</name>
<value>finance</value>
<operation>EQ</operation>
</attr>
```

### Multi-Valued Attributes

Multi-valued attributes are also supported in DAP and the DAP table is indexed :

```
aaa.saml.name.1 = "value"
aaa.saml.name.2 = "value"
```

### Active Directory memberOf Attributes

The Active Directory (AD) memberOf attribute receives a special processing that is consistent with the way it is handled through an LDAP query.

Group names are represented by the CN attribute of the DN.

Example Attributes received from the authorization server:

```
memberOf = "CN=FTD-VPN-Group,OU=Users,OU=TechspotUsers,DC=techspot,DC=us"
memberOf = "CN=Domain Admins,OU=Users,DC=techspot,DC=us"
```

Dynamic Access Policy attributes:

```
aaa.saml.memberOf.1 = "FTD-VPN-Group"
aaa.saml.memberOf.2 = "Domain Admins"
```

### Interpretation of the cisco\_group\_policy Attribute

A group-policy can be specified by a SAML assertion attribute. When an attribute "cisco\_group\_policy" is received by the threat defense, the corresponding value is used to select the connection group-policy

## Configure SAML Authorization

### Before you begin

Ensure that you have configured a single sign-on server like DUO and completed the required Identity Provider (IdP) and Service Provider (SP) settings.

For more information, see [Single Sign-On Authentication with SAML 2.0, on page 1761](#).

## Procedure

- 
- Step 1** Configure a single sign-on server object if not configured already.
- Choose **Object > Object Management > AAA Server > Single Sign-on Server**
  - Click **Add Single Sign-on Server**.
  - Enter the single sign-on server details and click **Save**.
- For more information, see [Add a Single Sign-on Server, on page 1466](#).
- Step 2** Configure SAML authentication in the remote access VPN connection profile.
- Choose **Devices > Remote Access**.
  - Click **Edit** on the remote access VPN policy for which you want to configure SAML authorization or create a new policy.
  - Edit the required connection profile and select **AAA**.
  - Select the single sign-on server object from the **Authentication Server** drop-down.
  - Save the remote access VPN configuration.
- Step 3** Match a SAML criteria in DAP policy.
- Select **Devices > Dynamic Access Policy**.
  - Create a new DAP or edit an existing one.
  - Create a DAP record or edit an existing record.
  - Click **AAA Criteria > SAML Criteria > Add SAML Criteria**.
  - Create a SAML criteria based on the SAML assertions returned by the SSO server.
- Step 4** Deploy the remote access VPN configuration.

---

# Advanced Secure Client Configurations

## Configure Secure Client Modules on a Threat Defense

Secure Client can integrate with various Cisco endpoint security solutions and offer enhanced security using different Secure Client modules.

You can use the managed headend threat defense to distribute and manage Secure Client modules to the endpoints. When a user connects to the threat defense, it downloads and installs Secure Client and the required modules on the endpoint.

In version 6.7 and later, you can use the headend threat defense, managed by a management center, to distribute and manage Secure Client modules to the endpoints. These modules then integrate with the corresponding Cisco endpoint security solution.

In versions 6.4 to 6.6, you can enable these modules and profiles on a threat defense using FlexConfig. For more information, see [Configure AnyConnect Modules and Profiles Using FlexConfig](#).

### Benefits

If you use a threat defense to distribute and manage Secure Client modules to the endpoints, you can easily perform the following tasks:

- Distribute and manage Secure Client modules and profiles on each endpoint.
- Upgrade Secure Client on each endpoint.

## Types of Secure Client Modules

### AMP Enabler

Use this module to deploy Cisco Secure Endpoint, formerly AMP for Endpoints, on endpoints. The module pushes Cisco Secure Endpoint to endpoints from a server hosted locally within the enterprise. This module provides an additional security agent that detects potential malware threats in the network, removes these threats, and protects the enterprise.

In Cisco Secure Client 5.0, AMP Enabler is only for macOS. Cisco Secure Client for Windows offers full integration with Cisco Secure Endpoint.

### ISE Posture

Use this module to perform endpoint posture checks such as antivirus, antispymware, operating system and so on using Cisco Identity Services Engine (ISE) and assess the endpoint's compliance. ISE provides next generation identity and access control policy. ISE Posture performs a client-side evaluation. The client receives the posture requirement policy from the headend, performs the posture data collection, compares the results against the policy, and sends the assessment results back to the headend.

### Network Visibility

Use this module to monitor the endpoint application usage using the Network visibility module. You can uncover potential behavior anomalies and make informed network design decisions. It enhances the enterprise

administrator's ability to do capacity and service planning, auditing, compliance, and security analytics. You can share the usage data with NetFlow analysis tools such as Cisco Stealthwatch.

### **Umbrella Roaming Security**

Use this module for a DNS-layer security using the Cisco Umbrella Roaming Security service. Cisco Umbrella provides content filtering, multiple policies, robust reporting, active directory integration, and much more.

### **Web Security**

Use this module to enable Cisco Secure Web Appliance (SWA), powered by Cisco Talos. This module protects the endpoint by blocking risky sites and testing unknown sites before allowing users to access them. It can deploy web security either through the on-prem WSA or the cloud-based Cisco Cloud Web Security. This module is not part of the AnyConnect package from release 4.5 and in Secure Client 5.0.

### **Network Access Manager**

This module provides a secure layer 2 network and performs device authentication to access wired and wireless networks. Network Access Manager manages user and device identity and the network access protocols required for secure access.

Network Access Manager is not supported on macOS or Linux.

### **Start Before Login**

Start Before Login (SBL) allows users to establish their VPN connection to the enterprise infrastructure before logging onto Windows. After the SBL module installation, you must enable SBL in the Secure Client VPN profile and add it to the remote access VPN group policy.

### **DART**

Diagnostics and Reporting Tool (DART) collates system logs and other diagnostic information to troubleshoot AnyConnect installation and connection problems. You can send this data to Cisco TAC for troubleshooting.

By default, DART is not enabled in new RA VPN group policies for 6.7 and later versions. In 6.6 and earlier versions, DART is enabled by default.

### **Feedback**

The customer experience feedback (CEF) module provides information about which features and modules you use and have enabled. This information gives an insight into the user experience so that Cisco can continue to improve the quality, reliability, performance, and user experience of the Cisco Secure Client. Secure Client does not download the Feedback module to the endpoint. The feedback data is sent to the Cisco Feedback Server.

## **Prerequisites for Configuring Secure Client Modules**

- Configure the associated products depending on the module that you are going to use.
- Download the following Secure Client-related packages from [Cisco Software Download Center](#) to your local host.
  - Cisco Secure Client Headend Deployment Package for the required platforms.

This package is for the headend and contains all the Secure Client modules. For Windows, the filename is cisco-secure-client-win-5.0.03076-webdeploy-k9.pkg.

- Profile Editor: Create profiles for the modules that require profiles.

Secure Client needs a Secure Client profile for some of the modules. A profile contains configurations to enable the modules and connect to the corresponding security services. The profile editor supports only Windows.

The following table lists if the modules require a client profile:

Secure Client Module	Requires a Client Profile
AMP Enabler	Yes
ISE Posture	Yes
Network Access Manager	Yes
Network Visibility Module	Yes
Umbrella Roaming Secure Module	Yes
Feedback	Yes
Web Security	Yes
DART	No
Start Before Login	No

- Licensing
  - You need one of the following Secure Client licenses: Secure Client Premier, Secure Client Advantage, or Secure Client VPN Only
  - Your management center Essentials license must allow export-controlled functionality. Choose **System > Licenses > Smart Licenses** to verify this functionality in the management center.

## Guidelines for Configuring Secure Client Modules

- All Secure Client modules are supported from AnyConnect 4.8 and later, and Secure Client 5.0.
- Different modules support profiles with different file extensions. The following table lists the modules and the supported file extensions of their profiles:

**Table 109: Supported File Extensions of Profiles**

Module	File Extension
AMP Enabler	*.xml, *.asp
Feedback	*.xml
ISE Posture	*.xml, *.isp

Module	File Extension
Network Access Manager	*.xml, *.nsp
Network Visibility	*.xml, *.nvmsp
Umbrella Roaming Security	*.xml, *.json
Web Security	*.xml, *.wsp, *.wso

- You can add only one entry per client module. You can edit or delete an entry for a module.
- If you plan to use ISE posture and Network Access Manager modules on a Windows OS, you must install Network Access Manager before you use the ISE Posture module.
- If you enable the Umbrella Roaming Security module, ensure that you disable the **Always send DNS requests over tunnel** option under split tunnelling in the VPN group policy.
- If you want to use SBL, then you must enable SBL in the Secure Client VPN profile.

## Install Secure Client Modules using a Threat Defense

### Before you begin

Ensure that you review the [Prerequisites for Configuring Secure Client Modules, on page 1767](#) and [Guidelines for Configuring Secure Client Modules, on page 1768](#) topics.

### Procedure

- 
- Step 1** The administrator creates profiles, if needed, for the required Secure Client modules.
- Step 2** The administrator uses the management center to:
- Configure the modules and add the profiles in the remote access VPN group policy.
  - Deploy the configuration on the threat defense.
- Step 3** The user uses Secure Client to initiate a VPN connection to the threat defense.
- Step 4** The threat defense authenticates the user.
- Step 5** The Secure Client checks for updates.
- Step 6** The threat defense distributes the Secure Client modules and the profiles on the endpoint.
- 

### What to do next

[Configure a Remote Access VPN Group Policy with Secure Client Modules, on page 1769.](#)

## Configure a Remote Access VPN Group Policy with Secure Client Modules

To install and update the Secure Client modules on the endpoint using a threat defense managed by a management center, you must update the remote access VPN group policy with the Secure Client module configurations.

### Before you begin

Ensure that you have configured a remote access VPN policy in the management center.

### Procedure

- 
- |                |                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b>  | Choose <b>Devices &gt; Remote Access</b> .                                                                             |
| <b>Step 2</b>  | Select a remote access VPN policy and click <b>Edit</b> .                                                              |
| <b>Step 3</b>  | Select a connection profile and click <b>Edit</b> .                                                                    |
| <b>Step 4</b>  | Click <b>Edit Group Policy</b> .                                                                                       |
| <b>Step 5</b>  | Click the <b>Secure Client</b> tab.                                                                                    |
| <b>Step 6</b>  | Click <b>Client Modules</b> .                                                                                          |
| <b>Step 7</b>  | Click <b>+</b> .                                                                                                       |
| <b>Step 8</b>  | Choose a module from the <b>Client Module</b> drop-down list.                                                          |
| <b>Step 9</b>  | Choose a profile for the module from the <b>Profile to download</b> drop-down list or click <b>+</b> to add a profile. |
| <b>Step 10</b> | Check the <b>Enable module download</b> check box to download the module on the endpoint.                              |
| <b>Step 11</b> | Click <b>Add</b> .                                                                                                     |
| <b>Step 12</b> | Repeat steps 7 to 11 if you want to add more modules.                                                                  |
| <b>Step 13</b> | Click <b>Save</b> .                                                                                                    |
- 

### What to do next

1. Deploy the configuration on the threat defense.
2. Launch the Secure Client, select the VPN profile, and connect to the VPN. Secure Client installs the configured modules on it.
3. Verify the configuration. For more information, see [Verify Secure Client Modules Configuration, on page 1770](#).

## Verify Secure Client Modules Configuration

### On the Threat Defense

Use the following commands on the threat defense to view the profiles and the Secure Client modules configuration:

- **show disk0**:- View the profiles and their configuration.
- **show run webvpn** - View details of the Secure Client configurations.
- **show run group-policy <ravpn\_group\_policy\_name>** - View details of the RA VPN group policy for Secure Client.
- **show vpn-sessiondb anyconnect** - View details of the active Secure Client VPN sessions.

### On the Endpoint

1. Use the Secure Client to establish a VPN connection to the threat defense.
2. Verify if the configured modules are downloaded and installed as part of the Secure Client.
3. Verify if the configured profiles, if any, are available in the locations documented in [Profile Locations for all Operating Systems](#).

### On the Management Center

You can monitor remote access VPN active sessions on the management center using the Remote Access VPN dashboard (**Overview > Remote Access VPN**). You can quickly determine problems related to user sessions and mitigate the problems for your network and users.

## Configure Application-Based (Per App VPN) Remote Access VPN on Mobile Devices

When you use Secure Client to establish a VPN connection from a mobile device, all the traffic including the traffic from personal applications is routed through the VPN.

For mobile devices that run on Android or iOS, you can restrict the applications that use the VPN tunnel. This application-based remote access VPN is called Per App VPN. To use Per App VPN, you must install and configure a third-party Mobile Device Manager (MDM) application. You must define the list of approved applications that can be used over the VPN tunnel in the MDM. You can enable Per App VPN on the threat defense headend so that your MDM can apply your policies on mobile devices.

### Benefits

Benefits of restricting the remote access VPN to approved applications include:

- Performance—Limits VPN traffic over the corporate network and frees up resources of the VPN headend.
- Protection—Protects the corporate VPN tunnel from unapproved malicious applications on the mobile device.

## Prerequisites and Licensing for Configuring Per App VPN Tunnels

### Prerequisites

- Install and configure a third-party Mobile Device Manager (MDM).

You must configure the applications that will be allowed in the VPN in the MDM itself, not on the threat defense headend device.

- Download the Cisco AnyConnect Enterprise Application Selector from [Cisco Software Download Center](#).

You need this tool to define the Per App VPN policy.

### Licensing

- Secure Client Premier, or Secure Client Advantage.
- Essentials license must allow export-controlled functionality.

To verify this functionality in the management center, choose **System > Licenses > Smart Licenses**.

## Determine the Application IDs for Mobile Applications

Before configuring the threat defense headend to allow application-based VPN from mobile devices, you must determine which applications should be allowed in the tunnel.

We strongly recommend that you configure the per-app policy in the MDM on the user's mobile device. This simplifies the headend configuration. If you decide to configure the list of allowed applications on the headend, you must determine the application IDs for each application on each type of endpoint.

The application ID, called the bundle ID in iOS, is a reverse DNS name. You can use an asterisk as a wildcard. For example, \*.\* indicates all applications, com.cisco.\* indicates all Cisco applications.

To determine the application IDs:

- **Android**—Go to Google Play in a web browser and select the Apps category. Click (or hover over) an application that you want to allow, then look at the URL. The app id is in the URL, on the **id=** parameter. For example, the following URL is for Facebook Messenger, so the app id is com.facebook.orca.

<https://play.google.com/store/apps/details?id=com.facebook.orca>

For applications that are not available through Google Play, such as your own applications, download a package name viewer application to extract the app ID. There are many of these applications available, one of them should provide what you need, but Cisco does not endorse any of them.

- **iOS**—There is no straight-forward way to get the bundle ID. Following is one way to find it:
  1. Use a desktop web browser such as Chrome to search for the application name.
  2. In the search results, look for the link to download the app from the Apple App Store. For example, Facebook Messenger would be similar to:
 

<https://apps.apple.com/us/app/messenger/id454638411>
  3. Copy the number after the **id** string. In this example, **454638411**.
  4. Open a new browser window, and add the number to the end of the following URL:
 

<https://itunes.apple.com/lookup?id=>

For this example: <https://itunes.apple.com/lookup?id=454638411>
  5. You will be prompted to download a text file, usually named 1.txt. Download the file.
  6. Open the file in a text editor such as WordPad, and search for bundleId. For example:
 

```
"bundleId": "com.facebook.Messenger",
```

In this example, the bundle ID is com.facebook.Messenger. Use this as the app ID.

Once you have your list of application IDs, you can configure the policy as explained in .

## Configure Application-Based VPN Tunnels

After you install and configure your MDM software, you can enable Per App VPN on the threat defense headend device. Once enabled on the headend, your MDM software will control which applications are tunneled over the VPN to the corporate network.

### Before you begin

- Ensure that you have a remote access VPN policy in the management center.
- Configure Per App VPN using MDM and enroll each device to the MDM server.
- Download the Cisco AnyConnect Enterprise Application Selector.

## Procedure

- 
- Step 1** Use the Cisco AnyConnect Enterprise Application Selector to define the Per App VPN policy. We recommend that you create a simple **Allow All** policy, and define the allowed applications in the MDM. However, you can specify a list of applications to allow and control the list from the headend. If you want to include specific applications, create a separate rule for each application, using a unique name and the application's app ID. For more information on getting the app IDs, see [Determine the Application IDs for Mobile Applications](#).
- To create an **Allow All** policy that supports both Android and iOS platforms using the AnyConnect Enterprise Application Selector:
- a) Choose **Android** from the drop-down list as the platform type and configure the following options:
    - **Friendly Name**—Enter a name for the policy. For example, Allow\_All.
    - **App ID**—Enter \*.\* to match all possible applications.
    - Leave the other options.
  - b) Choose **iOS** from the drop-down list as the platform type and configure the following options:
    - **Friendly Name**—Enter a name for the policy. For example, Allow\_All.
    - **App ID**—Enter \*.\* to match all possible applications.
    - Leave the other options.
  - c) Choose **Policy > View Policy** to get the base64 encoded string for the policy.

This string contains an encrypted XML file that allows the threat defense to see the policies. Copy this value. You need this string when you configure Per App VPN on the threat defense.
- Step 2** Use the management center to enable the Per App on the threat defense headend device.
- a) Choose **Devices > Remote Access**.
  - b) Select a remote access VPN policy and click **Edit**.
  - c) Select a connection profile and click **Edit**.
  - d) Click **Edit Group Policy**.
  - e) Click the **Secure Client** tab.
  - f) Click **Custom Attributes** and click +.
  - g) Choose **Per App VPN** from the **Secure Client Attribute** drop-down list.
  - h) Choose an object from the **Custom Attribute Object** drop-down list or click + to add an object.

When you add a new custom attribute object for Per App VPN, enter the name, description, and the base64 encoded policy string from the Cisco AnyConnect Enterprise Application Selector.

- i) Click **Save**.
- j) Click **Add** and click **Save**.

**Step 3** Deploy your changes on the management center.

#### What to do next

1. Launch the Secure Client, select the VPN profile, and connect to the VPN.
2. Verify the configuration. For more information, see [Verify Per App Configuration, on page 1774](#).

## Verify Per App Configuration

#### On the Threat Defense

Use the following commands on the threat defense to view the Per App configuration:

- `show run webvpn`
- `show run group-policy <ravpn_group_policy_name>`
- `show run anyconnect-custom-data`

#### On the Endpoint

After the endpoint establishes a VPN connection with the threat defense:

1. Click the **Statistics** icon of the Secure Client.
2. **Tunnel Mode** will be “Application Tunnel” instead of “Tunnel All Traffic.”
3. **Tunneled Apps** will list the applications you enabled for tunneling in the MDM.

## Remote Access VPN Examples

### How to Limit Secure Client Bandwidth Per User

This section provides instructions to limit the maximum bandwidth that the VPN users consume when they connect using the Secure Client to Secure Firewall Threat Defense remote access VPN gateway. You can limit the maximum bandwidth by using a Quality of service (QoS) policy in threat defense, to ensure that a single user or group or users do not take over the entire resource. This configuration lets you give priority to critical traffic, prevent bandwidth hogging, and manage the network. If a When traffic exceeds the maximum rate, the threat defense drops the excess traffic.

2	Create an identity policy and add an identity rule.	<ul style="list-style-type: none"> <li>• See <a href="#">Create an Identity Policy, on page 2611</a> to create an identity policy.</li> <li>• See <a href="#">Create an Identity Rule, on page 2618</a> to create an identity rule.</li> </ul>
3	Associate the identity policy with an access control policy.	<a href="#">Associating Other Policies with Access Control, on page 1844</a>
4	Configure remote access VPN policy and select the newly created realm for user authentication.	<a href="#">Create a New Remote Access VPN Policy, on page 1686</a>
5	Deploy the remote access VPN policy.	<a href="#">Deploy Configuration Changes, on page 240</a>

## Configure Threat Defense Multiple Certificate Authentication

### Multiple Certificate-based Authentication

Multiple certificate-based authentication allows the threat defense to validate the machine or device certificate. Multiple certificates can be enabled for certificate-based authentication in the remote access VPN connection profile. It can be combined with AAA authentication. The multiple certificates option in the remote access VPN connection profile allows certificate authentication of both the machine and user via certificates. This ensures that the device is a corporate-issued device, in addition to authenticating the user's identity certificate to allow RA VPN access. The administrator can choose if the username for the session should be taken from the machine certificate or user certificate.

When multiple certificate-based authentication is configured, two certificates are obtained from the VPN client:

- **First Certificate**—Machine certificate to authenticate the endpoint.
- **Second Certificate**—User certificate to authenticate the VPN user.

For detailed information about threat defense certificates, see [Managing Threat Defense Certificates, on page 1576](#).

### Limitations

- Multiple certificate authentication currently limits the number of certificates to two.
- Secure Client supports only RSA-based certificates.
- Only SHA256, SHA384, and SHA512 based certificates are supported during the Secure Client aggregate authentication.
- Certificate authentication cannot be combined with SAML authentication.

### Pre-fill Username from Certificate

The Pre-fill username option allows a field from the certificates to be parsed and used for subsequent AAA authentication (primary and secondary). When two certificates are used for authentication, the Administrator can choose the certificate from which the username should be derived for the prefill functionality. By default, username for prefill is retrieved from the User certificate (second certificate received from Secure Client). The pre-filled username is used as the VPN session username when the Certificate Only authentication method is enabled. When AAA and certificate authentication is enabled, VPN session username will be based on the pre-fill option.

### Configure Multiple Certificate Authentication for Remote Access VPN

1. On your Secure Firewall Management Center web interface, choose **Devices > VPN > Remote Access**.
2. Edit an existing remote access policy, or create a new one and then edit.  
See [Create a New Remote Access VPN Policy, on page 1686](#).
3. Select the connection profile to configure multiple certificate authentication, and click **Edit**.  
See [Configure Connection Profile Settings, on page 1696](#).
4. Choose **AAA**, and then select an **Authentication Method**:

Figure 371:

**Edit Connection Profile**

Connection Profile:\*

Group Policy:\*  +  
[Edit Group Policy](#)

Client Address Assignment   **AAA**   Aliases

**Authentication**

Authentication Method:  ▾  
 Enable multiple certificate authentication

Authentication Server:  ▾  
 Fallback to LOCAL Authentication

▾ **Map username from client certificate**

Certificate to choose:  ▾

Map specific field

Primary Field:  ▾      Secondary Field:  ▾

Use entire DN (Distinguished Name) as username

Prefill username from certificate on user login window

Hide username in login window

- **Client Certificate Only**—User is authenticated using client certificate. Client certificate must be configured on VPN client endpoints. By default, the username is derived from client certificate fields CN & OU respectively. In case, the username is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.
- **Client Certificate & AAA**—User is authenticated using both the types of authentication, AAA and client certificate.

5. Select **Enable multiple certificate authentication**.
6. Select **Map username from client certificate** and select a certificate from the **Certificate to choose** drop-down to choose the username for the VPN session from the machine certificate or user certificate.
  - **First Certificate**—Map the username from the Machine Certificate.
  - **Second Certificate**—Map the username from the User certificate to authenticate the VPN user.

7. Configure the required connection profile settings and remote access VPN settings.
8. Save the connection profile and remote access VPN policy. Deploy the remote access VPN on threat defense.

For information about remote access VPN AAA settings, see [Configure AAA Settings for Remote Access VPN](#), on page 1698.

### Certificate Configuration in DAP

You can also configure certificate criteria attributes in a DAP record. The user and machine certificate received from the VPN client during multiple-certificate authentication is loaded into dynamic access policy (DAP) to allow policies to be configured based on the field of the certificate. You can make policy decisions based on the fields of a certificate used to authenticate that connection attempt.

1. Choose **Devices > Dynamic Access Policy**.
2. Edit an existing DAP policy or create a new one and then edit the policy.
3. Choose an existing DAP record, or create a new one and then edit the record.
4. Select **Endpoint Criteria > Certificate**.
5. Select the Match Criteria **All** or **Any**.
6. Click **Add** to add certificate attributes.

*Figure 372:*

The screenshot shows a 'Certificate Criteria' configuration window. It includes the following elements:

- Certificate:** Radio buttons for 'Cert1' (selected) and 'Cert2'.
- Subject:** A dropdown menu set to 'Issuer' and a text input field containing 'finCA SHA'.
- Issuer:** A dropdown menu set to 'Name' and a text input field containing 'Finance CA'.
- Subject Alternate Name:** A dropdown menu set to 'User Principal Name' and a text input field containing 'Finance Group Cert'.
- Serial Number:** A text input field containing '0x04C11DB7'.
- Certificate Store:** Radio buttons for 'None', 'Machine' (selected), and 'User'.
- Buttons:** 'Cancel' and 'Save' buttons at the bottom right.

7. Select the certificate, **Cert1** or **Cert2**.
8. Select the **Subject** and specify the certificate subject value.

9. Select the **Issuer** and specify the certificate issuer name.
10. Select the **Subject Alternate Name** and specify the alternate name for the subject.
11. Specify the **Serial Number**.
12. Select the **Certificate Store**: None, Machine, or User.  
This option adds a condition to check for the store from which the certificate is picked on the endpoint.
13. Click **Save** to complete the certificate criteria settings.  
Configure the required DAP record settings and then associate the DAP with the remote access VPN.

For more information about DAP, see [Dynamic Access Policies](#) , on page 1781.

## CHAPTER 60

# Dynamic Access Policies

Dynamic access policies (DAP) enable you to configure authorization that addresses the dynamics of VPN environments. You create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. These attributes address issues of multiple group membership and endpoint security.

- [About Secure Firewall Threat Defense Dynamic Access Policy, on page 1781](#)
- [Prerequisites for Dynamic Access Policy , on page 1783](#)
- [Guidelines and Limitations for Dynamic Access Policies, on page 1783](#)
- [Configure a Dynamic Access Policy \(DAP\), on page 1783](#)
- [Associate Dynamic Access Policy with Remote Access VPN, on page 1791](#)
- [History for Dynamic Access Policy, on page 1792](#)

## About Secure Firewall Threat Defense Dynamic Access Policy

VPN gateways operate in dynamic environments. Multiple variables can affect each VPN connection. For example, intranet configurations that frequently change, the various roles each user inhabits within an organization, and log in attempts from remote access sites with different configurations and levels of security. The task of authorizing users is much more complicated in a VPN environment than it is in a network with a static configuration.

You can create a dynamic access policy by setting a collection of access control attributes that you associate with a specific user tunnel or session. These attributes address issues of multiple group memberships and endpoint security. The threat defense grants access to a particular user for a particular session according to the policies you define. The threat defense device generates a DAP during user authentication by selecting or aggregating attributes from one or more DAP records. The device then selects these DAP records based on the endpoint security information of the remote device and AAA authorization information for the authenticated user. Then the device applies the DAP record to the user tunnel or session.

## Hierarchy of Policy Enforcement of Permissions and Attributes in Threat Defense

The threat defense device supports applying user authorization attributes, also called user entitlements or permissions, to VPN connections. The attributes are applied from a DAP on the threat defense, external authentication server and/or authorization AAA server (RADIUS) or from a group policy on the threat defense device.

If the threat defense device receives attributes from all sources, the device evaluates, merges, and applies the attributes to the user policy. If there are conflicts between attributes coming from the DAP, the AAA server, or the group policy, the attributes from the DAP always take precedence.

The threat defense device applies attributes in the following order:

**Figure 373: Policy Enforcement Flow**

1. **DAP attributes on the FTD**—The DAP attributes take precedence over all others.
2. **User attributes on the external AAA server**—The server returns these attributes after successful user authentication and/or authorization.
3. **Group policy configured on the FTD** —If a RADIUS server returns the value of the RADIUS Class attribute IETF-Class-25 (OU= group-policy) for the user, the threat defense device places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.
4. **Group policy assigned by the Connection Profile (also known as Tunnel Group)**—The Connection Profile has the preliminary settings for the connection, and includes a default group policy that is applied to the user before authentication.

**Note** The threat defense device does not support inheriting system default attributes from the default group policy, *DfltGrpPolicy*. For the user session, the device uses the attributes on the group policy that you assign to the connection profile, unless the user attributes or the group policy from the AAA server overrides them.

## Prerequisites for Dynamic Access Policy

Licensing:

- Threat Defense must have at least one of the following Secure Client licenses:
  - Secure Client Premier
  - Secure Client Advantage
  - Secure Client VPN Only
- The threat defense Essentials license must allow export-controlled functionality.

## Guidelines and Limitations for Dynamic Access Policies

- Matching of AAA attributes in a DAP will work only if a AAA server is configured to return the correct attributes when authenticating or authorizing a remote access VPN session.
- Minimum Secure Client and HostScan package version supported for DAP is 4.6. But it is highly recommended to use the latest version of Secure Client.
- DAP does not support clustering or multi-instance mode.
- DAP condition with an assigned IPv4/IPv6 address does not work for local authentication.

## Configure a Dynamic Access Policy (DAP)

### Create a Dynamic Access Policy

#### Before you begin

Ensure that you have the HostScan package before you configure the dynamic access policy. You can add the HostScan file at **Objects > Object Management > VPN > Secure Client File**.

#### Procedure

- 
- |               |                                                                                      |
|---------------|--------------------------------------------------------------------------------------|
| <b>Step 1</b> | Choose <b>Devices &gt; Dynamic Access Policy &gt; Create Dynamic Access Policy</b> . |
| <b>Step 2</b> | Specify the <b>Name</b> for the DAP policy and an optional <b>Description</b> .      |
| <b>Step 3</b> | Select the <b>HostScan Package</b> from the list.                                    |
| <b>Step 4</b> | Click <b>Save</b> .                                                                  |
-

**What to do next**

To configure DAP record, see [Create a Dynamic Access Policy Record](#)

## Create a Dynamic Access Policy Record

A dynamic access policy (DAP) can contain multiple DAP records, where you configure user and endpoint attributes. You can prioritize the DAP records within a DAP so that the threat defense can select and sequence the required criteria when a user attempts VPN connection.

**Procedure**

- 
- Step 1** Choose **Devices > Dynamic Access Policy**.
- Step 2** Edit an existing dynamic access policy or click **Create Dynamic Access Policy** to create a new one and then edit the policy.
- Step 3** Click **Create DAP Record**.
- Step 4** Click the **General** tab.
- Step 5** Specify the **Name** for the DAP record.
- Step 6** Enter the **Priority** for the DAP record.  
The lower the number, the higher the priority.
- Step 7** Select one of the following actions to take when a DAP record matches:
- **Continue**—Applies access policy attributes to the session.
  - **Terminate**—Terminates the session.
  - **Quarantine**—Quarantines the connection.
- Step 8** Check the **Display User Message on Criterion Match** check-box and add the user message.  
The threat defense displays this message to the user when the DAP record matches.
- Step 9** Check the **Apply a Network ACL on Traffic** check-box and select the access control list from the drop-down.
- Step 10** Check the **Apply one or more Secure Client Custom Attributes** check-box and select the custom attributes object from the drop-down.
- Step 11** Click **Save**.
- 

## Configure AAA Criteria Settings for DAP

DAP complements AAA services by providing a limited set of authorization attributes that can override the attributes that AAA provides. The threat defense select DAP records based on the AAA authorization information for the user and posture assessment information for the session. The threat defense can choose multiple DAP records depending on this information, which it then aggregates to create DAP authorization attributes.

## Procedure

- 
- Step 1** Choose **Devices > Dynamic Access Policy**.
- Step 2** Edit an existing DAP policy or create a new one and then edit the policy.
- Step 3** Select a DAP record or create a new one, and edit the DAP record.
- Step 4** Click **AAA Criteria**.
- Step 5** Select one of the **Match criteria between sections**.
- Any—Matches any of the criteria.
  - All—Matches all the criteria.
  - None—Matches none of the set criteria.
- Step 6** Click **Add** to add the required **Cisco VPN Criteria**.
- Cisco VPN criteria include attributes for group policy, assigned IPv4 address, assigned IPv6 address, connection profile, username, username 2, and SCEP required.
- Select an attribute and specify the **Value**.
  - Click **Add another criteria** to add more criteria.
  - Click **Save**.
- SCEP Required
- Step 7** Select **LDAP Criteria**, **RADIUS Criteria**, or **SAML Criteria** and specify the **Attribute ID** and **Value**.
- Step 8** Click **Save**.
- 

## Configure Endpoint Attribute Selection Criteria in DAP

Endpoint attributes contain information about the endpoint system environment, posture assessment results, and applications. The threat defense dynamically generates a collection of endpoint attributes during session establishment and stores these attributes in a database that is associated with the session. Each DAP record specifies the endpoint selection attributes that must be satisfied for the threat defense to choose it for a session. The threat defense selects only DAP records that satisfy every condition configured.

## Procedure

- 
- Step 1** Choose **Devices > Dynamic Access Policy > Create Dynamic Access Policy**.
- Step 2** Edit a DAP policy and then DAP record.
- Note** Create a DAP policy and DAP record if not done already.
- Step 3** Click **Endpoint Criteria** and configure the following endpoint criteria attributes:

**Note** You can create multiple instances of each type of endpoint attribute. There is no limit for the number of endpoint attributes for each DAP record.

- [Add an Anti-Malware Endpoint Attribute to a DAP](#)
- [Add a Device Endpoint Attribute to a DAP](#)
- [Add Secure Client Endpoint Attributes to a DAP, on page 1787](#)
- [Add a NAC Endpoint Attribute to a DAP](#)
- [Add an Application Attribute to a DAP](#)
- [Add a Personal Firewall Endpoint Attribute to a DAP](#)
- [Add an Operating System Endpoint Attribute to a DAP](#)
- [Add a Process Endpoint Attribute to a DAP](#)
- [Add a Registry Endpoint Attribute to a DAP](#)
- [Add a File Endpoint Attribute to a DAP](#)
- [Add Certificate Authentication Attributes to a DAP](#)

**Step 4** Click **Save**.

---

## Add an Anti-Malware Endpoint Attribute to a DAP

### Procedure

---

- Step 1** Edit a DAP record and select **Endpoint Criteria > Anti-Malware**.
- Step 2** Select the Match Criteria **All** or **Any**.
- Step 3** Click **Add** to add anti-malware attributes.
- Step 4** Click **Installed** to indicate whether the selected endpoint attribute and its accompanying qualifiers are installed or not installed.
- Step 5** Choose **Enabled** or **Disabled** to activate or deactivate real-time malware scanning.
- Step 6** Select the name of the anti-malware **Vendor** from the list.
- Step 7** Select the anti-malware **Product Description**.
- Step 8** Choose the **Version** of the anti-malware product.
- Step 9** Specify the number of days since the **Last Update**.
- You can indicate that an anti-malware update must occur in less than (<) or more than (>) the number of days you specify.
- Step 10** Click **Save**.
-

## Add a Device Endpoint Attribute to a DAP

### Procedure

- 
- Step 1** Edit a DAP record and choose **Endpoint Criteria > Device**.
- Step 2** Select the Match Criteria **All** or **Any**.
- Step 3** Click **Add** and select the = or ≠ operator to check the attribute to be equal to or not equal to the value you enter for the following attributes:
- **Host Name**—Hostname of the device you are testing for. Use the computer's host name only, not the fully qualified domain name (FQDN).
  - **MAC Address**—MAC address of the network interface card you are testing for. The address must be in the format xxxx.xxxx.xxxx where x is a hexadecimal character.
  - **BIOS Serial Number**—BIOS serial number value of the device you are testing for. The number format is manufacturer-specific.
  - **Port Number**—Listening port number of the device.
  - **Secure Desktop Version**—Version of the Host Scan image running on the endpoint.
  - **OPSWAT Version**—The OPSWAT client version.
  - **Privacy Protection**—None, Cache cleaner, Secure Desktop.
  - **TCP/UDP Port Number**—TCP or UDP port in the listening state that you are testing for.
- Step 4** Click **Save**.
- 

## Add Secure Client Endpoint Attributes to a DAP

### Procedure

- 
- Step 1** Edit a DAP record and select **Endpoint Criteria > Secure Client**.
- Step 2** Select the Match Criteria **All** or **Any**.
- Step 3** Click **Add** and select the = or ≠ operator to check the attribute to be equal to or not equal to the value you enter.
- Step 4** Select the **Client Version** and **Platform**.
- Step 5** Select the **Platform Version**, and specify the **Device Type** and **Device Unique ID**.
- Step 6** Add the **MAC Addresses** the MAC Address Pool.
- Note** The MAC Address must be in the format XX-XX-XX-XX-XX-XX, where each X is a hexadecimal character. You can click **Add another MAC Address** to add more addresses.

**Step 7** Click **Save**.

---

## Add NAC Endpoint Attributes to a DAP

### Procedure

---

- Step 1** Edit a DAP record and select **Endpoint Criteria > NAC**.
  - Step 2** Select the Match Criteria **All** or **Any**.
  - Step 3** Click **Add** to add NAC attributes.
  - Step 4** Set the operator to be equal to = or not equal to ≠ the posture token string. Enter the posture token string in the **Posture Status** box.
  - Step 5** Click **Save**.
- 

## Add an Application Attribute to a DAP

### Procedure

---

- Step 1** Edit a DAP record and select **Endpoint Criteria > Application**.
  - Step 2** Select the Match Criteria **All** or **Any**.
  - Step 3** Click **Add** to add application attributes.
  - Step 4** Choose equals ( = ) or does not equal ( ≠ ) and specify the **Client Type** to indicate the type of remote access connection.
  - Step 5** Click **Save**.
- 

## Add a Personal Firewall Endpoint Attribute to a DAP

### Procedure

---

- Step 1** Edit a DAP record and select **Endpoint Criteria > Personal Firewall**.
- Step 2** Select the Match Criteria **All** or **Any**.
- Step 3** Click **Add** to add personal firewall attributes.
- Step 4** Click **Installed** to indicate whether the personal firewall endpoint attribute and its accompanying qualifiers (fields below the Name/Operation/Value column) are installed or not installed.
- Step 5** Choose **Enabled** or **Disabled** to activate or deactivate firewall protection.
- Step 6** Select the name of the firewall **Vendor** from the list.
- Step 7** Select the firewall **Product Description**.
- Step 8** Select the equals ( = ) or does not equal ( ≠ ) operator and choose the **Version** of the personal firewall product.

**Step 9** Click **Save**.

---

## Add an Operating System Endpoint Attribute to a DAP

### Procedure

---

- Step 1** Edit a DAP record and select **Endpoint Criteria > Operating System** .
  - Step 2** Select the Match Criteria **All** or **Any**.
  - Step 3** Click **Add** to add endpoint attributes.
  - Step 4** Select the equals ( = ) or does not equal ( ≠ ) operator and then select the **Operating System**.
  - Step 5** Select the equals ( = ) or does not equal ( ≠ ) operator and then specify the operating system **Version**.
  - Step 6** Click **Save**.
- 

## Add a Process Endpoint Attribute to a DAP

### Procedure

---

- Step 1** Edit a DAP record and click the **Endpoint Criteria** tab.
  - Step 2** Click **Process**.
  - Step 3** Select the **Match Criteria** as **All** or **Any**.
  - Step 4** Click + to add the process attributes.
  - Step 5** Select **Exists** or **Does not exist**.
  - Step 6** Specify the **Process Name**.
  - Step 7** Click **Save**.
- 

## Add a Registry Endpoint Attribute to a DAP

Scanning for registry endpoint attributes applies to Windows operating systems only.

### Before you begin

Before configuring a Registry endpoint attribute, define the registry key for which you want to scan in the Host Scan window for Cisco Secure Desktop.

### Procedure

---

- Step 1** Edit a DAP record and click the **Endpoint Criteria** tab.
- Step 2** Click **Registry**.

- Step 3** Select the **Match Criteria** as **All** or **Any**.
  - Step 4** Click + to add registry attributes.
  - Step 5** Select the **Entry Path** for the registry and specify the path.
  - Step 6** Choose the existence of the registry, **Exists** or **Does not Exist**.
  - Step 7** Select the registry **Type** from the list.
  - Step 8** Select the equals ( = ) or does not equal ( ≠ ) operator and enter the **Value** of the registry key.
  - Step 9** Select **Case insensitive** to disregard the case of the registry entry while scanning.
  - Step 10** Click **Save**.
- 

## Add a File Endpoint Attribute to a DAP

### Procedure

- Step 1** Edit a DAP record and click the **Endpoint Criteria** tab.
  - Step 2** Click **File**.
  - Step 3** Select the Match Criteria **All** or **Any**.
  - Step 4** Click + to add file attributes.
  - Step 5** Specify the **File Path**.
  - Step 6** Choose **Exists** or **Does not exist** to indicate the presence of the file.
  - Step 7** Select less than (<) or greater than (>) and specify the **Last Modified** days for the file.
  - Step 8** Select the equal to ( = ) or not equal to ≠ operator and enter the **Checksum**.
  - Step 9** Click **Save**.
- 

## Add Certificate Authentication Attributes to a DAP

You can index each certificate to allow referencing to any of the received certificates, by the configured rules. Based on these certificate fields, you can configure DAP rules to allow or disallow connection attempts.

### Procedure

- Step 1** Edit a DAP record and select **Endpoint Criteria > Certificate**.
- Step 2** Select the Match Criteria **All** or **Any**.
- Step 3** Click **Add** to add certificate attributes.
- Step 4** Select the certificate **Cert1** or **Cert2**.
- Step 5** Select the **Subject** and specify the subject value.
- Step 6** Select the **Issuer** and specify the issuer value.
- Step 7** Select the **Subject Alternate Name** and specify the subject value.
- Step 8** Specify the **Serial Number**.

- Step 9** Choose the **Certificate Store**: None, Machine, or User.  
The VPN client sends the certificate store information.
- Step 10** Click **Save**.
- 

## Configure Advanced Settings for DAP

You can use the **Advanced** tab for adding selection criteria other than what is possible in the AAA and endpoint attribute areas. For example, while you can configure the threat defense to use AAA attributes that satisfy any, all, or none of the specified criteria, the endpoint attributes are cumulative, and must satisfy all. To let the security appliance employ one endpoint attribute or another, you must create appropriate logical expressions in Lua and enter them here.

### Procedure

---

- Step 1** Choose **Devices > Dynamic Access Policy**.
- Step 2** Edit a DAP policy and then edit a DAP record.
- Note** Create a DAP policy and DAP record if not done already.
- Step 3** Click the **Advanced** tab.
- Step 4** Select **AND** or **OR** as the match criteria to use in the DAP configuration.
- Step 5** Add the Lua script in the **Lua script for advanced attribute matching** field.
- Step 6** Click **Save**.
- 

## Associate Dynamic Access Policy with Remote Access VPN

You can associate Dynamic Access Policy (DAP) with remote access VPN policy for the dynamic access policy attributes to match during VPN session authentication and authorization. You can then deploy the remote access VPN on the threat defense.

### Procedure

---

- Step 1** Choose **Devices > Remote Access**.
- Step 2** Click **Edit** next to the remote access VPN policy to which you want to associate dynamic access policy.
- Step 3** Click the link in remote access VPN to select the dynamic access policy.
- Step 4** Select the policy from the **Dynamic Access Policy** drop-down or click **Create a new Dynamic Access Policy** to configure a new dynamic access policy.
- Step 5** Click **OK**.

**Step 6** Click **Save** to save the remote access VPN policy.

---

When the remote access VPN user tries to connect, the VPN checks the configured dynamic access policy records and attributes. VPN creates a dynamic access policy based on the matching dynamic access policy records and takes appropriate action on the VPN session.

## History for Dynamic Access Policy

Feature	Minimum Management Center	Minimum Threat Defense	Details
Dynamic Access Policy	7.0	Any	The feature was introduced.

## CHAPTER 61

# VPN Monitoring and Troubleshooting in Security Cloud Control

---

- [VPN Summary Dashboard, on page 1793](#)
- [Monitor Remote Access VPN Sessions, on page 1793](#)
- [SD-WAN Summary Dashboard, on page 1794](#)
- [System Messages, on page 1797](#)
- [Debug Commands, on page 1797](#)

## VPN Summary Dashboard

System dashboards provide you with at-a-glance views of current system status, including data about the events collected and generated by the system. You can use the VPN dashboard to see consolidated information about VPN users, including the current status of users, device types, client applications, user geolocation information, and duration of connections. You can view details of the configured VPN topologies such as VPN interfaces, tunnel status, and so on.

For all VPN topologies, you can edit or delete the topology using the edit and delete buttons. For SASE topology VPNs, you have options to deploy, edit and delete any topology.

## Monitor Remote Access VPN Sessions

The Security Cloud Control Remote Access Monitoring dashboard can be used to view consolidated information about RA VPN users, including the current status of users, device types, client applications, user geolocation information, and duration of connections. You can also disconnect RA VPN sessions as needed.

Perform the following to see the VPN sessions:

1. In the cloud-delivered Firewall Management Center page, click **Return Home**.
2. In the Security Cloud Control navigation pane, click **VPN > Remote Access VPN Monitoring**.

See [Monitor Remote Access Virtual Private Network Sessions](#) for more information.

# SD-WAN Summary Dashboard

The SD-WAN Summary dashboard (**Analysis > SD-WAN Summary**) provides a snapshot of your WAN devices and their interfaces. This dashboard helps you to:

- Identify issues with the underlay and overlay (VPN) topologies.
- Troubleshoot VPN issues using the existing **Health Monitoring**, **Device Management**, and **Site-to-Site Monitoring** pages.
- Monitor application performance metrics of WAN interfaces. The threat defense steers application traffic based on these metrics.

A WAN device must meet one of the following criteria:

- The device must be a VPN peer.
- The device must have WAN interface.

A WAN interface must meet one of the following criteria:

- The interface has IP address-based path monitoring enabled on it.
- The interface has a Policy Based Routing (PBR) policy with at least one application configured to monitor it.

For more information about PBR policy and path monitoring, see [Policy Based Routing, on page 1431](#).

Click **Uplink Decisions** to view the **VPN Troubleshooting** page. You can view syslogs with ID: 880001. These syslogs show the threat defense interfaces through which it steers traffic based on the configured PBR policy.

To view the above syslogs and to view the data on this dashboard, ensure that you review [Prerequisites for Using SD-WAN Summary Dashboard, on page 1794](#).

For clusters, this dashboard displays application performance metrics of only the control node and not the data nodes.

## Prerequisites for Using SD-WAN Summary Dashboard

- You must be an Admin, Security Analyst, or Maintenance user to view this dashboard. See [Secure Firewall Management Center and Cloud-delivered Firewall Management Center User Role Mapping](#) for more information.
- Threat defense devices must be Version 7.2 or later.
- Enable IP-based path monitoring and HTTP-based application monitoring on the WAN interfaces.
  1. Choose **Devices > Device Management**.
  2. Click the edit icon adjacent to the device that you want to edit.
  3. Click the edit icon adjacent to the interface that you want to edit.
  4. Click the **Path Monitoring** tab.

5. Check the **Enable IP based Monitoring** check box.
  6. Check the **Enable HTTP based Application Monitoring** check box.
  7. Click **OK**.
- Configure a PBR policy with at least one application configured to monitor it:
    1. Choose **Devices > Device Management**.
    2. Click the edit icon adjacent to the device that you want to edit.
    3. Click **Routing**.
    4. In the left pane, click **Policy Based Routing**.
    5. Click **Add**.
    6. From the **Ingress Interface** drop-down list, choose an interface.
    7. Click **Add** to configure a forwarding action.
    8. Configure the parameters.
    9. Click **Save**.
  - To view syslogs when you click **Uplink Decisions**, you must:
    - Choose **Devices > Platform Settings** and create or edit a threat defense policy.
    - In the left pane, click **Syslog**.
    - Click the **Logging Setup** tab.
    - Check the **Enable Logging** check box to turn on the data plane system logging for the threat defense device.
    - Click the **All Logs** radio button to enable logging of all the troubleshooting syslog messages.  
or  
Click the **VPN Logs** radio button to enable logging of only the VPN troubleshooting messages.
    - Click **Save**.

## Monitor WAN Devices and Interfaces Using the SD-WAN Summary Dashboard

The SD-WAN Summary dashboard has the following widgets :

- [WAN Connectivity, on page 1796](#)
- [VPN Topology, on page 1796](#)
- [Interface Throughput, on page 1796](#)
- [Device Inventory, on page 1796](#)
- [WAN Device Health, on page 1796](#)

### WAN Connectivity

This widget provides a summary of the WAN interfaces statuses. It shows the number of WAN interfaces that are in the **Online**, **Offline** or **No Data** states. Note that you cannot monitor subinterfaces using this widget.

Click **View All Interfaces** to view more details about the interfaces in the health monitor page.

If a WAN interface is in the **Offline** or **No Data** state, you can troubleshoot it from the health monitor page:

1. In the **Monitoring** pane, expand **Devices**.
2. Click the corresponding WAN device to view the device-specific health details.
3. Click the **Interface** tab to view the interface status and aggregate traffic statistics for a specific time.

Alternatively, you can click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.

### VPN Topology

This widget provides a summary of the site-to-site VPN tunnel statuses. It shows the number of **Active**, **Inactive**, and **No Active Data** VPN tunnels.

Click **View All Connections** to view the VPN tunnel details in the **Site-to-site VPN Monitoring** dashboard.

If the tunnels are in the **Inactive** or **No Active Data** state, you can troubleshoot using the **Site-to-site VPN Monitoring** dashboard. In the **Tunnel Status** widget, hover your cursor over a topology, click the View  icon and do one of the following:

- Click the **CLI Details** tab to view the details of the VPN tunnels.
- Click the **Packet Tracer** tab to use the packet tracer tool for the topology.

### Interface Throughput

This widget monitors the throughput utilization of the WAN interfaces.

The interface throughput is classified into four bands. These details aid in cost planning and resourcing. You can choose a time range for the widget data from the **Show Last** drop-down list. The range is from 15 minutes to two weeks.

Click **View Health Monitoring** to view more details about the interface in the health monitor page.

### Device Inventory

This widget lists all the managed WAN devices and groups them according to the model.

Click **View Device Management** to view more details about the device in the **Device Management** page.

### WAN Device Health

This widget displays the device count according to the health of the WAN devices. You can view the number of devices with errors, warnings, or those that are in **Disabled** state.

Click **View Health Monitoring** to view the alarms, and quickly identify, isolate, and resolve issues.

If the health of a device is affected, you can troubleshoot it from the health monitor page.

1. In the **Monitoring** pane, expand **Devices**.

2. Click the corresponding WAN device to view the device-specific health details.
3. Click **View System & Troubleshoot Details**. The health monitor page is displayed with all the necessary details.

A device can be in **Disabled** state for multiple reasons, including the following:

- Management interface is disabled.
- Device is powered off.
- Device is being upgraded.

## Monitor Application Performance Metrics of WAN Interfaces Using the SD-WAN Summary Dashboard

Under the **Application Monitoring** tab, you can select a WAN device and view the application performance metrics for the corresponding WAN interfaces. These metrics include Jitter, Round Trip Time (RTT), Mean Opinion Score (MOS), and Packet Loss.

By default, the metrics data is refreshed every 5 minutes. You can change the refresh time; the range is from 5 to 30 minutes. You can view the metrics in tabular and graphical formats. For each WAN interface, the latest metric value appears in the table. For graphical data, you can choose a time interval of up to 24 hours to view the metrics data for the corresponding WAN interfaces.

## System Messages

The Message Center is the place to start your troubleshooting. This feature allows you to view messages that are continually generated about system activities and status. To open the Message Center, click **System Status**, located to the immediate right of the **Deploy** button in the main menu.

## Debug Commands

This section explains how you use debug commands to help you diagnose and resolve VPN-related problems. The commands described here are not exhaustive, this section include commands according to their usefulness in assisting you to diagnose VPN-related problems.

### Usage Guidelines

Because debugging output is assigned high priority in the CPU process, it can render the system unusable. For this reason, use **debug** commands only to troubleshoot specific problems or during troubleshooting sessions with the Cisco Technical Assistance Center (TAC). Moreover, it is best to use **debug** commands during periods of lower network traffic and fewer users. Debugging during these periods decreases the likelihood that increased **debug** command processing overhead will affect system use.

You can view debug output in a CLI session only. Output is directly available when connected to the Console port, or when in the diagnostic CLI (enter **system support diagnostic-cli**). You can also view output from the regular Firepower Threat Defense CLI using the **show console-output** command.

To show debugging messages for a given feature, use the **debug** command. To disable the display of debug messages, use the **no** form of this command. Use **no debug all** to turn off all debugging commands.

**debug feature** [*subfeature*] [*level*]  
**no debug feature** [*subfeature*]

### Syntax Description

<i>feature</i>	Specifies the feature for which you want to enable debugging. To see the available features, use the <b>debug ?</b> command for CLI help.
<i>subfeature</i>	(Optional) Depending on the feature, you can enable debug messages for one or more subfeatures. Use ? to see the available subfeatures.
<i>level</i>	(Optional) Specifies the debugging level. Use ? to see the available levels.

### Command Default

The default debugging level is 1.

### Example

With multiple sessions running on remote access VPN, troubleshooting can be difficult, given the size of the logs. You can use the **debug webvpn condition** command to set up filters to target your debug process more precisely.

**debug webvpn condition** {**group name** | **p-ipaddress** *ip\_address* [{**subnet** *subnet\_mask* | **prefix length**}] | **reset** | **user name**}

Where:

- **group name** filters on a group policy (not a tunnel group or connection profile).
- **p-ipaddress** *ip\_address* [{**subnet** *subnet\_mask* | **prefix length**}] filters on the public IP address of the client. The subnet mask (for IPv4) or prefix (for IPv6) is optional.
- **reset** resets all filters. You can use the **no debug webvpn condition** command to turn off a specific filter.
- **user name** filters by username.

If you configure more than one condition, the conditions are conjoined (ANDed), so that debugs appear only if all conditions are met.

After setting up the condition filter, use the base **debug webvpn** command to turn on the debug. Setting the conditions alone does not enable the debug. Use the **show debug** and **show webvpn debug-condition** commands to view the current state of debugging.

The following shows an example of enabling a conditional debug on the user jdoe.

```
firepower# debug webvpn condition user jdoe

firepower# show webvpn debug-condition
INFO: Webvpn conditional debug is turned ON
INFO: User name filters:
INFO: jdoe

firepower# debug webvpn
INFO: debug webvpn  enabled at level 1.

firepower# show debug
debug webvpn  enabled at level 1
INFO: Webvpn conditional debug is turned ON
INFO: User name filters:
```

INFO: jdoe

Related Commands	Command	Description
	<b>show debug</b>	Shows the currently active debug settings.
	<b>undebug</b>	Disables debugging for a feature. This command is a synonym for <b>no debug</b> .

## debug aaa

See the following commands for debugging configurations or authentication, authorization, and accounting (AAA) settings.

**debug** *aaa* [*accounting* | *authentication* | *authorization* | *common* | *internal* | *shim* | *url-redirect*]

Syntax Description	aaa	Enables debugging for AAA. Use ? to see the available subfeatures.
	<i>accounting</i>	(Optional) Enables AAA accounting debugging.
	<i>authentication</i>	(Optional) Enables AAA authentication debugging.
	<i>authorization</i>	(Optional) Enables AAA authorization debugging.
	<i>common</i>	(Optional) Specifies the AAA common debug level. Use ? to see the available levels.
	<i>internal</i>	(Optional) Enables AAA internal debugging.
	<i>shim</i>	(Optional) Specifies the AAA shim debug level. Use ? to see the available levels.
	<i>url-redirect</i>	(Optional) Enables AAA url-redirect debugging.

**Command Default** The default debugging level is 1.

Related Commands	Command	Description
	<b>show debug aaa</b>	Shows the currently active debug settings for AAA.
	<b>undebug aaa</b>	Disables debugging for AAA. This command is a synonym for <b>no debug aaa</b> .

## debug crypto

See the following commands for debugging configurations or settings associated with crypto.

**debug** *crypto* [*ca* | *condition* | *engine* | *ike-common* | *ikev1* | *ikev2* | *ipsec* | *ss-apic*]

Syntax Description	<i>crypto</i>	Enables debugging for <i>crypto</i> . Use ? to see the available subfeatures.
--------------------	---------------	-------------------------------------------------------------------------------

<i>ca</i>	(Optional) Specifies the PKI debug levels. Use ? to see the available subfeatures.
<i>condition</i>	(Optional) Specifies the IPsec/ISAKMP debug filters. Use ? to see the available filters.
<i>engine</i>	(Optional) Specifies the crypto engine debug levels. Use ? to see the available levels.
<i>ike-common</i>	(Optional) Specifies the IKE common debug levels. Use ? to see the available levels.
<i>ikev1</i>	(Optional) Specifies the IKE version 1 debug levels. Use ? to see the available levels.
<i>ikev2</i>	(Optional) Specifies the IKE version 2 debug levels. Use ? to see the available levels.
<i>ipsec</i>	(Optional) Specifies the IPsec debug levels. Use ? to see the available levels.
<i>condition</i>	(Optional) Specifies the Crypto Secure Socket API debug levels. Use ? to see the available levels.
<i>vpnclient</i>	(Optional) Specifies the EasyVPN client debug levels. Use ? to see the available levels.

**Command Default**

The default debugging level is 1.

**Related Commands**

Command	Description
<b>show debug crypto</b>	Shows the currently active debug settings for crypto.
<b>undebug crypto</b>	Disables debugging for crypto. This command is a synonym for <b>no debug crypto</b> .

**debug crypto ca**

See the following commands for debugging configurations or settings associated with crypto ca.

**debug crypto ca** [*cluster* | *messages* | *periodic-authentication* | *scep-proxy* | *transactions* | *trustpool*] [1-255]

**Syntax Description**

<i>crypto ca</i>	Enables debugging for <i>crypto ca</i> . Use ? to see the available subfeatures.
<i>cluster</i>	(Optional) Specifies the PKI cluster debug level. Use ? to see the available levels.
<i>cmp</i>	(Optional) Specifies the CMP transactions debug level. Use ? to see the available levels.
<i>messages</i>	(Optional) Specifies the PKI Input/Output message debug level. Use ? to see the available levels.
<i>periodic-authentication</i>	(Optional) Specifies the PKI periodic-authentication debug level. Use ? to see the available levels.

<i>scep-proxy</i>	(Optional) Specifies the SCEP proxy debug level. Use ? to see the available levels.
<i>server</i>	(Optional) Specifies the local CA server debug level. Use ? to see the available levels.
<i>transactions</i>	(Optional) Specifies the PKI transaction debug level. Use ? to see the available levels.
<i>trustpool</i>	(Optional) Specifies the trustpool debug level. Use ? to see the available levels.
<i>1-255</i>	(Optional) Specifies the debugging level.

**Command Default**

The default debugging level is 1.

**Related Commands**

Command	Description
<b>show debug crypto ca</b>	Shows the currently active debug settings for crypto ca.
<b>undebug</b>	Disables debugging for crypto ca. This command is a synonym for <b>no debug crypto ca</b> .

**debug crypto ikev1**

See the following commands for debugging configurations or settings associated with Internet Key Exchange version 1 (IKEv1).

**debug** *crypto ikev1* [*timers*] [*1-255*]

**Syntax Description**

<i>ikev1</i>	Enables debugging for <i>ikev1</i> . Use ? to see the available subfeatures.
<i>timers</i>	(Optional) Enables debugging for IKEv1 timers.
<i>1-255</i>	(Optional) Specifies the debugging level.

**Command Default**

The default debugging level is 1.

**Related Commands**

Command	Description
<b>show debug crypto ikev1</b>	Shows the currently active debug settings for IKEv1.
<b>undebug crypto ikev1</b>	Disables debugging for IKEv1. This command is a synonym for <b>no debug crypto ikev1</b> .

**debug crypto ikev2**

See the following commands for debugging configurations or settings associated with Internet Key Exchange version 2 (IKEv2).

**debug** *crypto ikev2* [*ha* | *platform* | *protocol* | *timers*]

<b>Syntax Description</b>	<i>ikev2</i>	Enables debugging <i>ikev2</i> . Use ? to see the available subfeatures.
	<i>ha</i>	(Optional) Specifies the IKEv2 HA debug level. Use ? to see the available levels.
	<i>platform</i>	(Optional) Specifies the IKEv2 platform debug level. Use ? to see the available levels.
	<i>protocol</i>	(Optional) Specifies the IKEv2 protocol debug level. Use ? to see the available levels.
	<i>timers</i>	(Optional) Enables debugging for IKEv2 timers.

**Command Default** The default debugging level is 1.

<b>Related Commands</b>	<b>Command</b>	<b>Description</b>
	<b>show debug crypto ikev2</b>	Shows the currently active debug settings for IKEv2.
	<b>undebugcrypto ikev2</b>	Disables debugging for IKEv2. This command is a synonym for <b>no debug crypto ikev2</b> .

## debug crypto ipsec

See the following commands for debugging configurations or settings associated with IPsec.

**debug** *crypto ipsec* [1-255]

<b>Syntax Description</b>	<i>ipsec</i>	Enables debugging for <i>ipsec</i> . Use ? to see the available subfeatures.
	<i>1-255</i>	(Optional) Specifies the debugging level.

**Command Default** The default debugging level is 1.

<b>Related Commands</b>	<b>Command</b>	<b>Description</b>
	<b>show debug crypto ipsec</b>	Shows the currently active debug settings for IPsec.
	<b>undebugcrypto ipsec</b>	Disables debugging for IPsec. This command is a synonym for <b>no debug crypto ipsec</b> .

## debug ldap

See the following commands for debugging configurations or settings associated with LDAP (Lightweight Directory Access Protocol).

**debug** *ldap* [1-255]

<b>Syntax Description</b>	<i>ldap</i>	Enables debugging for LDAP. Use ? to see the available subfeatures.
---------------------------	-------------	---------------------------------------------------------------------

<i>1-255</i>	(Optional) Specifies the debugging level.
--------------	-------------------------------------------

**Command Default**

The default debugging level is 1.

**Related Commands**

Command	Description
<b>show debug ldap</b>	Shows the currently active debug settings for LDAP.
<b>undebugldap</b>	Disables debugging for LDAP. This command is a synonym for <b>no debug ldap</b> .

## debug ssl

See the following commands for debugging configurations or settings associated with SSL sessions.

**debug ssl** [*cipher* | *device*] [*1-255*]

**Syntax Description**

<i>ssl</i>	Enables debugging for SSL. Use ? to see the available subfeatures.
<i>cipher</i>	(Optional) Specifies the SSL cipher debug level. Use ? to see the available levels.
<i>device</i>	(Optional) Specifies the SSL device debug level. Use ? to see the available levels.
<i>1-255</i>	(Optional) Specifies the debugging level.

**Command Default**

The default debugging level is 1.

**Related Commands**

Command	Description
<b>show debug ssl</b>	Shows the currently active debug settings for SSL.
<b>undebug ssl</b>	Disables debugging for SSL. This command is a synonym for <b>no debug ssl</b> .

## debug webvpn

See the following commands for debugging configurations or settings associated with WebVPN.

**debug webvpn** [*anyconnect* | *chunk* | *cifs* | *citrix* | *compression* | *condition* | *cstp-auth* | *customization* | *failover* | *html* | *javascript* | *kcd* | *listener* | *mus* | *nfs* | *request* | *response* | *saml* | *session* | *task* | *transformation* | *url* | *util* | *xml*]

**Syntax Description**

<i>webvpn</i>	Enables debugging for WebVPN. Use ? to see the available subfeatures.
<i>anyconnect</i>	(Optional) Specifies the WebVPN Secure Client debug level. Use ? to see the available levels.
<i>chunk</i>	(Optional) Specifies the WebVPN chunk debug level. Use ? to see the available levels.

<i>cifs</i>	(Optional) Specifies the WebVPN CIFS debug level. Use ? to see the available levels.
<i>citrix</i>	(Optional) Specifies the WebVPN Citrix debug level. Use ? to see the available levels.
<i>compression</i>	(Optional) Specifies the WebVPN compression debug level. Use ? to see the available levels.
<i>condition</i>	(Optional) Specifies the WebVPN filter conditions debug level. Use ? to see the available levels.
<i>cstp-auth</i>	(Optional) Specifies the WebVPN CSTP authentication debug level. Use ? to see the available levels.
<i>customization</i>	(Optional) Specifies the WebVPN customization debug level. Use ? to see the available levels.
<i>failover</i>	(Optional) Specifies the WebVPN failover debug level. Use ? to see the available levels.
<i>html</i>	(Optional) Specifies the WebVPN HTML debug level. Use ? to see the available levels.
<i>javascript</i>	(Optional) Specifies the WebVPN Javascript debug level. Use ? to see the available levels.
<i>kcd</i>	(Optional) Specifies the WebVPN KCD debug level. Use ? to see the available levels.
<i>listener</i>	(Optional) Specifies the WebVPN listener debug level. Use ? to see the available levels.
<i>mus</i>	(Optional) Specifies the WebVPN MUS debug level. Use ? to see the available levels.
<i>nfs</i>	(Optional) Specifies the WebVPN NFS debug level. Use ? to see the available levels.
<i>request</i>	(Optional) Specifies the WebVPN request debug level. Use ? to see the available levels.
<i>response</i>	(Optional) Specifies the WebVPN response debug level. Use ? to see the available levels.
<i>saml</i>	(Optional) Specifies the WebVPN SAML debug level. Use ? to see the available levels.
<i>session</i>	(Optional) Specifies the WebVPN session debug level. Use ? to see the available levels.
<i>task</i>	(Optional) Specifies the WebVPN task debug level. Use ? to see the available levels.

<i>transformation</i>	(Optional) Specifies the WebVPN transformation debug level. Use ? to see the available levels.
<i>url</i>	(Optional) Specifies the WebVPN URL debug level. Use ? to see the available levels.
<i>util</i>	(Optional) Specifies the WebVPN utility debug level. Use ? to see the available levels.
<i>xml</i>	(Optional) Specifies the WebVPN XML debug level. Use ? to see the available levels.

**Command Default**

The default debugging level is 1.

**Related Commands**

<b>Command</b>	<b>Description</b>
<b>show debug webvpn</b>	Shows the currently active debug settings for WebVPN.
<b>undebug webvpn</b>	Disables debugging for WebVPN. This command is a synonym for <b>no debug webvpn</b> .

- [Best Practices for Access Control Rules, on page 1823](#)

## Introduction to Access Control

Access control is a hierarchical policy-based feature that allows you to specify, inspect, and log (non-fast-pathed) network traffic.

Each managed device can be targeted by one access control policy. The data that the policy's *target devices* collect about your network traffic can be used to filter and control that traffic based on:

- simple, easily determined transport and network layer characteristics: source and destination, port, protocol, and so on
- the latest contextual information on the traffic, including characteristics such as reputation, risk, business relevance, application used, or URL visited
- realm, user, user group, or ISE attribute
- custom Security Group Tag (SGT)
- characteristics of encrypted traffic; you can also decrypt this traffic for further analysis
- whether unencrypted or decrypted traffic contains a prohibited file, detected malware, or intrusion attempt
- time and day (on supported devices)

Each type of traffic inspection and control occurs where it makes the most sense for maximum flexibility and performance. For example, reputation-based blocking uses simple source and destination data, so it can block prohibited traffic early in the process. In contrast, detecting and blocking intrusions and exploits is a last-line defense.

# Introduction to Rules

Rules in various policy types (access control, SSL, identity, and so on) exert granular control over network traffic. The system evaluates traffic against rules in the order that you specify, using a first-match algorithm.

Although these rules might include other configurations that are not consistent across policies, they share many basic characteristics and configuration mechanics, including:

- **Conditions:** Rule conditions specify the traffic that each rule handles. You can configure each rule with multiple conditions. Traffic must match all conditions to match the rule.
- **Action:** A rule's action determines how the system handles matching traffic. Note that even if a rule does not have an **Action** list you can choose from, the rule still has an associated action. For example, a custom network analysis rule uses a network analysis policy as its "action." As another example, QoS rules do not have an explicit action because all QoS rules do the same thing: rate limit traffic.
- **Position:** A rule's position determines its evaluation order. When using a policy to evaluate traffic, the system matches traffic to rules in the order you specify. Usually, the system handles traffic according to the first rule where all the rule's conditions match the traffic. (Monitor rules, which are designed to track and log, are an exception.) Proper rule order reduces the resources required to process network traffic, and prevents rule preemption.
- **Category:** To organize some rule types, you can create custom rule categories in each parent policy.
- **Logging:** For many rules, logging settings govern whether and how the system logs connections handled by the rule. Some rules (such as identity and network analysis rules) do not include logging settings because the rules neither determine the final disposition of connections, nor are they specifically designed to log connections. As another example, QoS rules do not include logging settings; you cannot log a connection simply because it was rate limited.
- **Comments:** For some rule types, each time you save changes, you can add comments. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change.

---

**Tip** A right-click menu in many policy editors provides shortcuts to many rule management options, including editing, deleting, moving, enabling, and disabling.

---

For more information, see the chapter that discusses the rules you're interested in (for example, access control rules).

## Related Topics

- [Configuring Application Conditions and Filters](#), on page 1869
- [Best Practices for Application Control](#), on page 1818

## Filtering Rules by Device

Some policy editors allow you to filter your rule view by affected devices.

The system uses a rule's interface constraints to determine if the rule affects a device. If you constrain a rule by interface (security zone or interface group condition), the device where that interface is located is affected by that rule. Rules with no interface constraint apply to any interface, and therefore every device.

QoS rules are always constrained by interface.

**Note** The following procedure does not apply to the access control policy. To see the rules that apply to a specific device or set of devices in the access control policy, click the filter icon and select the devices.

## Procedure

- 
- Step 1** In the policy editor, click **Rules**, then click **Filter by Device**.  
A list of targeted devices and device groups appears.
- Step 2** Check one or more check boxes to display only the rules that apply to those devices or groups. Or, check **All** to reset and display all of the rules.
- Tip** Hover your pointer over a rule criterion to see its value. If the criterion represents an object with device-specific overrides, the system displays the override value when you filter the rules list by only that device. If the criterion represents an object with domain-specific overrides, the system displays the override value when you filter the rules list by devices in that domain.
- Step 3** Click **OK**.
- 

## Rule and Other Policy Warnings

Policy and rule editors use icons to mark configurations that could adversely affect traffic analysis and flow. Depending on the issue, the system may warn you when you deploy or prevent you from deploying entirely.

**Tip** Hover your pointer over an icon to read the warning, error, or informational text.

**Table 110: Policy Error Icons**

Icon	Description	Example
Errors (✖)	If a rule or configuration has an error, you cannot deploy until you correct the issue, even if you disable any affected rules.	A rule that performs category and reputation-based URL filtering is valid until you target a device that does not have a URL Filtering license. At that point, an error icon appears next to the rule, and you cannot deploy until you edit or delete the rule, retarget the policy, or enable the license.

Icon	Description	Example
<b>Warning</b> 	You can deploy a policy that displays rule or other warnings. However, misconfigurations marked with warnings have no effect.  If you disable a rule with a warning, the warning icon disappears. It reappears if you enable the rule without correcting the underlying issue.	Preempted rules or rules that cannot match traffic due to misconfiguration have no effect. This includes conditions using empty object groups, application filters that match no applications, excluded LDAP users, invalid ports, and so on.  However, if a warning icon marks a licensing error or model mismatch, you cannot deploy until you correct the issue.
<b>Information</b> 	Information icons convey helpful information about configurations that may affect the flow of traffic. These issues do not prevent you from deploying.	The system might skip matching the first few packets of a connection against some rules, until the system identifies the application or web traffic in that connection. This allows connections to be established so that applications and HTTP requests can be identified.
<b>Rule Conflict</b> 	When you enable rule conflict analysis, this icon appears in the rule table for rules that have conflicts.	Conflicts include redundant rules, redundant objects, and shadowed rules. Redundant and shadowed rules do not match traffic because previous rules would already match the criteria. Redundant objects make your rules unnecessarily complex.

## Access Control Policy Default Action

A newly created access control policy directs its target devices to handle all traffic using its *default action*.

In a simple access control policy, the default action specifies how target devices handle all traffic. In a more complex policy, the default action handles traffic that:

- is not trusted by Intelligent Application Bypass
- is not on a Security Intelligence Block list
- is not blocked by SSL inspection (encrypted traffic only)
- matches none of the rules in the policy (except Monitor rules, which match and log—but do not handle or inspect—traffic)

The access control policy default action can block or trust traffic without further inspection, or inspect traffic for intrusions and discovery data.

**Note** You **cannot** perform file or malware inspection on traffic handled by the default action. Logging for connections handled by the default action is initially disabled, though you can enable it.

If you are using policy inheritance, the default action for the lowest-level descendant determines final traffic handling. Although an access control policy can inherit its default action from its base policy, you cannot enforce this inheritance.

The following table describes the types of inspection you can perform on traffic handled by each default action.

**Table 111: Access Control Policy Default Actions**

Default Action	Effect on Traffic	Inspection Type and Policy
Access Control: Block All Traffic	block without further inspection	none
Access Control: Trust All Traffic	trust (allow to its final destination without further inspection)	none
Intrusion Prevention	allow, as long as it is passed by the intrusion policy you specify	intrusion, using the specified intrusion policy and associated variable set, and discovery, using the network discovery policy
Network Discovery Only	allow	discovery only, using the network discovery policy
Inherit from base policy	defined in base policy	defined in base policy

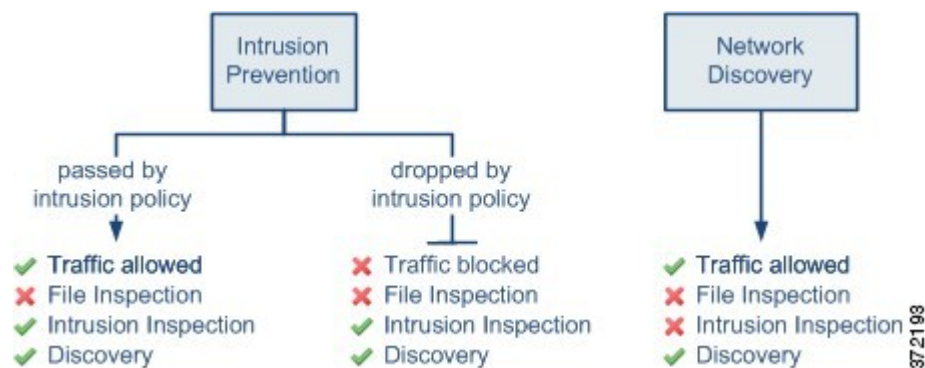

The following diagram illustrates the table.

The following diagrams illustrate the **Block All Traffic** and **Trust All Traffic** default actions.

The following diagrams illustrate the **Intrusion Prevention** and **Network Discovery Only** default actions.

372193

**Tip** The purpose of **Network Discovery Only** is to improve performance in a discovery-only deployment. Different configurations can disable discovery if you are only interested in intrusion detection and prevention.

## Deep Inspection Using File and Intrusion Policies

Deep inspection uses intrusion and file policies as the last line of defense before traffic is allowed to its destination.

- *Intrusion policies* govern the system's intrusion prevention capabilities.

For complete information, see [Intrusion Detection and Prevention, on page 2043](#).

- *File policies* govern the system's file control and malware defense capabilities.

For complete information, see [Network Malware Protection and File Policies, on page 2265](#).

Access control occurs before deep inspection; access control rules and the access control default action determine which traffic is inspected by intrusion and file policies.

By associating an intrusion or file policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy, a file policy, or both.

In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique **pair** of intrusion policy and variable set counts as one policy.

To associate intrusion and file policies with an access control rule, see:

- [Access Control Rule Configuration to Perform Intrusion Prevention, on page 2066](#)
- [Configuring an Access Control Rule to Perform Malware Protection, on page 2273](#)

**Note** By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

[File Policies](#), on page 2266

## Access Control Traffic Handling with Intrusion and File Policies

The following diagram shows the flow of traffic in an inline intrusion prevention and malware defense deployment, as governed by an access control policy that contains four different types of access control rules and a default action.

In the scenario above, the first three access control rules in the policy—Monitor, Trust, and Block—cannot inspect matching traffic. Monitor rules track and log but do not inspect network traffic, so the system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important exception and caveat at [Access Control Rule Monitor Action, on page 1858](#).) Trust and Block rules handle matching traffic without further inspection of any kind, while traffic that does not match continues to the next access control rule.

The fourth and final rule in the policy, an Allow rule, invokes various other policies to inspect and handle matching traffic, in the following order:

- **Discovery: Network Discovery Policy**—First, the network discovery policy inspects traffic for discovery data. Discovery is passive analysis and does not affect the flow of traffic. Although you do not explicitly enable discovery, you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy.
- **malware defense and File Control: File Policy**—After traffic is inspected by discovery, the system can inspect it for prohibited files and malware. malware defense detects and optionally blocks malware in many types of files, including PDFs, Microsoft Office documents, and others. If your organization wants to block not only the transmission of malware files, but all files of a specific type (regardless of whether the files contain malware), *file control* allows you to monitor network traffic for transmissions of specific file types, then either block or allow the file.
- **Intrusion Prevention: Intrusion Policy**—After file inspection, the system can inspect traffic for intrusions and exploits. An intrusion policy examines decoded packets for attacks based on patterns, and can block or alter malicious traffic. Intrusion policies are paired with *variable sets*, which allow you to use named values to accurately reflect your network environment.

- **Destination**—Traffic that passes all the checks described above passes to its destination.

An Interactive Block rule (not shown in the diagram) has the same inspection options as an Allow rule. This is so you can inspect traffic for malicious content when a user bypasses a blocked website by clicking through a warning page.

Traffic that does not match any access control rules in the policy with an action other than Monitor is handled by the default action. In this scenario, the default action is an Intrusion Prevention action, which allows traffic to its final destination as long as it is passed by the intrusion policy you specify. In a different deployment, you might have a default action that trusts or blocks all traffic without further inspection. Note that the system can inspect traffic allowed by the default action for discovery data and intrusions, but not prohibited files or malware. You **cannot** associate a file policy with the access control default action.

---

**Note** Sometimes, when a connection is analyzed by an access control policy, the system must process the first few packets in that connection, **allowing them to pass**, before it can decide which access control rule (if any) will handle the traffic. However, so these packets do not reach their destination uninspected, you can specify an intrusion policy (in the Advanced settings for the access control policy) to inspect these packets and generate intrusion events.

---

## File and Intrusion Inspection Order

In your access control policy, you can associate multiple Allow and Interactive Block rules with different intrusion and file policies to match inspection profiles to various types of traffic.

---

**Note** Traffic allowed by an Intrusion Prevention or Network Discovery Only default action can be inspected for discovery data and intrusions, but cannot be inspected for prohibited files or malware. You **cannot** associate a file policy with the access control default action.

---

You do not have to perform both file and intrusion inspection in the same rule. For a connection matching an Allow or Interactive Block rule:

- without a file policy, traffic flow is determined by the intrusion policy
- without an intrusion policy, traffic flow is determined by the file policy
- without either, allowed traffic is inspected by network discovery only

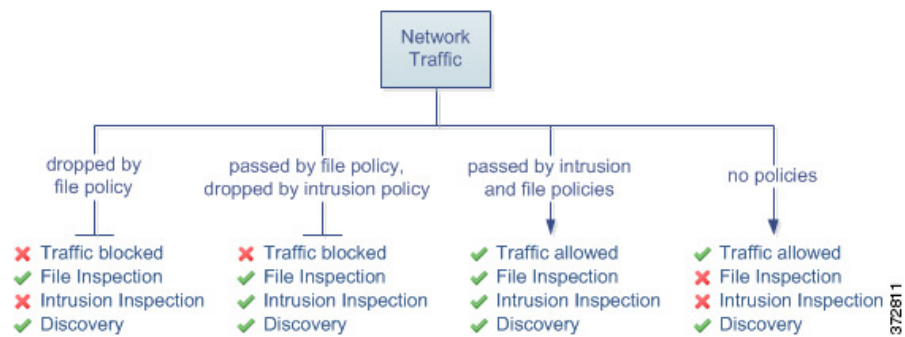

---

**Tip** The system does not perform any kind of inspection on trusted traffic. Although configuring an Allow rule with neither an intrusion nor file policy passes traffic like a Trust rule, Allow rules let you perform discovery on matching traffic.

---

The diagram below illustrates the types of inspection you can perform on traffic that meets the conditions of either an Allow or user-bypassed Interactive Block access control rule. For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with a single access control rule.

For any single connection handled by an access control rule, file inspection occurs before intrusion inspection. That is, the system does not inspect files blocked by a file policy for intrusions. Within file inspection, simple blocking by type takes precedence over malware inspection and blocking.

For example, consider a scenario where you normally want to allow certain network traffic as defined in an access control rule. However, as a precaution, you want to block the download of executable files, examine downloaded PDFs for malware and block any instances you find, and perform intrusion inspection on the traffic.

You create an access control policy with a rule that matches the characteristics of the traffic you want to provisionally allow, and associate it with both an intrusion policy and a file policy. The file policy blocks the download of all executables, and also inspects and blocks PDFs containing malware:

- First, the system blocks the download of all executables, based on simple type matching specified in the file policy. Because they are immediately blocked, these files are subject to neither malware nor intrusion inspection.
- Next, the system performs malware cloud lookups for PDFs downloaded to a host on your network. Any PDFs with a malware disposition are blocked, and are not subject to intrusion inspection.
- Finally, the system uses the intrusion policy associated with the access control rule to inspect any remaining traffic, including files not blocked by the file policy.

**Note** Until a file is detected and blocked in a session, packets from the session may be subject to intrusion inspection.

## Access Control Policy Inheritance

You can nest access control policies, where each policy inherits the rules and settings from an ancestor (or *base*) policy. You can enforce this inheritance, or allow lower-level policies to override their ancestors.

Access control uses a hierarchical policy-based implementation. Just as you create a domain hierarchy, you can create a corresponding hierarchy of access control policies. A *descendant*, or *child*, access control policy inherits rules and settings from its direct *parent*, or *base*, policy. That base policy may have its own parent policy from which it inherits rules and settings, and so on.

An access control policy's rules are nested between its parent policy's Mandatory and Default rule sections. This implementation enforces Mandatory rules from ancestor policies, but allows the current policy to write rules that preempt Default rules from ancestor policies.

You can lock the following settings to enforce them in all descendant policies. Descendant policies can override unlocked settings.

- Security Intelligence — connections that are allowed or blocked based on the latest reputation intelligence for IP addresses, URLs, and domain names.
- HTTP Response pages — Displaying a custom or system-provided response page when you block a user's website request.
- Advanced settings — Specifying associated subpolicies, network analysis settings, performance settings, and other general options.

When using policy inheritance, the default action for the lowest-level descendant determines final traffic handling. Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.

## Best Practices for Application Control

The following topics discuss our recommended best practices for controlling applications with access control rules.

### Recommendations for Application Control

Keep in mind the following guidelines and limitations for application control:

#### Ensuring that Adaptive Profiling is Enabled

If adaptive profiling is not enabled (its default state), access control rules cannot perform application control.

#### Automatically Enabling Application Detectors

If no detector is enabled for an application you want to detect, the system automatically enables all system-provided detectors for the application. If none exist, the system enables the most recently modified user-defined detector for the application.

#### Configure Your Policy to Examine the Packets That Must Pass Before an Application Is Identified

The system cannot perform application control, including Intelligent Application Bypass (IAB) and rate limiting, before *both* of the following occur:

- A monitored connection is established between a client and server
- The system identifies the application in the session

This identification should occur in 3 to 5 packets, or after the server certificate exchange in the SSL handshake if the traffic is encrypted.

**Important!** To ensure that your system examines these initial packets, see [Specify a Policy to Handle Packets That Pass Before Traffic Identification, on page 2750](#).

If early traffic matches all other criteria but application identification is incomplete, the system allows the packet to pass and the connection to be established (or the SSL handshake to complete). After the system completes its identification, the system applies the appropriate action to the remaining session traffic.

**Note** A server must adhere to the protocol requirements of an application for the system to be able to recognize it. For example, if you have a server that sends a keep-alive packet rather than an ACK when an ACK is expected, that application might not be identified, and the connection will not match the application-based rule. Instead, it will be handled by another matching rule or the default action. This might mean that connections you want to allow can be denied instead. If you run into this problem, and you cannot fix the server to follow the protocol standards, you need to write a non-application-based rule to cover traffic for that server, for example, by matching the IP address and port number.

### Create Separate Rules for URL and Application Filtering

Create separate rules for URL and application filtering whenever possible, because combining application and URL criteria can lead to unexpected results, especially for encrypted traffic.

Rules that include both application and URL criteria should come after application-only or URL-only rules, unless the application+URL rule is acting as an exception to a more general application-only or URL-only rule.

### URL Rules Before Application and Other Rules

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.

### Application Control for Encrypted and Decrypted Traffic

The system can identify and filter encrypted and decrypted traffic:

- Encrypted traffic—The system can detect application traffic encrypted with StartTLS, including SMTPS, POPS, FTPS, TelnetS, and IMAPS. In addition, it can identify certain encrypted applications based on the Server Name Indication in the TLS ClientHello message, or the subject distinguished name value from the server certificate. These applications are tagged `SSL Protocol`; in an SSL rule, you can choose only these applications. Applications without this tag can only be detected in unencrypted or decrypted traffic.
- Decrypted traffic—The system assigns the `decrypted traffic` tag to applications that the system can detect in decrypted traffic only, not encrypted or unencrypted.

### TLS Server Identity Discovery and Application Control

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by [RFC 8446](#), is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate *without* decrypting the entire packet.

We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. A decryption policy is not required because *traffic is not decrypted* in the process of extracting the server certificate.

For more information, see [Access Control Policy Advanced Settings, on page 1840](#).

### Exempting Applications from Active Authorization

In an identity policy, you can exempt certain applications from active authentication, allowing traffic to continue to access control. These applications are tagged `User-Agent Exclusion`. In an identity rule, you can choose only these applications.

### Handling Application Traffic Packets Without Payloads

When performing access control, the system applies the default policy action to packets that do not have a payload in a connection where an application is identified.

### Handling Referred Application Traffic

To handle traffic referred by a web server, such as advertisement traffic, match the referred application rather than the referring application.

### Controlling Application Traffic That Uses Multiple Protocols (Skype, Zoho)

Some applications use multiple protocols. To control their traffic, make sure your access control policy covers all relevant options. For example:

- Skype—To control Skype traffic, choose the **Skype** tag from the **Application Filters** list rather than selecting individual applications. This ensures that the system can detect and control all Skype traffic the same way.
- Zoho—To control Zoho mail, choose *both* **Zoho** and **Zoho mail** from the Available Application list.

### Search Engines Supported for Content Restriction Features

The system supports Safe Search filtering for specific search engines only. The system assigns the `safesearch supported` tag to application traffic from these search engines.

### Controlling Evasive Application Traffic

See [Application-Specific Notes and Limitations, on page 1822](#).

## Best Practices for Configuring Application Control

We recommend controlling applications' access to the network as follows:

- To allow or block application access from a less secure network to a more secure network: Use **Port** (Selected Destination Port) conditions on the access control rule  
For example, allow ICMP traffic from the internet (less secure) to an internal network (more secure.)
- To allow or block applications being accessed by user groups: Use **Application** conditions on the access control rule  
For example, block Facebook from being accessed by members of the Contractors group

**Caution** Failure to set up your access control rules properly can have unexpected results, including traffic being allowed that should be blocked. In general, application control rules should be lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example.

Access control rules that use *specific* conditions (such as networks and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this [Wikipedia article](#).

The following table provides an example of how to set up your access control rules:

Type of control	Action	Zones, Networks, VLAN Tags	Users	Applications	Ports	URLs	SGT/ISE Attributes	Inspection, Logging, Comments
Application from more secure to less secure network when application uses a port (for example, SSH)	Your choice ( <b>Allow</b> in this example)	Destination zones or networks using the outside interface	Any	Do not set	Available Ports : <b>SSH</b>  Add to <b>Selected Destination Ports</b>	Any	Use only with ISE/ISE-PIC.	Any
Application from more secure to less secure network when application does not use a port (for example, ICMP)	Your choice ( <b>Allow</b> in this example)	Destination zones or networks using the outside interface	Any	Do not set	Selected Destination Ports <b>Protocol: ICMP</b> <b>Type: Any</b>	Do not set	Use only with ISE/ISE-PIC.	Any
Application access by a user group	Your choice ( <b>Block</b> in this example)	Your choice	Choose a user group (Contractors group in this example)	Choose the name of the application ( <b>Facebook</b> in this example)	Do not set	Do not set	Use only with ISE/ISE-PIC.	Your choice

## Application Characteristics

The system characterizes each application that it detects using the criteria described in the following table. Use these characteristics as application filters.

Table 112: Application Characteristics

Characteristic	Description	Example
Type	Application protocols represent communications between hosts.  Clients represent software running on a host.  Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols.  Web browsers and email clients are clients.  MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged high bandwidth and displays ads.

## Application-Specific Notes and Limitations

- Office 365 Admin Portal:

Limitation: If the access policy has logging enabled at the beginning as well as at the end, the first packet will be detected as Office 365 and the end of connection will be detected as Office 365 Admin Portal. This should not affect blocking.

- Skype:

See [Recommendations for Application Control, on page 1818](#)

- GoToMeeting

In order to fully detect GoToMeeting, your rule must include all of the following applications:

- GoToMeeting
- Citrix Online
- Citrix GoToMeeting Platform
- LogMeIn
- STUN

- Zoho:  
See [Recommendations for Application Control, on page 1818](#)
- Evasive applications such as Bittorrent, Tor, Psiphon, and Ultrasurf:  
For evasive applications, only the highest-confidence scenarios are detected by default. If you need to take action on this traffic (such as block or implement QoS), it may be necessary to configure more aggressive detection with better effectiveness. To do this, contact TAC to review your configurations as these changes may result in false positives.
- WeChat:  
It is not possible to selectively block WeChat Media if you allow WeChat.
- RDP (Remote Desktop Protocol):  
If allowing the RDP application does not allow file transfers, ensure that the rule for RDP includes both the TCP and UDP port 3389. RDP file transfer uses UDP.

## Best Practices for Access Control Rules

Properly configuring and ordering rules is essential to building an effective deployment. The following topics summarize rule performance guidelines.

---

**Note** When you deploy configuration changes, the system evaluates all rules together and creates an expanded set of criteria that target devices use to evaluate network traffic. If these criteria exceed the resources (physical memory, processors, and so on) of a target device, you cannot deploy to that device.

---

## General Best Practices for Access Control

Review the following requirements and general best practices:

- Use a prefilter policy to provide early blocking for unwanted traffic, and to fastpath traffic that does not benefit from access control inspection. For more information, see [Best Practices for Fastpath Prefiltering, on page 1980](#).
- Although you can configure the system without licensing your deployment, many features require that you enable the appropriate licenses before you deploy.
- Access control rules are deployed as access control lists on the device. To minimize the number of access control entries created per access control rule, and improve overall performance, enable object group search for each device. Object group search is a device setting, not an access control policy setting, so you must edit each device to ensure the feature is enabled. For more information, see [Configure Object Group Search, on page 193](#).
- When you deploy an access control policy, its rules are not applied to existing connections. Traffic on an existing connection is not bound by the new policy that is deployed. In addition, the policy hit count is incremented only for the first packet of a connection that matches a policy. Thus, the traffic on an existing connection that could match a policy is omitted from the hit count. To have the policy rules effectively applied, clear the existing connections sessions, and then deploy the policy.

- Whenever possible, combine multiple network objects into a single object group. The system automatically creates an object group (during deployment) when you select more than one object (for source or destination separately). Selecting existing groups can avoid object group duplication and reduce the potential impact on CPU usage when there are a large number of duplicate objects.
- For the system to affect traffic, you must deploy relevant configurations to managed devices using routed, switched, or transparent interfaces, or inline interface pairs.

Sometimes, the system prevents you from deploying inline configurations to passively deployed devices, including inline devices in tap mode.

In other cases, the policy may deploy successfully, but attempting to block or alter traffic using passively deployed devices can have unexpected results. For example, the system may report multiple beginning-of-connection events for each blocked connection, because blocked connections are not blocked in passive deployments.

- Certain features, including URL filtering, application detection, rate limiting, and Intelligent Application Bypass, must allow some packets to pass in order for the system to identify the traffic.

To prevent these packets from reaching their destination uninspected, see [Best Practices for Handling Packets That Pass Before Traffic Identification, on page 2750](#) and [Specify a Policy to Handle Packets That Pass Before Traffic Identification, on page 2750](#).

- You cannot perform file or malware inspection on traffic handled by the access control policy's default action.
- Some features are only available on certain device models. Warning icons and confirmation dialog boxes designate unsupported features.
- If you will use syslog or store events externally, avoid special characters in object names such as policy and rule names. Object names should not contain special characters, such as commas, that the receiving application may use as separators.
- Logging for connections handled by the default action is initially disabled, though you can enable it.
- Best practices for creating, ordering, and implementing access control rules are detailed in [Best Practices for Access Control Rules, on page 1823](#) and subtopics.

## Best Practices for Ordering Rules

General guidelines:

- In general, place top-priority rules that must apply to all traffic near the top of the policy.
- Specific rules should come before general rules, especially when the specific rules are exceptions to general rules.  
Otherwise, traffic will match the general rule first and never hit the applicable specific rule.
- Rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number) should come as early as possible. Rules based on these criteria do not require inspection to identify matching connections.
- Whenever possible, put specific drop rules near the top of the policy. This ensures the earliest possible decision on undesirable traffic.

- URL filtering, application-based, and geolocation-based rules and others that require inspection should come after rules that drop traffic based on layer-3/4 criteria only (such as IP address, security zone, and port number), but before rules that specify file and intrusion policies.
- Put URL filtering rules above application rules, and follow application rules with micro-application rules and Common Industrial Protocol (CIP) sub-classification application filtering rules.
- Rules that specify file policies and intrusion policies should come at the bottom of the rule order. These rules require resource-intensive deep inspection, and you should eliminate as many threats as possible using less-intensive methods first, for performance reasons, in order to minimize the number of potential threats that require deep inspection.
- Always order rules to suit your organization's needs.

Exceptions and additions to the above guidelines are noted in the sections below.

## Rule Preemption

Rule preemption occurs when a rule will never match traffic because a rule earlier in the evaluation order matches the traffic first. A rule's conditions govern whether it preempts other rules. In the following example, the second rule cannot block Admin traffic because the first rule allows it:

Access Control Rule 1: allow Admin users

Access Control Rule 2: block Admin users

Any type of rule condition can preempt a subsequent rule. The VLAN range in the first SSL rule includes the VLAN in the second rule, so the first rule preempts the second:

SSL Rule 1: do not decrypt VLAN 22-33

SSL Rule 2: block VLAN 27

In the following example, Rule 1 matches any VLAN because no VLANs are configured, so Rule 1 preempts Rule 2, which attempts to match VLAN 2:

Access Control Rule 1: allow Source Network 10.4.0.0/16

Access Control Rule 2: allow Source Network 10.4.0.0/16, VLAN 2

A rule also preempts an identical subsequent rule where all configured conditions are the same:

QoS Rule 1: rate limit VLAN 1 URL www.netflix.com

QoS Rule 2: rate limit VLAN 1 URL www.netflix.com

A subsequent rule would not be preempted if any condition is different:

QoS Rule 1: rate limit VLAN 1 URL www.netflix.com

QoS Rule 2: rate limit VLAN 2 URL www.netflix.com

### Example: Ordering SSL Rules to Avoid Preemption

Consider a scenario where a trusted CA (Good CA) mistakenly issued a CA certificate to a malicious entity (Bad CA), but has not yet revoked that certificate. You want to use an SSL policy to block traffic encrypted with certificates issued by the untrusted CA, but otherwise allow traffic within the trusted CA's chain of trust. After you upload the CA certificates and all intermediate CA certificates, configure an SSL policy with rules in the following order:

SSL Rule 1: Block issuer CN=www.badca.com

SSL Rule 2: Do not decrypt issuer CN=www.goodca.com

If you reverse the rules, you first match all traffic trusted by Good CA, including traffic trusted by Bad CA. Because no traffic ever matches the subsequent Bad CA rule, malicious traffic may be allowed instead of blocked.

## Rule Actions and Rule Order

A rule's action determines how the system handles matching traffic. Improve performance by placing rules that do not perform or ensure further traffic handling before the resource-intensive rules that do. Then, the system can divert traffic that it might otherwise have inspected.

The following examples show how you might order rules in various policies, given a set of rules where none is more critical and preemption is not an issue.

If your rules include application conditions, also see [Best Practices for Configuring Application Control, on page 1820](#).

### Optimum Order: Decryption Rules

Not only does decryption require resources, but so does further analysis of the decrypted traffic. Place rules that decrypt traffic last.

1. Monitor—Rules that log matching connections, but take no other action on traffic.
2. Block, Block with reset—Rules that block traffic without further inspection.
3. Do not decrypt—Rules that do not decrypt encrypted traffic, passing the encrypted session to access control rules. The payloads of these sessions are not subject to deep inspection.
4. Decrypt - Known Key—Rules that decrypt incoming traffic with a known private key.
5. Decrypt - Resign—Rules that decrypt outgoing traffic by re-signing the server certificate.

### Optimum Order: Access Control Rules

Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Place access control rules that invoke deep inspection last.

1. Monitor—Rules that log matching connections, but take no other action on traffic. (However, see the important exception and caveat at [Access Control Rule Monitor Action, on page 1858](#).)
2. Trust, Block, Block with reset—Rules that handle traffic without further inspection. Note that trusted traffic is subject to authentication requirements imposed by an identity policy, and to rate limiting.
3. Allow, Interactive Block (no deep inspection)—Rules that do not inspect traffic further, but allow discovery. Note that allowed traffic is subject to authentication requirements imposed by an identity policy, and to rate limiting.
4. Allow, Interactive Block (deep inspection)—Rules associated with file or intrusion policies that perform deep inspection for prohibited files, malware, and exploits.

## Application Rule Order

Rules with application conditions are more likely to match traffic if you move them to a lower order in your list of rules.

Access control rules that use *specific* conditions (such as networks and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this [Wikipedia article](#).

For more information and an example, see [Best Practices for Configuring Application Control, on page 1820](#) and [Recommendations for Application Control, on page 1818](#).

## URL Rule Order

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.

If you configure exceptions to a rule, put the exception above the other rule.

## Best Practices for Simplifying and Focusing Rules

### Simplify: Do Not Overconfigure

Minimize individual rule criteria. Use as few individual elements in rule conditions as possible. For example, in network conditions use IP address blocks rather than individual IP addresses.

If one condition is enough to match the traffic you want to handle, do not use two. Using conditions that are redundant can greatly expand the deployed configuration, which can lead to problems in device performance, and unexpected device behavior in a cluster and high-availability unit re-join. For example:

- Use security zones that represent multiple interfaces carefully. If you specify source and destination networks as conditions, and these are enough to match the traffic you are targeting, then specifying a security zone is not required.
- If you want to match a set of internal interfaces to ANY destination on the Internet (for example), then simply use a source security zone that includes your internal interfaces. No network or destination interface criteria are needed.

Combining elements into objects does **not** improve performance. For example, using a network object that contains 50 individual IP addresses gives you only an organizational—not a performance—benefit over including those IP addresses in the condition individually.

For recommendations related to application detection, see [Best Practices for Configuring Application Control, on page 1820](#).

### Focus: Narrowly Constrain Resource-Intensive Rules, Especially by Interface

As much as possible, use rule conditions to narrowly define the traffic handled by resource-intensive rules. Focused rules are also important because rules with broad conditions can match many different types of traffic, and can preempt later, more specific rules. Examples of resource-intensive rules include:

- TLS/SSL rules that decrypt traffic—Not only the decryption, but further analysis of the decrypted traffic, requires resources. Narrow focus, and where possible, block or choose not to decrypt encrypted traffic.

- Access control rules that invoke deep inspection—Intrusion, file, and malware inspection requires resources, especially if you use multiple custom intrusion policies and variable sets. Make sure you only invoke deep inspection where required.

For maximum performance benefit, constrain rules by interface. If a rule excludes all of a device's interfaces, that rule does not affect that device's performance.

## Maximum Number of Access Control Rules and Intrusion Policies

The maximum number of access control rules or intrusion policies that are supported by a target device depends on many factors, including policy complexity, physical memory, and the number of processors on the device.

If you exceed the maximum supported by your device, you cannot deploy your access control policy and must reevaluate.

Guidelines for intrusion policies:

- In an access control policy, you can associate one intrusion policy with each Allow and Interactive Block rule, as well as with the default action. Every unique **pair** of intrusion policy and variable set counts as one policy.
- You may want to consolidate intrusion policies or variable sets so you can associate a single intrusion policy-variable set pair with multiple access control rules. On some devices you may find you can use only a single variable set for all your intrusion policies, or even a single intrusion policy-variable set pair for the whole device.

## CHAPTER 63

# Access Control Policies

---

The following topics describe how to work with access control policies:

- [Access Control Policy Components, on page 1829](#)
- [System-Created Access Control Policies, on page 1830](#)
- [Requirements and Prerequisites for Access Control Policies, on page 1830](#)
- [Managing Access Control Policies, on page 1831](#)
- [History for Access Control Policies, on page 1850](#)

## Access Control Policy Components

Following are the main elements of an access control policy.

### Name and Description

Each access control policy must have a unique name. A description is optional.

### Inheritance Settings

Policy inheritance allows you to create a hierarchy of access control policies. A parent (or *base*) policy defines and enforces default settings for its descendants.

A policy's inheritance settings allow you to select its base policy. You can also lock settings in the current policy to force any descendants to inherit them. Descendant policies can override unlocked settings.

### Policy Assignment

Each access control policy identifies the devices that use it. Each device can be targeted by only one access control policy.

### Rules

Access control rules provide a granular method of handling network traffic. Rules in an access control policy are numbered, starting at 1, including rules inherited from ancestor policies. The system matches traffic to access control rules in top-down order by ascending rule number.

Usually, the system handles network traffic according to the *first* access control rule where *all* the rule's conditions match the traffic. Conditions can be simple or complex, and their use often depends on certain licenses.

### Default Action

The default action determines how the system handles and logs traffic that is not handled by any other access control configuration. The default action can block or trust all traffic without further inspection, or inspect traffic for intrusions and discovery data.

Although an access control policy can inherit its default action from an ancestor policy, you cannot enforce this inheritance.

### Security Intelligence

Security Intelligence is a first line of defense against malicious internet content. This feature allows you to block connections based on the latest IP address, URL, and domain name reputation intelligence. To ensure continual access to vital resources, you can override Block list entries with custom Do Not Block list entries.

### HTTP Responses

When the system blocks a user's website request, you can either display a generic system-provided response page, or a custom page. You can also display a page that warns users, but also allows them to continue to the originally requested site.

### Logging

Settings for access control policy logging allow you to configure default syslog destinations for the current access control policy. The settings are applicable to the access control policy and all the included SSL, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

### Advanced Access Control Options

Advanced access control policy settings typically require little or no modification. Often, the default settings are appropriate. Advanced settings you can modify include traffic preprocessing, SSL inspection, identity, and various performance options.

## System-Created Access Control Policies

Depending on your devices' initial configurations, system-provided policies can include:

- Default Access Control—Blocks all traffic without further inspection.
- Default Intrusion Prevention—Allows all traffic, but also inspects with the Balanced Security and Connectivity intrusion policy and default intrusion variable set.
- Default Network Discovery—Allows all traffic while inspecting it for discovery data but not intrusions or exploits.

## Requirements and Prerequisites for Access Control Policies

### Model Support

Any

### Supported Domains

Any

### User Roles

- Admin
- Access Admin
- Network Admin
- You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions. The granular permissions are:
  - **Policies > Access Control > Access Control Policy > Modify Access Control Policy > Modify Threat Configuration** allows the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for Network Analysis and Intrusion Policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.
  - **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

## Managing Access Control Policies

You can edit system-provided access control policies and create custom access control policies.

### Procedure

---

**Step 1** Choose **Policies > Access Control**.

At the top of the page, there are convenient links to some related features: Object management, Intrusion policies, Network Analysis policies, DNS policies, and policy Import/Export.

**Step 2** Manage access control policies:

- Create—Click **New Policy**; see [Creating a Basic Access Control Policy, on page 1832](#).
- Inheritance—Click **Plus** next to a policy with descendants to expand your view of the policy's hierarchy.
- Edit—Click **Edit** (✎); see [Editing an Access Control Policy, on page 1833](#)
- Delete—Click **Delete** (🗑). You must remove any device assignments before deleting a policy.
- Copy—Click **Copy** (📄). Device assignments are not retained in the copy.

- Report—Click **Report** (📄).
  - Lock or unlock a policy—See [Locking an Access Control Policy, on page 1834](#).
- 

## Creating a Basic Access Control Policy

When you create a new access control policy, it contains default actions and settings. After creating the policy, you are immediately placed in an edit session so that you can adjust the policy to suit your requirements.

### Procedure

---

**Step 1** Choose **Policies > Access Control**.

**Step 2** Click **New Policy**.

**Step 3** Enter a unique **Name** and, optionally, a **Description**.

**Step 4** Optionally, choose a base policy from the **Select Base Policy** drop-down list.

If an access control policy is enforced on your domain, this step is not optional. You must choose the enforced policy or one of its descendants as the base policy.

If you select a base policy, the base policy defines the default action and you cannot select a new one in this dialog box. Logging for connections handled by the default action depends on the base policy.

**Step 5** When you do not select a base policy, specify the initial **Default Action**:

- **Block all traffic** creates a policy with the **Access Control: Block All Traffic** default action.
- **Intrusion Prevention** creates a policy with the **Intrusion Prevention: Balanced Security and Connectivity** default action, associated with the default intrusion variable set.
- **Network Discovery** creates a policy with the **Network Discovery Only** default action.

When you select a default action, logging of connections handled by the default action is initially disabled. You can enable it later when you edit the policy.

**Tip** If you want to trust all traffic by default, or if you chose a base policy and do not want to inherit the default action, you can change the default action later.

**Step 6** Optionally, choose the **Available Devices** where you want to deploy the policy, then click **Add to Policy** (or drag and drop) to add the selected devices. To narrow the devices that appear, type a search string in the **Search** field.

If you want to deploy this policy immediately, you must perform this step.

**Step 7** Click **Save**.

The new policy opens for edit. You can add rules to it and make other changes as needed. See [Editing an Access Control Policy, on page 1833](#).

---

## Editing an Access Control Policy

When you edit an access control policy, you should lock it to ensure that your changes do not get overridden by another person who might edit it simultaneously.

You can only edit access control policies that were created in the current domain. Also, you cannot edit settings that are locked by an ancestor access control policy.

**Note** If you do not lock the policy, consider the following: Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

### Procedure

**Step 1** Choose **Policies > Access Control**.

**Step 2** Click **Edit** () next to the access control policy you want to edit.

If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Edit your access control policy.

**Tip** You can operate on multiple rules at one time by selecting their checkboxes in the left column, then selecting the action you want to perform from the **Select Action** drop-down list next to the search box. Bulk editing is available for enabling and disabling, copying, cloning, moving, deleting, and editing rules, or viewing hit counts or related events.

You can change the following settings or perform these actions:

- Name and Description—Click **Edit** () next to the name, make your changes, and click **Save**.
- Default Action—Choose a value from the **Default Action** drop-down list.
- Default Action Settings—Click **Cog** () , make your changes, and click **OK**. You can configure settings for logging, the location of an external syslog server or SNMP trap server, and the variable set associated with an intrusion prevention default action.
- Associated Policies—To edit or change policies in the packet flow, click the policy type in the packet flow representation below the policy name. You can select the **Prefilter Rules**, **Decryption**, **Security Intelligence**, and **Identity** policies. When necessary, click **Access Control** to return to the access control rules.
- Policy Assignment—To identify the managed devices targeted by this policy, or enforce this policy in a subdomain, click the **Targeted: x devices** link.
- Rules—To manage access control rules, and to inspect and block malicious traffic using intrusion and file policies, click **Add Rule**, or right-click an existing rule and select **Edit** or another appropriate action.

The actions are also available from the **More** (⋮) button for each rule. See [Create and Edit Access Control Rules, on page 1863](#).

- **Layout**—Use the **Grid/Table View** icon above the list of rules to change the layout. Grid view provides color-coded objects in an easy-to-see layout. Table view provides a summary list so that you can see more rules at once. You can freely switch views without impacting the rules.
- **Columns (Table view only)**—Click the **Show/Hide Columns** icon above the list of rules to select which information to show in the table. Click **Hide Empty Columns** to quickly remove all columns that have no information, that is, you are not using those conditions in any rule. Click **Revert to Default** to undo all of your customizations.
- **Analyze rule logic**. You can select the following options from the **Analyze** menu to examine the logic of your rules:
  - **Hit Count**—To view statistics on how many connections matched each rule.
  - **Enable/Disable Rule Conflicts**—Select whether you want to see information on whether rules interfere with each other.
  - **Show Rule Conflicts**—See whether you have redundant or shadowed rules. These conflicts could prevent certain rules from ever being matched by connections, meaning either that you need to fix the match criteria, move the rule, or simply delete the rule.
  - **Show Warnings**—See whether there are rules with configuration issues that you need to address.
- **Additional Settings**—To change additional settings for the policy, select one of the following options from the **More** drop-down arrow at the end of the packet flow line.
  - **Advanced Settings**—To set preprocessing, SSL inspection, identity, performance, and other advanced options. See [Access Control Policy Advanced Settings, on page 1840](#).
  - **HTTP Responses**—To specify what the user sees in a browser when the system blocks a website request. See [Choosing HTTP Response Pages, on page 1936](#).
  - **Inheritance Settings**—To change the base access control policy for this policy, and to enforce this policy's settings in its descendant policies. See [Choosing a Base Access Control Policy, on page 1836](#) and [Locking Settings in Descendant Access Control Policies, on page 1837](#).
  - **Logging**—To set the default logging options for the policy.

**Step 4** Click **Save**.

---

#### What to do next

- Deploy configuration changes.

## Locking an Access Control Policy

You can lock an access control policy to prevent other administrators from editing it. Locking the policy ensures that your changes will not be invalidated if another administrator edits the policy and saves changes

before you save your changes. Without locking, if multiple administrators edit the policy simultaneously, the first person who saves changes wins, and all other users have their changes erased.

The lock is for the access control policy itself. The lock does not apply to objects used in the policy. For example, another user can edit a network object that is used in a locked access control policy. Your lock remains in place until you explicitly unlock the policy, so you can log out and come back to your edits later.

When locked, other administrators have read-only access to the policy. However, other administrators can assign a locked policy to a managed device.

### Before you begin

Any user role that has permission to modify the access control policy has permission to lock it, and to unlock a policy that was locked by another user.

However, the ability to unlock a policy that was locked by another administrator is controlled by the following permission: **Policies > Access Control > Access Control Policy > Modify Access Control Policy > Override Access Control Policy Lock**.

If you are using custom roles, your organization might have limited your unlocking abilities by not assigning this permission. Without this permission, only the administrator who locks a policy can unlock it.

## Procedure

---

**Step 1** Choose **Policies > Access Control**.

**Step 2** Click **Edit** (✎) next to the access control policy you want to lock or unlock.

The **Lock Status** column shows whether a policy is already locked, and if so, who locked it. An empty cell indicates that the policy is not locked.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration. Or, it is locked by another user.

**Step 3** Click the lock icon next to the policy name to lock or unlock the policy.

If the policy inherits settings from a parent policy, you must choose one of the following options when you click the lock icon.

- **Lock/Unlock This Policy**—The locking or unlocking is for this policy only.
  - **Lock/Unlock This Policy and Parents in the Hierarchy**—This policy and all parent policies are locked or unlocked. If a parent policy is already locked by another administrator, you will see a message and you will not be able to lock that parent policy. When unlocking policies, if you have the Override Access Control Policy Lock permission, all parent policies are unlocked even if they were locked by other users.
-

## Managing Access Control Policy Inheritance

Inheritance relates to using another policy as a base policy for an access control policy. This allows you to use one policy to define some baseline characteristics that can be applied to multiple policies. To understand how inheritance works, see [Access Control Policy Inheritance, on page 1817](#).

### Procedure

---

- Step 1** Edit the access control policy whose inheritance settings you want to change; see [Editing an Access Control Policy, on page 1833](#).
- Step 2** Manage policy inheritance:
- Change Base Policy — To change the base access control policy for this policy, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line and proceed as described in [Choosing a Base Access Control Policy, on page 1836](#).
  - Lock Settings in Descendants — To enforce this policy's settings in its descendant policies, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line and proceed as described in [Locking Settings in Descendant Access Control Policies, on page 1837](#).
  - Required in Domains — To enforce this policy in a subdomain, click the **Targeted: x devices** link and proceed as described in [Requiring an Access Control Policy in a Domain, on page 1838](#).
  - Inherit Settings from Base Policy — To inherit settings from a base access control policy, click **Security Intelligence**, or select **HTTP Responses** or **Advanced Settings** from the drop-down arrow at the end of the packet flow line, and proceed as directed in [Inheriting Access Control Policy Settings from the Base Policy, on page 1837](#).
- 

## Choosing a Base Access Control Policy

You can use one access control policy as the base (parent) for another. By default, a child policy inherits its settings from its base policy, though you can change unlocked settings.

When you change the base policy for the current access control policy, the system updates the current policy with any locked settings from the new base policy.

### Procedure

---

- Step 1** In the access control policy editor, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line.
- Step 2** Choose a policy from the **Select Base Policy** drop-down list.
- Step 3** Click **Save**.
- 

#### What to do next

- Deploy configuration changes.

## Inheriting Access Control Policy Settings from the Base Policy

A new child policy inherits many settings from its base policy. If these settings are unlocked in the base policy, you can override them.

If you later reinherit the settings from the base policy, the system displays the base policy's settings and dims the controls. However, the system saves the overrides you made, and restores them if you disable inheritance again.

### Procedure

- 
- Step 1** In the access control policy editor, click **Security Intelligence**, or select **HTTP Responses** or **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line
- Step 2** Check the **Inherit from base policy** check box for each setting you want to inherit.
- If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.
- Step 3** Click **Save**.
- 

#### What to do next

- Deploy configuration changes.

## Locking Settings in Descendant Access Control Policies

Lock a setting in an access control policy to enforce the setting in all descendant policies. Descendant policies can override unlocked settings.

When you lock settings, the system saves overrides already made in descendant policies so that the overrides can be restored if you unlock settings again.

### Procedure

- 
- Step 1** In the access control policy editor, select **Inheritance Settings** from the **More** drop-down arrow at the end of the packet flow line.
- Step 2** In the Child Policy Inheritance Settings area, check the settings you want to lock.
- If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration.
- Step 3** Click **OK** to save the inheritance settings.
- Step 4** Click **Save** to save the access control policy.
- 

#### What to do next

- Deploy configuration changes.

## Requiring an Access Control Policy in a Domain

You can require that every device in a domain use the same base access control policy or one of its descendant policies. This procedure is relevant in a multi-domain deployment only.

### Procedure

- 
- Step 1** In the access control policy editor, click the **Targeted: x devices** link.
- Step 2** Click **Required on Domains**.
- Step 3** Build your domain list:
- Add — Select the domains where you want to enforce the current access control policy, then click **Add** or drag and drop into the list of selected domains.
  - Delete — Click **Delete** (  ) next to a leaf domain, or right-click an ancestor domain and choose **Delete Selected**.
  - Search — Type a search string in the search field. Click **Clear** (  ) to clear the search.
- Step 4** Click **OK** to save the domain enforcement settings.
- Step 5** Click **Save** to save the access control policy.
- 

### What to do next

- Deploy configuration changes.

## Setting Target Devices for an Access Control Policy

An access control policy specifies the devices that use it. Each device can be targeted by only one access control policy.

### Procedure

- 
- Step 1** In the access control policy editor, click the **Targeted: x devices** link.
- Step 2** On **Targeted Devices**, build your target list:
- Add — Select one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**.
  - Delete — Click **Delete** (  ) next to a single device, or select multiple devices, right-click, then choose **Delete Selected**.
  - Search — Type a search string in the search field. Click **Clear** (  ) to clear the search.
- Under **Impacted Devices**, the system lists the devices whose assigned access control policies are children of the current policy. Any change to the current policy affects these devices.
- Step 3** Click **OK** to save your targeted device settings.

**Step 4** Click **Save** to save the access control policy.

---

#### What to do next

- Deploy configuration changes.

## Logging Settings for Access Control Policies

To configure logging settings for an access control policy, select **Logging** from the **More** drop-down arrow at the end of the packet flow line.

You can configure default syslog destinations and syslog alert for the access control policy. The settings are applicable to the access control policy and all the included SSL/TLS decryption, prefilter, and intrusion policies unless the syslog destination settings are explicitly overridden with custom settings in included rules and policies.

Logging for connections handled by the default action is initially disabled.

IPS and File and Malware Settings are effective only after you have selected an option at the top of the page for sending syslog messages generally.

#### Default Syslog Settings

- **Send using specific syslog alert**—If you select this option, the events are sent based on the selected syslog alert as configured using the instructions in *Creating a Syslog Alert Response* in the [Cisco Secure Firewall Management Center Administration Guide](#). You can select the syslog alert from the list or add one by specifying the name, logging host, port, facility, and severity. For more information, see *Facilities and Severities for Intrusion Syslog Alerts* in the [Cisco Secure Firewall Management Center Administration Guide](#). This option is applicable to all devices.

When using this option, the system sends syslog messages to the server using the Management interface. Ensure there is a route from the Management interface to the syslog server, or messages will not arrive at the server.

- **Use the syslog settings configured in the Threat Defense Platform Settings policy deployed on the device**—If you select this option and select the severity, connection or intrusion events are sent with the selected severity to syslog collectors configured in Platform Settings. Using this option, you can unify the syslog configuration by configuring it in Platform Settings and reusing the settings in access control policy. Severity selected in this section is applied to all connection and intrusion events. The default severity is ALERT.

This option is applicable only to Secure Firewall Threat Defense devices 6.3 and later.

#### IPS Settings

- **Send Syslog messages for IPS events**—Send IPS events as syslog messages. The defaults set above are used unless you override them.
- **Show/Hide Overrides**—If you want to use the default syslog destination and severity, leaves these options empty. Otherwise, you can set a different syslog server destination for IPS events, and change the severity of the events.

### File and Malware Settings

- **Send Syslog messages for File and Malware events**—Send file and malware events as syslog messages. The defaults set above are used unless you override them.
- **Show/Hide Overrides**—If you want to use the default syslog destination and severity, leaves these options empty. Otherwise, you can set a different syslog server destination for file and malware events, and change the severity of the events.

## Access Control Policy Advanced Settings

To configure advanced settings for an access control policy, select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

Advanced access control policy settings typically require little or no modification. The default settings are appropriate for most deployments. Note that many of the advanced preprocessing and performance options in access control policies may be modified by rule updates as described in *Update Intrusion Rules* in the [Cisco Secure Firewall Management Center Administration Guide](#).

If **View** () appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.

---

**Caution** See [Configurations that Restart the Snort Process When Deployed or Activated, on page 236](#) for a list of advanced setting modifications that restart the Snort process, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

---

### Inheriting Settings from a Parent Policy

If the access control policy has a base policy, you can elect to inherit settings from the base policy. Select **Inherit from base policy** for each setting group where you want to use the parent policy's settings. If inheritance has been configured so that these settings are locked, you cannot configure unique settings for the policy, these settings are read-only.

If you are allowed to configure unique settings for the policy, you must deselect **Inherit from base policy** to make your edits.

### General Settings

Option	Description
<b>Maximum URL characters to store in connection events</b>	To customize the number of characters you store for each URL requested by your users.  To customize the length of time before you re-block a website after a user bypasses an initial block, see <a href="#">Setting the User Bypass Timeout for a Blocked Website, on page 1938</a> .
<b>Allow an Interactive Block to bypass blocking for (seconds)</b>	See <a href="#">Setting the User Bypass Timeout for a Blocked Website, on page 1938</a> .

Option	Description
<b>Retry URL cache miss lookup</b>	<p>The first time the system encounters a URL that does not have a locally stored category and reputation, it looks up that URL in the cloud and adds the result to the local data store, for faster processing of that URL in the future.</p> <p>This setting determines what the system does when it needs to look up a URL's category and reputation in the cloud.</p> <p>By default, this setting is enabled: The system momentarily delays the traffic while it checks the cloud for the URL's reputation and category, and uses the cloud verdict to handle the traffic.</p> <p>If you disable this setting: When the system encounters a URL that is not in its local cache, the traffic is immediately passed and handled according to the rules configured for Uncategorized and reputationless traffic.</p> <p>In passive deployments, the system does not retry the lookup, as it cannot hold packets.</p>
<b>Enable Threat Intelligence Director</b>	Disable this option to stop publishing TID data to your configured devices.
<b>Enable reputation enforcement on DNS traffic</b>	This option is enabled by default, for improved URL filtering performance and efficacy. For details and additional instructions, see <a href="#">DNS Filtering: Identify URL Reputation and Category During DNS Lookup</a> , on page 1932 and subtopics.
<b>Inspect traffic during policy apply</b>	<p>To inspect traffic when you deploy configuration changes unless specific configurations require restarting the Snort process, ensure that <b>Inspect traffic during policy apply</b> is set to its default value (enabled).</p> <p>When this option is enabled, resource demands could result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See <a href="#">Snort Restart Scenarios</a>, on page 232 for more information.</p>

### Associated Policies

Use advanced settings to associate subpolicies (decryption, identity, prefilter) with access control; see [Associating Other Policies with Access Control](#), on page 1844.

### TLS Server Identity Discovery

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by [RFC 8446](#), is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate *without* decrypting the entire packet.

You can enable this feature, referred to as *TLS server identity discovery*, when you configure advanced settings for an access control policy.

If you enable this option, we recommend you also enable the decryption policy's advanced TLS adaptive server identity probe option as well. Together, these options enable more efficient decryption of TLS 1.3 traffic. For more information, see [TLS 1.3 Decryption Best Practices, on page 2357](#).

When a new connection starts that will be affected by TLS server identity discovery, the threat defense holds the original ClientHello packet to determine the identity of the server to which it connects before continuing. The threat defense device sends a specialized connection from the threat defense to the server. The server's response includes the server certificate, the specialized connection is terminated, and the original connection is evaluated as required by the access control policy.

TLS server identity discovery prioritizes the certificate's Common Name (CN) over the [Server Name Indication \(SNI\)](#).

To enable TLS server identity discovery, click the **Advanced** tab, click **Edit** (✎) for the setting, and select **Early application detection and URL categorization**.

### TLS Server Identity Discovery ?

**Early application detection and URL categorization**  

We recommend that you enable early application detection and server identity. Since TLS 1.3 certificates are encrypted, for traffic encrypted with TLS to match access rules that use application or URL filtering, the system must decrypt it. The setting decrypts the certificate only; the connection remains encrypted. Enabling this option is sufficient to decrypt TLS 1.3 certificates; you do not need to create a corresponding SSL decryption rule.

Revert to Defaults
Cancel
OK

We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. A decryption policy is not required because *traffic is not decrypted* in the process of extracting the server certificate.

#### Note

- Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.
- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.
- Enabling TLS server identity discovery is not supported on any Secure Firewall Threat Defense Virtual deployed to AWS. If you have any such managed devices managed by the Secure Firewall Management Center, the connection event **PROBE\_FLOW\_DROP\_BYPASS\_PROXY** increments every time the device attempts to extract the server certificate.
- TLS Server Identity Discovery also operates on TLS 1.2 sessions.

## Network Analysis and Intrusion Policies

Advanced network analysis and intrusion policy settings allow you to:

- Specify the intrusion policy and associated variable set that are used to inspect packets that must pass before the system can determine exactly how to inspect that traffic.
- Change the access control policy's default network analysis policy, which governs many preprocessing options.
- Use custom network analysis rules and network analysis policies to tailor preprocessing options to specific security zones, networks, and VLANs.

For more information, see [Advanced Access Control Settings for Network Analysis and Intrusion Policies, on page 2749](#).

## Threat Defense Service Policy

You can use the Threat Defense Service Policy to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. This policy applies to threat defense devices only, and will be ignored for any other device type. The service policy rules are applied after the access control rules. For more information, see [Service Policies, on page 1997](#).

## File and Malware Settings

[Tuning File and Malware Inspection Performance and Storage, on page 2294](#) provides information on performance options for file control and malware defense.

## Portscan Threat Detection

Portscan detector is a threat detection mechanism designed to help you detect and prevent portscan activity in all types of traffic to protect networks from eventual attacks. Portscan traffic can be detected efficiently in both allowed and denied traffic..

## Elephant Flow Settings

Elephant flows are large, long duration, and fast flows that can cause duress for Snort cores. There are two actions that can be applied on elephant flows to reduce system stress, CPU hogging, packet drops, and so on. These actions are:

- Bypass any or all applications—This action bypasses flow from Snort inspection.
- Throttle—This action applies dynamic rate limit policy (10% reduction) on elephant flows.

For more information, see the Elephant Flow Detection chapter in the [Cisco Secure Firewall Management Center Snort 3 Configuration Guide](#).

## Intelligent Application Bypass Settings

Intelligent Application Bypass (IAB) is an expert-level configuration that specifies applications to bypass or test for bypass if traffic exceeds a combination of inspection performance and flow thresholds. For more information, see [Intelligent Application Bypass, on page 2015](#).

### Transport/Network Layer Preprocessor Settings

Advanced transport and network preprocessor settings apply globally to all networks, zones, and VLANs where you deploy your access control policy. You configure these advanced settings in an access control policy rather than in a network analysis policy. For more information, see [Advanced Transport/Network Preprocessor Settings, on page 2882](#).

### Detection Enhancement Settings

Advanced detection enhancement settings allow you to configure adaptive profiles so you can:

- Use file policies and applications in access control rules.
- Use service metadata in intrusion rules.
- In passive deployments, improve reassembly of packet fragments and TCP streams based on your network's host operating systems.

For more information, see [Adaptive Profiles, on page 2937](#).

### Performance Settings and Latency-Based Performance Settings

[About Intrusion Prevention Performance Tuning, on page 2249](#) provides information on improving the performance of your system as it analyzes traffic for attempted intrusions.

For information specific to latency-based performance settings, see [Packet and Intrusion Rule Latency Threshold Configuration, on page 2254](#).

### Encrypted Visibility Engine

For details about this feature, see the Encrypted Visibility Engine chapter in the [Cisco Secure Firewall Management Center Snort 3 Configuration Guide](#).

## Associating Other Policies with Access Control

The easiest way to associate the major policy's to an access control policy is by clicking the policy's link in the packet flow shown at the top of the access control policy. You can quickly select the associated policy. Alternatively, you can use the policy's advanced settings to associate the policy, as described in this topic. These policies include the following:

- Prefilter policy—Performs early traffic handling using limited network (layer 4) outer-header criteria.
- Decryption policy—Monitors, decrypts, blocks, or allows application layer protocol traffic encrypted with Secure Socket Layer (SSL) or Transport Layer Security (TLS).

---

**Caution** *Snort 2 only.* Adding or removing an SSL policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

---

- Identity policy—Performs user identification based on the realm and authentication method associated with the traffic.

### Before you begin

Before associating an SSL policy with an access control policy, review the information about TLS server identity discovery in [Access Control Policy Advanced Settings, on page 1840](#).

### Procedure

- 
- Step 1** In the access control policy editor, select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.
- Step 2** Click **Edit** () in the appropriate Policy Settings area.
- If **View** () appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 3** Choose a policy from the drop-down list.
- If you choose a user-created policy, you can click edit that appears to edit the policy.
- Step 4** Click **OK**.
- Step 5** Click **Save** to save the access control policy.
- 

### What to do next

- Deploy configuration changes.

## Viewing Rule Hit Counts

Hit count indicates the number of times a policy rule or default action has been matched to a connection. The hit count is incremented only for the first packet of a connection that matches a rule. You can use this information to identify the efficacy of your rules. Hit count information is available only for access control and prefilter rules applied to threat defense devices.

- 
- Note**
- The count persists through reboots and upgrades.
  - Counts are maintained by each unit in an HA pair or cluster separately.
  - You will not be able to derive the hit count information from a device when deployment or a task is in progress on the device.
  - You can also see rule hit count information in the device CLI using the **show rule hits** command.
  - If you have accessed the Hit Count page from the Access Control Policy page, you will not be able to view or edit prefilter rules and vice-versa.
  - Hit counts are not available for rules that use the Monitor action.
-

### Before you begin

If you use custom user roles, ensure that the roles include the following privileges:

- View Device, to see the hit counts.
- Modify Device, to refresh the hit counts.

### Procedure

- 
- Step 1** In the access control policy or prefilter policy editor, click **Analyze Hit Counts** on the top-right of the page.
- Step 2** On the Hit Count page, select the device from the **Select a device** drop-down list.
- If it is not the first time that you are generating hit counts for this device, the last fetched hit count information appears next to the drop-down box. Also, verify the **Last Deployed** time to confirm recent policy changes.
- Step 3** If necessary, click **Refresh** () to obtain current hit count data from the selected device.
- In the prefilter policy, you might need to click **Fetch Current Hit Count** to get initial hit count data.
- You cannot refresh the hit count while deployment to the device is in progress.
- Step 4** View and analyze the data.
- You can do the following:
- Click **Prefilter** or **Access Control** to switch between the hit counts for these policies.
  - Search for a specific rule by entering a search string in **Filter** box.
  - Broadly limit the list to **Hit Rules** or **Never Hit Rules** by selecting these options in the **Filter by** field. When viewing hit rules, you can further limit the list by selecting a time range in the **In Last** field (for example, in the last 1 day).
  - (When viewed from the access control policy.) You can do the following with individual rules:
    - Edit the rule by clicking **Edit** ()
    - Delete the rule from the policy by clicking **Delete** ()
    - Enable or disable the rule by clicking the **Slider** ()
    - Clear the hit count (reset it to zero) for the rule by clicking the **X** for the rule. You cannot undo this action.
  - (When viewed from the prefilter policy.) Change the displayed columns by clicking **Cog** () and selecting the columns to show.
  - (When viewed from the prefilter policy.) Click on a rule name to edit it, or click **View** () in the last column to view the rule details. Clicking on the rule name highlights it in the policy page where you can edit it.

- (When viewed from the prefilter policy.) Clear the hit count information (reset it to zero) for a rule by right-clicking the rule and selecting **Clear Hit Count**. You can select multiple rules by using Ctrl+click. You cannot undo this action.
- Generate a comma-separated values report of the details on the page by clicking **Generate CSV** on the bottom-left of the page.

**Step 5** Click **Close** to return to the policy page.

---

## Analyzing Rule Conflicts and Warnings

You can view warnings and information about rule conflicts to examine the logic of your access control policy and to identify rules that need changes. When rules overlap, you can end up with unnecessary rules in the policy, and these rules will never be matched to traffic. The analysis can help you delete unnecessary rules, or identify rules that should be moved or modified so they enforce the desired policy.

Policy warnings and errors point out things that you should understand and perhaps address to ensure that your rules provide the desired services.

Rule conflict analysis identifies the following types of problem:

- **Object Overlap**—An element in a field of a rule is a subset of one or more elements in the same field of the rule. For example, the source field might include a network object for 10.1.1.0/24, and another object for the host 10.1.1.1. Because 10.1.1.1 is within the network covered by 10.1.1.0/24, the object for 10.1.1.1 is redundant and can be deleted, simplifying the rule and saving device memory.
- **Redundant Rule**—Two rules apply the same action to the same type of traffic and removing the base rule would not change the ultimate result. For example, if a rule permitting FTP traffic for a particular network were followed by a rule allowing IP traffic for that same network, and there were no rules in between denying access, then the first rule is redundant and you can delete it.
- **Shadowed Rule**—This is the reverse of a redundant rule. In this case, one rule will match the same traffic as another rule such that the second rule will never be applied to any traffic because it comes later in the access list. If the action for both rules is the same, you can delete the shadowed rule. If the two rules specify different actions for traffic, you might need to move the shadowed rule or edit one of the two rules to implement your desired policy. For example, the base rule might deny IP traffic, and the shadowed rule might permit FTP traffic, for a given source or destination.

### Before you begin

When doing the analysis:

- Only the first conflict for a given rule is identified. Once you fix the problem, the rule might be identified as having a conflict with another rule in the table. However, a rule might have multiple warnings or errors.
- Rule conflict analysis considers source/destination security zone, network, VLAN, and service/port match conditions and action only. It does not consider other match criteria, so an apparently redundant rule might not be completely redundant.
- FQDN network objects cannot be analyzed for conflict, because the IP address of an FQDN cannot be known prior to DNS lookup.

- Disabled rules are ignored.
- Time range attributes are ignored. Rules for different time periods might be marked as redundant when they are not actually redundant for the time ranges.
- Icons for warnings and errors, and rule conflicts when you enable the feature, are shown in the rules table. For a reference to the icons, see [Rule and Other Policy Warnings, on page 1811](#).

## Procedure

---

**Step 1** Choose **Policy > Access Control** and edit an access control policy.

**Step 2** Do one of the following to open the rule conflicts and warnings dialog box:

- To view rule conflicts, click the **Analyze** drop-down and click **Enable Rule Conflicts**. When the analysis completes, you see a summary of the conflicts at the top of the page. Then, click **Show Rule Conflicts** from the same menu to see the specific results.

You must re-enable rule conflict detection each time you open the policy or make a change and save the policy.

- To view rule warnings and errors, click **Analyze > Show Warnings**.

After you make a change to the policy, you can refresh the results by clicking the reload icon next to the Analyze button.

- To view policy warnings, click **Analyze > Show Policy Warnings**.
- If you are finished viewing rule conflicts, click **Analyze > Disable Rule Conflicts**.

**Step 3** In the rule conflicts and warnings dialog box:

- Warnings and Errors are shown on a separate tab from Rule Conflicts.
- Each tab contains sub-tabs to let you examine individual types of problems, such as redundant vs. shadowed or warnings vs. errors. You can also search for an item.
- **More** (⚙) next to each rule name provides shortcuts to edit, disable, or delete the rule.

**Step 4** Click **Close** when finished.

---

## Searching for Rules

You can use search to help you find rules, especially when you have a large number of them.

When you search for an IP address in the source or destination network (but not as a simple text search), the system returns rules that will match the address. This includes not only exact matches, but also subnet matches. For example, searching for 10.1.1.1 will include rules for 10.1.1.0/24.

## Procedure

- 
- Step 1** When editing an access control policy, build the search string by clicking in the **Search** box.
- For a simple text string search, type the string. The search returns rules that have that string in any column. You cannot do a string search in conjunction with a tag search, such as combining a string search with a Source Networks search.
  - To search on a specific column, start typing the name of the column until the system prompts you with the full name, such as Source Networks, or select the name from the list of searchable fields. When you select the search tag, you can then enter the search string for that tag. For example, **Source Networks 10.1.1.1**.
  - After your first search, clicking in the search box prompts you with recent searches and tags. You can quickly repeat a search by selecting it, or build similar searches by selecting previous searches or tags and building on them.
  - When building a search string with multiple tags, do not include spaces between the tags.
  - When you select a tag, you are prompted with values that appear in those columns. Select the values you want to search for.
  - You can quickly filter based on some common features by clicking the filter icon to the left of the search box and selecting to show rules with any combination of the following: Allow, Block, Monitor, Intrusion Policy, Time Range.
  - To see the rules that apply to a specific device or set of devices, click the filter icon and select the devices. Rules apply to a device if they use security zones that contain at least one interface on the device, or if they do not include security zones.
- Step 2** With your cursor at the end of the search string in the search box, press Enter.
- The rules that satisfy the search string are highlighted and non-matching rules are hidden. You can deselect **Show Only Matching Rules** to see the entire table, with the highlighted rules within the table. This lets you see the surrounding rules.
- Beside the Show Only Matching Rules checkbox is a summary of the total number of rules in the policy compared to the number that match the search string.
- Step 3** To close the search and return to the unfiltered and unhighlighted table, click the **X** at the right of the search box. You can also put your cursor at the end of the search string and press the Esc key.
-

## History for Access Control Policies

Feature	Minimum Management Center	Minimum Threat Defense	Details
Granular permissions for modifying access control policies and rules.	7.4.0	Any	<p>You can define custom user roles to differentiate between the intrusion configuration in access control policies and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams.</p> <p>When defining user roles, you can select the <b>Policies &gt; Access Control &gt; Access Control Policy &gt; Modify Access Control Policy &gt; Modify Threat Configuration</b> option to allow the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for Network Analysis and Intrusion Policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions in the policy default action. You can use the <b>Modify Remaining Access Control Policy Configuration</b> to control the ability to edit all other aspects of the policy. The existing pre-defined user roles that included the Modify Access Control Policy permission continue to support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions.</p>
New access control policy user interface and rule conflict analysis.	7.3.0	Any	<p>The access control policy user interface introduced in 7.2 is now the default interface. You can also enable rule conflict analysis to help identify redundant rules and objects, and shadowed rules that cannot be matched due to previous rules in the policy.</p>
Access control policy locking.	7.2.0	Any	<p>You can lock an access control policy to prevent other administrators from editing it. Locking the policy ensures that your changes will not be invalidated if another administrator edits the policy and saves changes before you save your changes. Any user who has permission to modify the access control policy has permission to lock it.</p> <p>We added an icon to lock or unlock a policy next to the policy name while editing the policy. In addition, there is a new permission to allow users to unlock policies locked by other administrators: <b>Override Access Control Policy Lock</b>. This permission is enabled by default in the Administrator, Access Admin, and Network Admin roles.</p>
Rule hit counts persist over reboot.	7.2.0	Any	<p>Rebooting a managed device no longer resets access control rule hit counts to zero. Hit counts are reset only if you actively clear the counters. In addition, counts are maintained by each unit in an HA pair or cluster separately. You can use the <b>show rule hits</b> command to see cumulative counters across the HA pair or cluster, or see the counts per node.</p> <p>We modified the following device CLI command: <b>show rule hits</b>.</p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Usability improvements for the access control policy.	7.2.0	Any	There is a new user interface available for the access control policy. You can continue to use the legacy user interface, or you can try out the new user interface. The new interface has both a table and a grid view for the rules list, the ability to show or hide columns, enhanced search, infinite scroll, a clearer view of the packet flow related to policies associated with the access control policy, and a simplified add/edit dialog box for creating rules. You can freely switch back and forth between the legacy and new user interfaces while editing an access control policy.
DNS filtering	7.0.0 6.7.0 (experimental)	Any	<p>If URL filtering is enabled and configured, a new option to enhance category and reputation filtering efficacy is enabled by default for each new access control policy.</p> <p>For more information, see <a href="#">DNS Filtering: Identify URL Reputation and Category During DNS Lookup</a> , on page 1932 and subtopics.</p> <p>The Advanced tab of access control policy has a new option under General Settings: <b>Enable reputation enforcement on DNS traffic</b>.</p>
TLS server identity discovery	6.7.0	Any	<p>Enable access control policies to evaluate URL and application conditions when a client connects to a TLS 1.3-enabled server. TLS server identity discovery enables these conditions to be evaluated without decrypting traffic.</p> <p>Enabling this feature can impact device performance, depending on model.</p> <p>The Advanced tab page of access control policy has new options:</p> <ul style="list-style-type: none"> <li>Warning is displayed on the Advanced tab; moving the slider to the right enables TLS server identity discovery.</li> <li>New option on the Advanced tab page: <b>TLS Server Identity Discovery</b>.</li> </ul>
New Security Intelligence categories	—	Any	<p>The following categories were introduced at about the time of the 6.6 release, but are not specific to 6.6:</p> <ul style="list-style-type: none"> <li>banking_fraud</li> <li>high_risk</li> <li>ioc</li> <li>link_sharing</li> <li>malicious</li> <li>newly_seen</li> <li>spyware</li> </ul>

## CHAPTER 64

# Access Control Rules

---

The following topics describe how to configure access control rules:

- [Introduction to Access Control Rules, on page 1853](#)
- [Requirements and Prerequisites for Access Control Rules, on page 1861](#)
- [Guidelines and Limitations for Access Control Rules, on page 1862](#)
- [Managing Access Control Rules, on page 1863](#)
- [Examples for Access Control Rules, on page 1878](#)

## Introduction to Access Control Rules

Within an access control policy, *access control rules* provide a granular method of handling network traffic across multiple managed devices.

---

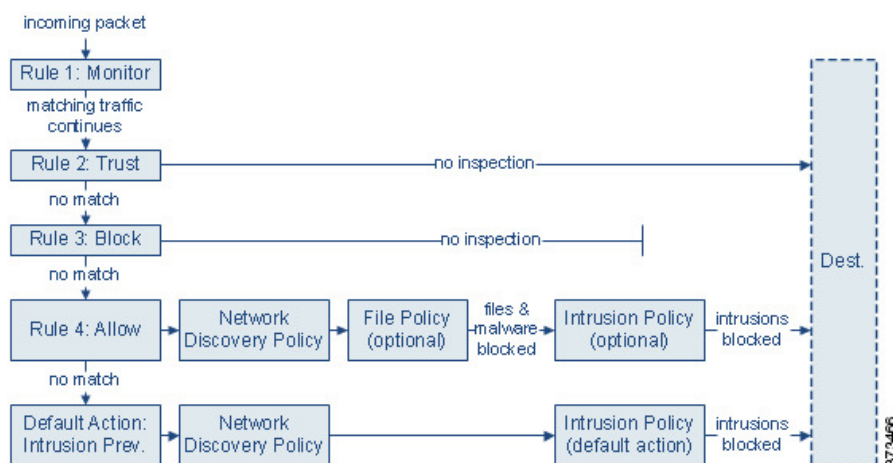

**Note** Security Intelligence filtering, decryption, user identification, and some decoding and preprocessing occur before access control rules evaluate network traffic.

---

The system matches traffic to access control rules in the order you specify. In most cases, the system handles network traffic according to the *first* access control rule where *all* the rule's conditions match the traffic.

Each rule also has an *action*, which determines whether you monitor, trust, block, or allow matching traffic. When you allow traffic, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

The following scenario summarizes the ways that traffic can be evaluated by access control rules in an inline, intrusion prevention deployment.

In this scenario, traffic is evaluated as follows:

- **Rule 1: Monitor** evaluates traffic first. Monitor rules track and log network traffic. The system continues to match traffic against additional rules to determine whether to permit or deny it. (However, see an important exception and caveat at [Access Control Rule Monitor Action, on page 1858.](#))
- **Rule 2: Trust** evaluates traffic next. Matching traffic is allowed to pass to its destination without further inspection, though it is still subject to identity requirements and rate limiting. Traffic that does not match continues to the next rule.
- **Rule 3: Block** evaluates traffic third. Matching traffic is blocked without further inspection. Traffic that does not match continues to the final rule.
- **Rule 4: Allow** is the final rule. For this rule, matching traffic is allowed; however, prohibited files, malware, intrusions, and exploits within that traffic are detected and blocked. Remaining non-prohibited, non-malicious traffic is allowed to its destination, though it is still subject to identity requirements and rate limiting. You can configure Allow rules that perform only file inspection, or only intrusion inspection, or neither.
- **Default Action** handles all traffic that does not match any of the rules. In this scenario, the default action performs intrusion prevention before allowing non-malicious traffic to pass. In a different deployment, you might have a default action that trusts or blocks all traffic, without further inspection. (You cannot perform file or malware inspection on traffic handled by the default action.)

Traffic you allow, whether with an access control rule or the default action, is automatically eligible for inspection for host, application, and user data by the network discovery policy. You do not explicitly enable discovery, although you can enhance or disable it. However, allowing traffic does not automatically guarantee discovery data collection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy; additionally, application discovery is limited for encrypted sessions.

Note that access control rules handle encrypted traffic when your decryption configuration allows it to pass, or if you do not configure decryption. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

## Access Control Rule Management

The rules table of the access control policy editor allows you to add, edit, categorize, search, filter, move, enable, disable, delete, and otherwise manage access control rules in the current policy.

Properly creating and ordering access control rules is a complex task, but one that is essential to building an effective deployment. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. To help ensure that the system handles traffic as you expect, the access control policy interface has a robust warning and error feedback system for rules.

Use the search bar to filter the list of access control policy rules. You can deselect the **Show Only Matching Rules** option to see all rules. Matched rules are highlighted.

For each access control rule, the policy editor displays its name, a summary of its conditions, the rule action, and icons that communicate the rule's inspection options or status. These icons represent:

- **Time Range Option** (🕒)
- **Intrusion policy** (🛡️)
- **File policy** (📁)
- **Logging** (📄)
- **Warning** (⚠️)
- **Errors** (❌)
- **Rule Conflict** (⚡)

Disabled rules are dimmed and marked (disabled) after the rule name.

To create or edit a rule, use the access control rule editor.

—You can:

- Configure the rule name and select its placement in the upper portion of the editor.
- Switch to editing a different rule by selecting its row above or below the editor.
- Use the left-hand list to select the rule action, and apply intrusion policies and variable sets, file policies, and time range, and to set logging options.
- Use the options next to the rule name to select the rule action, and apply intrusion policies and variable sets, file policies, and time range, and to set logging options.
- Use the **Sources** and **Destinations and Applications** columns to add matching criteria. You can add options from the All list, or move to different tabs to more easily find the type of option you want, such as security zone or networks.
- Add comments to the rule at the bottom of the editor.

## Access Control Rule Components

In addition to its unique name, each access control rule has the following basic components:

### State

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

### Position

Rules in an access control policy are numbered, starting at 1. If you are using policy inheritance, rule 1 is the first rule in the outermost policy. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.

Rules can also belong to a section and a category, which are organizational only and do not affect rule position. Rule position goes across sections and categories.

### Section and Category

To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize access control rules, you can create custom rule categories inside the Mandatory and Default sections.

If you are using policy inheritance, the current policy's rules are nested between its parent policy's Mandatory and Default sections.

### Conditions

Conditions specify the specific traffic the rule handles. Conditions can be simple or complex; their use often depends on license.

Traffic must meet all of the conditions specified in a rule. For example, if the Application condition specifies HTTP but not HTTPS, the URL category and reputation conditions will not apply to HTTPS traffic.

### Applicable Time

You can specify days and times during which a rule is applicable.

### Action

A rule's action determines how the system handles matching traffic. You can monitor, trust, block, or allow (with or without further inspection) matching traffic. The system does not perform deep inspection on trusted, blocked, or encrypted traffic.

### Inspection

Deep inspection options govern how the system inspects and blocks malicious traffic you would otherwise allow. When you allow traffic with a rule, you can specify that the system first inspect it with intrusion or file policies to block any exploits, malware, or prohibited files before they reach your assets or exit your network.

## Logging

A rule's logging settings govern the records the system keeps of the traffic it handles. You can keep a record of traffic that matches a rule. In general, you can log sessions at the beginning or end of a connection, or both. You can log connections to the database, as well as to the system log (syslog) or to an SNMP trap server.

## Comments

Each time you save changes to an access control rule, you can add comments.

[Access Control Rule Comments](#)

# Access Control Rule Order

Rules in an access control policy are numbered, starting at 1. The system matches traffic to access control rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the *first* access control rule where *all* the rule's conditions match the traffic. Except for Monitor rules, the system does not continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule.

To help you organize access control rules, every access control policy has two system-provided rule sections, Mandatory and Default. To further organize, you can create custom rule categories inside the Mandatory or Default sections. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The system assigns rule numbers across sections and categories.

If you use policy inheritance, the current policy's rules are nested between its parent policy's Mandatory and Default rule sections. Rule 1 is the first rule in the outermost policy, not the current policy, and the system assigns rule numbers across policies, sections, and categories.

Any predefined user role that allows you to modify access control policies also allows you to move and modify access control rules within and among rules categories. You can, however, create custom roles that restrict users from moving and modifying rules. Any user who is allowed to modify access control policies can add rules to custom categories and modify rules in them without restriction.

### Caution

Failure to set up your access control rules properly can have unexpected results, including traffic being allowed that should be blocked. In general, application control rules should be lower in your access control list because it takes longer for those rules to match than rules based on IP address, for example.

Access control rules that use *specific* conditions (such as networks and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your access control rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your access control rules. For more information about the OSI model, see this [Wikipedia article](#).

---

**Tip** Proper access control rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

---

#### Related Topics

[Best Practices for Ordering Rules](#), on page 1824

## Access Control Rule Actions

Every access control rule has an *action* that determines how the system handles and logs matching traffic. You can monitor, trust, block, or allow (with or without further inspection).

The access control policy's *default action* handles traffic that does not meet the conditions of any access control rule with an action other than Monitor.

### Access Control Rule Monitor Action

The **Monitor** action is not designed to permit or deny traffic. Rather, its primary purpose is to force connection logging, regardless of how matching traffic is eventually handled.

If a connection matches a Monitor rule, the next non-Monitor rule that the connection matches should determine traffic handling and any further inspection. If there are no additional matching rules, the system should use the default action.

There is an exception, however. If a Monitor rule contains layer 7 conditions—such as an application condition—the system *allows early packets to pass* and the connection to be established (or the SSL handshake to complete). This occurs even if the connection should be blocked by a subsequent rule; this is because these early packets *are not evaluated against subsequent rules*. So that these packets do not reach their destination completely uninspected, you can specify an intrusion policy for this purpose in the access control policy's Advanced settings; see [Inspection of Packets That Pass Before Traffic Is Identified, on page 2750](#). After the system completes its layer 7 identification, it applies the appropriate action to the remaining session traffic.

---

**Caution** As a best practice, *avoid placing layer 7 conditions on broadly-defined monitor rules high in your rule priority order*, to prevent inadvertently allowing traffic into your network. Also, if locally bound traffic matches a Monitor rule in a Layer 3 deployment, that traffic may bypass inspection. To ensure inspection of the traffic, enable **Inspect Local Router Traffic** in the advanced device settings for the managed device routing the traffic.

---

### Access Control Rule Trust Action

The **Trust** action allows traffic to pass without deep inspection or network discovery. Trusted traffic is still subject to identity requirements and rate limiting.

 **Note**

- Some protocols, such as FTP and SIP, use secondary channels, which the system opens through the process of inspection. In some cases, trusted traffic can bypass all inspection, and these secondary channels cannot be opened properly. If you run into this problem, change the trust rule to **Allow**.
- For an access control policy with rule action as **Trust** and logging options disabled, you will observe that the end-of-flow events are still generated in the system. The events are not visible on the management center event pages.

## Access Control Rule Blocking Actions

The **Block** and **Block with reset** actions deny traffic without further inspection of any kind.

Block with reset rules reset the connection, with the exception of web requests met with an *HTTP response page*. This is because the response page, which you configure to appear when the system blocks web requests, cannot display if the connection is immediately reset.

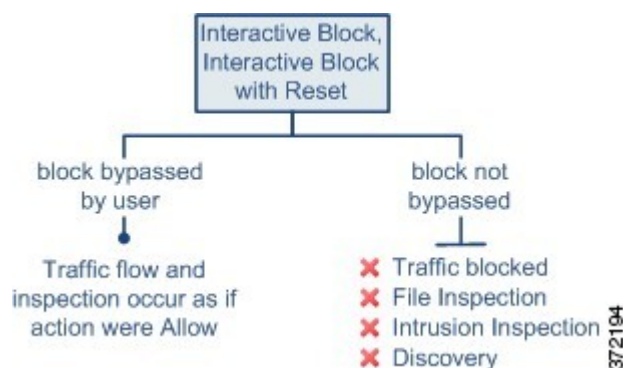

For more information, see [Configure HTTP Response Pages, on page 1935](#).

### Related Topics

[Configure HTTP Response Pages, on page 1935](#)

## Access Control Rule Interactive Blocking Actions

The **Interactive Block** and **Interactive Block with reset** actions give web users a choice to continue to their intended destinations.

If a user bypasses the block, the rule mimics an allow rule. Therefore, you can associate interactive block rules with file and intrusion policies, and matching traffic is also eligible for network discovery.

If a user does not (or cannot) bypass the block, the rule mimics a block rule. Matching traffic is denied without further inspection.

Note that if you enable interactive blocking, you cannot reset *all* blocked connections. This is because the response page cannot display if the connection is immediately reset. Use the **Interactive Block with reset** action to (non-interactively) block-with-reset all non-web traffic, while still enabling interactive blocking for web requests.

For more information, see [Configure HTTP Response Pages, on page 1935](#).

#### Related Topics

[Decryption Rule Blocking Actions, on page 2392](#)

## Access Control Rule Allow Action

The **Allow** action allows matching traffic to pass, though it is still subject to identity requirements and rate limiting.

Optionally, you can use deep inspection to further inspect and block unencrypted or decrypted traffic before it reaches its destination:

- You can use an intrusion policy to analyze network traffic according to intrusion detection and prevention configurations, and drop offending packets depending on the configuration.
- You can perform file control using a file policy. File control allows you to detect and block your users from uploading (sending) or downloading (receiving) files of specific types over specific application protocols.
- You can perform network-based advanced malware protection (AMP), also using a file policy. malware defense can inspect files for malware, and block detected malware depending on the configuration.

The following diagram illustrates the types of inspection performed on traffic that meets the conditions of an Allow rule (or a user-bypassed Interactive Block rule. Notice that file inspection occurs before intrusion inspection; blocked files are not inspected for intrusion-related exploits.

For simplicity, the diagram displays traffic flow for situations where both (or neither) an intrusion and a file policy are associated with an access control rule. You can, however, configure one without the other. Without a file policy, traffic flow is determined by the intrusion policy; without an intrusion policy, traffic flow is determined by the file policy.

Regardless of whether the traffic is inspected or dropped by an intrusion or file policy, the system can inspect it using network discovery. However, allowing traffic does not automatically guarantee discovery inspection. The system performs discovery only for connections involving IP addresses that are explicitly monitored by your network discovery policy; additionally, application discovery is limited for encrypted sessions.

## Requirements and Prerequisites for Access Control Rules

### Model Support

Any

### Supported Domains

Any

### User Roles

- Admin
- Access Admin
- Network Admin
- You can define custom user roles to differentiate between the intrusion configuration in access control policy and rules and the rest of the access control policy and rules. Using these permissions, you can separate the responsibilities of your network administration team and your intrusion administration teams. The existing pre-defined user roles that included the Modify Access Control Policy permission support all sub-permissions; you need to create your own custom roles if you want to apply granular permissions. The granular permissions are:
  - **Policies > Access Control > Access Control Policy > Modify Access Control Policy > Modify Threat Configuration** allows the selection of intrusion policy, variable set, and file policy in a rule, the configuration of the advanced options for Network Analysis and Intrusion Policies, the configuration of the Security Intelligence policy for the access control policy, and intrusion actions

in the policy default action. If a user has this option only, the user can modify no other part of the policy or rule.

- **Modify Remaining Access Control Policy Configuration** controls the ability to edit all other aspects of the policy.

## Guidelines and Limitations for Access Control Rules

- If you edit an access control rule that is actively in use, the changes do not apply to established connections at deploy-time. The updated rule is used to match against future connections. However, if the system is actively inspecting a connection (for example, with an intrusion policy), it *will* apply changed matching or action criteria to existing connections.

For threat defense, you can ensure that your changes apply to all current connections by using the threat defense **clear conn** CLI command to end established connections. Note that you should only do this if it is acceptable to end those connections, on the assumption that the sources for the connections will then attempt to reestablish the connection and thus be matched appropriately against the new rule.

- VLAN tags in access rules only apply to inline sets; they cannot be used in access rules applied to firewall interfaces.
- To use fully-qualified domain name (FQDN) network objects as source or destination criteria, you must also configure DNS for the data interfaces in the platform settings policy. The system does not use the management DNS server setting to do lookups for FQDN objects used in access control rules.

Note that controlling access by FQDN is a best-effort mechanism. Consider the following points:

- Whenever possible, use Security Intelligence or URL filtering instead of FQDN rules.
- Because DNS replies can be spoofed, only use fully trusted internal DNS servers.
- Some FQDNs, especially for very popular servers, can have hundreds if not thousands of IP addresses, and these can frequently change. Because the system uses cached DNS lookup results, users might get addresses that are not yet in the cache, and their connections will not match the FQDN rule. Rules that use FQDN network objects function effectively only for names that resolve to fewer than 100 addresses.

We recommend that you do not create network object rules for an FQDN that resolves to more than 100 addresses, as the likelihood of the address in a connection being one that has been resolved and available in the DNS cache on the device is low. For these cases, use a URL-based rule instead of an FQDN network object rule.

- For popular FQDNs, different DNS servers can return a different set of IP addresses. Thus, if your users use a different DNS server than the one you configure, FQDN-based access control rules might not apply to all IP addresses for the site that are used by your clients, and you will not get the intended results for your rules.
- Some FQDN DNS entries have very short time to live (TTL) values. This can result in frequent recompilation of the lookup table, which can impact overall system performance.
- If more than 8 FQDNs resolve to the same IP address, the system cannot reliably match traffic to the rules for those FQDN. At most 8 FQDNs per IP address can be handled.

- The maximum objects per match criteria per access control rule is 200. For example, you can have up to 200 network objects in a single access control rule.

## Managing Access Control Rules

The following topics explain how to manage access control rules.

### Adding an Access Control Rule Category

You can divide an access control policy's Mandatory and Default rule sections into custom categories. After you create a category, you cannot move it, although you can delete it, rename it, and move rules into, out of, within, and around it. The system assigns rule numbers across sections and categories.

#### Procedure

- 
- Step 1** In the access control policy editor, click **Add Category**.
- Tip** If your policy already contains rules, you can click a blank area in the row for an existing rule to set the position of the new category before you add it. You can also right-click an existing rule and select **Insert new category**.
- Step 2** Enter a **Name**.
- Step 3** From the **Insert** drop-down list, choose where you want to add the category:
- To insert a category below all existing categories in a section, choose **into Mandatory** or **into Default**.
  - To insert a category above an existing category, choose **above category**, then choose a category.
  - To insert a category above or below an access control rule, choose **above rule** or **below rule**, then enter an existing rule number.
- Step 4** Click **Apply**.
- Step 5** Click **Save** to save the policy.
- 

### Create and Edit Access Control Rules

Use access control rules to apply actions to specific traffic classes. Rules allow you to selectively allow desirable traffic and drop unwanted traffic.

#### Procedure

- 
- Step 1** In the access control policy editor, you have the following options:
- To add a new rule, click **Add Rule**.

- To edit an existing rule, click **Edit** (✎).
- To edit multiple rules, use the checkboxes to select multiple rules, then select **Edit** or another action from the **Select Action** list next to the search box.
- To do inline editing, where you change the configuration of an object in a rule condition, right-click the value and choose **Edit**. You can also use the right-click menu to remove a item, add it to the filter, or copy the text or value.

If **View** (👁) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

**Step 2** If this is a new rule, enter a **Name**.

**Step 3** Configure the rule components.

If you are bulk-editing multiple rules, only a subset of options are available.

- Position—Specify the rule position; see [Access Control Rule Order, on page 1857](#).
- Action—Choose a rule **Action**; see [Access Control Rule Actions, on page 1858](#).
- Deep Inspection—(Optional.) For Allow and Interactive Block rules, select options for **Intrusion Policy**, **Variable Set**, and **File Policy**. You can apply intrusion and file policies independently; you do not need to configure both.
- Time Range—(Optional.) For threat defense devices, choose the days and times when the rule is applicable. If you do not choose an option, the rule is always active. For details, see [Creating Time Range Objects, on page 1538](#).
- Logging—Click **Logging** to specify options for connection logging and SNMP traps.
- Conditions—Select the objects you want to add or either source or destination, then click either **Add to Sources** or **Add to Destinations and Applications** to add matching conditions for connections. You can click a tab to restrict the list of available objects, for example, to Networks, Security Zones, Applications, and so forth. However, the sources and destination column always show all selected objects regardless of the tab you are on. See [Access Control Rule Conditions, on page 1865](#) for more information.
- Comments—Open the comments list at the bottom of the dialog box, enter your comment, and click **Post** to add a comment.

**Step 4** Click **Add** or **Apply** to save the rule.

**Step 5** Click **Save** to save the policy.

### What to do next

If you will deploy time-based rules, specify the time zone of the device to which the policy is assigned. See [Time Zone, on page 1128](#).

Deploy configuration changes.

### Related Topics

[Best Practices for Access Control Rules](#), on page 1823

## Access Control Rule Conditions

Rule conditions define the characteristics of the connections you want to target with each rule. Use the conditions precisely to fine-tune the rule to apply to all, and only, the traffic that should be handled by the rule. The following topics explain the match conditions that you can use.

### Security/Tunnel Zone Rule Conditions

You can use security zones and tunnel zones to select traffic for a rule.

Security zones segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices. Tunnel zones allow you to identify tunneled traffic, such as GRE, that should be handled as a tunnel rather than apply access control rules to the encapsulated connections within the tunnel.

You can use security zones to control traffic by its source and destination interfaces. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones for it to match the rule. Just as all interfaces in a security zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

When using tunnel zones, ensure that you have matching rules in the prefilter policy to associate tunneled traffic with the zone. Then, you can select the tunnel zone as a source zone in a rule; tunnel zones cannot be destinations. If you do not have prefilter rules to rezone the tunnels into the tunnel zone, an access control rule for the tunnel will never apply to any connections. You can specify destination security zones to target tunnels that leave the device through specific interfaces.

### Security Zone Considerations

Consider the following when deciding on security zone criteria:

- Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.
- Access control rules generate ACL entries (ACEs) in the device configuration to provide early processing and drops whenever possible. If you specify security zones in rules, ACEs are created for each interface in the zone, which can greatly increase the size of the ACL. Excessively large ACLs generated from access control rules can impact system performance.

### Network Rule Conditions

Network rule conditions are the network objects or geographical locations that define the network addresses or locations of the traffic.

- To match traffic from an IP address or geographical location, add the criteria to the Sources list.
- To match traffic to an IP address or geographical location, add the criteria to the Destinations list.
- If you add both source and destination network conditions to a rule, matching traffic must originate from one of the specified IP addresses and be destined for one of the destination IP addresses.

When you add this criteria, you select from the following tabs:

- **Network**—Select the network objects or groups that define the source or destination IP addresses for the traffic you want to control.

Whenever possible, combine multiple network objects into a single object group. The system automatically creates an object group (during deployment) when you select more than one object (for source or destination separately). Selecting existing groups can avoid object group duplication and reduce the potential impact on CPU usage when there are a large number of duplicate objects.

You can use objects that define the address using the fully-qualified domain name (FQDN); the address is determined through a DNS lookup. However, FQDN objects are not supported in the following sections in access control policies: Original Client networks, SGT/ISE attributes, Network Analysis And Intrusion policy, Security Intelligence, Threat Detection, Elephant Flow Settings.

- **Geolocation**—Select the geographical location to control traffic based on its source or destination country or continent. Selecting a continent selects all countries within the continent. Besides selecting geographical location directly in the rule, you can also select a geolocation object that you created to define the location. Using geographical location, you could easily restrict access to a particular country without needing to know all of the potential IP addresses used there.

---

**Note** To ensure that you are using up-to-date geographical location data to filter your traffic, Cisco strongly recommends that you regularly update the geolocation database (GeoDB).

---

### Original Client in Network Conditions (Filtering Proxied Traffic)

For some rules, you can handle proxied traffic based on the originating client. Use a source network condition to specify proxy servers, then add an original client constraint to specify original client IP addresses. The system uses a packet's X-Forwarded-For (XFF), True-Client-IP, or custom-defined HTTP header field to determine original client IP.

Traffic matches the rule if the proxy's IP address matches the rule's source network constraint, **and** the original client's IP address matches the rule's original client constraint. For example, to allow traffic from a specific original client address, but only if it uses a specific proxy, create three access control rules:

Access Control Rule 1: Blocks proxied traffic from a specific IP address (209.165.201.1)

Source Networks: 209.165.201.1  
 Original Client Networks: none/any  
 Action: Block

Access Control Rule 2: Allows proxied traffic from the same IP address, but only if the proxy server for that traffic is one you choose (209.165.200.225 or 209.165.200.238)

Source Networks: 209.165.200.225 and 209.165.200.238  
 Original Client Networks: 209.165.201.1  
 Action: Allow

Access Control Rule 3: Blocks proxied traffic from the same IP address if it uses any other proxy server.

Source Networks: any  
 Original Client Networks: 209.165.201.1  
 Action: Block

## VLAN Tags Rule Conditions

**Note** VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

VLAN rule conditions control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic. The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note the following Q-in-Q support:

- Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

## User Rule Conditions

User rule conditions match traffic based the user who initiates the connection, or the group to which the user belongs. For example, you could configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in [Associating Other Policies with Access Control, on page 1844](#).

In addition to configuring users and groups for configured realms, you can set policies for the following Special Identities users:

- Failed Authentication: User that failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified; for example, users that are not downloaded by a configured realm.

## Application Rule Conditions

When the system analyzes IP traffic, it can identify and classify the commonly used applications on your network. This discovery-based *application awareness* is the basis for *application control*—the ability to control application traffic.

System-provided *application filters* help you perform application control by organizing applications according to basic characteristics: type, risk, business relevance, category, and tags. You can create reusable user-defined filters based on combinations of the system-provided filters, or on custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled for an application, the system automatically enables all system-provided detectors for the application; if none exist, the system enables the most recently modified user-defined detector for the application. For more information about application detectors, see [Application Detector Fundamentals, on page 2660](#).

You can use both application filters and individually specified applications to ensure complete coverage. However, understand the following note before you order your access control rules.

### Benefits of Application Filters

Application filters help you quickly configure application control. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

### Application Characteristics

The system characterizes each application that it detects using the criteria described in the following table. Use these characteristics as application filters.

**Table 113: Application Characteristics**

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email clients are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged high bandwidth and displays ads.

## Related Topics

[Best Practices for Configuring Application Control](#), on page 1820

### *Configuring Application Conditions and Filters*

To build an application condition or filter, choose the applications whose traffic you want to control from a list of available applications. Optionally (and recommended), constrain the available applications using filters. You can use filters and individually specified applications in the same condition.

### Before you begin

- Adaptive profiling must be enabled (its default state) as described in [Configuring Adaptive Profiles, on page 2940](#) for access control rules to perform application control.
- If you are implementing content restrictions, follow the procedure in [Using Access Control Rules to Enforce Content Restriction, on page 2025](#) instead of this one.
- For Classic device models, you must have the Control license to configure these conditions.

## Procedure

- 
- Step 1** Invoke the rule or configuration editor:
- Access control, decryption, QoS rule condition—In the rule editor, click **Applications**.
  - Identity rule condition—In the rule editor, click **Realms & Settings** and enable active authentication; see [Create an Identity Rule, on page 2618](#).
  - Application filter—On the Application Filters page of the object manager, add or edit an application filter. Provide a unique **Name** for the filter.
  - Intelligent Application Bypass (IAB)—In the access control policy editor, click **Advanced**, edit IAB settings, then click **Bypassable Applications and Filters**.
- Step 2** Find and choose the applications you want to add from the **Available Applications** list.
- To constrain the applications displayed in **Available Applications**, choose one or more **Application Filters** or search for individual applications.
- Tip** Click **Information** (i) next to an application to display summary information and internet search links. **Unlock** marks applications that the system can identify only in decrypted traffic.
- When you choose filters, singly or in combination, the Available Applications list updates to display only the applications that meet your criteria. You can choose system-provided filters in combination, but not user-defined filters.
- Multiple filters for the same characteristic (risk, business relevance, and so on)—Application traffic must match only one of the filters. For example, if you choose both the medium and high-risk filters, the Available Applications list displays all medium and high-risk applications.
  - Filters for different application characteristics—Application traffic must match both filter types. For example, if you choose both the high-risk and low business relevance filters, the Available Applications list displays only applications that meet both criteria.
- Step 3** Click **Add Application** or **Add to Rule**, or drag and drop.

**Tip** Before you add more filters and applications, click **Clear Filters** to clear your current choices.

**Step 4** Save or continue editing the rule or configuration.

---

### What to do next

- Deploy configuration changes.

## Port, Protocol, and ICMP Code Rule Conditions

Port conditions match traffic based on the source and destination ports. Depending on the rule type, “port” can represent any of the following:

- TCP and UDP—You can control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP(6)/22.
- ICMP—You can control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—You can control traffic using other protocols that do not use ports.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

### Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic. Note that application filtering is not available in prefilter rules.

Application filtering is also recommended for applications, like FTP, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

### Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

### Matching Non-TCP Traffic with Port Conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although you can configure port conditions to match non-TCP traffic, there are some restrictions:

- Access control rules—For Classic devices, you can match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule,

you can add only network-based conditions: zone, IP address, port, and VLAN tag. Also, the system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For threat defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.

- Decryption rules—These rules support TCP port conditions only.
- ICMP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies sent in response to ICMP echo requests are ignored. For a rule to match on any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

## URL Rule Conditions

Use URL conditions to control the websites that users on your network can access.

For complete information, see [URL Filtering, on page 1919](#).

## Dynamic Attributes Rule Conditions

Dynamic attributes include the following:

- Dynamic objects (such as from the Cisco Secure Dynamic Attributes Connector)

The dynamic attributes connector enables you to collect data (such as networks and IP addresses) from cloud providers and send it to the Firepower Management Center so it can be used in access control rules.

For more information about the dynamic attributes connector, see the information later in this guide.

- SGT objects
- Location IP objects
- Device type objects
- Endpoint profile objects

Dynamic attributes can be used as source criteria and destination criteria in access control rules. Use the following guidelines:

- Objects of different types are ANDd together
- Objects of a similar type are ORd together

For example, if you choose source destination criteria SGT 1, SGT 2, and device type 1; the rule is matched if device type 1 is detected on either SGT 1 or SGT 2.

### About API-Created Dynamic Objects

A *dynamic object* is an object that specifies one or many IP addresses retrieved either using REST API calls or using the Cisco Secure Dynamic Attributes Connector, which is capable of updating IP addresses from cloud sources. These dynamic objects can be used in access control rules without the need to deploy the access control policy afterward.

For more information about the dynamic attributes connector, see the information later in this guide.

Differences between dynamic objects and network objects follow:

- Dynamic objects created using the dynamic attributes connector are pushed to the management center as soon as they're created and are updated at a regular interval.

- API-created dynamic objects:
  - Are IP addresses, with or without or classless inter-domain routing (CIDR), that can be used in access control rules much like a network object.
  - Do not support fully-qualified domain names or address ranges.
  - Must be updated using an API.

### Related Topics

[Add or Edit an API-Created Dynamic Object](#), on page 1487

### Configure Dynamic Attributes Conditions

When you configure dynamic attributes for an access control rule, objects of the same type are ORed together and objects of different types are ANDed together. An example is shown at the end of this topic.

---

**Note** This procedure is based on the Legacy UI. In the New UI Layout you can add dynamic attributes by clicking **Add (+)** in the **Sources** and **Destinations and Applications** fields.

---

### Before you begin

Create some dynamic objects and understand how those objects are used in access control policy.

For more information about dynamic objects, see [About API-Created Dynamic Objects, on page 1487](#).

For more information about how dynamic objects are used in access control policy, see [Dynamic Attributes Rule Conditions, on page 1871](#).

### Procedure

- 
- Step 1** In the rule editor, click **Dynamic Attributes**.
- Step 2** Do any of the following in the Available Attributes section:
- Enter part of all of the name of an attribute in the field.
  - Click **Security Group Tag** or **Dynamic Objects** to view only objects of that type.
- Step 3** To apply the objects you selected to source matching criteria, click **Add to Source**.
- Step 4** To apply the objects you selected to destination matching criteria, click **Add to Destination**.
- Step 5** When you're finished configuring the rule, click **Save**.
- 

### Example: Using multiple source conditions in a block rule

The following example blocks traffic from Security Group Tags Contractors or Guests; and device types Android or Blackberry from accessing the dynamic object `__azure1`.

Add Rule +

Name: SampleGoodRule  Enabled Insert: into Mandatory

Action: Block Time Range: None

Zones Networks VLAN Tags **Users** Applications Ports URLs Dynamic Attributes Inspection Logging Comments

- Network\_Services

Add to Source Add to Destination

Selected Source Attributes (4)

- Security Group Tags
- Contractors
- Guests
- Device types
- Android
- BlackBerry

Add a Location IP Address Add

Selected Destination Attributes (1)

- Dynamic Objects
- \_\_azure1

Attributes of the same type (for example, SGT) match the rule if any attribute is matched.  
Attributes of different types match the rule only if all attributes are matched. [More info](#)

Cancel Add

### What to do next

- Deploy configuration changes.

## Time and Day Rule Conditions

You can specify a continuous time range or a recurring time period.

For example, a rule can apply only during weekday working hours, or every weekend, or during a holiday shutdown period.

Time-based rules are applied based on the local time of the device that processes the traffic.

Time-based rules are supported only on threat defense devices. If you assign a policy with a time-based rule to a different type of device, the time restriction associated with the rule is ignored on that device. You will see warnings in this case.

## Enabling and Disabling Access Control Rules

When you create an access control rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing the list of rules in an access control policy, disabled rules are grayed out, although you can still modify them.

You can also enable or disable an access control rule using the rule editor.

### Procedure

- 
- Step 1** In the access control policy editor, right-click the rule and choose a rule state.

If **View** (👁) appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.

**Step 2** Click **Save**.

---

#### What to do next

- Deploy configuration changes.

## Copying Access Control Rules from One Access Control Policy to Another

You can copy access control rules from one access control policy to another. You can copy the rules either to the **Default** section or the **Mandatory** section of the access control policy.

All the settings of the copied rules, except the comments, are retained in the pasted version.

### Procedure

---

**Step 1** Do one of the following:

- To copy a single rule, right-click the rule and select **Copy to Different Policy**.
- To copy multiple rules, select their checkboxes, then select **Copy to Different Policy** from the **Select Bulk Action** menu.

**Step 2** Select the destination access control policy from the **Access Policy** drop-down list.

**Step 3** From the **Place Rules** drop-down list, choose where you want to position the copied rules. You can place them at the bottom of either the Mandatory or Default sections.

**Step 4** Click **Copy**.

---

#### What to do next

- Deploy configuration changes.

## Moving Access Control Rules to a Prefilter Policy

You can move access control rules from an access control policy to the associated non-default prefilter policy.

You must first apply a user-defined prefilter policy to the access control policy. The access control rules cannot be moved to the default prefilter policy because the default prefilter policy cannot have rules.

#### Before you begin

Note the following conditions before you proceed:

- When moving an access control rule to a prefilter policy the layer 7 (L7) parameters in the access control rule cannot be moved. The L7 parameters are dropped during the operation.

- The comments in the access control rule configuration are lost after moving the rule. However, a new comment is added in the moved rule mentioning the source access control policy.
- You cannot move access control rules with **Monitor** set as the **Action** parameter.
- The **Action** parameter in the access control rule is changed to a suitable action in the prefilter rule when moved. To know what each action in the access control rule maps to, see the following table:

Action in the access control rule	Action in the prefilter rule
Allow	Analyze
Block	Block
Block with reset	Block
Interactive Block	Block
Interactive Block with reset	Block
Trust	Fastpath

- Similarly, based on the action configured in the access control rule, the logging configuration is set to an appropriate setting after the rule is moved, as mentioned in the following table.

Action in the access control rule	Enabled Logging configurations in the prefilter rule
Allow	None of the check boxes are checked.
Block	<ul style="list-style-type: none"> <li>• Log at Beginning of Connection</li> <li>• Event Viewer</li> <li>• Syslog Server</li> <li>• SNMP Trap</li> </ul>
Block with reset	<ul style="list-style-type: none"> <li>• Log at Beginning of Connection</li> <li>• Event Viewer</li> <li>• Syslog Server</li> <li>• SNMP Trap</li> </ul>
Interactive Block	<ul style="list-style-type: none"> <li>• Log at Beginning of Connection</li> <li>• Event Viewer</li> <li>• Syslog Server</li> <li>• SNMP Trap</li> </ul>

Action in the access control rule	Enabled Logging configurations in the prefilter rule
Interactive Block with reset	<ul style="list-style-type: none"> <li>• Log at Beginning of Connection</li> <li>• Event Viewer</li> <li>• Syslog Server</li> <li>• SNMP Trap</li> </ul>
Trust	<ul style="list-style-type: none"> <li>• Log at Beginning of Connection</li> <li>• Log at End of Connection</li> <li>• Event Viewer</li> <li>• Syslog Server</li> <li>• SNMP Trap</li> </ul>

- While moving rules from the source policy, if another user modifies those rules, you will see get a message. You may continue with the process after refreshing the page.

## Procedure

- 
- Step 1** Do one of the following:
- To move a single rule, right-click the rule and select **Move to Prefilter Policy**.
  - To move multiple rules, select their checkboxes, then select **Move to Prefilter Policy** from the **Select Bulk Action** menu.
- Step 2** From the **Place Rules** drop-down list, choose where you want to position the moved rules:
- To position as the last set of rules, choose **At the bottom**.
  - To position as the first set of rules, choose **At the top**.
- Step 3** Click **Move**.
- 

### What to do next

- Deploy configuration changes.

## Positioning an Access Control Rule

You can move an existing rule within an access control policy, or insert new rules in a desired location. When you add or move a rule to a category, the system places it last in the category.

### Before you begin

Review rule order guidelines in [Best Practices for Access Control Rules](#), on page 1823.

### Procedure

- 
- Step 1** Do one of the following:
- New rule—Insert a new rule by hovering over the line between the existing rules, and clicking **Add Rule**. The location is selected in the **Insert** box in the Add Rule dialog box; you can select a different rule to adjust the location. You can also select **Add Rule Above** or **Add Rule Below** from the right-click menu.
  - Existing rules when viewing the rule table—Click and drag the rule to the new position.
  - Existing rules when viewing the rule table—Right-click a single rule and select **Reposition Rule**. To move multiple rules as a group, select their checkboxes, then select **Reposition Rules** from the **Select Bulk Action** menu.
  - Existing rule when editing the rule—Click the **Reposition Rule** icon next to the rule name.
- Step 2** Choose where you want to move or insert the rule:
- Choose **into Mandatory** or **into Default**.
  - Choose a **into Category**, then choose the category.
  - Choose **above rule** or **below rule**, then select the rule.
- Step 3** Click **Move** or **Confirm**, and save the rule if you are editing it.
- Step 4** Click **Save** to save the policy.
- 

### What to do next

- Deploy configuration changes.

## Adding Comments to an Access Control Rule

When you create or edit an access control rule, you can add a comment. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change. You can display a list of all comments for a rule along with the user who added each comment and the date the comment was added.

When you save a rule, all comments made since the last save become read-only.

To search access control rule comments, use the "Search Rules" bar on the rule listing page.

### Procedure

- 
- Step 1** In the access control rule editor, click **Comments**.
- Step 2** Enter your comment and click **Add Comment**. You can edit or delete this comment until you save the rule.

**Step 3** Save the rule.

---

## Examples for Access Control Rules

The following topics provide examples of access control rules.

### How to Control Access Using Security Zones

Consider a deployment where you want hosts to have unrestricted access to the internet, but you nevertheless want to protect them by inspecting incoming traffic for intrusions and malware.

First, create two security zones: Internal and External. Then, assign interface pairs on one or more devices to those zones, with one interface in each pair in the Internal zone and one in the External zone. Hosts connected to the network on the Internal side represent your protected assets.

---

**Note** You are not required to group all internal (or external) interfaces into a single zone. Choose the grouping that makes sense for your deployment and security policies.

---

Then, configure an access control rule with a destination zone condition set to Internal. This simple rule matches traffic that leaves the device from any interface in the Internal zone. To inspect matching traffic for intrusions and malware, choose a rule action of **Allow**, then associate the rule with an intrusion and a file policy.

### How to Control Application Usage

The Web has become the ubiquitous platform for application delivery in the enterprise, whether that is browser based application platforms, or rich media applications that use web protocols as the transport in and out of enterprise networks.

Threat Defense inspects connections to determine the application being used. This makes it possible to write access control rules targeted at applications, rather than just targeting specific TCP/UDP ports. Thus, you can selectively block or allow web-based applications even though they use the same port.

Although you can select specific applications to allow or block, you can also write rules based on type, category, tag, risk, or business relevance. For example, you could create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the session is blocked.

Cisco frequently updates and adds additional application detectors via system and vulnerability database (VDB) updates. Thus, a rule blocking high risk applications can automatically apply to new applications without you having to update the rule manually.

In this use case, we will block any application that belongs to the **anonymizer/proxy** category.

## Procedure

**Step 1** Choose **Policies > Access Control** and edit the access control policy.

**Step 2** Click **Add Rule** and configure the rule for application control.

- a) Give the rule a meaningful name, such as `Block_Anonymizers`.
- b) Select **Block** for **Action**.

Name:  Action:

- c) Assuming that you have configured zones, and want this rule to apply to traffic going from the inside to outside, select the **Zones** tab, and choose your inside zone as the source zone, and the outside zone as the destination zone.
- d) Click the **Applications** tab, select the applications to match, and click **Add Application**.

As you select criteria, such as category and risk level, the list to the right of the criteria updates to show exactly which applications match the criteria. The rule you are writing applies to these applications.

**Look at this list carefully.** For example, you might be tempted to block all very high risk applications. However, as of this writing, TFPT is classified as very high risk. Most organizations would not want to block this application. Take the time to experiment with various filter criteria to see which applications match your selections. Keep in mind that these lists can change with every VDB update.

For purposes of this example, select anonymizers/proxies from the Categories list and add it to Destinations and Applications. The match criteria should now look like the following graphic.

Selected Sources: 1		Selected Destinations and Applications: 2	
<a href="#">Collapse All</a>	<a href="#">Remove All</a>	<a href="#">Collapse All</a>	<a href="#">Remove All</a>
<b>ZONE</b>	▼ 1 object inside-zone	<b>ZONE</b>	▼ 1 object outside-zone
		<b>APP</b>	▼ 1 object Categories: anonymizer/proxy

- e) Click **Logging** next to the rule action, and enable logging at the start of the connection. You can select a syslog server if you use one.

You must enable logging to get information about any connections blocked by this rule.

**Step 3** Move the rule so that it comes after any rules that use protocol and port criteria only, but that would not allow traffic that should be blocked by the application rule.

Matching applications requires Snort inspection. Because Snort inspection is not needed by rules that use protocol and port only, you can improve system performance by grouping these simple rules at the top of the access control policy as much as possible.

**Step 4** Deploy the changes.

You can use the application rule hit counts and analysis dashboards to see how this rule is performing and how often users try these applications.

## How to Block Threats

You can implement next generation Intrusion Prevention System (IPS) filtering by adding intrusion policies to your access control rules. Intrusion policies analyze network traffic, comparing the traffic contents against known threats. If a connection matches a threat you are monitoring, the system drops the connection, thus preventing the attack.

All other traffic handling occurs before network traffic is examined for intrusions. By associating an intrusion policy with an access control rule, you are telling the system that before it passes traffic that matches the access control rule's conditions, you first want to inspect the traffic with an intrusion policy.

You can configure intrusion policies on rules that **allow** traffic only. Inspection is not performed on rules set to **trust** or **block** traffic. In addition, you can configure an intrusion policy as the default action if you do not want to use a simple block.

Besides inspecting traffic that you allow for potential intrusions, you can use the Security Intelligence policy to preemptively block all traffic to or from known bad IP addresses, or to known bad URLs.

This example adds an intrusion policy that allows the internal 192.168.1.0/24 network to go outside, and assumes you already have block rules to selectively eliminate unwanted connections, while also adding a Security Intelligence policy to do pre-emptive blocking.

### Before you begin

You must apply the IPS license to any managed device that uses this rule.

This example assumes you have already created security zones for inside and outside interfaces, and the network object for the inside network.

## Procedure

### Step 1

Create the access control rule that applies the intrusion policy.

- While editing the access control policy, click **Add Rule**.
- Give the rule a meaningful name, such as `Inside_Outside`, and ensure the rule action is **Allow**.

Name:

Action:

- For **Intrusion Policy**, select **Balanced Security and Connectivity**. You can either accept the default variable set or select your own if you want to customize it.

The **Balanced Security and Connectivity** policy is appropriate for most networks. It provides a good intrusion defense without being overly aggressive, which has the potential of dropping traffic that you might not want to be dropped. If you determine that too much traffic is getting dropped, you can ease up on intrusion inspection by selecting the **Connectivity over Security** policy.

If you need to be aggressive about security, try the **Security over Connectivity** policy. The **Maximum Detection** policy offers even more emphasis on network infrastructure security with the potential for even greater operational impact.

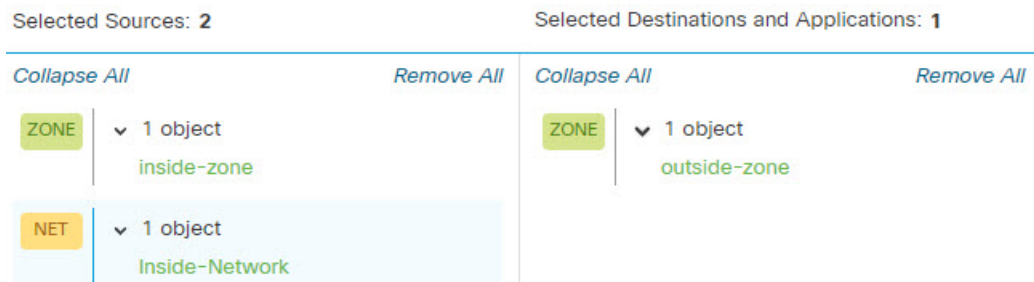

If you create your own custom policy, you can select that one instead.

A discussion of variable sets is beyond the scope of this example. Please read the chapters on intrusion policy for detailed information about variable sets and custom policies.

- d) Select the **Zones** tab, and add your inside security zone to the source criteria, and outside zone to the destination criteria.
- e) Select the **Networks** tab, and add the network object that defines your inside network to the source criteria.

The match criteria should look similar to the following:

- f) Click **Logging** and enable logging at the beginning or end of the connection, or both, as desired.
- g) Click **Apply** to save the rule, and then **Save** to save the updated policy.
- h) Move the rule to the appropriate location in the access control policy.

## Step 2

Configure the Security Intelligence policy to preemptively drop connections with known bad hosts and sites.

By using Security Intelligence to block connections with hosts or sites that are known to be threats, you save your system the time needed to do deep packet inspection to identify threats in each connection. Security Intelligence provides an early block of undesirable traffic, leaving more system time to handle the traffic you really care about.

- a) While editing the access control policy, click the **Security Intelligence** link in the packet path.  
The link includes two policies: the DNS policy at the top, and the Security Intelligence (Network and URL) at the bottom. In this example, we are configuring the Network and URL lists. By default, these lists already include the global block and do not block lists, but these lists are empty by default until you add items to them.
- b) With **Networks** selected and the **Any** security zone selected, scroll down in the list until you get to the global lists, and the first Security Intelligence category (probably Attackers). Click Attackers, then scroll to the end of the categories (probably Tor\_exit\_node), and Shift+Click to select all of the categories. Click **Add To Block List**.
- c) Select the **URL** tab, and **Any** security zone, and use Shift+Click to select URL versions of the same categories. Click **Add To Block List**.
- d) Click **Save** to save the policy.
- e) As necessary, you can add network and URL objects to the block or do not block lists.

The **Do Not Block** lists are not real "allow" lists. They are exception lists. If an address or URL in the exception list also appears in the blocked list, the connection for the address or URL is allowed to pass on to the access control policy. This way, you can block a feed, but if you later find that a desirable address or site is being blocked, you can use the exception list to override that block without needing to remove the feed entirely. Keep in mind that these connections are subsequently evaluated by access control, and if configured, an intrusion policy. Thus, if any connections do contain threats, they can be identified and blocked during intrusion inspection.

Use the events and dashboards to determine what traffic is actually being dropped by the policy, and whether you need to add addresses or URLs to the **Do Not Block** lists.

**Step 3** Deploy your changes.

---

## How to Block QUIC Traffic

As a best practice, we recommend you to block QUIC traffic. Chrome browsers have the QUIC protocol enabled by default. When you try to access Google applications using the Chrome browser, a session to a Google server is established using the QUIC protocol instead of TLS/SSL. QUIC is an experimental protocol at its early stages of development, and it uses proprietary encryption methods.

Secure Hypertext Transfer Protocol (HTTPS) uses Transmission Control Protocol (TCP), as does Hypertext Transfer Protocol (HTTP). Transmission Control Protocol is connection oriented or stateful. HTTPS uses TCP port 443 and HTTP uses TCP port 80. HTTP/3 runs on the QUIC protocol. For QUIC, HTTP/3 relies on the User Datagram Protocol (UDP), not the TCP.

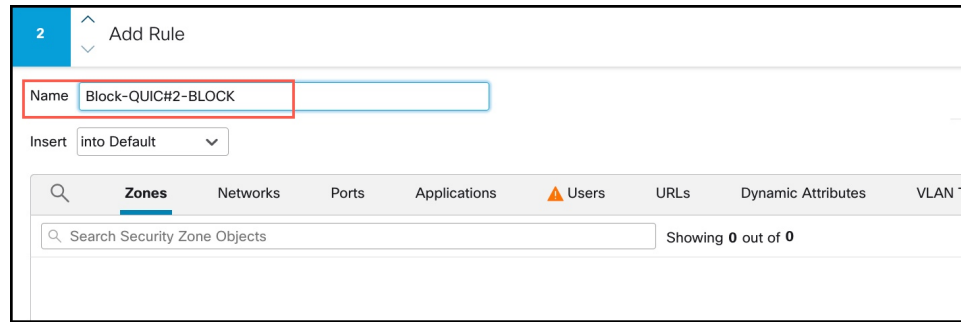

QUIC could inadvertently have a negative impact on network security. Security appliances, such as firewalls and network sensors, typically are not able to access information that can be accessed with legacy TCP sessions. With the QUIC traffic getting blocked by the firewall, the Chrome browser falls back to using traditional TLS/SSL. Note that this does not cause loss of any functionality on the browser. Firewall gains better visibility and control of Google applications with or without the SSL decryption enabled. QUIC traffic is therefore not scrutinized as it should be and it is not forwarded to the firewall's web protection features.

In this use case, we show how to create an access control rule to block QUIC and HTTP/3 traffic.

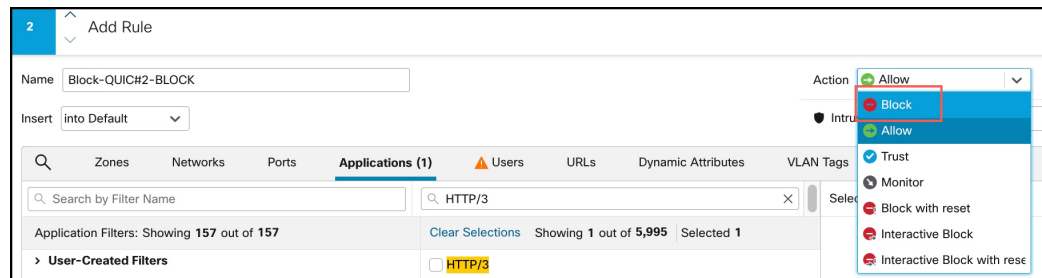

### Procedure

---

- Step 1** Choose **Policies > Access Control** and edit the access control policy.
- Step 2** Click **Add Rule**.
- Step 3** Enter a meaningful name for the rule, such as Block-QUIC.

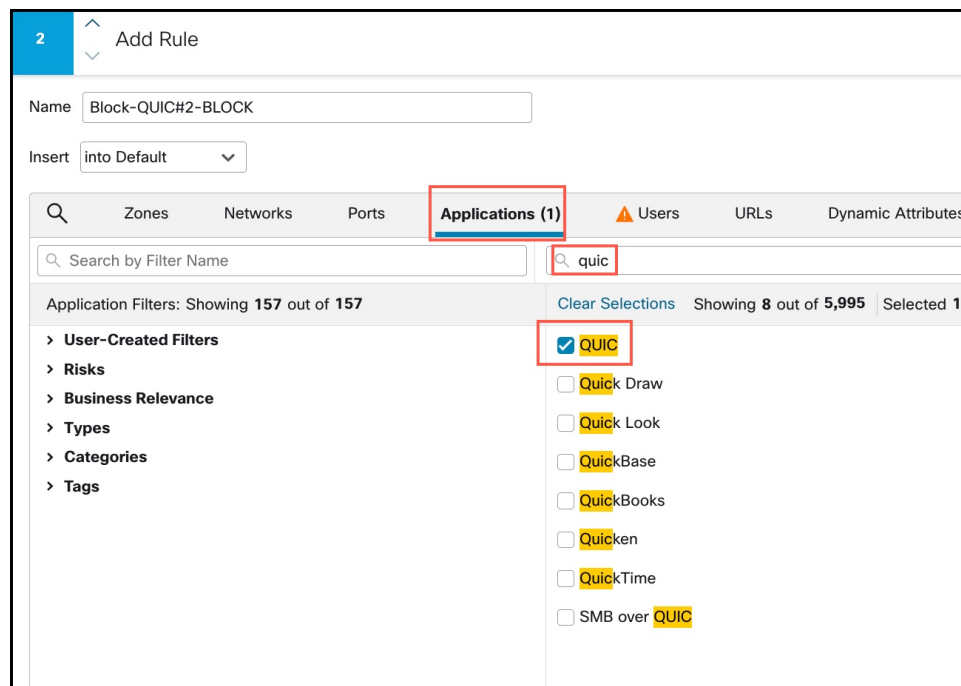

**Step 4** From the **Actions** drop-down list, choose **Block**.

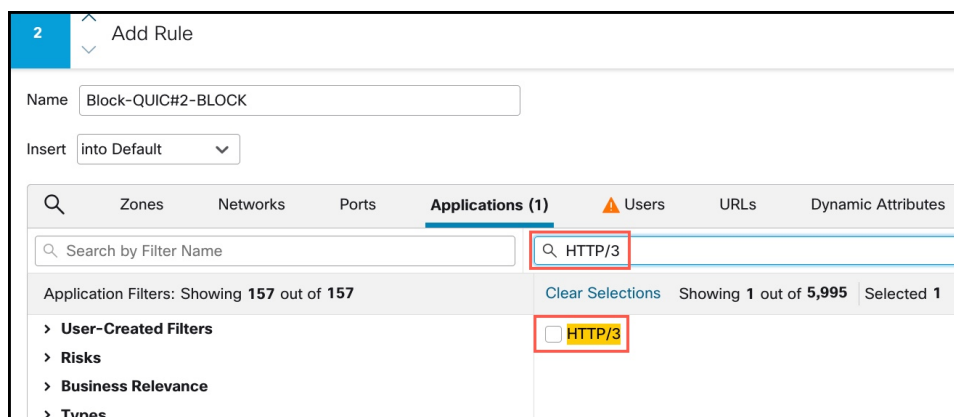

**Step 5** Click the **Applications** tab.

**Step 6** Search for "quic" in the Search box and check the QUIC application check box.

**Step 7** Search for "HTTP/3" in the search box and check the HTTP/3 check box.

**Step 8** Click **Add Application** to add to Destinations and Applications.

**Step 9** Click **Logging** next to the rule action, and enable logging at the start of the connection. You must enable logging to get information about any connections blocked by this rule.

**Step 10** Click **Apply** to save the rule, and then **Save** to save the updated policy.

**Step 11** Move the rule to the appropriate location in the access control policy.

**Step 12** Deploy your changes.

# CHAPTER 65

## Cisco Secure Dynamic Attributes Connector

The following topics discuss how to configure and use the Cisco Secure Dynamic Attributes Connector.

- [About the Cisco Secure Dynamic Attributes Connector](#) , on page 1885
- [Enable the Cisco Secure Dynamic Attributes Connector](#), on page 1887
- [About the Dashboard](#), on page 1888
- [Create a Connector](#), on page 1894
- [Create an Adapter](#), on page 1911
- [Create Dynamic Attributes Filters](#), on page 1913
- [Disable the Cisco Secure Dynamic Attributes Connector](#), on page 1915
- [Use Dynamic Objects in Access Control Policies](#), on page 1916
- [Troubleshoot the Dynamic Attributes Connector](#), on page 1917

### About the Cisco Secure Dynamic Attributes Connector

The Cisco Secure Dynamic Attributes Connector enables you to use service tags and categories from various cloud service platforms in Cisco Security Cloud Control access control rules.

#### Supported connectors

We currently support:

**Table 114: List of supported connectors by Cisco Secure Dynamic Attributes Connector version and platform**

CSDAC version/platform	AWS	AWS security groups	AWS service tags	Azure	Azure Service Tags	Cisco Cyber Vision	Cisco Multicloud Defense	Generic text	GitHub	Google Cloud	Microsoft Office 365	vCenter	Webex	Zoom
Version 1.1 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	No	No	Yes	Yes	No	No
Version 2.0 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	No	Yes	Yes	Yes	No	No
Version 2.2 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	Yes	Yes	Yes	Yes	No	No
Version 2.3 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	Yes	Yes	Yes	Yes	Yes	Yes
Version 3.0 (on-premises)	Yes	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes

CSDAC version/platform	AWS	AWS security groups	AWS service tags	Azure	Azure Service Tags	Cisco Cyber Vision	Cisco Multicloud Defense	Generic text	GitHub	Google Cloud	Microsoft Office 365	vCenter	Webex	Zoom
Cloud-delivered (Security Cloud Control)	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes

- Zoom IP addresses  
For more information, see [Create a Zoom Connector, on page 1910](#).

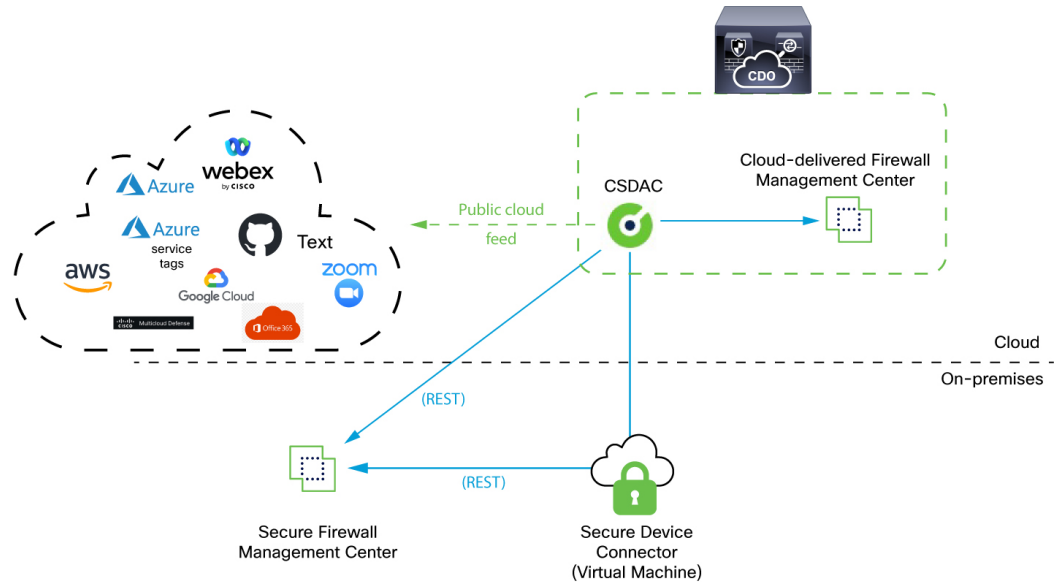

## How It Works

Network constructs such as IP address are not reliable in virtual, cloud and container environments due to the dynamic nature of the workloads and the inevitability of IP address overlap. Customers require policy rules

to be defined based on non-network constructs such as VM name or security group, so that firewall policy is persistent even when the IP address or VLAN changes.

The following figure shows how the system functions at a high level.

- The system supports certain public cloud providers.

This topic discusses supported *connectors* (which are the connections to those providers).

- The dynamic attributes connector is provided with Security Cloud Control; it includes a Cloud-delivered Firewall Management Center adapter and you can connect to an On-Prem Firewall Management Center using the Secure Device Connector.

For more information about the Secure Device Connector, see [Secure Device Connector \(SDC\)](#).

- The *adapter* defined by the dynamic attributes connector receives those dynamic attributes filters as *dynamic objects* and enables you to use them in access control rules.

You can create the following types of adapters:

- *On-Prem Firewall Management Center* for an on-premises device.

This type of device might be managed by Security Cloud Control or it might be a standalone.

- *Cloud-delivered Firewall Management Center* for devices managed by Security Cloud Control.

## Enable the Cisco Secure Dynamic Attributes Connector

This task discusses how to enable the dynamic attributes connector in Security Cloud Control. The dynamic attributes connector is an integration that enables objects from cloud networking products to be used in Security Cloud Control access control rules.

## Procedure

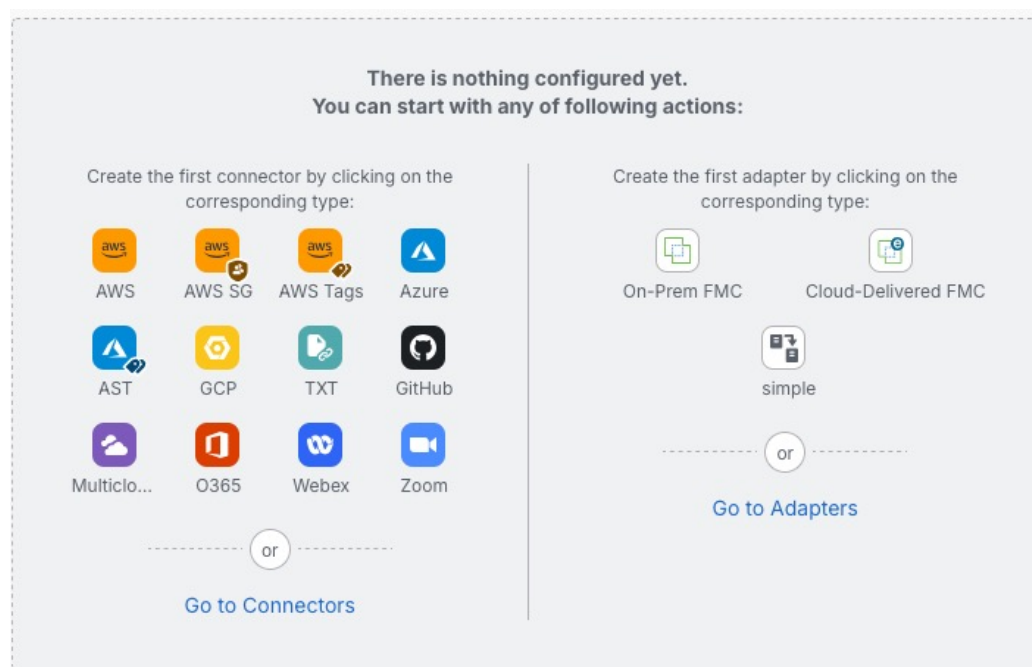

- 
- Step 1** Log in to the Security Cloud Control if you have not done so already.
- Step 2** Click **Administration > Dynamic Attributes Connector**.
- Step 3** Slide to **Enabled**.
- Step 4** Messages are displayed while the dynamic attributes connector is enabled.
- In the event of errors, try again. If errors persist, contact Cisco TAC.
- 

## About the Dashboard

To access the Cisco Secure Dynamic Attributes Connector Dashboard, log in to the Secure Firewall Manager and click **Integration > Dynamic Attributes Connector** at the top of the page.

If the Cisco Secure Dynamic Attributes Connector is not enabled, move the slider to enable it. This process could take several minutes to complete.

The Cisco Secure Dynamic Attributes Connector Dashboard page displays the status of your connectors, adapters, and filters at a glance. Following is an example of the Dashboard of an unconfigured system:

Among the things you can do with the Dashboard are:

- Add, edit, and delete connectors and dynamic attributes filters.
- See how connectors and dynamic attributes filters are related to each other.

- View warnings and errors.

### Related Topics

- [Dashboard of a Configured System, on page 1890](#)
- [Add, Edit, or Delete Connectors, on page 1891](#)
- [Add, Edit, or Delete Dynamic Attributes Filters, on page 1893](#)

## Dashboard of an Unconfigured System

Sample Cisco Secure Dynamic Attributes Connector Dashboard page of an unconfigured system:

The Dashboard initially displays all the types of connectors you can configure for your system. You can do any of the following:

- Hover the mouse pointer over a connector and click  to create a new one.
- Click **Go to Connectors** to add, edit, or delete connectors (good for creating, editing, or deleting multiple connectors at the same time).

For more information, see [Create a Connector, on page 1894](#).

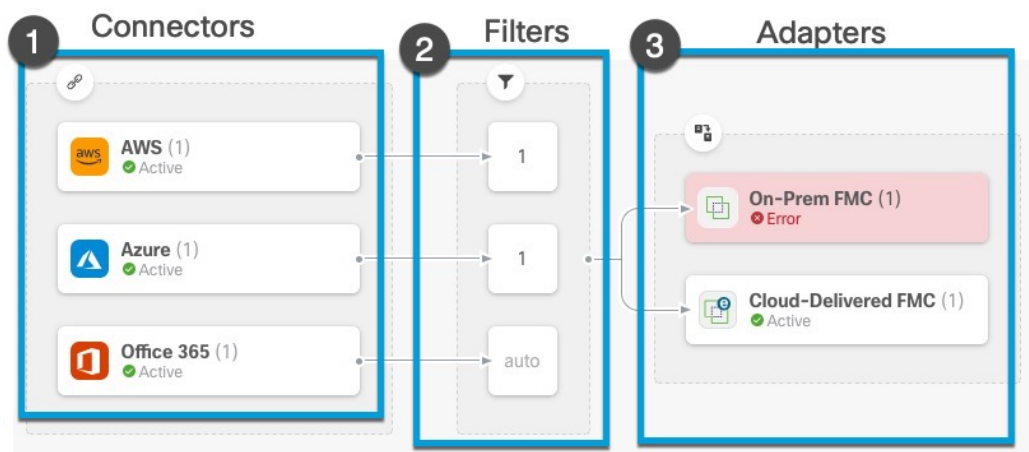

### Related Topics:

## Dashboard of a Configured System

Sample Cisco Secure Dynamic Attributes Connector Dashboard page of a configured system:  
Click an area in the figure to learn more about it or click one of the links following the figure.

- 1 [Create a Connector](#), on page 1894
- 2 [Create Dynamic Attributes Filters](#), on page 1913
- 3 [Create an Adapter](#), on page 1911

The Dashboard shows the following (from left to right):

Connectors column	Filters column	Adapters column
<p>List of connectors with a number indicating how many of each type are configured. Connectors collect dynamic attributes that could be sent to the configured adapter. Dynamic attributes filters specify what data is sent.</p> <p>Click  to view more information about all configured connectors. You can also click the name of a connector to add, edit, or delete connectors; or to view detailed information about them. For more information, see <a href="#">Add, Edit, or Delete Connectors</a>, on page 1891.</p>	<p>List of dynamic attributes filters associated with each connector with a number indicating how many of each filter are associated with a connector.</p> <p>Click  to view more information about all configured filters. You can also click the name of a filter to add, edit, or delete filters; or to view detailed information about them. For more information, see <a href="#">Add, Edit, or Delete Dynamic Attributes Filters</a>, on page 1893.</p>	<p>List of adapters. Adapters receive dynamic objects from configured connectors using configured dynamic attributes filters; these dynamic objects can be used in access control policies without the need to deploy them.</p> <p>Click  to view more information about all configured adapters. You can also click the name of an adapter to add, edit, or delete adapters; or to view detailed information about them. For more information, see <a href="#">Create an Adapter</a>, on page 1911.</p>

**Note** Some connectors, such as Outlook 365 and Azure Service tags, automatically pull available dynamic objects without the need for a dynamic attributes filters. Those connectors display **Auto** in the  column.

The Dashboard indicates whether or not an object is available. The Dashboard page is refreshed every 15 seconds but you can click **Refresh** () at the top of the page at any time to refresh immediately. If issues persist, check your network connection.

#### Related Topics:

- [Add, Edit, or Delete Dynamic Attributes Filters, on page 1893](#)
- [Create an Adapter, on page 1911](#)

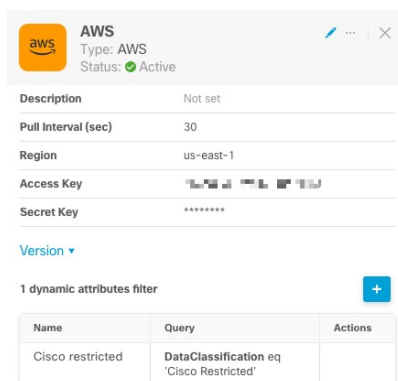

## Add, Edit, or Delete Connectors

The Dashboard enables you to view or edit connectors. You can click the name of a connector to view all

instances of that connector or you can click  for the following additional options:

- **Go to Connectors** to view all connectors at the same time; you can add, edit, and delete connectors from there.
- **Add Connector** > *type* to add a connector of the indicated type.

Click any connector in the connectors column () to display more information about it; an example follows:

Name	Query	Actions
Cisco restricted	DataClassification eq 'Cisco Restricted'	

You have the following options:

- Click the Edit icon () to edit this connector.
- Click the More icon () for additional options.
- Click  to close the panel.

- Click **Version** to display the version of the . You can optionally copy the version to the clipboard if necessary for [Cisco TAC](#).

The table at the bottom of the panel enables you to add dynamic attributes filters; or to edit or dynamic attributes connector delete connectors. A sample follows:

1 dynamic attributes filter +

Name	Query	Actions
Cisco restricted	DataClassification eq 'Cisco Restricted'	 

Click the Add icon () to add a dynamic attributes filter for this connector. For more information, see [Create Dynamic Attributes Filters, on page 1913](#).

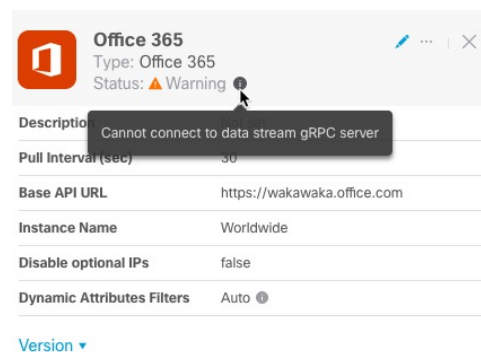

Hover the mouse pointer over the Actions column to either edit or delete the indicated connector.

### View error information

To view error information for a connector:

1. On the Dashboard, click the name of the connector that is displaying the error.
2. In the right pane, click **Information** ()

An example follows.

**Office 365**  
Type: Office 365  
Status: ▲ Warning

Description: Cannot connect to data stream gRPC server

Pull Interval (sec) 30

Base API URL https://wakawaka.office.com

Instance Name Worldwide

Disable optional IPs false

Dynamic Attributes Filters Auto

Version ▾

3. To resolve this issue, edit the connector settings as discussed in [Create an Office 365 Connector, on page 1908](#).
4. If you cannot resolve the issue, click **Version** and copy the version to a text file.
5. Get your Security Cloud Control tenant ID as discussed in [Get Your Tenant ID, on page 1918](#)
6. Provide all of this information to [Cisco TAC](#).

## Add, Edit, or Delete Dynamic Attributes Filters

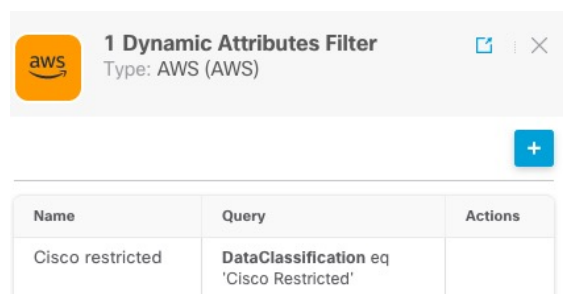

The Dashboard enables you to add, edit, or delete dynamic attributes filters. You can click the name of a filter

to view all instances of that filter or you can click  for the following additional options:

- **Go to Dynamic Attributes Filters** to view all configured dynamic attributes filters. You can add, edit, or delete dynamic attributes filters from there.
- **Add Dynamic Attributes Filters** to add a filter.

For more information about adding dynamic attributes filters, see [Create Dynamic Attributes Filters, on page 1913](#).

An example follows:

Name	Query	Actions
Cisco restricted	DataClassification eq 'Cisco Restricted'	

**Note** Some connectors, such as Outlook 365 and Azure Service tags, automatically pull available dynamic objects without the need for a dynamic attributes filters. Those connectors display **Auto** in the  column.

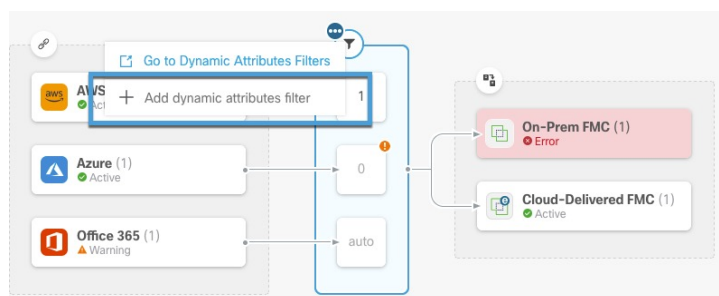

You have the following options:

- Click a filter instance to view summary information about dynamic attributes filters associated with a connector.
- Click the Add icon () to add a new dynamic attributes filter.

For more information, see [Create Dynamic Attributes Filters, on page 1913](#).

- Click  in the filters column () indicates the indicated connector has no associated dynamic attributes filters. Without associated filters, the connector can send nothing to management center.

One way to resolve the issue is to click  in the filters column and click **Add Dynamic Attributes Filter**. A sample follows.

- Click  to add, edit, or delete filters.
- Click  to close the panel.

## Create a Connector

A *connector* is an interface with a cloud service. The connector retrieves network information from the cloud service so the network information can be used in access control policies on the Security Cloud Control.

We support the following:

**Table 115: List of supported connectors by Cisco Secure Dynamic Attributes Connector version and platform**

CSDAC version/platform	AWS	AWS security groups	AWS service tags	Azure	Azure Service Tags	Cisco Cyber Vision	Cisco Multicloud Defense	Generic text	GitHub	Google Cloud	Microsoft Office 365	vCenter	Webex	Zoom
Version 1.1 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	No	No	Yes	Yes	No	No
Version 2.0 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	No	Yes	Yes	Yes	No	No
Version 2.2 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	Yes	Yes	Yes	Yes	No	No
Version 2.3 (on-premises)	Yes	No	No	Yes	Yes	No	No	No	Yes	Yes	Yes	Yes	Yes	Yes
Version 3.0 (on-premises)	Yes	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	Yes	Yes
Cloud-delivered (Security Cloud Control)	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes	Yes	Yes	Yes	No	Yes	Yes

## Amazon Web Services Connector—About User Permissions and Imported Data

The Cisco Secure Dynamic Attributes Connector imports dynamic attributes from AWS to Security Cloud Control for use in access control policies.

### Dynamic attributes imported

We import the following dynamic attributes from AWS:

- *Tags*, user-defined key-value pairs you can use to organize your AWS EC2 resources.

For more information, see [Tag your EC2 Resources](#) in the AWS documentation

- *IP addresses* of virtual machines in AWS.

### Minimum permissions required

The Cisco Secure Dynamic Attributes Connector requires a user at minimum with a policy that permits `ec2:DescribeTags`, `ec2:DescribeVpcs`, and `ec2:DescribeInstances` to be able to import dynamic attributes.

## Create an AWS User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector

This task discusses how to set up a service account with minimum permissions to send dynamic attributes to Security Cloud Control. For a list of these attributes, see [Amazon Web Services Connector—About User Permissions and Imported Data, on page 1895](#).

### Before you begin

You must already have set up your Amazon Web Services (AWS) account. For more information about doing that, see [this article](#) in the AWS documentation.

### Procedure

- Step 1** Log in to the AWS console as a user with the admin role.
- Step 2** From the Dashboard, click **Security, Identity & Compliance > IAM**.
- Step 3** Click **Access Management > Users**.
- Step 4** Click **Add Users**.
- Step 5** In the **User Name** field, enter a name to identify the user.
- Step 6** Click **Access Key - Programmatic Access**.
- Step 7** At the Set permissions page, click **Next** without granting the user access to anything; you'll do this later.
- Step 8** Add tags to the user if desired.
- Step 9** Click **Create User**.
- Step 10** Click **Download .csv** to download the user's key to your computer.  
**Note** This is the only opportunity you have to retrieve the user's key.
- Step 11** Click **Close**.
- Step 12** At the Identity and Access Management (IAM) page in the left column, click **Access Management > Policies**.
- Step 13** Click **Create Policy**.
- Step 14** On the Create Policy page, click **JSON**.

- Step 15** Enter the following policy in the field:

```
{
  "Version": "2012-10-17",
  "Statement": [
    {
      "Effect": "Allow",
      "Action": [
        "ec2:DescribeTags",

```

```

        "ec2:DescribeInstances",
        "ec2:DescribeVpcs"
    ],
    "Resource": "*"
}
]
}

```

- Step 16** Click **Next**.
- Step 17** Click **Review**.
- Step 18** On the Review Policy page, enter the requested information and click **Create Policy**.
- Step 19** On the Policies page, enter all or part of the policy name in the search field and press Enter.
- Step 20** Click the policy you just created.
- Step 21** Click **Actions > Attach**.
- Step 22** If necessary, enter all or part of the user name in the search field and press Enter.
- Step 23** Click **Attach Policy**.

---

### What to do next

[Create an AWS Connector, on page 1897.](#)

## Create an AWS Connector

This task discusses how to configure a connector that sends data from AWS to the Security Cloud Control for use in access control policies.

### Before you begin

Create a user with at least the privileges discussed in [Create an AWS User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector, on page 1896.](#)

### Procedure

- 
- Step 1** Log in to Security Cloud Control.
- Step 2** Click **Administration > Dynamic Attributes Connector**.
- Step 3** Do any of the following:
- Add a new connector: click Add icon (  ), then click the name of the connector.
  - Edit a connector: click Edit icon (  Edit ).
  - Delete a connector: click Delete icon (  Delete ).
- Step 4** Enter the following information.

Value	Description
Name	(Required.) Enter a name to uniquely identify this connector.

Value	Description
<b>Description</b>	Optional description.
<b>Pull Interval</b>	(Default 30 seconds.) Interval at which IP mappings are retrieved from AWS.
<b>Region</b>	(Required.) Enter your AWS region code.
<b>Access Key</b>	(Required.) Enter your access key.
<b>Secret Key</b>	(Required.) Enter your secret key.

**Step 5** Click **Test** and make sure the test succeeds before you save the connector.

**Step 6** Click **Save**.

**Step 7** Make sure **Ok** is displayed in the Status column.

## Azure Connector—About User Permissions and Imported Data

The Cisco Secure Dynamic Attributes Connector imports dynamic attributes from Azure to Security Cloud Control for use in access control policies.

### Dynamic attributes imported

We import the following dynamic attributes from Azure:

- *Tags*, key-value pairs associated with resources, resource groups, and subscriptions.  
For more information, see [this page](#) in the Microsoft documentation.
- *IP addresses* of virtual machines in Azure.

### Minimum permissions required

The Cisco Secure Dynamic Attributes Connector requires a user at minimum with the **Reader** permission to be able to import dynamic attributes.

## Create an Azure User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector

This task discusses how to set up a service account with minimum permissions to send dynamic attributes to Security Cloud Control. For a list of these attributes, see [Azure Connector—About User Permissions and Imported Data, on page 1898](#).

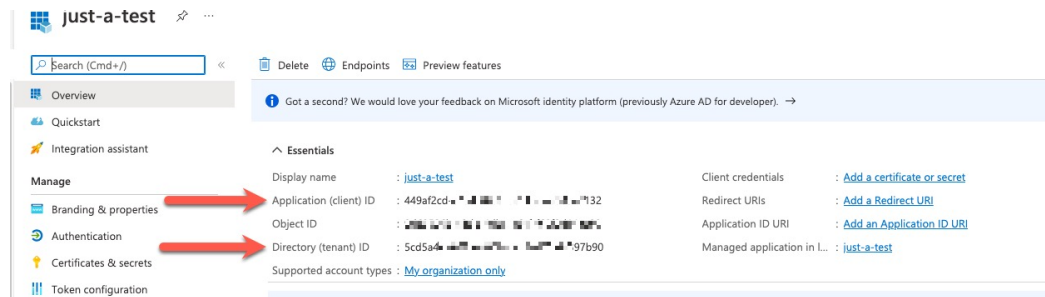

### Before you begin

You must already have a Microsoft Azure account. To set one up, see [this page](#) on the Azure documentation site.

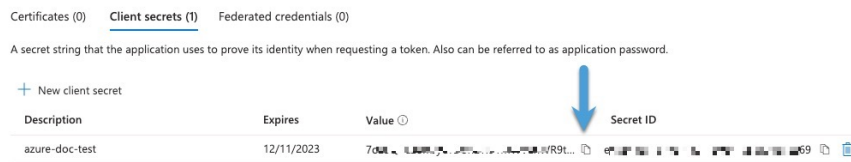

**Procedure**

- Step 1** Log in to the [Azure Portal](#) as the owner of the subscription.
- Step 2** Click **Azure Active Directory**.
- Step 3** Find the instance of Azure Active Directory for the application you want to set up.
- Step 4** Click **Add > App registration**.
- Step 5** In the **Name** field, enter a name to identify this application.
- Step 6** Enter other information on this page as required by your organization.
- Step 7** Click **Register**.
- Step 8** On the next page, make note of the Client ID (also referred to as *application ID*) and the tenant ID (also referred to as the *directory ID*).

A sample follows.

- Step 9** Next to Client Credentials, click **Add a certificate or secret**.
- Step 10** Click **New Client Secret**.
- Step 11** Enter the requested information and click **Add**.
- Step 12** Copy the value of the **Value** field to the clipboard. This value, *and not the Secret ID*, is the client secret.

- Step 13** Go back to the main Azure Portal page and click **Subscriptions**.
- Step 14** Click the name of your subscription.
- Step 15** Copy the subscription ID to the clipboard.

- Step 16** Click **Access Control (IAM)**.
- Step 17** Click **Add > Add role assignment**.
- Step 18** Click **Reader** and click **Next**.
- Step 19** Click **Select Members**.
- Step 20** On the right side of the page, click the name of the app you registered and click **Select**.

The screenshot shows the 'Add role assignment' page in the Azure portal. The 'Members' tab is selected, and the 'Selected role' is 'Reader'. The 'Assign access to' section has 'User, group, or service principal' selected. The 'Members' section is empty, and the '+ Select members' link is visible. The 'Description' field is optional. The 'Review + assign', 'Previous', and 'Next' buttons are at the bottom of the main page. The 'Select members' dialog is open on the right, showing a search box with 'just' entered. Below the search box, it says 'No users, groups, or service principals found.' Under 'Selected members:', there is one entry 'just-a-test' with a 'Remove' button next to it. The 'Select' button in the dialog is highlighted with a red box.

- Step 21** Click **Review + Assign** and follow the prompts to complete the action.

### What to do next

See [Create an Azure Connector](#), on page 1900.

## Create an Azure Connector

This task discusses how to create a connector to send data from Azure to Security Cloud Control for use in access control policies.

### Before you begin

Create an Azure user with at least the privileges discussed in [Create an Azure User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector](#), on page 1898.

### Procedure

- Step 1** Log in to Security Cloud Control.
- Step 2** Click **Administration > Dynamic Attributes Connector > Connectors**.
- Step 3** Do any of the following:
- Add a new connector: click Add icon (  ), then click the name of the connector.
  - Edit a connector: click Edit icon (  Edit ).
  - Delete a connector: click Delete icon (  Delete ).

- Step 4** Enter the following information.

Value	Description
<b>Name</b>	(Required.) Enter a name to uniquely identify this connector.
<b>Description</b>	Optional description.
<b>Pull Interval</b>	(Default 30 seconds.) Interval at which IP mappings are retrieved from Azure. The minimum value for <b>Pull Interval</b> is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
<b>Subscription Id</b>	(Required.) Enter your Azure subscription ID.
<b>Tenant Id</b>	(Required.) Enter your tenant ID.
<b>Client Id</b>	(Required.) Enter your client ID.
<b>Client Secret</b>	(Required.) Enter your client secret.

- Step 5** Click **Test** and make sure **Test connection succeeded** is displayed before you save the connector.
- Step 6** Click **Save**.
- Step 7** Make sure **Ok** is displayed in the Status column.

## Create an Azure Service Tags Connector

This topic discusses how to create a connector for Azure service tags to the Security Cloud Control for use in access control policies. The IP addresses associated with these tags are updated every week by Microsoft.

For more information, see [Virtual network service tags on Microsoft TechNet](#).

## Procedure

- Step 1** Log in to Security Cloud Control.
- Step 2** Click **Administration > Dynamic Attributes Connector > Connectors**.
- Step 3** Do any of the following:

- Add a new connector: click Add icon (  ), then click the name of the connector.
- Edit a connector: click Edit icon (  Edit ).
- Delete a connector: click Delete icon (  Delete ).

- Step 4** Enter the following information.

Value	Description
<b>Name</b>	(Required.) Enter a name to uniquely identify this connector.
<b>Description</b>	Optional description.
<b>Pull Interval</b>	(Default 30 seconds.) Interval at which IP mappings are retrieved from Azure.  The minimum value for <b>Pull Interval</b> is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
<b>Subscription Id</b>	(Required.) Enter your Azure subscription ID.
<b>Tenant Id</b>	(Required.) Enter your tenant ID.
<b>Client Id</b>	(Required.) Enter your client ID.
<b>Client Secret</b>	(Required.) Enter your client secret.

- Step 5** Click **Test** and make sure **Test connection succeeded** is displayed before you save the connector.
- Step 6** Click **Save**.
- Step 7** Make sure **Ok** is displayed in the Status column.

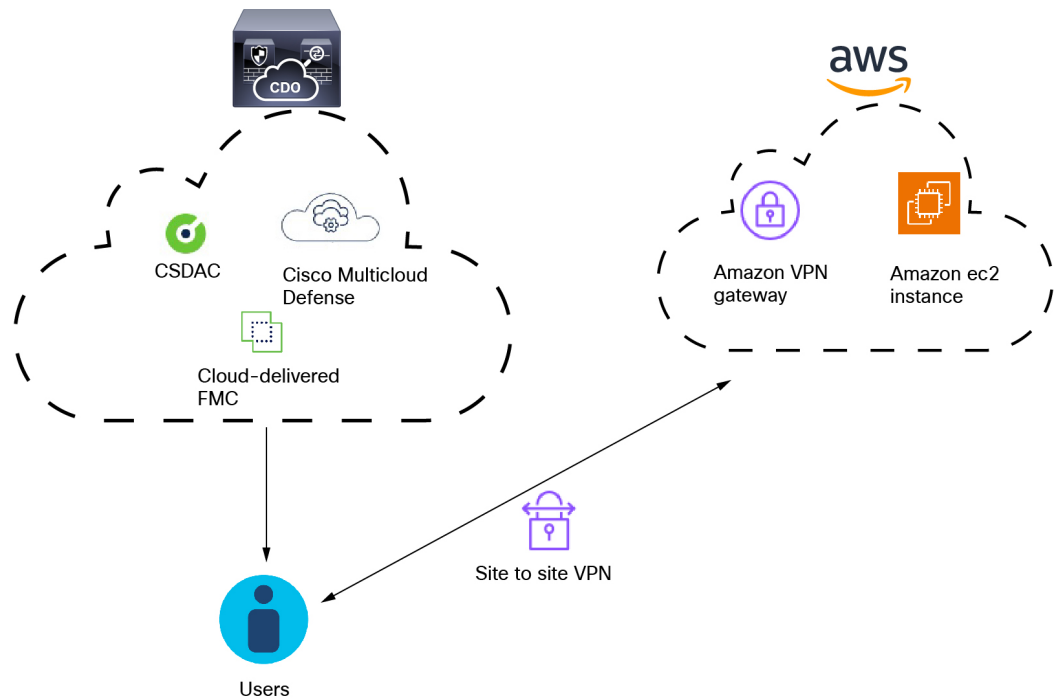

## Create a Multicloud Defense Connector

This topic discusses how to create a connector for Cisco Multicloud Defense. The connector sends dynamic application address objects to the configured Cloud-delivered Firewall Management Center.

For more information, see the [Address Objects](#) chapter in the *Cisco Multicloud Defense User Guide* and [address object API documentation](#).

The following figure shows how the Cisco Multicloud Defense connector works.

As the figure shows:

- Users logging in and out of AWS create activity monitored by Multicloud Defense.
- The dynamic attributes connector and Multicloud Defense, both included in Security Cloud Control, send IP addresses from that activity to the Cloud-delivered Firewall Management Center.
- These IP addresses can then be used in access control rules by the Cloud-delivered Firewall Management Center.

## Procedure

- 
- Step 1** Log in to Security Cloud Control.
- Step 2** Click **Administration** > **Dynamic Attributes Connector** > **Connectors**.
- Step 3** Do any of the following:
- Add a new connector: click Add icon (  ), then click the name of the connector.
  - Edit a connector: click Edit icon (  Edit ).
  - Delete a connector: click Delete icon (  Delete ).
- Step 4** Enter a **Name** and optional **Description** to identify the connector.

- Step 5** Enter a **Pull Interval**. (Default 30 seconds.) Interval at which objects are retrieved from the Multicloud Defense Connector.
- Step 6** Click **Test** and make sure the test succeeds before you save the connector.
- Step 7** Click **Save**.
- Step 8** Make sure **Ok** is displayed in the Status column.

---

### What to do next

You must create a Cloud-delivered Firewall Management Center adapter as discussed in [Create an Adapter, on page 1911](#).

## Create a Generic Text Connector

This task discusses how to create an ad hoc list of IP addresses you maintain manually and retrieve at an interval you select (30 seconds by default). You can update the list of addresses anytime you want.

### Before you begin

Create text files with IP addresses and put it on a web server that is accessible from the Security Cloud Control. IP addresses can include CIDR notation. The text file must have only one IP address per line.

For example, you might have a list of IP addresses for an "allow list" in access control rules and another list of IP addresses for a "block list" in access control rules.

You can specify up to 10,000 IP addresses per text file.

---

**Note** Do not include a scheme (`http://` or `https://`) in your IP addresses.

---

### Procedure

- 
- Step 1** Log in to Security Cloud Control.
- Step 2** Click .
- Step 3** Do any of the following:
- Add a new connector: click Add icon (  ), then click the name of the connector.
  - Edit a connector: click Edit icon (  ).
  - Delete a connector: click Delete icon (  ).
- Step 4** Enter a **Name** and an optional description.
- Step 5** (Optional.) In the **Pull Interval** field, change the frequency, in seconds, at which the dynamic attributes connector retrieves IP addresses from the text file. The default is 30 seconds.

The minimum value for **Pull Interval** is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.

- Step 6** In the **URLs** field, enter each URL from which to retrieve IP addresses, one URL per line.
- Step 7** (Optional.) Click **Add another URL** to add an additional URL to monitor.
- Step 8** (Optional.) In the **Certificate** field, paste your server's certificate chain
- Step 9** Click **Test** and make sure the test succeeds before you save the connector.
- Step 10** Click **Save**.
- Step 11** Make sure **Ok** is displayed in the Status column.

---

## Create a GitHub Connector

This section discusses how to create a GitHub connector that sends data to the Security Cloud Control for use in access control policies. The IP addresses associated with these tags are maintained by GitHub. You do not have to create a dynamic attributes filters.

For more information, see [About GitHub's IP addresses](#).

---

**Note** Do not change the URL because doing so will fail to retrieve any IP addresses.

---

### Procedure

- 
- Step 1** Log in to Security Cloud Control.
  - Step 2** Click **Administration > Dynamic Attributes Connector > Connectors**.
  - Step 3** Do any of the following:
    - Add a new connector: click Add icon (  ), then click the name of the connector.
    - Edit a connector: click Edit icon (  Edit ).
    - Delete a connector: click Delete icon (  Delete ).
  - Step 4** Enter a **Name** and an optional description.
  - Step 5** (Optional.) In the **Pull Interval** field, change the frequency, in seconds, at which the dynamic attributes connector retrieves IP addresses from GitHub. The default is 21,600 seconds (6 hours).
  - Step 6** Click **Test** and make sure the test succeeds before you save the connector.
  - Step 7** Click **Save**.
  - Step 8** Make sure **Ok** is displayed in the Status column.
-

## Google Cloud Connector—About User Permissions and Imported Data

The Cisco Secure Dynamic Attributes Connector imports dynamic attributes from Google Cloud to Security Cloud Control for use in access control policies.

### Dynamic attributes imported

We import the following dynamic attributes from Google Cloud:

- *Labels*, key-value pairs you can use to organize your Google Cloud resources.  
For more information, see [Creating and Managing Labels](#) in the Google Cloud documentation.
- *Network tags*, key-value pairs associated with an organization, folder, or project.  
For more information, see [Creating and Managing Tags](#) in the Google Cloud documentation.
- *IP addresses* of virtual machines in Google Cloud.

### Minimum permissions required

The Cisco Secure Dynamic Attributes Connector requires a user at minimum with the **Basic > Viewer** permission to be able to import dynamic attributes.

## Create a Google Cloud User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector

This task discusses how to set up a service account with minimum permissions to send dynamic attributes to Security Cloud Control. For a list of these attributes, see [Google Cloud Connector—About User Permissions and Imported Data, on page 1906](#).

### Before you begin

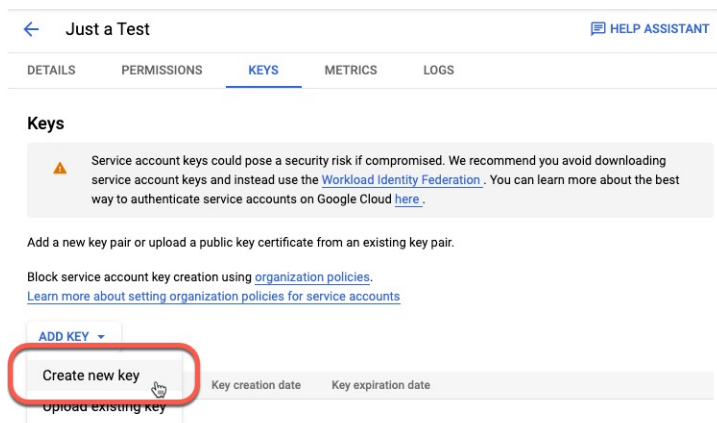

You must already have set up your Google Cloud account. For more information about doing that, see [Setting Up Your Environment](#) in the Google Cloud documentation.

### Procedure

- 
- Step 1** Log in to your Google Cloud account as a user with the owner role.
  - Step 2** Click **IAM & Admin > Service Accounts > Create Service Account**.
  - Step 3** Enter the following information:
    - **Service account name:** A name to identify this account; for example, **CSDAC**.
    - **Service account ID:** Should be populated with a unique value after you enter the service account name.
    - **Service account description:** Enter an optional description.

For more information about service accounts, see [Understanding Service Accounts](#) in the Google Cloud documentation.
  - Step 4** Click **Create and Continue**.

- Step 5** Follow the prompts on your screen until the Grant users access to this service account section is displayed.
- Step 6** Grant the user the **Basic > Viewer** role.
- Step 7** Click **Done**.  
A list of service accounts is displayed.
- Step 8** Click **More** (⋮) at the end of the row of the service account you created.
- Step 9** Click **Manage Keys**.
- Step 10** Click **Add Key > Create New Key**.

- Step 11** Click **JSON**.
- Step 12** Click **Create**.  
The JSON key is downloaded to your computer.
- Step 13** Keep the key handy when you configure the GCP connector.

### What to do next

See [Create a Google Cloud Connector, on page 1907](#).

## Create a Google Cloud Connector

### Before you begin

Have your Google Cloud JSON-formatted service account data ready; it's required to set up the connector.

### Procedure

- Step 1** Log in to Security Cloud Control.
- Step 2** Click **Administration > Dynamic Attributes Connector > Connectors**.
- Step 3** Do any of the following:

- Add a new connector: click Add icon (  ), then click the name of the connector.
- Edit a connector: click Edit icon (  Edit ).
- Delete a connector: click Delete icon (  Delete ).

**Step 4** Enter the following information.

Value	Description
<b>Name</b>	(Required.) Enter a name to uniquely identify this connector.
<b>Description</b>	Optional description.
<b>Pull Interval</b>	(Default 30 seconds.) Interval at which IP mappings are retrieved from AWS.  The minimum value for <b>Pull Interval</b> is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
<b>GCP region</b>	(Required.) Enter the GCP region in which your Google Cloud is located. For more information, see <a href="#">Regions and Zones</a> in the Google Cloud documentation.
<b>Service account</b>	Paste the JSON code for your Google Cloud service account.

**Step 5** Click **Test** and make sure the test succeeds before you save the connector.

**Step 6** Click **Save**.

**Step 7** Make sure **Ok** is displayed in the Status column.

## Create an Office 365 Connector

This task discusses how to create a connector for Office 365 tags to send data to the Security Cloud Control for use in access control policies. The IP addresses associated with these tags are updated every week by Microsoft. You do not have to create a dynamic attributes filter to use the data.

For more information, see [Office 365 URLs and IP address ranges](#) on docs.microsoft.com.

### Procedure

**Step 1** Log in to Security Cloud Control.

**Step 2** Click **Administration > Dynamic Attributes Connector > Connectors**.

**Step 3** Do any of the following:

- Add a new connector: click Add icon (  ), then click the name of the connector.
- Edit a connector: click Edit icon (  Edit ).

- Delete a connector: click Delete icon ( Delete).

**Step 4** Enter the following information.

Value	Description
<b>Name</b>	(Required.) Enter a name to uniquely identify this connector.
<b>Description</b>	Optional description.
<b>Pull Interval</b>	(Default 30 seconds.) Interval at which IP mappings are retrieved from Azure.  The minimum value for <b>Pull Interval</b> is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
<b>Base API URL</b>	(Required.) Enter the URL from which to retrieve Office 365 information, if it's different from the default. For more information, see <a href="#">Office 365 IP Address and URL web service</a> on the Microsoft documentation site.
<b>Instance name</b>	(Required.) From the list, click an instance name. For more information, see <a href="#">Office 365 IP Address and URL web service</a> on the Microsoft documentation site.
<b>Disable optional IPs</b>	(Required.) Enter <b>true</b> or <b>false</b> .

**Step 5** Click **Test** and make sure the test succeeds before you save the connector.

**Step 6** Click **Save**.

**Step 7** Make sure **Ok** is displayed in the Status column.

## Create a Webex Connector

This section discusses how to create a Webex connector that sends data to the Security Cloud Control for use in access control policies. The IP addresses associated with these tags are maintained by Webex. You do not have to create a dynamic attributes filters.

For more information, see [Port Reference for Webex Calling](#).

### Procedure

**Step 1** Log in to Security Cloud Control.

**Step 2** Click **Administration > Dynamic Attributes Connector > Connectors**.

**Step 3** Do any of the following:

- Add a new connector: click Add icon () , then click the name of the connector.
- Edit a connector: click Edit icon ( Edit).

- Delete a connector: click Delete icon (  Delete ).

**Step 4** Enter the following information.

Value	Description
<b>Name</b>	(Required.) Enter a name to uniquely identify this connector.
<b>Description</b>	Optional description.
<b>Pull Interval</b>	(Default 30 seconds.) Interval at which IP mappings are retrieved from Webex.  The minimum value for <b>Pull Interval</b> is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
<b>Provider Reserved IPs</b>	(Required.) (Required.) Slide to enabled to retrieve any reserved IP addresses.

**Step 5** Click **Test** and make sure the test succeeds before you save the connector.

**Step 6** Click **Save**.

**Step 7** Make sure **Ok** is displayed in the Status column.

## Create a Zoom Connector

This section discusses how to create a Zoom connector that sends data to the Security Cloud Control for use in access control policies. The IP addresses associated with these tags are maintained by Zoom. You do not have to create a dynamic attributes filters.

For more information, see [Zoom network firewall or proxy server settings](#).

### Procedure

**Step 1** Log in to Security Cloud Control.

**Step 2** Click **Administration > Dynamic Attributes Connector > Connectors**.

**Step 3** Do any of the following:

- Add a new connector: click Add icon (  ), then click the name of the connector.
- Edit a connector: click Edit icon (  Edit ).
- Delete a connector: click Delete icon (  Delete ).

**Step 4** Enter the following information.

Value	Description
<b>Name</b>	(Required.) Enter a name to uniquely identify this connector.
<b>Description</b>	Optional description.
<b>Pull Interval</b>	(Default 30 seconds.) Interval at which IP mappings are retrieved from Zoom.  The minimum value for <b>Pull Interval</b> is 1 second. You can set the maximum to any value you want. We recommend against setting the minimum to a low value because it can generate a lot of traffic, and, when applicable, can result in your being billed for the traffic.
<b>Provider Reserved IPs</b>	(Required.) Slide to enabled to retrieve any reserved IP addresses.

**Step 5** Click **Test** and make sure the test succeeds before you save the connector.

**Step 6** Click **Save**.

**Step 7** Make sure **Ok** is displayed in the Status column.

## Create an Adapter

An *adapter* is a secure connection to Cloud-delivered Firewall Management Center to which you push network information from cloud objects for use in access control policies.

You can create the following adapters:

- *On-Prem Firewall Management Center* for an on-premises Secure Firewall Management Center
- *Cloud-delivered Firewall Management Center* for devices managed by Security Cloud Control

**Note** You must have a **Super Admin** user role to create the first Cloud-delivered Firewall Management Center adapter. To view or modify existing adapters, you must have an Admin or Super Admin user role.

**Note** Deleting an adapter does not delete dynamic objects created by the adapter. If you wish to delete those objects permanently, do so on the device associated with the adapter.

## How to Create an On-Prem Firewall Management Center Adapter

This topic discusses how to create an adapter to push dynamic objects from the dynamic attributes connector to Security Cloud Control.

**Before you begin**

Onboard the firewall manager to Security Cloud Control as discussed in *Onboard a Management Center* in the *Managing Security and Network Devices with Cisco Security Cloud Control* online help.

**Required User Role:**

- Super Admin

**Procedure**

- 
- Step 1** Log in to Security Cloud Control as a user with the Super Admin role.
- Step 2** Click **Administration > Dynamic Attributes Connector > Adapters**.
- Step 3** To add an adapter, click Add icon (  ) > On-Prem Firewall Management Center.
- Step 4** To edit or delete an adapter, click Edit icon (  Edit ), or Delete icon (  Delete ).
- Step 5** Add or edit the following information.

Value	Description
<b>Name</b>	(Required.) Enter a unique name to identify this adapter.
<b>Description</b>	Optional description of the adapter.
<b>Primary Device</b>	From the list, click the IP address of a management center associated with your tenant.
<b>Secondary Device</b>	(Optional.) If you have a secondary On-Prem Firewall Management Center, click its name from the list.

- Step 6** Click **OK**.
- 

## How to Create a Cloud-delivered Firewall Management Center Adapter

This topic discusses how to create an adapter to push dynamic objects from the dynamic attributes connector to Security Cloud Control.

**Before you begin****Required User Role:**

- Super Admin

**Procedure**

- 
- Step 1** Log in to Security Cloud Control as a user with the Super Admin role.
- Step 2** Click **Administration > Dynamic Attributes Connector > Adapters**.

**Step 3** To add an adapter, click Add icon (  ) > Cloud-delivered Firewall Management Center.

**Step 4** To edit or delete an adapter, click Edit icon (  Edit ), or Delete icon (  Delete ).

**Step 5** Edit the following information.

Value	Description
<b>Name</b>	(Required.) Enter a unique name to identify this adapter.
<b>Description</b>	Optional description of the adapter.
<b>Cloud FMC URL</b>	From the list, click the URL for your Cloud-delivered Firewall Management Center.

**Step 6** Click **Test** and make sure the test succeeds before you save the adapter.

**Step 7** Click **Save**.

## Create Dynamic Attributes Filters

Dynamic attributes filters that you define using the Cisco Secure Dynamic Attributes Connector are exposed in the Security Cloud Control as dynamic objects that can be used in access control policies. For example, you could restrict access to an AWS server for the Finance Department to only members of the Finance group defined in Microsoft Active Directory.

**Note** You cannot create dynamic attributes filters for AWS, Azure, Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Google Cloud, and Outlook 365, pxGrid cloud identity source, vCenter, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

For more information about access control rules, see [Create Access Control Rules Using Dynamic Attributes Filters, on page 1916](#).

### Before you begin

[Create a Connector, on page 1894](#)

### Procedure

**Step 1** Click **Administration > Dynamic Attributes Connector > Adapters**.

**Step 2** Click **Dynamic Attributes Filters**.

**Step 3** Do any of the following:

- Add a new filter: click Add icon (  )
- Edit a filter: click Edit icon (  Edit )

- Delete a filter: click Delete icon (  Delete )

**Step 4** Enter the following information.

Item	Description
Name	Unique name to identify the dynamic filter (as a dynamic object) in access control policy and in the Security Cloud Control Object Manager ( <b>External Attributes &gt; Dynamic Object</b> ).
Connector	From the list, click the name of a connector to use.
Query	<ul style="list-style-type: none"> <li>• Add a new filter: click Add icon (  )</li> <li>• Edit a filter: click Edit icon (  Edit )</li> <li>• Delete a filter: click Delete icon (  Delete )</li> </ul>

**Step 5** To add or edit a query, enter the following information.

Item	Description
Key	Click a key from the list. Keys are fetched from the connector.
Operation	Click one of the following: <ul style="list-style-type: none"> <li>• <b>Equals</b> to exactly match the key to the value.</li> <li>• <b>Contains</b> to match the key to the value if any part of the value matches.</li> </ul>
Values	Click either <b>Any</b> or <b>All</b> and click one or more values from the list. Click <b>Add another value</b> to add values to your query.

**Step 6** Click **Show Preview** to display a list of networks or IP addresses returned by your query.

**Step 7** When you're finished, click **Save**.

**Step 8** (Optional.) Verify the dynamic object in the Security Cloud Control.

- Log in to the Security Cloud Control.
- Click **Policies > FTD Policies**.
- Click **Objects > Object Management**.
- In the left pane, click **External Attributes > Dynamic Object**.  
The dynamic attribute query you created should be displayed as a dynamic object.

## Dynamic Attribute Filter Examples

This topic provides some examples of setting up dynamic attribute filters.

**Example: Azure**

The following example shows one criterion: a server tagged as a Finance app.

Add Dynamic Attribute Filter

Name\*  Connector\*

Query\*

Type	Op.	Value
<input type="button" value="all"/> Finance	eq	<input type="button" value="any"/> App

> Show Preview

**Example: AWS**

The following example shows one criterion: a FinanceApp with a value of 1.

Add Dynamic Attribute Filter

Name\*  Connector\*

Query\*

Type	Op.	Value
<input type="button" value="all"/> FinanceApp	eq	<input type="button" value="any"/> 1

> Show Preview

## Disable the Cisco Secure Dynamic Attributes Connector

If you no longer wish to collect dynamic objects from cloud sources, you can disable the Cisco Secure Dynamic Attributes Connector in Security Cloud Control as discussed in the following task.

### Procedure

- 
- Step 1** Log in to the Security Cloud Control if you have not done so already.
  - Step 2** Click **Administration** > **Dynamic Attributes Connector**.
  - Step 3** Slide to **Disabled**.
-

# Use Dynamic Objects in Access Control Policies

The dynamic attributes connector enables you to configure dynamic filters, seen in the Security Cloud Controls dynamic objects, in access control rules.

## About Dynamic Objects in Access Control Rules

A *dynamic object* is automatically pushed from the dynamic attributes connector to the Secure Firewall Manager after you create connectors and save a dynamic attributes filter on the connector.

You can use these dynamic objects on the access control rule's **Dynamic Attributes** tab page, similarly to the way you used Security Group Tags (SGTs). You can add dynamic objects as source or destination attributes; for example, in an access control block rule, you can add a Finance dynamic object as a destination attribute to block access to Finance servers by whatever objects match the other criteria in the rule.

---

**Note** You cannot create dynamic attributes filters for AWS, Azure, Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Google Cloud, and Outlook 365, pxGrid cloud identity source, vCenter, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

---

## Create Access Control Rules Using Dynamic Attributes Filters

This topic discusses how to create access control rules using dynamic objects (these dynamic objects are named after the dynamic attributes filters you created previously).

### Before you begin

Create dynamic attributes filters as discussed in [Create Dynamic Attributes Filters, on page 1913](#).

---

**Note** You cannot create dynamic attributes filters for AWS, Azure, Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Google Cloud, and Outlook 365, pxGrid cloud identity source, vCenter, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

---

### Procedure

- 
- Step 1** Log in to Security Cloud Control.
  - Step 2** Click **Policies > FTD Policies**.
  - Step 3** Click **Edit** (✎) next to an access control policy.
  - Step 4** Click **Add Rule**.
  - Step 5** Click the **Dynamic Attributes** tab.
  - Step 6** In the Available Attributes section, from the list, click **Dynamic Objects**.

The following figure shows an example.

The preceding example shows a dynamic object named `FinanceNetwork` that corresponds to the dynamic attribute filter created in the Cisco Secure Dynamic Attributes Connector.

- Step 7** Add the desired object to source or destination attributes.
- Step 8** Add other conditions to the rule if desired.

### What to do next

[Dynamic Attributes Rule Conditions](#) in the *Cisco Secure Firewall Management Center Device Configuration Guide*.

## Troubleshoot the Dynamic Attributes Connector

How to troubleshoot issues with the dynamic attributes connector, including using provided tools.

### Troubleshoot Error Messages

#### Problem: Name or service not known error

This error is displayed as a tooltip when you hover the mouse over an error condition on a connector. An example follows; yours might look different.

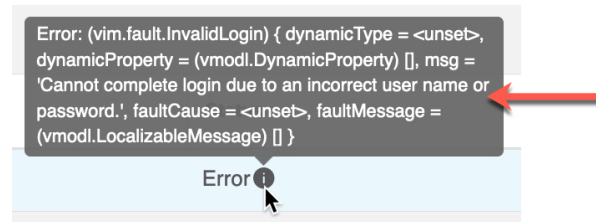

**Solution:** Edit the connector and check for:

- A trailing slash on a host name

- Verify the password is correct

### Problem: Incorrect username or password

This error is displayed as a tooltip when you hover the mouse over an error condition on a connector.

**Solution:** Edit the connector and change the user name or password.

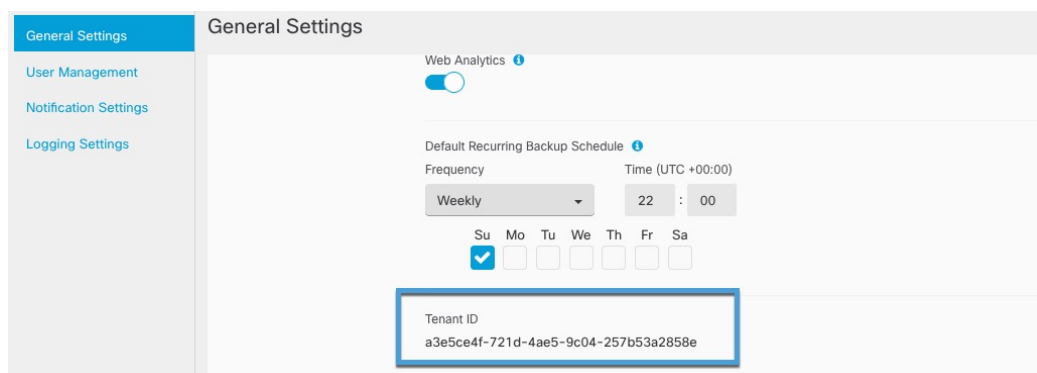

## Get Your Tenant ID

If you require assistance with the Cisco Secure Dynamic Attributes Connector, you must provide your tenant ID to Cisco TAC so we can look at your logs.

### Procedure

- Step 1** Log in to Security Cloud Control.
- Step 2** Click **Settings** > **General Settings**.
- Step 3** Copy your tenant ID to the clipboard to provide to Cisco TAC.

A sample follows.

## CHAPTER 66

# URL Filtering

---

You can implement URL filtering using access control rules.

- [URL Filtering Overview, on page 1919](#)
- [Best Practices for URL Filtering, on page 1921](#)
- [License Requirements for URL Filtering, on page 1926](#)
- [Requirements and Prerequisites for URL Filtering, on page 1926](#)
- [How to Configure URL Filtering with Category and Reputation, on page 1927](#)
- [Manual URL Filtering, on page 1933](#)
- [Configure HTTP Response Pages, on page 1935](#)
- [Configure URL Filtering Health Monitors, on page 1939](#)
- [Dispute URL Category and Reputation, on page 1939](#)
- [If the URL Category Set Changes, Take Action, on page 1940](#)
- [Troubleshoot URL Filtering, on page 1941](#)

## URL Filtering Overview

Use the URL filtering feature to control the websites that users on your network can access:

- **Category and reputation-based URL filtering**—With a URL Filtering license, you can control access to websites based on the URL's general classification (category) and risk level (reputation). This is the recommended option.
- **Manual URL filtering**—With any license, you can manually specify individual URLs, groups of URLs, and URL lists and feeds to achieve granular, custom control over web traffic. For more information, see [Manual URL Filtering, on page 1933](#).

See also [Security Intelligence, on page 1945](#), a similar but different feature for blocking malicious URLs, domains, and IP addresses.

## About URL Filtering with Category and Reputation

With a URL Filtering license, you can control access to websites based on the category and reputation of requested URLs:

- **Category**—A general classification for the URL. For example, ebay.com belongs to the Auctions category, and monster.com belongs to the Job Search category.

A URL can belong to more than one category.

- Reputation—How likely the URL is to be used for purposes that might be against your organization's security policy. Reputations range from Unknown risk (level 0) or Untrusted (level 1) to Trusted (level 5).

### Benefits of Category and Reputation-Based URL Filtering

URL categories and reputations help you quickly configure URL filtering. For example, you can use access control to block untrusted URLs in the Hacking category. Or, you can use QoS to rate limit traffic from sites in the Streaming Video category. There are also categories for types of threats, such as a Spyware and Adware category.

Using category and reputation data simplifies policy creation and administration. It grants you assurance that the system controls web traffic as expected. Because Cisco continually updates its threat intelligence with new URLs, as well as new categories and risks for existing URLs, the system uses up-to-date information to filter requested URLs. Sites that (for example) represent security threats, or that serve undesirable content, may appear and disappear faster than you can update and deploy new policies.

Some examples of how the system can adapt include:

- If an access control rule blocks all gaming sites, as new domains get registered and classified as Games, the system can block those sites automatically. Similarly, if a QoS rule rate limits all streaming video sites, the system can automatically limit traffic to new Streaming Video sites.
- If an access control rule blocks all malware sites and a shopping page gets infected with malware, the system can recategorize the URL from Shopping to Malware Sites and block that site.
- If an access control rule blocks untrusted social networking sites and somebody posts a link on their profile page that contains links to malicious payloads, the system can change the reputation of that page from Favorable to Untrusted and block it.

### Limitations of category-based filtering in decryption policy Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security.

---

**Note** Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see [Best Practices for Configuring Application Control, on page 1820](#).

---

For more information, see [Use Categories in URL Filtering, on page 1925](#).

## URL Category and Reputation Descriptions

### Category Descriptions

A description of each URL category is available from <https://www.talosintelligence.com/categories>.

Be sure to click **Threat Categories** to see those categories.

### Reputation Level Descriptions

Go to [https://talosintelligence.com/reputation\\_center/support](https://talosintelligence.com/reputation_center/support) and look in the Common Questions section.

## URL Filtering Data from the Cisco Cloud

Adding a URL Filtering license automatically enables the URL filtering feature. This allows traffic handling based on a website's general classification, or *category*, and risk level, or *reputation*.

By default, when users browse to an URL whose category and reputation is not in a local cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache.

Optionally, you can use a local URL dataset of categories and reputations, which can make web browsing faster. When you enable (or re-enable) URL filtering, the management center automatically queries Cisco for URL data and pushes the dataset to managed devices. Then, when users browse to an URL, the system checks the local dataset and the cache for category and reputation information before submitting it to the cloud for threat intelligence evaluation. To see your options for using the local dataset, including how to disable individual cloud lookups altogether, see [URL Filtering Options, on page 1928](#).

Automatic updates of URL data is enabled by default; we strongly recommend you do not disable these updates.

The set of URL categories may change periodically. When you receive a change notification, review your URL filtering configurations to make sure traffic is handled as expected. For more information, see [If the URL Category Set Changes, Take Action, on page 1940](#).

## Best Practices for URL Filtering

Keep in mind the following guidelines and limitations for URL filtering:

### Filter by Category and Reputation

Follow the instructions in [How to Configure URL Filtering with Category and Reputation, on page 1927](#).

### Configure Your Policy to Inspect Packets That Must Pass Before a URL Can Be Identified

The system cannot filter URLs before:

- A monitored connection is established between a client and server.
- The system identifies the DNS, HTTP or HTTPS application in the session.
- The system identifies the requested domain or URL (for encrypted sessions, from a non-encrypted domain name, the ClientHello message or the server certificate).

This identification should occur within 3 to 5 packets, or after the server certificate exchange in the TLS/SSL handshake if the traffic is encrypted.

**Important!** To ensure that your system examines these initial packets that would otherwise pass, see [Inspection of Packets That Pass Before Traffic Is Identified, on page 2750](#) and subtopics.

If early traffic matches all other rule conditions but identification is incomplete, the system allows the packet to pass and the connection to be established (or the TLS/SSL handshake to complete). After the system completes its identification, the system applies the appropriate rule action to the remaining session traffic.

### Block Threat Categories

Be sure that your policies specifically address Threat categories, which identify known malicious sites. Do this in addition to blocking sites with poor reputations.

For example, to protect your network from malicious sites, you must block all Threat categories. Additionally, Talos recommends that you block only sites with Poor category. You can block questionable reputations if you have an aggressive security posture, but this may result in a higher amount of false positives.

For specifics, see **Threat Categories** at the URL in [URL Category and Reputation Descriptions, on page 1920](#).

### URL Conditions and Rule Order

- Position URL rules after all other rules that *must* be hit.
- URLs can belong to more than one category. It is possible to want to allow one category of websites and block another—whether explicitly or by relying on the default action. In this case, make sure you create and order URL rules so you get the desired effect, depending on whether the allow or the block should take precedence.

For additional guidelines for rules, see the following topics: [Best Practices for Access Control Rules, on page 1823](#).

### Uncategorized or Reputationless URLs

When you build a URL rule, you first choose the category you want to match. If you explicitly choose **Uncategorized** URLs, you cannot further constrain by reputation.

Uncategorized URLs with Untrusted reputation are handled by the **Malicious Sites** category. If you want to block uncategorized sites with any other reputation level (such as Questionable), you must block all uncategorized sites.

After selecting a category and a reputation level, you can optionally select **Apply to unknown reputation**. For example, you can create a rule that applies to sites with Untrusted, Questionable, and unknown reputations.

You cannot manually assign categories and reputations to URLs, but in access control and QoS policies, you can manually block specific URLs. See [Manual URL Filtering, on page 1933](#). See also [Dispute URL Category and Reputation, on page 1939](#).

### URL Filtering for Encrypted Web Traffic

When performing URL filtering on encrypted web traffic, the system:

- (If DNS filtering is enabled) Checks to see if the system has previously seen the originating domain or the domain is in the local reputation database, and if so, takes action based on the reputation and category of the domain. Otherwise, the system processes the traffic based on your configurations for encrypted traffic, even if **Retry URL cache miss lookup** is enabled in the access control policy's advanced settings.
- Disregards the encryption protocol; a rule matches both HTTPS and HTTP traffic if the rule has a URL condition but not an application condition that specifies the protocol.
- Does not use URL lists. You must use URL objects and groups instead.

- Matches HTTPS traffic based on the subject common name in the public key certificate used to encrypt the traffic, and also evaluates the reputation of any other URLs presented at any time during the transaction, including the post-decryption HTTP URL.
- Disregards subdomains within the subject common name.
- Does not display an HTTP response page for encrypted connections blocked by access control rules (or any other configuration); see [Limitations to HTTP Response Pages, on page 1935](#).

### URL Filtering and TLS Server Identity Discovery

The latest version of the Transport Layer Security (TLS) protocol 1.3, defined by [RFC 8446](#), is the preferred protocol for many web servers to provide secure communications. Because the TLS 1.3 protocol encrypts the server's certificate for additional security, and the certificate is needed to match application and URL filtering criteria in access control rules, the Firepower System provides a way to extract the server certificate *without* decrypting the entire packet.

Access control policy advanced settings offer an **Early application detection and URL categorization** option for TLS Server Identity Discovery.

We strongly recommend enabling it for any traffic you want to match on application or URL criteria, especially if you want to perform deep inspection of that traffic. A decryption policy is not required because *traffic is not decrypted* in the process of extracting the server certificate.

---

**Note**

- Because the certificate is decrypted, TLS server identity discovery can reduce performance depending on the hardware platform.
- TLS server identity discovery is not supported in inline tap mode or passive mode deployments.
- Enabling TLS server identity discovery is not supported on any Secure Firewall Threat Defense Virtual deployed to AWS. If you have any such managed devices managed by the Secure Firewall Management Center, the connection event **PROBE\_FLOW\_DROP\_BYPASS\_PROXY** increments every time the device attempts to extract the server certificate.
- TLS Server Identity Discovery also operates on TLS 1.2 sessions.

---

For more information, see [Access Control Policy Advanced Settings, on page 1840](#).

### HTTP/2

The system can extract HTTP/2 URLs from TLS certificates, but not from a payload.

### Manual URL Filtering

- Specify URLs using a custom Security Intelligence list or feed object. Do not use a URL object or directly enter a URL into the rule. For details, see [Manual URL Filtering Options, on page 1934](#).
- If you manually filter specific URLs using URL objects or by entering URLs directly into the rule, carefully consider other traffic that might be affected. To determine whether network traffic matches a URL condition, the system performs a simple substring match. If the requested URL matches any part of the string, the URLs are considered to match.

- If you use manual URL filtering to create exceptions to other rules, position the specific rule with the exceptions above the general rule that would otherwise apply.

### Search Query Parameters in URLs

The system does not use search query parameters in the URL to match URL conditions. For example, consider a scenario where you block all shopping traffic. In that case, using a web search to search for amazon.com is not blocked, but browsing to amazon.com is.

### URL Filtering in High Availability Deployments

For guidelines for URL filtering with Firepower Management Centers in high availability, see *URL Filtering and Security Intelligence* in the [Cisco Secure Firewall Management Center Administration Guide](#).

### Memory Limitations for Selected Device Models

- Device models with less memory store less URL data locally, and the system may therefore check the cloud more frequently to determine category and reputation for sites that are not in the local database.

Lower-memory devices include:

- Firepower 1010
- Threat Defense Virtual with 8 GB of RAM

### URL Matching for TLS session Resumption on Threat Defense

Use URL matching with Snort 2 under the following conditions:

- If there is no TLS session resumption and SSL policy is enabled or the Client Hello message contains Server Name Indication (SNI) extension.
- If there is TLS session resumption and SSL policy is not enabled or the Client Hello message does not contain SNI extension.

## Filtering HTTPS Traffic

To filter encrypted traffic, the system determines the requested URL based on information passed during the TLS/SSL handshake: the subject common name in the public key certificate used to encrypt the traffic.

HTTPS filtering, unlike HTTP filtering, disregards subdomains within the subject common name. Do not include subdomain information when manually filtering HTTPS URLs in access control or QoS policies. For example, use example.com rather than www.example.com.

---

**Tip** In an decryption policies, you can handle and decrypt traffic to specific URLs by defining a distinguished name decryption policy rule condition. The common name attribute in a certificate's subject distinguished name contains the site's URL. Decrypting HTTPS traffic allows access control rules to evaluate the decrypted session, which improves URL filtering.

---

### Controlling Traffic by Encryption Protocol

The system disregards the encryption protocol (HTTP vs HTTPS) when performing URL filtering in access control or QoS policies. This occurs for both manual and reputation-based URL conditions. In other words, URL filtering treats traffic to the following websites identically:

- <http://example.com/>
- <https://example.com/>

To configure a rule that matches only HTTP or HTTPS traffic, add an application condition to the rule. For example, you could allow HTTPS access to a site while disallowing HTTP access by constructing two access control rules, each with an application and URL condition.

The first rule allows HTTPS traffic to the website:

Action: Allow  
Application: HTTPS  
URL: example.com

The second rule blocks HTTP access to the same website:

Action: Block  
Application: HTTP  
URL: example.com

## Use Categories in URL Filtering

### Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the [WebMD](#) website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for [WebMD](#) and everything else. General information about decryption rules can be found in [Guidelines for Using TLS/SSL Decryption, on page 2360](#).

1	DR	any	any	any	any	any	any	any	any	any	any	1 DN selection	→ Decrypt - Resign
2	DND	any	any	any	any	any	any	any	any	any	Health and Medic	any	Do not decrypt
3	DR for all other traffic	any	any	any	any	any	any	any	any	any	any	any	→ Decrypt - Resign
Root Rules													
This category is empty													
Default Action												Block	

**Note** Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see [Best Practices for Configuring Application Control, on page 1820](#).

## License Requirements for URL Filtering

### Threat Defense License

- Category and reputation filtering—URL Filtering
- Manual filtering—No additional license.

### Classic License

- Category and reputation filtering—URL Filtering
- Manual filtering—No additional license.

### URL Filtering Licenses for Threat Defense Devices

See *URL Licenses* in the *Licenses* chapter in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Requirements and Prerequisites for URL Filtering

### Model Support

- Network Admin

## How to Configure URL Filtering with Category and Reputation

	Do This	More Information
Step 1	Ensure that you have the correct licenses.	Assign the URL Filtering license to each managed device that will filter URLs.
Step 2	Ensure that your management center can communicate with the cloud to obtain URL filtering data.	<i>Internet Access Requirements</i> and <i>Communication Port Requirements</i> in the <a href="#">Cisco Secure Firewall Management Center Administration Guide</a> .
Step 3	Understand limitations and guidelines and take any necessary actions.	<a href="#">Best Practices for URL Filtering, on page 1921</a>
Step 4	Enable the URL Filtering feature.	<a href="#">Enable URL Filtering Using Category and Reputation, on page 1928</a>
Step 5	Configure rules to filter URLs by category and reputation.	<a href="#">Configuring URL Conditions, on page 1930</a>  For the best protection against malicious sites, you must block sites by reputation AND block URLs in all Threat categories.  (Optional) <a href="#">Supplement or Selectively Override Category and Reputation-Based URL Filtering, on page 1934</a>
Step 6	(Optional) Allow users to bypass a website block by clicking through a warning page.	<a href="#">Configure HTTP Response Pages, on page 1935</a>
Step 7	Order your rules so that traffic hits key rules first.	<a href="#">URL Rule Order, on page 1827</a>

	Do This	More Information
Step 8	(Optional) Modify advanced options related to URL filtering.	<p>Generally, use the defaults unless you have a specific reason to change them.</p> <p>For information about advanced options, including the following, see <a href="#">Access Control Policy Advanced Settings, on page 1840</a>.</p> <ul style="list-style-type: none"> <li>• <b>Maximum URL characters to store in connection events</b></li> <li>• <b>Allow an Interactive Block to bypass blocking for (seconds)</b></li> <li>• <b>Retry URL cache miss lookup</b></li> <li>• <b>Enable reputation enforcement on DNS traffic</b></li> </ul>
Step 9	Deploy your changes.	<a href="#">Deploy Configuration Changes, on page 240</a>
Step 10	Ensure that your system receives future URL data updates as expected	<a href="#">Configure URL Filtering Health Monitors, on page 1939</a>
Step 11	Be sure you have enabled other features that protect your network from malicious sites	See <a href="#">Security Intelligence, on page 1945</a> .

## Enable URL Filtering Using Category and Reputation

You must be an Admin user to perform this task.

### Before you begin

Complete prerequisites described in [How to Configure URL Filtering with Category and Reputation, on page 1927](#).

### Procedure

- 
- Step 1** Choose **Integration > Other Integrations**.
  - Step 2** Click **Cloud Services**.
  - Step 3** Configure [URL Filtering Options, on page 1928](#).
  - Step 4** Click **Save**.
- 

## URL Filtering Options

Adding a URL Filtering license automatically enables the URL filtering feature. This allows traffic handling based on a website's general classification, or *category*, and risk level, or *reputation*.

Although by default the system is configured to submit all URLs to the cloud for threat intelligence evaluation, using a local dataset of category and reputation data can make web browsing faster. When you enable (or re-enable) URL filtering, the management center automatically queries Cisco for URL data and pushes the dataset to managed devices. This process may take some time.

If you use SSL rules to handle encrypted traffic, also see [Decryption Rule Guidelines and Limitations, on page 2360](#).

### Enable Automatic Updates

If you **Enable Automatic Updates** (the default), the management center checks the cloud every 30 minutes for updates. If you need strict control over when the system contacts external resources, disable automatic updates and instead create a recurring task using the scheduler. See *Automated URL Filtering Updates Using a Scheduled Task* in the [Cisco Secure Firewall Management Center Administration Guide](#).

### Update Now

Click **Update Now** to perform a one-time, on-demand URL data update. You cannot start an on-demand update if an update is already in progress. Although daily updates tend to be small, if it has been more than five days since your last update, new URL data may take up to 20 minutes to download, depending on your bandwidth. Then, it may take up to 30 minutes to perform the update itself.

### URL Query Source

You can choose how the system assigns a category and reputation to the URLs that your users browse to. You can choose:

- **Local Database Only:** Uses the local dataset only. Use this option if you do not want to submit your uncategorized URLs (category and reputation not in the local dataset) to Cisco, for example, for privacy reasons. However, note that connections to uncategorized URLs do *not* match rules with category or reputation-based URL conditions. You cannot assign categories or reputations to URLs manually.
- **Local Database and Cisco Cloud:** Uses the local dataset when possible, which can make web browsing faster. When users browse to an URL whose category and reputation is not in the local dataset or a cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache.
- **Cisco Cloud Only** (default): Does not use the local dataset. When users browse to an URL whose category and reputation is not in a local cache of previously accessed websites, the system submits it to the cloud for threat intelligence evaluation and adds the result to the cache. This option guarantees the most up-to-date category and reputation information.

This option requires threat defense Version 7.3. If you enable this option, devices running earlier versions will use the **Local Database and Cisco Cloud** option.

### Cached URLs Expire

Caching category and reputation data makes web browsing faster. By default, cached data for URLs never expires, for fastest performance.

To minimize instances of URLs matching on stale data, you can set URLs in the cache to expire. For greater accuracy and currency of threat data, choose a shorter expiration time. A cached URL refreshes *after* the first time a user on the network accesses it after the specified time has passed. The first user does not see the refreshed result, but the next user who visits this URL does see the refreshed result.

## Configuring URL Conditions

Protect your network by controlling access to sites based on URL category and reputation.

### Before you begin

**Attention** As a prerequisite, ensure that you create at least a Monitor rule at the top of your access control policy, containing Category or Reputation parameters. This is essential to see ANY category or reputation data for ANY URLs that hit the particular access control policy.

If there is no rule in the access control policy with the category or reputation parameters configured, the **Connection Events** page in the management center shows no data for Category or Reputation for any URL traffic that hits the access control policy.

### Procedure

**Step 1** In the rule editor, click the following for URL conditions:

- Access control or QoS—Click **URLs**.
- SSL—Click **Category**.

**Step 2** Find and choose the URL categories that you want to control:

In an access control or QoS rule, click **Category**.

For effective protection from malicious sites, you must block URLs in all Threat categories. Additionally, Talos recommends that you block only sites with Poor category. You can block questionable reputations if you have an aggressive security posture, but this may result in a higher amount of false positives. For a list of Threat categories, see [URL Category and Reputation Descriptions, on page 1920](#).

Be sure to click the arrows at the bottom of the list to see all available categories.

**Step 3** (Optional) Constrain URL categories by choosing a **Reputation**.

Note that if you explicitly match **Uncategorized** URLs, you cannot further constrain by reputation. Choosing a reputation level also includes other reputations either more or less severe than the level you choose, depending on the rule action:

- Includes less severe reputations—If the rule allows or trusts web traffic. For example, if you configure an access control rule to allow Favorable (level 4), it also automatically allows Trusted (level 5) sites.
- Includes more severe reputations—If the rule rate limits, decrypts, blocks, or monitors web traffic. For example, if you configure an access control rule to block Questionable sites (level 2), it also blocks Untrusted (level 1) sites.

If you change the rule action, the system automatically changes the reputation levels in URL conditions.

Optionally, select **Apply to unknown reputation**.

**Step 4** Click **Add URL** or **Add to Rule**, or drag and drop.

**Step 5** (Optional) To choose predefined URL objects, or URL lists and feeds in an access control or QoS rule, click **URL**, select the objects, and add them to the destination.

These objects implement manual URL filtering rather than category-based filtering.

**Step 6** Save or continue editing the rule.

### Example: URL Condition in an Access Control Rule

The following graphic shows the URL condition for an access control rule that blocks all malware sites, all untrusted sites, and all social networking sites with a reputation level of Neutral or worse.

The following table summarizes how you build the condition.

Blocked URL	Category	Reputation
Malware sites, regardless of reputation	Malware Sites	Any
Any untrusted URL (level 1)	Any	1 - Untrusted
Social networking sites with a reputation level of Neutral or worse (levels 1 through 3)	Social Network	3 - Neutral

## Rules with URL Conditions

The following table lists rules that support URL conditions, and the types of filtering that each rule type supports.

Rule Type	Supports Category and Reputation Filtering?	Supports Manual Filtering?
Access control	Yes	Yes
Decryption policy	Yes	No; use distinguished name conditions instead
QoS	Yes	Yes

To use URL filtering in a decryption policy that has **Do Not Decrypt** rule conditions, see [Use Categories in URL Filtering, on page 1925](#).

## URL Rule Order

For the most effective URL matching, place rules that include URL conditions before other rules, particularly if the URL rules are block rules and the other rules meet both of the following criteria:

- They include application conditions.
- The traffic to be inspected is encrypted.

If you configure exceptions to a rule, put the exception above the other rule.

## DNS Filtering: Identify URL Reputation and Category During DNS Lookup

The **Enable reputation enforcement on DNS traffic** option is enabled by default on the **Advanced** tab of each new access control policy. This option slightly modifies URL filtering behavior and is applicable only when URL filtering is enabled and configured.

When this option is enabled:

- The system evaluates domain category and reputation early in URL transactions, when the browser looks up the domain name to get the IP address
  - Category and reputation of encrypted traffic can often be determined without decryption
- If DNS filtering cannot determine the URL of encrypted traffic, that traffic is processed using your configurations for encrypted traffic.

## Enable DNS Filtering to Identify URLs During Domain Lookup

DNS filtering is enabled by default in new access control policies. However, additional configurations may be required in order for this setting to take effect.

### Before you begin

- URL filtering using category and reputation must be licensed, enabled, and configured.  
(DNS filtering does not use the following settings in the URLs tab: URL groups, URL objects, URL lists and feeds, and URLs entered into the "Enter URL" text box.)
- See limitations at [DNS Filtering Limitations, on page 1933](#).

## Procedure

- 
- Step 1** In your access control policy's advanced settings, select **Enable reputation enforcement on DNS traffic**.
- Step 2** In the same policy, for each access control rule that has URL category and reputation blocking configured:
- Application conditions—If the application condition is anything other than **any** (or empty), add **DNS** to that list. Other DNS-related options are not relevant for this purpose.
  - Port condition—If the port/protocol condition is anything other than **any** (or empty), add **DNS\_over\_TCP** and **DNS\_over\_UDP**.

**Step 3** Save your changes.

---

#### What to do next

If you are done making changes: [Deploy Configuration Changes, on page 240](#).

## DNS Filtering Limitations

Traffic that matches rules having action **Block with reset**, **Interactive Block**, or **Interactive Block with reset** will be treated as if the rule action were **Block**.

End users trying to access a blocked URL will experience this as an unexplained inability to connect to their page; the connection will spin and then time out.

## DNS Filtering and Events

Connection events generated by DNS filtering are logged using the following fields: DNS Query, URL Category, URL Reputation, and Destination Port. The DNS Query field holds the domain name; the URL field will be blank for DNS filtering matches. The Destination Port will be 53.

Also:

- When the access control rule action is **Allow** or **Trust**, two connection events will be generated for the same traffic, one for DNS filtering (with the **DNS Query** field populated) and one for URL filtering (with the **URL** field populated).
- The first time the system encounters a particular URL, you will see two events for that single session: One event showing uncategorized/reputationless for the DNS Query, and one event showing the actual category and reputation for the URL, which were retrieved during the DNS Query and applied to the session while processing using standard URL filtering.

## Manual URL Filtering

In access control and QoS rules, you can supplement or selectively override category and reputation-based URL filtering by manually filtering individual URLs, groups of URLs, or URL lists and feeds.

For example, you might use access control to block a category of websites that are not appropriate for your organization. However, if the category contains a website that is appropriate, and to which you want to provide access, you can create a manual Allow rule for that site and place it before the Block rule for the category.

You can perform this type of URL filtering without a special license.

Manual URL filtering is not supported in SSL rules; instead, use distinguished name conditions.

---

**Caution** Depending on how you implement manual URL filtering, URL matching may not be what you intend. See [Manual URL Filtering Options, on page 1934](#).

---

## Manual URL Filtering Options

There are several ways to specify URLs for manual URL filtering:

Option	Description
<p><b>(Best practice)</b></p> <p>Use custom Security Intelligence URL list or feed objects.</p>	<p>This is the recommended method for manual URL filtering.</p> <p>You can create a new list or feed, or choose an existing one in an access control or QoS rule.</p> <p>For more information, see <a href="#">Custom Security Intelligence Lists and Feeds, on page 1530</a> and subtopics.</p>
<p>Use URL objects, individually or as groups. URL objects are described at <a href="#">URL, on page 1539</a>.</p> <p>Or</p> <p>Enter URLs directly into the access control rule. (The <b>Enter URL</b> option on the rule page in the web interface.)</p>	<p>If you do not include a path (that is, there are no / characters in the URL), the match is based on the server's hostname only. If you include one or more / character, the entire URL string is used for a substring match. Then, a URL is considered a match if any of the following are true:</p> <ul style="list-style-type: none"> <li>• The string is at the beginning of the URL.</li> <li>• The string follows a dot.</li> <li>• The string contains a dot in the beginning.</li> <li>• The string follows the :// characters.</li> </ul> <p>For example, ign.com matches ign.com or www.ign.com, but not versign.com.</p> <p><b>Note</b> We recommend that you do not use manual URL filtering to block or allow individual web pages or parts of sites (that is, URL strings with / characters), as servers can be reorganized and pages moved to new paths.</p> <p>The <b>Enter URL</b> option does not support wildcards.</p>

## Supplement or Selectively Override Category and Reputation-Based URL Filtering

In access control or QoS rules, you can use Security Intelligence URL lists and feeds to supplement, or to specify exceptions to, your category and reputation-based URL filtering rules.

**Important!** If the list or feed you are configuring in this procedure contains exceptions to category- or reputation-based rules, put this rule above those rules in the rule order.

In SSL rules, use distinguished name conditions to configure parallel behavior.

### Before you begin

- Configure URL filtering using category and reputation. See [Configuring URL Conditions, on page 1930](#).
- Understand important best practices for manual URL filtering. See [Best Practices for URL Filtering, on page 1921](#) and [Manual URL Filtering Options, on page 1934](#).

- Configure one or more Security Intelligence objects (lists or feeds) containing the URLs that you want to use for manual filtering. See [Custom Security Intelligence Lists and Feeds, on page 1530](#).

## Procedure

- 
- Step 1** Navigate to the access control or QoS policy in which you will define the rule.
- Step 2** Create or edit the rule in which you will add the new condition:
- If you are supplementing a category- or reputation-based URL filtering rule, edit the existing rule.
  - If you are overriding or creating exceptions to a category- or reputation-based URL filtering rule, create a new rule.
- Step 3** Select the list or feed you created as the destination URL criteria.
- Step 4** Save the rule.
- 

# Configure HTTP Response Pages

As part of access control, you can configure an *HTTP response page* to display when the system blocks web requests, using either access control rules or the access control policy default action.

The response page displayed depends on how you block the session:

- **Block Response Page:** Overrides the default browser or server page that explains that the connection was denied.
- **Interactive Block Response Page:** Warns users, but also allows them to click a button (or refresh the page) to load the originally requested site. Users may have to refresh after bypassing the response page to load page elements that did not load.

If you do not choose a response page, the system blocks sessions without interaction or explanation.

## Limitations to HTTP Response Pages

- The system displays a response page only for unencrypted or decrypted HTTP/HTTPS connections blocked (or interactively blocked) either by access control rules or by the access control policy default action. The system does not display a response page for connections that are blocked by any other policy or mechanism.
- The system cannot display a response page if the connection is reset (RST packet sent). If you enable response pages, the system prioritizes that configuration. Even if you choose **Block with reset** or **Interactive Block with reset** as the rule action, the system displays the response page and does not reset matching web connections. To ensure that blocked web connections are reset, you must disable response pages.

Note that all non-web traffic that matches the rule *is* blocked with reset.

- The system does not display a response page for encrypted connections that are blocked by access control rules (or any other configuration). Access control rules evaluate encrypted connections if you did not configure an SSL policy, or your SSL policy passes encrypted traffic.

For example, the system cannot decrypt HTTP/2 or SPDY sessions. If web traffic encrypted using one of these protocols reaches access control rule evaluation, the system does not display a response page if the session is blocked.

However, the system does display a response page for connections that are decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. In these cases, the system encrypts the response page and sends it at the end of the reencrypted SSL stream.

- The system does not display a response page when web traffic is blocked because of a promoted access control rule (an early-placed blocking rule with only simple network conditions).
- If a URL is entered without specifying "http" or "https", and the browser initiates the connection on port 80, and the user clicks through a response page, and the connection is subsequently redirected to port 443, the user will not see a second interactive response page because the response to this URL is already cached.
- The system does not display a response page when web traffic is blocked before the system identifies the requested URL; see [Best Practices for URL Filtering, on page 1921](#).

## Requirements and Prerequisites for HTTP Response Pages

### Model Support

Any

### Supported Domains

Any

### User Roles

- Admin
- Access Admin
- Network Admin

## Choosing HTTP Response Pages

Reliable display of HTTP response pages depends on your network configuration, traffic loads, and size of the page. Smaller pages are more likely to display successfully.

## Procedure

- 
- Step 1** In the access control policy editor, select **HTTP Responses** from the **More** drop-down arrow at the end of the packet flow line.
- If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 2** Choose the **Block Response Page** and **Interactive Block Response Page**:
- System-provided—Displays a generic response. Click **View** (👁) to view the code for this page.
  - Custom—Create a custom response page. A pop-up window appears, prepopulated with system-provided code that you can replace or modify by clicking **Edit** (✎). A counter shows how many characters you have used.
  - None—Disables the response page and blocks sessions without interaction or explanation. To quickly disable interactive blocking for the whole access control policy, choose this option.
- Step 3** Click **Save** to save the policy.
- 

### What to do next

- Deploy configuration changes.

## Configure Interactive Blocking with HTTP Response Pages

When you configure interactive blocking, users can load an originally requested site after reading a warning. Users may have to refresh after bypassing the response page to load page elements that did not load.

---

**Tip** To quickly disable interactive blocking for the whole access control policy, display neither the system-provided page nor a custom page. The system then blocks all connections without interaction.

---

If a user does not bypass an interactive block, matching traffic is denied without further inspection. If a user bypasses an interactive block, the access control rule allows the traffic, although the traffic may still be subject to deep inspection and blocking.

By default, a user bypass is in effect for 10 minutes (600 seconds) without displaying the warning page on subsequent visits. You can set the duration to as long as a year, or you can force the user to bypass the block every time. This limit applies to every Interactive Block rule in the policy. You cannot set the limit per rule.

Logging options for interactively blocked traffic are identical to those in allowed traffic, but if a user does not bypass the interactive block, the system can log only beginning-of-connection events. When the system initially warns the user, it marks any logged beginning-of-connection event with the `Interactive Block` or `Interactive Block with reset` action. If the user bypasses the block, additional connection events logged for the session have an action of `Allow`.

## Configuring Interactive Blocking

The following procedure explains how to allow users to bypass URL filtering rules.

### Procedure

- 
- Step 1** As part of access control, configure an access control rule that matches web traffic; see [Create and Edit Access Control Rules](#), on page 1863:
- Action—Set the rule action to **Interactive Block** or **Interactive Block with reset**; see [Access Control Rule Interactive Blocking Actions](#), on page 1859.
  - Conditions—Use URL conditions to specify the web traffic to interactively block; see [URL Conditions \(URL Filtering\)](#).
  - Logging—Assume users will bypass the block and choose logging options accordingly.
  - Inspection—Assume users will bypass the block and choose deep inspection options accordingly; see [Access Control Overview](#), on page 1809.
- Step 2** (Optional) In the access control policy **HTTP Responses**, choose a custom interactive-block HTTP response page; see [Choosing HTTP Response Pages](#), on page 1936.
- Step 3** (Optional) In access control policy **Advanced** settings, change the user bypass timeout; see [Setting the User Bypass Timeout for a Blocked Website](#), on page 1938.
- After a user bypasses a block, the system allows the user to browse to that page without warning until the timeout period elapses.
- Step 4** Save the access control policy.
- Step 5** Deploy configuration changes.
- 

## Setting the User Bypass Timeout for a Blocked Website

The following procedure explains how to set the time allowed for browsing after the user bypasses a URL filtering block. After the timeout expires, the user must bypass the block again.

### Procedure

- 
- Step 1** Click **Policies > Access Control** and edit the policy.
- Step 2** Select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.
- Step 3** Click **Edit** (✎) next to General Settings.
- If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 4** In the **Allow an Interactive Block to bypass blocking for (seconds)** field, enter the number of seconds that must elapse before the user bypass expires.
- Setting this value to 0 means the interactive block response is displayed once and the user bypass never expires.
- Step 5** Click **OK**.

**Step 6** Click **Save** to save the policy.

#### What to do next

- Deploy configuration changes.

## Configure URL Filtering Health Monitors

The following health policies alert if the system has problems obtaining or updating URL category and reputation data.

- URL Filtering Monitor
- Threat Data Updates on Device

To ensure that these are configured the way you want them, see *Health Modules* and *Configuring Health Monitoring* in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Dispute URL Category and Reputation

If you disagree with a category or reputation assigned by Talos, you can submit a request for re-evaluation.

#### Before you begin

You will need your Cisco account credentials.

#### Procedure

**Step 1** In the management center web interface, do one of the following:

Location of Dispute Option	Path to Dispute Option
Cloud Services configuration page	<ol style="list-style-type: none"> <li>Navigate to the <b>Integration &gt; Other Integration &gt; Cloud Services</b> page.</li> <li>Select <b>Dispute URL categories and reputations</b>.</li> </ol>
Manual URL Lookup page	<ol style="list-style-type: none"> <li>Navigate to the manual URL Lookup page: <b>Analysis &gt; Advanced &gt; URL</b>.</li> <li>Look up the URL in question.</li> <li>To see <b>Dispute</b> at the end of the table row, hover over the relevant entry in the list of results, then click dispute.</li> </ol>
URL Connection Event	<ol style="list-style-type: none"> <li>Navigate to any page under the <b>Analysis &gt; Connections</b> menu that has a table that includes URLs.</li> <li>Right-click an item in the <b>URL Category</b> or <b>URL Reputation</b> column (show hidden columns if needed) and select an option.</li> </ol>

The Talos web site opens in a separate browser window.

- Step 2** Sign in to the Talos site with your Cisco credentials.
  - Step 3** Review the information and follow the instructions on the Talos page.
  - Step 4** Look for information on the Talos site about how submitted disputes are handled and what response to expect, if any.
- The dispute process is independent of Firepower products.

---

## If the URL Category Set Changes, Take Action

The set of URL Filtering categories may occasionally change, in order to accommodate new web trends and evolving usage patterns.

These changes affect both policies and events.

Shortly before URL category changes are scheduled to occur, and after they occur, you will see alerts in the list of rules in any access control, SSL, and QoS policy that is affected by the changes, and on URL or Category in rules that you edit.

You should take action when you see these alerts.

---

**Note** Updates to the URL category set as described in this topic are distinct from the changes that simply add new URLs to existing categories or re-classify misclassified URLs. This topic does not apply to category changes for individual URLs.

---

### Procedure

- 
- Step 1** If you see an alert beside a rule in an access control policy, hover over the alert to see details.
  - Step 2** If the alert mentions changes to URL categories, edit the rule to see further details.
  - Step 3** Hover over the URL or Category in the rule dialog to see general information about the type of changes.
  - Step 4** If you see an alert beside a category, click the alert to view details.
  - Step 5** If you see a "More information" link in the description of a change, click it to view information about the category on the Talos web site.

Alternately, see a list and descriptions all categories at the link in [URL Category and Reputation Descriptions, on page 1920](#).

- Step 6** Depending on the type of change, take appropriate action:

Type of Category Change	What The System Will Do	What You Should Do
Existing category will soon be deprecated	Nothing yet. You have a few weeks to change affected rules.  If you do not take action in that time, the system eventually will not be able to redeploy the policy.	Remove this category from all rules that include it. If there is a similar new category, consider using that category instead.
New category is added	By default, the system does not use newly added categories.	Consider creating new rules for the new category.
Existing category is deleted	The category will appear in the rule in strikethrough text (that is, with a line through the category name.)	You must delete the obsolete category from the rule before you can deploy the policy.

**Step 7** Check your SSL rules (Category) for these changes and take action as needed.

**Step 8** Check your QoS rules (URL) for these changes and take action as needed.

#### What to do next

Deploy configuration changes.

## URL Category and Reputation Changes: Effect on Events

- When URL categories change, events that the system processed before the category change will be associated with their original category names and will be labeled with **Legacy**. Events that the system processed after the category change will be associated with the new categories.  
  
Older, legacy events will age out of the system over time.
- If a URL does not have a reputation at the time it was processed, the URL Reputation column in the event viewer will be empty.

## Troubleshoot URL Filtering

### Expected URL Category is Missing from the Categories List

The URL filtering feature uses a different set of categories than the Security Intelligence feature; the category that you expect to see may be a Security Intelligence category. To see those categories, look at the **URLs** tab on the **Security Intelligence** tab in an access control policy.

### Initial Packets Are Passing Uninspected

See [Inspection of Packets That Pass Before Traffic Is Identified](#), on page 2750 and subtopics.

See also [DNS Filtering: Identify URL Reputation and Category During DNS Lookup](#), on page 1932.

**Health alert: "URL Filtering registration failure"**

Verify that your management center and any proxies can connect to the Cisco cloud. You may need information about URL Filtering and URL categories in the following topics: *Internet Access Requirements* and *Communication Port Requirements* in the [Cisco Secure Firewall Management Center Administration Guide](#).

**How can I find the category and reputation of a particular URL?**

Do a manual lookup. See *Finding URL Category and Reputation* in the [Cisco Secure Firewall Management Center Administration Guide](#).

**Error when attempting a manual lookup: "Cloud Lookup Failure for <URL>"**

Make sure the feature is properly enabled. See the prerequisites in *Finding URL Category and Reputation* in the [Cisco Secure Firewall Management Center Administration Guide](#).

**URL appears to be incorrectly handled based on its URL category and reputation**

**Problem:** The system does not handle the URL correctly based on its URL category and reputation.

**Solutions:**

- Verify that the URL category and reputation associated with the URL are what you think they are. See *Finding URL Category and Reputation* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- The following issues may be addressed by settings described in [URL Filtering Options, on page 1928](#), accessible using [Enable URL Filtering Using Category and Reputation, on page 1928](#).
  - The URL cache may hold stale information. See information about the **Cached URLs Expire** setting in [URL Filtering Options, on page 1928](#).
  - The local data set may not be updated with current information from the cloud. See information about the **Enable Automatic Updates** setting in [URL Filtering Options, on page 1928](#).
  - The system may be configured to *not* check the cloud for current data. See information about the **Query Cisco cloud for unknown URLs** setting in [URL Filtering Options, on page 1928](#).
- Your access control policy may be configured to pass traffic to the URL without checking the cloud. See information about the **Retry URL cache miss lookup** setting in [Access Control Policy Advanced Settings, on page 1840](#).
- See also [Best Practices for URL Filtering, on page 1921](#).
- If the URL is processed using an SSL rule, see [Decryption Rule Guidelines and Limitations, on page 2360](#) and [SSL Rule Order](#)
- Verify that the URL is being handled using the access control rule that you think it is being handled by, and that the rule does what you think it does. Consider rule order.
- Verify that the local URL category and reputation database on the management center is successfully being updated from the cloud and that managed devices are successfully being updated from the management center.

Status of these processes are reported in the Health Monitor, in the **URL Filtering Monitor** module and the **Threat Data Updates on Devices** module. For details, see *Health* in the [Cisco Secure Firewall Management Center Administration Guide](#).

If you want to immediately update the local URL category and reputation database, go to **Integration > Other Integrations**, click **Cloud Services**, then click **Update Now**. For more information, see [URL Filtering Options, on page 1928](#).

### **A URL category or reputation is not correct**

For access control or QoS rules: Use manual filtering, paying careful attention to rule order. See [Manual URL Filtering, on page 1933](#) and [Configuring URL Conditions, on page 1930](#).

For SSL rules: Manual filtering is not supported. Instead, use distinguished name conditions.

See also [Dispute URL Category and Reputation, on page 1939](#).

### **Web pages are slow to load**

There is a tradeoff between security and performance. Some options:

- Consider modifying the **Cached URLs Expire** setting. Click **Integration > Other Integrations**, then select **Cloud Services**. For information, see [URL Filtering Options, on page 1928](#).
- Consider deselecting the **Retry URL cache miss lookup** setting in [Access Control Policy Advanced Settings, on page 1840](#).

### **Events Do Not Include URL Category and Reputation**

- Make sure you have included applicable URL rules in an access control policy, the rules are active, and the policies have been deployed to the relevant devices.
- URL category and reputation do not appear in an event if the connection is processed before it matches a URL rule.
- The rule that handles the connection must be configured for URL category and reputation.
- Even if you have configured URL categories in the Categories tab in an SSL rule, you must also configure the URLs tab in a rule in your access control policy.

### **DNS Filtering is not working**

Make sure you have completed all prerequisites and steps in [Enable DNS Filtering to Identify URLs During Domain Lookup, on page 1932](#).

### **An End User Tries to Access a Blocked URL and the Page Just Spins and Times Out**

When DNS Filtering is enabled and end users access a URL that is blocked, the page will spin but not load. End users are not notified that the page is blocked. This is currently a limitation when DNS filtering is enabled.

See [DNS Filtering Limitations, on page 1933](#).

### **Events Include URL Category and Reputation but URL Field is Blank**

If the DNS Query field is populated and the URL field is empty, this is expected when the DNS filtering feature is enabled.

See [DNS Filtering and Events, on page 1933](#).

### Multiple Events are Generated for a Single Transaction

A single web transaction sometimes generates two connection events, one for DNS filtering and one for URL filtering. This is expected when DNS filtering is enabled and:

- the access control rule action for the traffic is Allow or Trust.
- the system encounters a URL for the first time.

See [DNS Filtering and Events, on page 1933](#).

## CHAPTER 67

# Security Intelligence

---

The following topics provide an overview of Security Intelligence, including use of lists for blocking and allowing traffic and basic configuration.

- [About Security Intelligence, on page 1945](#)
- [Best Practices for Security Intelligence, on page 1946](#)
- [License Requirements for Security Intelligence, on page 1946](#)
- [Requirements and Prerequisites for Security Intelligence, on page 1947](#)
- [Security Intelligence Sources, on page 1947](#)
- [Configure Security Intelligence, on page 1948](#)
- [Security Intelligence Monitoring, on page 1954](#)
- [Override Security Intelligence Blocking, on page 1954](#)
- [Troubleshooting Security Intelligence, on page 1955](#)

## About Security Intelligence

As an early line of defense against malicious internet content, Security Intelligence uses reputation intelligence to quickly block connections to or from IP addresses, URLs, and domain names. This is called *Security Intelligence block listing*.

Security Intelligence is an early phase of access control, before the system performs more resource-intensive evaluation. Using a Block list improves performance by quickly excluding traffic that does not require inspection.

---

**Note** You cannot use a Block list to block fastpathed traffic. Prefilter evaluation occurs before Security Intelligence filtering. Fastpathed traffic bypasses all further evaluation, including Security Intelligence.

---

Although you can configure custom Block lists, Cisco provides access to regularly updated intelligence feeds. Sites representing security threats such as malware, spam, botnets, and phishing appear and disappear faster than you can update and deploy custom configurations.

You can refine Security Intelligence Block listing with Do Not Block lists and monitor-only Block lists. These mechanisms exempt traffic from being blocked by a Block list, but do **not** automatically trust or fastpath matching traffic. Traffic added to a Do Not Block list or monitored at the Security Intelligence stage is intentionally subject to further analysis with the rest of access control.

### Related Topics

[Security Intelligence](#), on page 1526

## Best Practices for Security Intelligence

- Configure your access control policies to block threats detected by Cisco-provided Security Intelligence feeds. See [Configuration Example: Security Intelligence Blocking, on page 1953](#).
- If you want to supplement the Cisco-provided Security Intelligence feeds with custom threat data, or manually block emerging threats:
  - For IP addresses, use custom Security Intelligence lists and feeds, or Network objects or groups. To create these, see [Security Intelligence, on page 1526](#) and [Network, on page 1497](#), and their subtopics. To use them for Security Intelligence, see [Configure Security Intelligence, on page 1948](#). Network objects used in Security Intelligence policy require an IPS license.
  - For URLs and domains, use custom Security Intelligence lists and feeds, *not* objects or groups. See details at [Manual URL Filtering Options, on page 1934](#).
  - You can also add entries to a Block list from events. See [Global and Domain Security Intelligence Lists, on page 1527](#).
- To test new feeds, or for passive deployments, set the action from block to monitor only. See [Security Intelligence Monitoring, on page 1954](#).
- If you need to exclude specific sites or addresses from Security Intelligence blocking, see [Override Security Intelligence Blocking, on page 1954](#).
- If your Firepower deployment is integrated with Cisco XDR and you use custom Security Intelligence lists and feeds, be sure to update Security Services Exchange with these lists and feeds. For details, see instructions for configuring auto-promotion of events in the Security Services Exchange online help.
- System-provided Security Intelligence categories may change over time and without notification; you should plan to check periodically for changes, and modify your policies accordingly.
- You should also configure URL filtering, a separate feature with separate licensing requirements, for further protection against malicious sites. See [URL Filtering, on page 1919](#).

- Access Admin
- Network Admin

---

**Important** You must apply the Network Discovery policy on the device for a successful application of the SI policy.

---

## Security Intelligence Sources

- System-provided feeds

Cisco provides access to regularly updated intelligence feeds for domains, URLs and IP addresses. For more information, see [Security Intelligence, on page 1526](#).

- Third-party feeds

Optionally, supplement Cisco-provided feeds with third-party reputation feeds, which are dynamic lists that the Secure Firewall Management Center downloads from the internet on a regular basis. See [Custom Security Intelligence Feeds, on page 1532](#).

- Custom Block lists or feeds (or objects or groups)

Block specific IP addresses, URLs, or domain names using a manually-created list or feed (for IP addresses, you can also use network objects or groups.)

For example, if you become aware of malicious sites or addresses that are not yet blocked by a feed, add these sites to a custom Security Intelligence list and add this custom list to the Block list in the Security Intelligence tab of your access control policy, as described in [Custom Security Intelligence Lists, on page 1533](#) and [Configure Security Intelligence, on page 1948](#).

For IP addresses, you can optionally use network objects rather than lists or feeds for this purpose; for information, see [Network, on page 1497](#). (For URLs, using lists and feeds is strongly recommended over other methods.)

- Custom Do Not Block lists or feeds

Override Security Intelligence blocking for specific sites or addresses. See [Override Security Intelligence Blocking, on page 1954](#).

- Global Block lists (one each for Network, URL and DNS)

While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Block List so that Security Intelligence will handle future traffic from that source. See [Global and Domain Security Intelligence Lists, on page 1527](#).

- Global Do Not Block lists (one each for Network, URL and DNS)

While reviewing events, you can immediately add an event's IP address, URL, or domain to the applicable Global Do Not Block List if you do not want Security Intelligence to block future traffic from that source. See [Global and Domain Security Intelligence Lists, on page 1527](#).

## Configure Security Intelligence

Each access control policy has Security Intelligence options. You can add network objects, URL objects and lists, and Security Intelligence feeds and lists to a Block list or Do Not Block list, and constrain any of these by security zone. You can also associate a DNS policy with your access control policy, and add domain names to a Block or Do Not Block list.

The number of objects in the Do Not Block lists plus the number in the Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

### Before you begin

- Tip: For guidance on minimum configuration recommendations, see also [Configuration Example: Security Intelligence Blocking, on page 1953](#).
- To ensure that all options are available to select, add at least one managed device to your management center.
- In passive deployments, or if you want to set Security Intelligence filtering to monitor-only, enable logging
- Configure a DNS policy to take Security Intelligence action for domains. For more information, see [DNS Policies, on page 1957](#).

### Procedure

- 
- Step 1** In the access control policy editor, click **Security Intelligence**.
- If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 2** You have the following options:
- Click **Networks** to add network objects (IP addresses).
- Note** Network objects used in a Security Intelligence policy require a IPS license.
- Click **URLs** to add URL objects.
- Step 3** Find the **Available Objects** you want to add to the Block or Do Not Block list. You have the following options:

- Search the available objects by typing in the **Search by name or value** field. Clear the search string by clicking **Reload** (↻) or **Clear** (✕).
- If no existing list or feed meets your needs, click **Add** (+), select **New Network List** or **New URL List**, and proceed as described in [Creating Security Intelligence Feeds, on page 1532](#) or [Uploading New Security Intelligence Lists to the Secure Firewall Management Center, on page 1534](#).
- If no existing object meets your needs, click **Add** (+), select **New Network Object** or **New URL Object**, and proceed as described in [Creating Network Objects, on page 1499](#).

Security Intelligence ignores IP address blocks using a /0 netmask.

**Step 4** Choose one or more **Available Objects** to add.

**Step 5** (Optional) Choose an **Available Zone** to constrain the selected objects by zone.

You cannot constrain system-provided Security Intelligence lists by zone.

**Note** The **Any** zone for an SI list applies only to interfaces that are part of a security zone. However, an exception is that if a device does not have any interfaces associated with a security zone, then the **Any** zone will match any interface.

For example, if you have five interfaces on a device and none of them are associated with a security zone, any SI list that is assigned to the **Any** zone will be inspected against traffic on ALL interfaces on the device. If you add one interface to a security zone on that device, it effectively would remove SI inspection on the other four interfaces, where the zone is set to **Any** for an SI list. If you add the other four interfaces to a security zone, they will be evaluated by the SI list attached to the **Any** zone.

**Step 6** Click **Add to Do Not Block list** or **Add to Block list**, or click and drag the selected objects to either list.

To remove an object from a Block or Do Not Block list, click **Delete** (🗑) To remove multiple objects, choose the objects and right-click to **Delete Selected**.

**Step 7** (Optional) Set objects on the Block list to monitor-only by right-clicking the object under **Block List**, then choosing **Monitor-only (do not block)**.

You cannot set system-provided global Security Intelligence lists to monitor only.

**Step 8** Choose a DNS policy from the **DNS Policy** drop-down list.

**Step 9** Click **Save**.

---

### What to do next

- Deploy configuration changes.

### Related Topics

[Security Intelligence](#), on page 1526

[Snort Restart Scenarios](#), on page 232

## Security Intelligence Options

Use the Security Intelligence tab in the access control policy editor to configure network (IP address) and URL Security Intelligence, and to associate the access control policy with a DNS policy in which you have configured Security Intelligence for domains.

### Available Objects

Available objects include:

- Security Intelligence categories populated by the system-provided feed.  
For details, see [Security Intelligence Categories, on page 1951](#).
- System-provided Global Block and Do Not Block lists.  
For descriptions, see [Security Intelligence Sources, on page 1947](#).
- Security Intelligence lists and feeds that you create under Object > Object Management > Security Intelligence.  
For descriptions, see [Security Intelligence Sources, on page 1947](#).
- Network and URL objects and groups that are configured on the respective pages under Object > Object Management. These are different from the Security Intelligence objects in the previous bullet.  
For details about network objects, see [Network, on page 1497](#). (For URLs, use Security Intelligence lists or feeds rather than objects or groups.)

### Available Zones

Except for the system-provided Global lists, you can constrain Security Intelligence filtering by zone.

For example: To improve performance, you may want to target enforcement. As a more specific example, you can block spam only for a security zone that handles email traffic.

To enforce Security Intelligence filtering for an object on multiple zones, you must add the object to the Block or Do Not Block list separately for each zone.

### DNS Policy

In order to match DNS traffic using Security Intelligence, you must select a DNS policy for your Security Intelligence configuration.

Using Block or Do Not Block lists, or monitoring traffic based on a DNS list or feed, also requires that you:

- Configure DNS Security Intelligence lists and feeds. See [Security Intelligence, on page 1526](#).
- Create a DNS policy. See [Creating Basic DNS Policies, on page 1960](#) for more information.
- Configure DNS rules that reference your DNS lists or feeds. See [Creating and Editing DNS Rules, on page 1962](#) for more information.
- Because you deploy the DNS policy as part of your access control policy, you must associate both policies. See [DNS Policy Deploy, on page 1969](#) for more information.

**Do Not Block List**

See [Override Security Intelligence Blocking, on page 1954](#).

To select all objects in the list, right-click an object.

**Block List**

See [Configuration Example: Security Intelligence Blocking, on page 1953](#) and other topics in this chapter.

For explanations of the visual indicators in the Block list, see [Block List Icons, on page 1953](#).

To select all objects in the list, right-click an object.

**Logging**

Security Intelligence logging, enabled by default, logs all blocked and monitored connections handled by an access control policy's target devices. However, the system does not log Do Not Block list matches; logging of connections on the Do Not Block list depends on their eventual disposition. Logging must be enabled for connections on the Block list before you can set objects on that list to monitor-only.

To enable, disable, or view logging settings, right-click an object in the Block list.

**Related Topics**

[Global and Domain Security Intelligence Lists, on page 1527](#)

[Security Intelligence Lists and Multitenancy, on page 1528](#)

## Security Intelligence Categories

Security Intelligence categories are determined by the system-provided feeds described in [Security Intelligence, on page 1526](#).

These categories are used in the following locations:

- The Networks sub-tab on the Security Intelligence tab of an access control policy
- The URLs sub-tab beside the Networks tab on the Security Intelligence tab of an access control policy
- In a DNS policy on the DNS tab in the DNS rule configuration page
- In events generated when traffic matches Block or Monitor configurations in the above locations

**Note** If your organization is using Secure Firewall threat intelligence director: When viewing events, you may see categories that indicate that the action was taken by TID, such as TID URL Block.

Categories are updated by Talos from the cloud, and this list may change independently of Firepower releases.

*Table 116: Cisco Talos Intelligence Group (Talos) Feed Categories*

Security Intelligence Category	Description
Attackers	Active scanners and hosts known for outbound malicious activity

Security Intelligence Category	Description
Banking_fraud	Sites that engage in fraudulent activities that relate to electronic banking
Bogon	Bogon networks and unallocated IP addresses
Bots	Sites that host binary malware droppers
CnC	Sites that host command-and-control servers for botnets
Cryptomining	Hosts providing remote access to pools and wallets for the purpose of mining cryptocurrency
Dga	Malware algorithms used to generate a large number of domain names acting as rendezvous points with their command-and-control servers
Exploitkit	Software kits designed to identify software vulnerabilities in clients
High_risk	Domains and hostnames that match against the OpenDNS predictive security algorithms from security graph
Ioc	Hosts that have been observed to engage in Indicators of Compromise (IOC)
Link_sharing	Websites that share copyrighted files without permission
Malicious	Sites exhibiting malicious behavior that do not necessarily fit into another, more granular, threat category
Malware	Sites that host malware binaries or exploit kits
Newly_seen	Domains that have recently been registered, or not yet seen via telemetry. <b>Attention</b> Currently, this category does not have any active feed and is reserved for future use.
Open_proxy	Open proxies that allow anonymous web browsing
Open_relay	Open mail relays that are known to be used for spam
Phishing	Sites that host phishing pages
Response	IP addresses and URLs that are actively participating in malicious or suspicious activity
Spam	Mail hosts that are known for sending spam
Spyware	Sites that are known to contain, serve, or support spyware and adware activities
Suspicious	Files that appear to be suspicious and have characteristics that resemble known malware
Tor_exit_node	Hosts known to offer exit node services for the Tor Anonymizer network

## Block List Icons

The following visual indicators may appear in the Block list on the Security Intelligence tab in an access control policy:

Icon or Visual Indicator	Description
<b>Block</b> (🚫)	The object is set to block.
<b>Monitor</b> (👁️)	The object is set to monitor-only. See <a href="#">Security Intelligence Monitoring, on page 1954</a>
An object is displayed in strikethrough text	The same object is also on the Do Not Block list, which overrides the block.

## Configuration Example: Security Intelligence Blocking

Configure your access control policy to block all threats detectable by the system's regularly updated Security Intelligence feeds.

The number of objects in the Block lists plus the number in the Do Not Block lists cannot exceed 125 network objects, or 32767 URL objects and lists.

### Before you begin

- To ensure that all options are available to select, add at least one managed device to your management center.
- Configure a DNS policy to block all Security Intelligence threat categories for domains. For more information, see [DNS Policies, on page 1957](#).
- If you have, or will have, custom lists of entities to block, create a Security Intelligence object of each type (URLs, DNS, Networks.) See [Security Intelligence, on page 1526](#).

### Procedure

**Step 1** Click **Policies > Access Control**.

**Step 2** Create a new access control policy or edit an existing policy.

**Step 3** In the access control policy editor, click **Security Intelligence**.

If the controls are dimmed, settings are inherited from an ancestor policy, or you do not have permission to modify the configuration. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

**Step 4** Click **Networks** to add blocking criteria for IP addresses.

- Scroll down in the Networks list and select all of the threat categories listed below the Global lists.
- If applicable, select the security zones for which you want to block these threats.
- Click **Add to Block List**.
- If you have created custom lists or feeds with addresses to block, add those to the Block List using the same steps as above.

- Step 5** Click **URLs** to add blocking criteria for URLs, and repeat the steps you followed for Networks.
- Step 6** Choose a DNS policy from the **DNS Policy** drop-down list; see [DNS Policy Overview, on page 1957](#).
- Step 7** Click **Save**.
- 

#### What to do next

- Enable logging for these connections
- Deploy configuration changes.
- For additional protection, configure URL filtering to block malicious URLs. See [URL Filtering, on page 1919](#).

## Security Intelligence Monitoring

Monitoring logs connection events for traffic that would have been blocked by Security Intelligence, but does not block the traffic. Monitoring is especially useful for:

- Testing feeds before you implement them.

Consider a scenario where you want to test a third-party feed before you implement blocking using that feed. When you set the feed to monitor-only, the system allows connections that would have been blocked to be further analyzed by the system, but also logs a record of each of those connections for your evaluation.

- Passive deployments, to optimize performance.

Managed devices that are deployed passively cannot affect traffic flow; there is no advantage to configuring the system to block traffic. Additionally, because blocked connections are not actually blocked in passive deployments, the system may report multiple beginning-of-connection events for each blocked connection.

---

**Note** If configured, Secure Firewall threat intelligence director may impact the action taken (Monitor or Block.)

---

#### To Configure Security Intelligence Monitoring:

After you configure Security Intelligence blocking following the instructions in [Configuration Example: Security Intelligence Blocking, on page 1953](#), right-click each applicable object in the Block list and choose **Monitor-only**. You cannot set system-provided Security Intelligence lists to monitor only.

## Override Security Intelligence Blocking

Optionally, you can use Do Not Block lists to exempt specific domains, URLs, or IP addresses from being blocked by Security Intelligence lists or feeds.

For example, you can:

- Override the occasional false-positive block in a reputable Security Intelligence feed

- Inspect specific traffic in depth instead of blocking it early based on reputation
- Exempt otherwise-restricted transactions based on zone from Security Intelligence blocking

For example, you can add an improperly classified URL to a Do Not Block list, but then restrict the Do Not Block list object using a security zone used by those in your organization who need to access those URLs. That way, only those with a business need can access the URLs on the Do Not Block list.

---

**Note** Entries on a Do Not Block list are simply exemptions from the block list. Any connection that passes the Security Intelligence policy is subject to the access control rules. Thus, an entry in the Do Not Block list can subsequently be blocked by an access control rule or intrusion policy. Your Do Not Block entries should always be exemptions from your block lists.

---

## Procedure

- 
- Step 1** Option 1: Add an IP address, URL, or domain from an event to the Global Do Not Block List. See [Global and Domain Security Intelligence Lists, on page 1527](#).
- Step 2** Option 2: Use a custom Security Intelligence list or feed.
- a) Create the custom Security Intelligence list or feed. See [Custom Security Intelligence Lists, on page 1533](#) or [Creating Security Intelligence Feeds, on page 1532](#).
  - b) For IP addresses (Networks) and URLs: Edit your access control policy, click the Security Intelligence tab, then click the custom list or feed in the Networks or URLs sub-tab, then click **Add to Do Not Block List**.
  - c) Save your changes.
  - d) For domains (DNS): See the "DNS Policy" section in the [Security Intelligence Options, on page 1950](#) topic.
  - e) Deploy your changes.
- 

# Troubleshooting Security Intelligence

See the following topics for troubleshooting Security Intelligence.

## Security Intelligence Categories Are Missing from the Available Options List

**Symptoms:** On the Security Intelligence tab of the access control policy, Security Intelligence categories (such as CnC or Exploitkit) are not displayed in the Networks tab under Available Options.

**Cause:**

- These categories do not appear until you have added at least one managed device to your management center. You must add a device in order to pull all TALOS feeds.
- The URL filtering feature uses a different set of categories than the Security Intelligence feature; the category that you expect to see may be a URL filtering category. To see URL filtering categories, look at the **URLs** tab in an access control rule.

## CHAPTER 68

# DNS Policies

---

The following topics explain DNS policies, DNS rules, and how to deploy DNS policies to managed devices.

- [DNS Policy Overview, on page 1957](#)
- [Cisco Umbrella DNS Policies, on page 1958](#)
- [DNS Policy Components, on page 1958](#)
- [License Requirements for DNS Policies, on page 1959](#)
- [Requirements and Prerequisites for DNS Policies, on page 1959](#)
- [Managing DNS and Umbrella DNS Policies, on page 1960](#)
- [DNS Rules, on page 1962](#)
- [How to Create DNS Rules, on page 1967](#)
- [DNS Policy Deploy, on page 1969](#)
- [Cisco Umbrella DNS Policies, on page 1970](#)

## DNS Policy Overview

DNS-based Security Intelligence allows you to block traffic based on the domain name requested by a client, using a Security Intelligence Block list. Cisco provides domain name intelligence you can use to filter your traffic; you can also configure custom lists and feeds of domain names tailored to your deployment.

Traffic on a DNS policy Block list is immediately blocked and therefore is not subject to any further inspection—not for intrusions, exploits, malware, and so on, but also not for network discovery. You can use a Security Intelligence Do Not Block list to override a Block list and force access control rule evaluation, and, recommended in passive deployments, you can use a “monitor-only” setting for Security Intelligence filtering. This allows the system to analyze connections that would have been blocked by a Block list, but also logs the match to the Block list and generates an end-of-connection Security Intelligence event.

---

**Note** DNS-based Security Intelligence may not work as intended for a domain name unless the DNS server deletes a domain cache entry due to expiration, or a client’s DNS cache or the local DNS server’s cache is cleared or expires.

---

You configure DNS-based Security Intelligence using a DNS policy and associated DNS rules. To deploy it to your devices, you must associate your DNS policy with an access control policy, then deploy your configuration to managed devices.

# Cisco Umbrella DNS Policies

Cisco Umbrella DNS Connection in the management center helps to redirect DNS queries to Cisco Umbrella. This allows Cisco Umbrella to validate requests, allow or block them based on the domain names, and apply DNS-based security policy on the request. If you use Cisco Umbrella, you must configure the Cisco Umbrella Connection (**Integration > Other Integrations > Cloud Services > Cisco Umbrella Connection**) to redirect DNS queries to Cisco Umbrella.

The Umbrella Connector is part of the system's DNS inspection. If your existing DNS inspection policy map decides to block or drop a request based on your DNS inspection settings, the request is not forwarded to Cisco Umbrella. Thus, you have two lines of protection:

- Your local DNS inspection policy
- Your Cisco Umbrella cloud-based policy

When redirecting DNS lookup requests to Cisco Umbrella, the Umbrella Connector adds an EDNS (Extension mechanisms for DNS) record. An EDNS record includes the device identifier information, organization ID, and client IP address. Your cloud-based policy can use those criteria to control access in addition to the reputation of the FQDN. You can also elect to encrypt the DNS request using DNSCrypt to ensure the privacy of usernames and internal IP addresses.

To redirect DNS requests from the management center to Cisco Umbrella:

1. Configure the Cisco Umbrella connection settings.
2. Create and configure an Umbrella DNS policy.
3. Associate the Umbrella DNS policy with an access control policy.
4. Deploy the changes.

For detailed information about how to set up the Umbrella DNS Connector in the management center, see [Configuring the Umbrella DNS Connector for Cisco Secure Firewall Management Center](#).

## DNS Policy Components

A DNS policy allows you to block connections based on domain name, using a Block list, or exempt such connections from this type of blocking using a Do Not Block list. The following list describes the configurations you can change after creating a DNS policy.

### Name and Description

Each DNS policy must have a unique name. A description is optional.

### Rules

Rules provide a granular method of handling network traffic based on the domain name. Rules in a DNS policy are numbered, starting at 1. The system matches traffic to DNS rules in top-down order by ascending rule number.

When you create a DNS policy, the system populates it with a default Global Do-Not-Block List for DNS rule and a default Global Block List for DNS rule. Both rules are fixed to the first position in their respective categories. You cannot modify these rules, but you can disable them.

**Note** If multitenancy is enabled for your management center, the system is organized into a hierarchy of domains, including ancestor and descendant domains. These domains are distinct and separate from the domain names used in DNS management.

A descendant list contains the domains on the Block or Do Not Block lists of system subdomain users. From an ancestor domain, you cannot view the contents of descendant lists. If you do not want subdomain users to add domains to a Block or Do Not Block list:

- disable the descendant list rules, and
- enforce Security Intelligence using the access control policy inheritance settings

The system evaluates rules in the following order:

- Global Do-Not-Block List for DNS rule (if enabled)
- Descendant DNS Do-Not-Block Lists rule (if enabled)
- Rules with a Do Not Block action
- Global Block List for DNS rule (if enabled)
- Descendant DNS Block Lists rule (if enabled)
- Rules with an action other than Do Not Block

Usually, the system handles DN-based network traffic according to the *first* DNS rule where *all* the rule's conditions match the traffic. If no DNS rules match the traffic, the system continues evaluating the traffic based on the associated access control policy's rules. DNS rule conditions can be simple or complex.

## License Requirements for DNS Policies

**Important** You must apply the Network Discovery policy on the device for a successful DNS validation on the traffic.

---

## Managing DNS and Umbrella DNS Policies

Use the DNS Policy page (**Policies > Access Control > DNS**) to manage custom DNS and Umbrella DNS policies.

In addition to custom policies that you create, the system provides the Default DNS Policy and Default Umbrella DNS Policy. The default DNS policy uses the default Block list and Do Not Block list. You can edit and use this system-provided custom policies.

### Procedure

---

**Step 1** Choose **Policies > Access Control > DNS**.

**Step 2** Manage your DNS policy:

- Compare—To compare DNS policies, click **Compare Policies** and proceed as described in [Compare Policies, on page 252](#).
  - Copy—To copy a DNS policy, click **Copy** () and proceed as described in [Editing DNS Policies, on page 1961](#).
  - Create—To create a new Umbrella DNS policy, click **New Policy > Umbrella DNS Policy** and proceed as described in [Create an Umbrella DNS Policy, on page 1973](#).
  - Delete—To delete a DNS or Umbrella DNS policy, click **Delete** () , then confirm you want to delete the policy.
  - Edit—To modify an existing DNS policy, click **Edit** () and proceed as described in [Editing DNS Policies, on page 1961](#). To modify an existing Umbrella DNS policy, click **Edit** () and proceed as described in [Edit Umbrella DNS Policies and Rules, on page 1973](#).
- 

## Creating Basic DNS Policies

When you create a new DNS policy, it contains default settings. You must then edit it to customize the behavior.

## Procedure

- 
- Step 1** Choose **Policies > Access Control > DNS**.
  - Step 2** Click **Add DNS Policy > DNS Policy**.
  - Step 3** Give the policy a unique **Name** and, optionally, a **Description**.
  - Step 4** Click **Save**.
- 

### What to do next

Configure the policy. See [Editing DNS Policies, on page 1961](#).

## Editing DNS Policies

Only one person should edit a DNS policy at a time, using a single browser window. If multiple users attempt to save the same policy, only the first set of saved changes are retained.

To protect the privacy of your session, after thirty minutes of inactivity on the policy editor, a warning appears. After sixty minutes, the system discards your changes.

## Procedure

- 
- Step 1** Choose **Policies > Access Control > DNS**.
  - Step 2** Click **Edit** (✎) next to the DNS policy you want to edit.  
  
If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
  - Step 3** Edit your DNS policy:
    - Name and Description—To change the name or description, click the field and type the new information.
    - Rules—To add, categorize, enable, disable, or otherwise manage DNS rules, click **Rules** and proceed as described in [Creating and Editing DNS Rules, on page 1962](#).
  - Step 4** Click **Save**.
- 

### What to do next

- Optionally, further configure the new policy as described in *Logging Connections with Security Intelligence* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- Deploy configuration changes; see [Deploy Configuration Changes, on page 240](#).

# DNS Rules

DNS rules handle traffic based on the domain name requested by a host. As part of Security Intelligence, this evaluation happens after any traffic decryption, and before access control evaluation.

The system matches traffic to DNS rules in the order you specify. In most cases, the system handles network traffic according to the *first* DNS rule where *all* the rule's conditions match the traffic.

In addition to its unique name, each DNS rule has the following basic components:

## State

By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.

## Position

Rules in a DNS policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.

## Conditions

Conditions specify the specific traffic the rule handles. A DNS rule must contain a DNS feed or list condition, and can also match traffic by security zone, network, or VLAN.

## Action

A rule's action determines how the system handles matching traffic:

- Traffic with a **Do Not Block** action is allowed, subject to further access control inspection.
- Monitored traffic is subject to further evaluation by remaining rules on the DNS Block list. If the traffic does not match a DNS Block list rule, it is inspected with access control rules. The system logs a Security Intelligence event for the traffic.
- Traffic on a Block list is dropped without further inspection. You can also return a Domain Not Found response, or redirect the DNS query to a sinkhole server.

## Related Topics

[About Security Intelligence](#), on page 1945

# Creating and Editing DNS Rules

In a DNS policy, you can add up to a total of 32767 DNS lists to the Block list and Do Not Block list rules; that is, the number of lists in the DNS policy cannot exceed 32767.

## Procedure

---

**Step 1** In the DNS policy editor, you have the following options:

- To add a new rule, click **Add DNS Rule**.
- To edit an existing rule, click **Edit** (✎).

**Step 2** Enter a **Name**.

**Step 3** Configure the rule components, or accept the defaults:

- Action—Choose a rule **Action**; see [DNS Rule Actions, on page 1964](#).
- Conditions—Configure the rule's conditions; see [DNS Rule Conditions, on page 1965](#).
- Enabled—Specify whether the rule is **Enabled**.

**Step 4** Click **Save**.

---

#### What to do next

- Deploy configuration changes; see [Deploy Configuration Changes, on page 240](#).

## DNS Rule Management

The **Rules** tab of the DNS policy editor allows you to add, edit, move, enable, disable, delete, and otherwise manage DNS rules within your policy.

For each rule, the policy editor displays its name, a summary of its conditions, and the rule action. Other icons represent **Warning** (⚠), **Error** (✖), and other important **Information** (ℹ). Disabled rules are dimmed and marked (disabled) beneath the rule name.

### Enabling and Disabling DNS Rules

When you create a DNS rule, it is enabled by default. If you disable a rule, the system does not use it to evaluate network traffic and stops generating warnings and errors for that rule. When viewing the list of rules in a DNS policy, disabled rules are dimmed, although you can still modify them. Note that you can also enable or disable a DNS rule using the DNS rule editor.

#### Procedure

---

**Step 1** In the DNS policy editor, right-click the rule and choose a rule state.

**Step 2** Click **Save**.

---

#### What to do next

- Deploy configuration changes.

## DNS Rule Order Evaluation

Rules in a DNS policy are numbered, starting at 1. The system matches traffic to DNS rules in top-down order by ascending rule number. In most cases, the system handles network traffic according to the *first* DNS rule where *all* the rule's conditions match the traffic:

- For Monitor rules, the system logs the traffic, then continues evaluating traffic against lower-priority DNS Block list rules.
- For non-Monitor rules, the system does **not** continue to evaluate traffic against additional, lower-priority DNS rules after that traffic matches a rule.

Note the following regarding rule order:

- The Global Do-Not-Block List for DNS is always first, and takes precedence over all other rules.
- The Do-Not-Block List section precedes the Block List section; Do-Not-Block List rules always take precedence over other rules.
- The Global Block List for DNS is always first in the Block List section, and takes precedence over all other Monitor and Block list rules.
- The Block List section contains Monitor and Block list rules.
- When you first create a DNS rule, the system positions it last in the Do-Not-Block List section if you assign a **Do Not Block** action, or last in the Block List section if you assign any other action.

You can drag and drop rules to reorder them.

## DNS Rule Actions

Every DNS rule has an *action* that determines the following for matching traffic:

- handling—foremost, the rule action governs whether the system will block, not block, or monitor traffic that matches the rule's conditions, based on a Block or Do Not Block list
- logging—the rule action determines when and how you can log details about matching traffic

### Do Not Block Action

The **Do Not Block** action allows traffic to pass to the next phase of inspection, which is access control rules.

The system does not log Do Not Block list matches. Logging of these connections depends on their eventual disposition.

### Monitor Action

The **Monitor** action is designed to force connection logging; matching traffic is neither immediately allowed nor blocked. Rather, traffic is matched against additional rules to determine whether to permit or deny it. The first non-Monitor DNS rule matched determines whether the system blocks the traffic. If there are no additional matching rules, the traffic is subject to access control evaluation.

For connections monitored by a DNS policy, the system logs end-of-connection Security Intelligence and connection events to the management center database.

## Block Actions

These actions block traffic without further inspection of any kind:

- The **Drop** action drops the traffic.
- The **Domain Not Found** action returns a non-existent internet domain response to the DNS query, which prevents the client from resolving the DNS request.
- The **Sinkhole** action returns a sinkhole object's IPv4 or IPv6 address in response to the DNS query (A and AAAA records only). The sinkhole server can log, or log and block, follow-on connections to the IP address. If you configure a **Sinkhole** action, you must also configure a sinkhole object.

For a connection blocked based on the **Drop** or **Domain Not Found** actions, the system logs beginning-of-connection Security Intelligence and connection events. Because blocked traffic is immediately denied without further inspection, there is no unique end of connection to log.

For a connection blocked based on the **Sinkhole** action, logging depends on the sinkhole object configuration. If you configure your sinkhole object to only log sinkhole connections, the system logs end-of-connection connection events for the follow-on connection. If you configure your sinkhole object to log and block sinkhole connections, the system logs beginning-of-connection connection events for the follow-on connection, then blocks that connection.

## DNS Rule Conditions

A DNS rule's conditions identify the type of traffic that rule handles. Conditions can be simple or complex. You must define a DNS feed or list condition within a DNS rule. You can also optionally control traffic by security zone, network, or VLAN.

When adding conditions to a DNS rule:

- If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion.
- You can configure multiple conditions per rule. Traffic must match **all** the conditions in the rule for the rule to apply to traffic. For example, a rule with a DNS feed or list condition and network condition but no VLAN tag condition evaluates traffic based on the domain name and source or destination, regardless of any VLAN tagging in the session.
- For each condition in a rule, you can add up to 50 criteria. Traffic that matches **any** of a condition's criteria satisfies the condition. For example, you can use a single rule to block traffic based on up to 50 DNS lists and feeds.

### Related Topics

[VLAN Tags Rule Conditions](#), on page 1867

[DNS Rule Conditions](#), on page 1967

## Security Zone Rule Conditions

Security zones segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices.

Zone rule conditions control traffic by its source and destination security zones. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

Just as all interfaces in a zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

---

**Tip** Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

---

## Network Rule Conditions

Network rule conditions control traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

---

**Note** You *cannot* use FDQN network objects in identity rules.

---

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

## VLAN Tags Rule Conditions

---

**Note** VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

---

VLAN rule conditions control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic. The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note the following Q-in-Q support:

- Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

## DNS Rule Conditions

DNS conditions in DNS rules allow you to control traffic if a DNS list, feed, or category contains the domain name requested by the client. You must define a DNS condition in a DNS rule.

Regardless of whether you add a global or custom Block or Do Not Block list to a DNS condition, the system applies the configured rule action to the traffic. For example, if you add the Global Do Not Block List to a rule, and configure a **Drop** action, the system blocks all traffic that should have been allowed to pass to the next phase of inspection.

## How to Create DNS Rules

The following topics discuss how to create DNS rules.

### Related Topics

[Controlling Traffic Based on DNS and Security Zone](#), on page 1967

[Controlling Traffic Based on DNS and Network](#), on page 1968

[Controlling Traffic Based on DNS and VLAN](#), on page 1968

[Controlling Traffic Based on DNS List or Feed](#), on page 1969

## Controlling Traffic Based on DNS and Security Zone

Zone conditions in DNS rules allow you to control traffic by its source security zone. A *security zone* is a grouping of one or more interfaces, which may be located across multiple devices.

### Procedure

- 
- Step 1** In the DNS rule editor, click **Zones**.
  - Step 2** Find and select the zones you want to add from the **Available Zones**. To search for zones to add, click the **Search by name** prompt above the **Available Zones** list, then type a zone name. The list updates as you type to display matching zones.
  - Step 3** Click to select a zone, or right-click and then select **Select All**.
  - Step 4** Click **Add to Source**, or drag and drop.
  - Step 5** Save or continue editing the rule.
- 

### What to do next

- Deploy configuration changes.

## Controlling Traffic Based on DNS and Network

Network conditions in DNS rules allow you to control traffic by its source IP address. You can explicitly specify the source IP addresses for the traffic you want to control.

### Procedure

---

**Step 1** In the DNS rule editor, click **Networks**.

**Step 2** Find and select the networks you want to add from the **Available Networks**, as follows:

- To add a network object on the fly, which you can then add to the condition, click **Add (+)** above the **Available Networks** list and proceed as described in [Creating Network Objects, on page 1499](#).
- To search for network objects to add, click the **Search by name or value** prompt above the **Available Networks** list, then type an object name or the value of one of the object's components. The list updates as you type to display matching objects.

**Step 3** Click **Add to Source**, or drag and drop.

**Step 4** Add any source IP addresses or address blocks that you want to specify manually. Click the **Enter an IP address** prompt below the **Source Networks** list; then type an IP address or address block and click **Add**.

**Step 5** Save or continue editing the rule.

---

### What to do next

- Deploy configuration changes.

## Controlling Traffic Based on DNS and VLAN

VLAN conditions in DNS rules allow you to control VLAN-tagged traffic. The system uses the innermost VLAN tag to identify a packet by VLAN.

When you build a VLAN-based DNS rule condition, you can manually specify VLAN tags. Alternately, you can configure VLAN conditions with VLAN tag *objects*, which are reusable and associate a name with one or more VLAN tags.

### Procedure

---

**Step 1** In the DNS rule editor, select **VLAN Tags**.

**Step 2** Find and select the VLANs you want to add from the **Available VLAN Tags**, as follows:

- To add a VLAN tag object on the fly, which you can then add to the condition, click **Add (+)** above the **Available VLAN Tags** list and proceed as described in [Creating VLAN Tag Objects, on page 1556](#).

- To search for VLAN tag objects and groups to add, click the **Search by name or value** prompt above the **Available VLAN Tags** list, then type either the name of the object, or the value of a VLAN tag in the object. The list updates as you type to display matching objects.

- Step 3** Click **Add to Rule**, or drag and drop.
- Step 4** Add any VLAN tags that you want to specify manually. Click the **Enter a VLAN Tag** prompt below the **Selected VLAN Tags** list; then type a VLAN tag or range and click **Add**. You can specify any VLAN tag from 1 to 4094; use a hyphen to specify a range of VLAN tags.
- Step 5** Save or continue editing the rule.

---

**What to do next**

- Deploy configuration changes.

## Controlling Traffic Based on DNS List or Feed

### Procedure

- 
- Step 1** In the DNS rule editor, click **DNS**.
- Step 2** Find and select the DNS lists and feeds you want to add from the **DNS Lists and Feeds**, as follows:
- To add a DNS list or feed on the fly, which you can then add to the condition, click **Add (+)** above the **DNS Lists and Feeds** list and proceed as described in [Creating Security Intelligence Feeds, on page 1532](#).
  - To search for DNS lists, feeds, or categories to add, click the **Search by name or value** prompt above the **DNS Lists and Feeds** list, then type an object name or the value of one of the object's components. The list updates as you type to display matching objects.
  - For descriptions of the system-provided threat categories, see [Security Intelligence Categories, on page 1951](#).
- Step 3** Click **Add to Rule**, or drag and drop.
- Step 4** Save or continue editing the rule.

---

**What to do next**

- Deploy configuration changes.

## DNS Policy Deploy

After you finish updating your DNS policy configuration, you must deploy it as part of access control configuration.

- Associate your DNS policy with an access control policy, as described in [Configure Security Intelligence, on page 1948](#).
- Deploy configuration changes.

## Cisco Umbrella DNS Policies

Cisco Umbrella DNS Connection in the management center helps to redirect DNS queries to Cisco Umbrella. This allows Cisco Umbrella to validate requests, allow or block them based on the domain names, and apply DNS-based security policy on the request. If you use Cisco Umbrella, you must configure the Cisco Umbrella Connection (**Integration > Other Integrations > Cloud Services > Cisco Umbrella Connection**) to redirect DNS queries to Cisco Umbrella.

The Umbrella Connector is part of the system's DNS inspection. If your existing DNS inspection policy map decides to block or drop a request based on your DNS inspection settings, the request is not forwarded to Cisco Umbrella. Thus, you have two lines of protection:

- Your local DNS inspection policy
- Your Cisco Umbrella cloud-based policy

When redirecting DNS lookup requests to Cisco Umbrella, the Umbrella Connector adds an EDNS (Extension mechanisms for DNS) record. An EDNS record includes the device identifier information, organization ID, and client IP address. Your cloud-based policy can use those criteria to control access in addition to the reputation of the FQDN. You can also elect to encrypt the DNS request using DNSCrypt to ensure the privacy of usernames and internal IP addresses.

To redirect DNS requests from the management center to Cisco Umbrella:

1. Configure the Cisco Umbrella connection settings.
2. Create and configure an Umbrella DNS policy.
3. Associate the Umbrella DNS policy with an access control policy.
4. Deploy the changes.

For detailed information about how to set up the Umbrella DNS Connector in the management center, see [Configuring the Umbrella DNS Connector for Cisco Secure Firewall Management Center](#).

## How to Redirect DNS Requests to Cisco Umbrella

This section provides instructions to redirect DNS requests from the device to Cisco Umbrella using the management center.

Step	Do This	More Info
1	Ensure that you meet the prerequisites.	<a href="#">Prerequisites for Configuring the Umbrella DNS Connector, on page 1971</a>
2	Configure the Cisco Umbrella connection settings.	<a href="#">Configure Cisco Umbrella Connection Settings, on page 1972</a>

Step	Do This	More Info
3	Create an Umbrella DNS policy	<a href="#">Create an Umbrella DNS Policy, on page 1973</a>
4	Configure the Umbrella DNS policy	<a href="#">Edit Umbrella DNS Policies and Rules, on page 1973</a>
5	Associate the Umbrella DNS policy with an access control policy	<a href="#">Associate the Umbrella DNS Policy with an Access Control Policy, on page 1974</a>

## Prerequisites for Configuring the Umbrella DNS Connector

*Table 117: Minimum Supported Platforms*

Product	Version
Secure Firewall Threat Defense	6.6 and above
Secure Firewall Management Center	7.2 and above

- Establish an account with Cisco Umbrella at <https://umbrella.cisco.com>, and log into Umbrella at <http://login.umbrella.com>.
- Import the CA certificate from the Cisco Umbrella server to the management center. In Cisco Umbrella, choose **Deployments > Configuration > Root Certificate** and download the certificate.

You must import the root certificate to establish the HTTPS connection with the Cisco Umbrella registration server. The certificate needs to be trusted for SSL server validation, which is a non-default option in the management center. Copy and paste the following certificate for the device in the management center (**Device > Certificates**).

SaZMkE4f97Q=
```

When you add the certificate in the management center, ensure that you check the **CA Only** check box.

- Install the certificate on the device.

- Obtain the following data from Umbrella:
  - Organization ID
  - Network Device Key
  - Network Device Secret
  - Legacy Network Device Token
- Ensure that the management center is connected to the internet.
- Ensure that the base license with the export-controlled feature option is enabled in the management center.
- Ensure that the DNS server is configured to resolve api.opendns.com.
- Ensure that the management center can resolve management.api.umbrella.com for policy configuration.
- Configure the threat defense route to api.opendns.com.

## Configure Cisco Umbrella Connection Settings

The Cisco Umbrella Connection settings define the token that is needed to register the device with Cisco Umbrella.

### Before you begin

Establish an account with Cisco Umbrella <https://umbrella.cisco.com>, and then log into Umbrella at <https://dashboard.umbrella.com> and obtain the required information to establish connection to Cisco Umbrella.

### Procedure

---

**Step 1** Choose **Integration > Other Integrations > Cloud Services > Cisco Umbrella Connection**.

**Step 2** Obtain the following details and add them to the **General** settings:

- **Organization ID**—A unique number that identifies your organization on Cisco Umbrella. Every Umbrella organization is a separate instance of Umbrella and has its own dashboard. Organizations are identified by their name and their organization ID (Org ID).
- **Network Device Key**—The key to fetch umbrella policy from Cisco Umbrella.
- **Network Device Secret**—The secret to fetch umbrella policy from Cisco Umbrella.
- **Legacy Network Device Token**—An Umbrella Legacy Network Devices API token is issued through the Cisco Umbrella dashboard. Umbrella requires the API token to register a network device.

**Step 3** Under **Advanced**, configure the following optional settings:

- **DNSCrypt Public Key**—DNSCrypt authenticates and encrypts the DNS queries between the endpoint and the DNS server. To enable DNSCrypt, you can configure the DNSCrypt public key for certificate verification. The key is a 32-byte hexadecimal value and is preconfigured to

B735:1140:206F:225d:3E2B:d822:D7FD:691e:A1C3:3cc8:D666:8d0c:BE04:bfab:CA43:FB79, which is the public key of the Umbrella Anycast servers.

- **Management Key**—A key to fetch datacenter details from Umbrella cloud for VPN policy.
- **Management Secret**—A secret used to fetch datacenters from Umbrella cloud for VPN.

- Step 4** Click **Test Connection**—Test if the Cisco Umbrella Cloud is reachable from the management center. When you provide the required organization ID and network device details, the umbrella connection is created.
- Step 5** Click **Save**.
- 

## Create an Umbrella DNS Policy

### Procedure

---

- Step 1** Choose **Policies > Access Control > DNS**.
- Step 2** Click **Add DNS Policy > Umbrella DNS Policy**.
- Step 3** Give the policy a unique **Name** and, optionally, a **Description**.
- Step 4** Click **Save**.
- 

### What to do next

Configure the policy. See [Edit Umbrella DNS Policies and Rules, on page 1973](#).

## Edit Umbrella DNS Policies and Rules

### Procedure

---

- Step 1** Choose **Policies > Access Control > DNS**.
- Step 2** In the DNS Policy page, select the Umbrella DNS policy that you want to edit and click **Edit** (✎).

### Refresh the Umbrella Protection Policy

If you want to get the latest Umbrella Protection Policy from Cisco Umbrella, click the **Refresh** icon next to **Umbrella Protection Policy Last Updated**.

To configure or modify Umbrella Connection settings for the Management Center, go to **Integration > Other Integrations > Cloud Services > Cisco Umbrella Connection**.

- Step 3** In the Umbrella DNS policy editor, select the Umbrella DNS rule and click **Edit** (✎).
- Step 4** Configure the rule components, or accept the defaults:
- **Umbrella Protection Policy**—Specify the name of the Cisco Umbrella policy to apply to the device.

- **Bypass Domain**—Specify the name of the local domains for which DNS requests should bypass Cisco Umbrella and instead go directly to the configured DNS servers.

For example, you can have your internal DNS server resolve all names for the organization's domain name on the assumption that all internal connections are allowed.

- **DNSCrypt**— Enable DNSCrypt to encrypt connections between the device and Cisco Umbrella.

Enabling DNSCrypt starts the key-exchange thread with the Umbrella resolver. The key-exchange thread performs the handshake with the resolver every hour and updates the device with a new secret key. As DNSCrypt uses UDP/443, you must ensure that the class map used for DNS inspection includes that port. Note that the default inspection class already includes UDP/443 for DNS inspection.

- **Idle Timeout**—Configure the idle timeout after which a connection from a client to the Umbrella server will be removed if there is no response from the server.

**Step 5** Click **Save**.

---

#### What to do next

Associate the Umbrella DNS policy with an access control policy. For more information, see [Associate the Umbrella DNS Policy with an Access Control Policy, on page 1974](#).

## Associate the Umbrella DNS Policy with an Access Control Policy

Before you deploy the Umbrella DNS policy on the device, you must associate it with an access control policy.

### Procedure

---

- Step 1** Choose **Policies > Access Control** and select the access policy to edit.
  - Step 2** Select **Security Intelligence**.
  - Step 3** From the **Umbrella DNS Policy** drop-down list, select the Umbrella DNS policy.
  - Step 4** Click **Save**.
- 

#### What to do next

Deploy configuration changes; see [Deploy Configuration Changes, on page 240](#).

## CHAPTER 69

# Prefiltering and Prefilter Policies

- [About Prefiltering, on page 1975](#)
- [Best Practices for Fastpath Prefiltering, on page 1980](#)

- [Large Flow Offloads, on page 1993](#)

## About Prefiltering

Prefiltering is the first phase of access control, before the system performs more resource-intensive evaluation. Prefiltering is simple, fast, and early. Prefiltering uses limited outer-header criteria to quickly handle traffic. Compare this to subsequent evaluation, which uses inner headers and has more robust inspection capabilities.

Configure prefiltering to:

- **Improve performance**— The sooner you exclude traffic that does not require inspection, the better. You can fastpath or block certain types of plaintext, passthrough tunnels based on their outer encapsulation headers, without inspecting their encapsulated connections. You can also fastpath or block any other connections that benefit from early handling.
- **Tailor deep inspection to encapsulated traffic**—You can rezone certain types of tunnels so that you can later handle their encapsulated connections using the same inspection criteria. Rezoning is necessary because after prefiltering, access control uses inner headers.

## About Prefilter Policies

Prefiltering is a policy-based feature. To assign it to a device, you assign it to the access control policy that is assigned to the device.

### Policy Components: Rules and Default Action

In a prefilter policy, *tunnel rules*, *prefilter rules*, and a *default action* handle network traffic:

- Tunnel and prefilter rules—First, rules in a prefilter policy handle traffic in the order you specify. Tunnel rules match specific tunnels only and support rezoning. Prefilter rules have a wider range of constraints and do not support rezoning. For more information, see [Tunnel vs Prefilter Rules, on page 1976](#).
- Default action (tunnels only)—If a tunnel does not match any rules, the default action handles it. The default action can block these tunnels, or continue access control on their individual encapsulated connections. You cannot rezone tunnels with the default action.

There is no default action for nonencapsulated traffic. If a nonencapsulated connection does not match any prefilter rules, the system continues with access control.

### Connection Logging

You can log connections fastpathed and blocked by the prefilter policy.

Connection events contain information on whether and how logged connections—including entire tunnels—were prefiltered. You can view this information in event views (workflows), dashboards, and reports, and use it as correlation criteria. Keep in mind that because fastpathed and blocked connections are not subject to deep inspection, associated connection events contain limited information.

### Default Prefilter Policy

Every access control policy has an associated prefilter policy.

The system uses a default policy if you do not configure custom prefiltering. Initially, this system-provided policy passes all traffic to the next phase of access control. You can change the policy's default action and configure its logging options, but you cannot add rules to it or delete it.

### Prefilter Policy Inheritance and Multitenancy

Access control uses a hierarchical implementation that complements multitenancy. Along with other advanced settings, you can lock a prefilter policy association, enforcing that association in all descendant access control policies. For more information, see [Access Control Policy Inheritance, on page 1817](#).

## Tunnel vs Prefilter Rules

Whether you configure a tunnel or prefilter rule depends on the specific type of traffic you want to match and the actions or further analysis you want to perform.

Characteristic	Tunnel Rules	Prefilter Rules
Primary function	Quickly fastpath, block, or rezone plaintext, passthrough tunnels.	Quickly fastpath or block any other connection that benefits from early handling.
Encapsulation and port/protocol criteria	Encapsulation conditions match only plaintext tunnels over selected protocols, listed in <a href="#">Encapsulation Rule Conditions, on page 1987</a> .	Port conditions can use a wider range of port and protocol constraints than tunnel rules; see <a href="#">Port, Protocol, and ICMP Code Rule Conditions, on page 1067</a> .
Network criteria	Tunnel endpoint conditions constrain the endpoints of the tunnels you want to handle; see <a href="#">Network Rule Conditions, on page 1065</a> .	Network conditions constrain the source and destination hosts in each connection; see <a href="#">Network Rule Conditions, on page 1065</a> .

Characteristic	Tunnel Rules	Prefilter Rules
Direction	Bidirectional or unidirectional (configurable).  Tunnel rules are bidirectional by default, so they can handle all traffic between tunnel endpoints.	Unidirectional only (nonconfigurable).  Prefilter rules match source-to-destination traffic only. Return traffic for allowed connections is also permitted.
Rezone sessions for further analysis	Supported, using tunnel zones; see <a href="#">Tunnel Zones and Prefiltering, on page 1988</a> .	Not supported.

## Prefiltering vs Access Control

Prefilter and access control policies both allow you to block and trust traffic, though the prefiltering "trust" functionality is called "fastpathing" because it skips more inspection. The following table explains this and other differences between prefiltering and access control, to help you decide whether to configure custom prefiltering.

If you do not configure custom prefiltering, you can only approximate—not replicate—prefilter functionality with early-placed Block and Trust rules in the access control policy.

Characteristic	Prefiltering	Access Control	For more information, see...
Primary function	Quickly fastpath or block certain types of plaintext, passthrough tunnels (see <a href="#">Encapsulation Rule Conditions, on page 1987</a> ), or tailor subsequent inspection to their encapsulated traffic.  Fastpath or block any other connections that benefit from early handling.	Inspect and control all network traffic, using simple or complex criteria, including contextual information and deep inspection results.	<a href="#">About Prefiltering, on page 1975</a>
Implementation	Prefilter policy.  The prefilter policy is invoked by the access control policy.	Access control policy.  The access control policy is a main configuration. In addition to invoking subpolicies, access control policies have their own rules.	<a href="#">About Prefilter Policies, on page 1975</a>  <a href="#">Associating Other Policies with Access Control, on page 1844</a>
Sequence within access control	First.  The system matches traffic to prefilter criteria before all other access control configurations.	—	—

Characteristic	Prefiltering	Access Control	For more information, see...
Rule actions	Fewer. You can stop further inspection (Fastpath and Block) or allow further analysis with the rest of access control (Analyze).	More. Access control rules have a larger variety of actions, including monitoring, deep inspection, block with reset, and interactive blocking.	<a href="#">Tunnel and Prefilter Rule Components, on page 1983</a> <a href="#">Access Control Rule Actions, on page 1858</a>
Bypass capability	Fastpath rule action. Fastpathing traffic in the prefilter stage bypasses all further inspection and handling, including: <ul style="list-style-type: none"> <li>• Security Intelligence</li> <li>• authentication requirements imposed by an identity policy</li> <li>• SSL decryption</li> <li>• access control rules</li> <li>• deep inspection of packet payloads</li> <li>• discovery</li> <li>• rate limiting</li> </ul>	Trust rule action. Traffic trusted by access control rules is only exempt from deep inspection and discovery.	<a href="#">Introduction to Access Control Rules, on page 1853</a>
Rule criteria	Limited. Rules in the prefilter policy use simple network criteria: IP address, VLAN tag, port, and protocol. For tunnels, tunnel endpoint conditions specify the IP address of the routed interfaces of the network devices on either side of the tunnel.	Robust. Access control rules use network criteria, but also user, application, requested URL, and other contextual information available in packet payloads. Network conditions specify the IP address of source and destination hosts.	<a href="#">Tunnel vs Prefilter Rules, on page 1976</a> <a href="#">Prefilter Rule Conditions, on page 1985</a> <a href="#">Tunnel Rule Conditions, on page 1987</a>
IP headers used (tunnel handling)	Outermost. Using outer headers allows you to handle entire plaintext, passthrough tunnels. For nonencapsulated traffic, prefiltering still uses "outer" headers—which in this case are the only headers.	Innermost possible. For a nonencrypted tunnel, access control acts on its individual encapsulated connections, not the tunnel as a whole.	<a href="#">Passthrough Tunnels and Access Control, on page 1979</a>

Characteristic	Prefiltering	Access Control	For more information, see...
Rezone encapsulated connections for further analysis	Rezones tunneled traffic. Tunnel zones allow you to tailor subsequent inspection to prefiltered, encapsulated traffic.	Uses tunnel zones. Access control uses the tunnel zones you assign during prefiltering.	<a href="#">Tunnel Zones and Prefiltering, on page 1988</a>
Connection logging	Fastpathed and blocked traffic only. Allowed connections may still be logged by other configurations.	Any connection.	
Supported devices	Secure Firewall Threat Defense only.	All.	—

## Passthrough Tunnels and Access Control

Plaintext (nonencrypted) tunnels can encapsulate multiple connections, often flowing between discontinuous networks. These tunnels are especially useful for routing custom protocols over IP networks, IPv6 traffic over IPv4 networks, and so on.

An outer *encapsulation header* specifies the source and destination IP addresses of the *tunnel endpoints*—the routed interfaces of the network devices on either side of the tunnel. Inner *payload headers* specify the source and destination IP addresses of the encapsulated connections' actual endpoints.

Often, network security devices handle plaintext tunnels as *passthrough* traffic. That is, the device is not one of the tunnel endpoints. Instead, it is deployed between the tunnel endpoints and monitors the traffic flowing between them.

Some network security devices enforce security policies using outer IP headers. Even for plaintext tunnels, these devices have no control over or insight into individual encapsulated connections and their payloads.

By contrast, the system leverages access control as follows:

- Outer header evaluation—First, prefiltering uses outer headers to handle traffic. You can block or fastpath entire plaintext, passthrough tunnels at this stage.
- Inner header evaluation—Next, the rest of access control (and other features such as QoS) use the innermost detectable level of headers to ensure the most granular level of inspection and handling possible.

If a passthrough tunnel is not encrypted, the system acts on its individual encapsulated connections at this stage. You must *rezone* a tunnel (see [Tunnel Zones and Prefiltering, on page 1988](#)) to act on all its encapsulated connections.

Access control has no insight into encrypted passthrough tunnels. For example, access control rules see a passthrough VPN tunnel as one connection. The system handles the entire tunnel using only the information in its outer, encapsulation header.

## Best Practices for Fastpath Prefiltering

When you use the fastpath action in a prefilter rule, the matching traffic bypasses inspection and is simply transmitted through the device. Use this action for traffic that you can trust and that would not benefit from any of the security features available.

The following types of traffic are ideal for fastpathing. For example, you could configure the rules to fastpath any traffic from or to the IP addresses of the endpoints or servers. You can further limit the rule based on ports used.

- VPN traffic that is going through the device. That is, the device is not an endpoint in the VPN topology.
- SQL traffic between trusted endpoints on the internal network.
- Scanner traffic. Scanner probes can create a lot of false-positive responses from intrusion policies.
- Voice/video.
- Backups.
- Management traffic (sftunnel) that traverses threat defense devices. Performing deep inspection on management traffic (using access control policies) can cause issues. You can prefilter based on port TCP/8305 between the management center and managed devices.

## Best Practices for Encapsulated Traffic Handling

This topic discusses guidelines for the following types of encapsulated traffic:

- Generic Routing Encapsulation (GRE)
- Point-to-Point Protocol (PPTP)
- IPinIP
- IPv6inIP
- Teredo

### GRE Tunnel Limitations

GRE tunnel processing is limited to IPv4 and IPv6 passenger flows. Other protocols, such as PPTP and WCCP, are not supported within the GRE tunnel.

### Understand Snort version support for your managed devices

The inspection engine used by managed devices is known as Snort. Snort 3 supports more features than Snort 2. To understand how these affect managed devices on your network, you must know:

- Which versions of Snort your device supports.  
Snort version support can be found in the section on bundled components in the *Cisco Firepower Compatibility Guide*.
- How the management center and threat defense software support Snort 2 and Snort 3

Limitations of Snort 2 and Snort 3 can be found in the *Feature Limitations of Snort 3 for Management Center-Managed Threat Defense* topic in the [Cisco Secure Firewall Management Center Snort 3 Configuration Guide](#).

### GRE v1 and PPTP bypass outer flow processing

GRE v1 (sometimes referred to as *stateful GRE*) and PPTP traffic bypass outer flow processing.

Passenger flow processing is supported for IPv6inIP and Teredo but the following limitations apply:

- Sessions are over a single tunnel that is not load-balanced
- There is no HA or clustering replication
- Primary and secondary flow relationships are not maintained
- Prefilter policy white and black lists are not supported

### GRE v0 sequence number field must be optional

All endpoints sending traffic on the network must send GREv0 traffic with the sequence number field as optional; otherwise, the sequence number field is removed. RFC 1701 and RFC 2784 both specify the sequence field as optional.

### How tunnels work with interfaces

Prefilter and access control policy rules are applied to all tunnel types on routed, transparent, inline-set, inline-tap, and passive interfaces.

### References

For more information about the GRE and PPTP protocols, see the following:

- [RFC 1701](#), [RFC 2784](#), and [RFC 2890](#) (GRE protocol v0)

- Network Admin

## Configure Prefiltering

To perform custom prefiltering, configure prefilter policies and assign the policies to access control policies. It is through the access control policy that prefilter policies get assigned to managed devices.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

### Procedure

**Step 1** Choose **Policies > Access Control > Prefilter**.

**Step 2** Click **New Policy** to create a custom prefilter policy.

A new prefilter policy has no rules and a default action of Analyze all tunnel traffic. It performs no logging or tunnel rezoning. You can also **Copy** (📄) or **Edit** (✎) an existing policy.

**Step 3** Configure the prefilter policy's default action and its logging options.

- Default action—Choose a default action for supported plaintext, passthrough tunnels: **Analyze all tunnel traffic** (with access control) or **Block all tunnel traffic**.
- Default action logging—Click **Logging** (📄) next to the default action. You can configure default action logging for blocked tunnels only.

**Step 4** Configure tunnel and prefilter rules.

In a custom prefilter policy, you can use both kinds of rule, in any order. Create rules depending on the specific type of traffic you want to match and the actions or further analysis you want to perform; see [Tunnel vs Prefilter Rules, on page 1976](#).

**Caution** Exercise caution when using tunnel rules to assign tunnel zones. Connections in rezoned tunnels may not match security zone constraints in later evaluation. For more information, see [Tunnel Zones and Prefiltering, on page 1988](#).

For detailed information on configuring rule components, see [Tunnel and Prefilter Rule Components, on page 1983](#).

**Step 5** Evaluate rule order. To move a rule, click and drag or use the right-click menu to cut and paste.

Properly creating and ordering rules is a complex task, but one that is essential to building an effective deployment. If you do not plan carefully, rules can preempt other rules or contain invalid configurations. For more information, see [Best Practices for Access Control Rules, on page 1823](#).

**Step 6** Save the prefilter policy.

**Step 7** For configurations that support tunnel zone constraints, appropriately handle rezoned tunnels.

Match connections in rezoned tunnels by using tunnel zones as source zone constraints.

**Step 8** Associate the prefilter policy with the access control policy deployed to your managed devices.  
See [Associating Other Policies with Access Control, on page 1844](#).

**Step 9** Deploy configuration changes.

**Note** When you deploy a prefilter policy, its rules are not applied on the existing tunnel sessions. Hence, traffic on an existing connection is not bound by the new policy that is deployed. In addition, the policy hit count is incremented only for the first packet of a connection that matches a policy. Thus, the traffic on an existing connection that could match a policy is omitted from the hit count. To have the policy rules effectively applied, clear the existing tunnel sessions, and then deploy the policy.

---

### What to do next

If you will deploy time-based rules, specify the time zone of the device to which the policy is assigned. See [Time Zone, on page 1128](#).

## Tunnel and Prefilter Rule Components

### State (Enabled/Disabled)

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

### Position

Rules are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic, regardless of rule type (tunnel vs prefilter).

### Action

A rule's action determines how the system handles and logs matching traffic:

- **Fastpath**—Exempts matching traffic from all further inspection and control, including access control, identity requirements, and rate limiting. Fastpathing a tunnel fastpaths all encapsulated connections.
- **Block**—Blocks matching traffic without further inspection of any kind. Blocking a tunnel blocks all encapsulated connections.
- **Analyze**—Allows traffic to continue to be analyzed by the rest of access control, using inner headers. If passed by access control and any related deep inspection, this traffic may also be rate limited. For tunnel rules, enables rezoning with the Assign Tunnel Zone option.

---

**Note** For a prefilter rule with action as **Fastpath** and logging options disabled, you will observe that the end-of-flow events are still generated in the system. The events are not visible on the management center event pages.

---

### Direction (Tunnel Rules Only)

A tunnel rule's direction determines how the system source and destination criteria:

- Match tunnels only from source (unidirectional)—Match source-to-destination traffic only. Matching traffic must originate from one of the specified source interfaces or tunnel endpoints, and leave through one of the destination interfaces or tunnel endpoints. Return traffic for allowed connections is also permitted.
- Match tunnels from source and destination (bidirectional)—Match both source-to-destination traffic and destination-to-source traffic. The effect is identical to writing two unidirectional rules, one the mirror of the other.

Prefilter rules are always unidirectional.

### Assign Tunnel Zone (Tunnel Rules Only)

In a tunnel rule, assigning a tunnel zone (whether existing or created on the fly), *rezones* matching tunnels. Rezoning requires the Analyze action.

Rezoning a tunnel allows other configurations—such as access control rules—to recognize all the tunnel's encapsulated connections as belonging together. By using a tunnel's assigned tunnel zone as an interface constraint, you can tailor inspection to its encapsulated connections. For more information, see [Tunnel Zones and Prefiltering, on page 1988](#).

---

**Caution** Exercise caution when assigning tunnel zones. Connections in rezoned tunnels may not match security zone constraints in later evaluation. See [Using Tunnel Zones, on page 1988](#) for a brief walkthrough of a tunnel zone implementation, and a discussion of the implications of rezoning without explicitly handling rezoned traffic.

---

### Conditions

Conditions specify the specific traffic the rule handles. Traffic must match all a rule's conditions to match the rule. Each condition type has its own tab in the rule editor.

You can prefilter traffic using the following *outer-header* constraints. You must constrain tunnel rules by encapsulation protocol.

- Interface—[Interface Rule Conditions, on page 1064](#)
- Network (prefilter rule)/Tunnel Endpoints (tunnel rule)—[Network Rule Conditions, on page 1065](#)
- VLAN—[VLAN Tags Rule Conditions, on page 1867](#)
- Ports (prefilter rule)/Encapsulation and Ports (tunnel rule)—[Port Rule Conditions for Prefilter Rules, on page 1986](#) or [Encapsulation Rule Conditions, on page 1987](#)
- Time Range—[Time and Day Rule Conditions, on page 1873](#)

### Logging

A rule's logging settings govern the records the system keeps of the traffic it handles.

In tunnel and prefilter rules, you can log fastpathed and blocked traffic (the Fastpath and Block actions). For traffic subject to further analysis (the Analyze action), logging in the prefilter policy is disabled, although

matching connections may still be logged by other configurations. Logging is performed on inner flows, not on the encapsulating flow.

### Comments

Each time you save changes to a rule you can add comments. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change.

You cannot edit or delete these comments after you save the rule.

### Related Topics

[Best Practices for Access Control Rules](#), on page 1823

## Prefilter Rule Conditions

Rule conditions enable you to fine-tune your prefilter policy to target the networks you want to control. See one of the following sections for more information.

### Interface Rule Conditions

Interface rule conditions control traffic by its source and destination interfaces.

Depending on the rule type and the devices in your deployment, you can use predefined *interface objects* called *security zones* or *interface groups* to build interface conditions. Interface objects segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices; see [Interface](#), on page 1494.

---

**Tip** Constraining rules by interface is one of the best ways to improve system performance. If a rule excludes all of a device's interfaces, that rule does not affect that device's performance.

---

Just as all interfaces in an interface object must be of the same type (all inline, passive, switched, routed, or ASA FirePOWER), all interface objects used in an interface condition must be of the same type. Because devices deployed passively do not transmit traffic, in passive deployments you cannot constrain rules by destination interface.

### Network Rule Conditions

Network rule conditions control traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

---

**Note** You *cannot* use FDQN network objects in identity rules.

---

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

## VLAN Tags Rule Conditions

**Note** VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

VLAN rule conditions control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic. The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note the following Q-in-Q support:

- Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

## Port Rule Conditions for Prefilter Rules

Port conditions match traffic based on the source and destination ports. Depending on the rule type, “port” can represent any of the following:

- TCP and UDP—You can control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP(6)/22.
- ICMP—You can control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—You can control traffic using other protocols that do not use ports.

### Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

### Matching Non-TCP Traffic with Port Conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although you can configure port conditions to match other protocols in prefilter rules, you should use tunnel rules instead when matching GRE, IP in IP, IPv6 in IP, and Teredo Port 3544.

## Time and Day Rule Conditions

You can specify a continuous time range or a recurring time period.

For example, a rule can apply only during weekday working hours, or every weekend, or during a holiday shutdown period.

Time-based rules are applied based on the local time of the device that processes the traffic.

Time-based rules are supported only on threat defense devices. If you assign a policy with a time-based rule to a different type of device, the time restriction associated with the rule is ignored on that device. You will see warnings in this case.

## Tunnel Rule Conditions

Rule conditions enable you to fine-tune your tunnel policy to target the networks you want to control. For tunnel rules, you can use the following conditions:

- **Interface Objects**—The security zones or interface groups that define the device interfaces through which the connections pass. See [Interface Rule Conditions, on page 1064](#).
- **Tunnel Endpoints**—The network objects that define the source and destination IP addresses of the tunnel.
- **VLAN Tags**—The outermost VLAN tag in the tunnel. See [VLAN Tags Rule Conditions, on page 1867](#).
- **Encapsulation and Ports**—The encapsulation protocol of the tunnel. See [Encapsulation Rule Conditions, on page 1987](#).
- **Time Range**—The days and times when the rule is active. If you do not specify a time range, the rule is always active. See [Time and Day Rule Conditions, on page 1873](#).

## Encapsulation Rule Conditions

Encapsulation conditions are specific to tunnel rules.

These conditions control certain types of plaintext, passthrough tunnels by their encapsulation protocol. You must choose at least one protocol to match before you can save the rule. You can choose:

- GRE (47)
- IP-in-IP (4)
- IPv6-in-IP (41)
- Teredo (UDP (17)/3455)

# Tunnel Zones and Prefiltering

Tunnel zones allow you to use prefiltering to tailor subsequent traffic handling to encapsulated connections.

A special mechanism is required because usually, the system handles traffic using the innermost detectable level of headers. This ensures the most granular level of inspection possible. But it also means that if a passthrough tunnel is not encrypted, the system acts on its individual encapsulated connections; see [Passthrough Tunnels and Access Control, on page 1979](#).

Tunnel zones solve this problem. During the first phase of access control (prefiltering) you can use outer headers to identify certain types of plaintext, passthrough tunnels. Then, you can *rezone* those tunnels by assigning a custom *tunnel zone*.

Rezoning a tunnel allows other configurations—such as access control rules—to recognize all the tunnel's encapsulated connections as belonging together. By using a tunnel's assigned tunnel zone as an interface constraint, you can tailor inspection to its encapsulated connections.

Despite its name, a tunnel zone is not a security zone. A tunnel zone does not represent a set of interfaces. It is more accurate to think of a tunnel zone as a tag that, in some cases, replaces the security zone associated with an encapsulated connection.

---

**Caution** For configurations that support tunnel zone constraints, connections in rezoned tunnels do **not** match security zone constraints. For example, after you rezone a tunnel, access control rules can match its encapsulated connections with their newly assigned *tunnel zone*, but not with any original *security zone*.

---

See [Using Tunnel Zones, on page 1988](#) for a brief walkthrough of a tunnel zone implementation, and a discussion of the implications of rezoning without explicitly handling rezoned traffic.

## Configurations Supporting Tunnel Zone Constraints

Only access control rules support tunnel zone constraints.

No other configurations support tunnel zone constraints. For example, you cannot use QoS to rate limit a plaintext tunnel as a whole; you can only rate limit its individual encapsulated sessions.

## Using Tunnel Zones

This example procedure summarizes how you might rezone GRE tunnels for further analysis, using tunnel zones. You can adapt the concepts described in this example to other scenarios where you need to tailor traffic inspection to connections encapsulated in plaintext, passthrough tunnels.

Consider a situation where your organization's internal traffic flows through the Trusted security zone. The Trusted security zone represents a set of interfaces across multiple managed devices deployed in various locations. Your organization's security policy requires that you allow internal traffic after deep inspection for exploits and malware.

Internal traffic sometimes includes plaintext, passthrough, GRE tunnels between particular endpoints. Because the traffic profile of this encapsulated traffic is different from your "normal" interoffice activity—perhaps it is known and benign—you can limit inspection of certain encapsulated connections while still complying with your security policy.

In this example, after you deploy configuration changes:

- Plaintext, passthrough, GRE-encapsulated tunnels detected in the Trusted zone have their individual encapsulated connections evaluated by one set of intrusion and file policies.
- All other traffic in the Trusted zone is evaluated with a different set of intrusion and file policies.

You accomplish this task by *rezoning* GRE tunnels. Rezoning ensures that access control associates GRE-encapsulated connections with a custom *tunnel* zone, rather than their original Trusted *security* zone. Rezoning is required due to the way access control handles encapsulated traffic; see [Passthrough Tunnels and Access Control, on page 1979](#) and [Tunnel Zones and Prefiltering, on page 1988](#).

## Procedure

**Step 1** Configure custom intrusion and file policies that tailor deep inspection to encapsulated traffic, and another set of intrusion and file policies tailored to nonencapsulated traffic.

**Step 2** Configure custom prefiltering to rezone GRE tunnels flowing through the Trusted security zone.

Create a custom prefilter policy and associate it with access control. In that custom prefilter policy, create a tunnel rule (in this example, **GRE\_tunnel\_rezone**) and a corresponding tunnel zone (**GRE\_tunnel**). For more information, see [Configure Prefiltering, on page 1982](#).

**Table 118: GRE\_tunnel\_rezone Tunnel Rule**

Rule Component	Description
Interface object condition	Match internal-only tunnels by using the Trusted security zone as both a Source Interface Object and Destination Interface Object constraint.
Tunnel endpoint condition	Specify the source and destination endpoints for the GRE tunnels used in your organization.  Tunnel rules are bidirectional by default. If you do not change the <b>Match tunnels from...</b> option, it does not matter which endpoints you specify as source and which as destination.
Encapsulation condition	Match GRE traffic.
Assign Tunnel Zone	Create the <b>GRE_tunnel</b> tunnel zone, and assign it to tunnels that match the rule.
Action	Analyze (with the rest of access control).

**Step 3** Configure access control to handle connections in rezoned tunnels.

In the access control policy deployed to your managed devices, configure a rule (in this example, **GRE\_inspection**) that handles the traffic you rezoned. For more information, see [Create and Edit Access Control Rules, on page 1863](#).

Table 119: GRE\_inspection Access Control Rule

Rule Component	Description
Security zone condition	Match rezoned tunnels by using the GRE_tunnel security zone as a Source Zone constraint.
Action	Allow, with deep inspection enabled. Choose the file and intrusion policies tailored to inspect encapsulated internal traffic.

**Caution** If you skip this step, the rezoned connections may match **any** access control rule not constrained by security zone. If the rezoned connections do not match any access control rules, they are handled by the access control policy default action. Make sure this is your intent.

**Step 4** Configure access control to handle nonencapsulated connections flowing through the Trusted security zone.

In the same access control policy, configure a rule (in this example, **internal\_default\_inspection**) that handles non-rezoned traffic in the Trusted security zone.

Table 120: internal\_default\_inspection Access Control Rule

Rule Component	Description
Security zone condition	Match non-rezoned internal-only traffic by using the Trusted security zone as both a Source Zone and Destination Zone constraint.
Action	Allow, with deep inspection enabled. Choose the file and intrusion policies tailored to inspect nonencapsulated internal traffic.

**Step 5** Evaluate the position of the new access control rules relative to preexisting rules. Change rule order if necessary.

If you place the two new access control rules next to each other, it does not matter which you place first. Because you rezoned GRE tunnels, the two rules cannot preempt each other.

**Step 6** Save all changed configurations.

#### What to do next

- Deploy configuration changes.

## Creating Tunnel Zones

The following procedure explains how to create a tunnel zone in the object manager. You can also create zones when editing a tunnel rule.

## Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Chose **Tunnel Zone** from the list of object types.
  - Step 3** Click **Add Tunnel Zone**.
  - Step 4** Enter a **Name** and, optionally, a **Description**.
  - Step 5** Click **Save**.
- 

### What to do next

- Assign tunnel zones to plaintext, passthrough tunnels as part of custom prefiltering; see [Configure Prefiltering, on page 1982](#).

# Moving Prefilter Rules to an Access Control Policy

You can move prefilter rules from a prefilter policy to the associated access control policy.

### Before you begin

Note the following conditions before you proceed:

- Only prefilter rules can be moved to an access control policy. Tunnel rules cannot be moved.
- The prefilter rules can be moved only to the associated access control policy.
- The prefilter rules with configured interface groups cannot be moved.
- The **Action** parameter in the prefilter rule is changed to a suitable action in the access control rule when moved. To know what each action in the prefilter rule maps to, see the following table:

Action in the prefilter rule	Action in the access control rule
Analyze	Allow
Block	Block
Fastpath	Trust

- Similarly, based on the action configured in the prefilter rule, the logging configuration is set to an appropriate setting after the rule is moved, as mentioned in the following table.

Action in the prefilter rule	Enabled Logging configurations in the access control rule
Analyze	None of the log settings are enabled.

Action in the prefilter rule	Enabled Logging configurations in the access control rule
Block	<ul style="list-style-type: none"> <li>• Log at Beginning of Connection</li> <li>• Event Viewer</li> <li>• Syslog Server</li> <li>• SNMP Trap</li> </ul>
Fastpath	<ul style="list-style-type: none"> <li>• Log at Beginning of Connection</li> <li>• Log at End of Connection</li> <li>• Event Viewer</li> <li>• Syslog Server</li> <li>• SNMP Trap</li> </ul>

- The comments in the prefilter rule configuration are lost after moving the rule. However, a new comment is added in the moved rule mentioning the source prefilter policy.
- While moving rules from the source policy, if another user modifies those rules, the management center displays a message. You may continue with the process after refreshing the page.

## Procedure

---

**Step 1** In the prefilter policy editor, select the rules that you want to move with a left-click on your mouse.

**Tip** To select multiple rules, use the Ctrl (Control) key on your keyboard.

**Step 2** Right-click the selected rules and choose **Move to another policy**.

**Step 3** Select the destination access control policy from the **Access Policy** drop-down list.

**Step 4** From the **Place Rules** drop-down list, choose where you want to position the moved rules:

- To position as the last set of rules in the **Default** section, choose **At the bottom (within the Default section)**.
- To position as the first set of rules in the **Mandatory** section, choose **At the top (within the Mandatory section)**.

**Step 5** Click **Move**.

---

### What to do next

- Deploy configuration changes.

# Prefilter Policy Hit Counts

Hit count indicates the number of times a policy rule has triggered for a matching connection.

For complete information on viewing prefilter policy hit counts, see [Viewing Rule Hit Counts, on page 1845](#).

## Large Flow Offloads

On Secure Firewall 3100, Secure Firewall 4200, Firepower 4100/9300 chassis, certain traffic that you configure to be fastpathed by a prefilter policy is handled by the hardware (specifically, in the NIC), not by your threat defense software. Offloading these connection flows results in higher throughput and lower latency, especially for data-intensive applications such as large file transfers. This feature is especially useful for data centers. This is called *static flow offload*.

In addition, by default, threat defense devices offload flows based on other criteria, including trust. This is called *dynamic flow offload*.

Offloaded flows continue to receive limited stateful inspection, such as basic TCP flag and option checking. The system can selectively escalate packets to the firewall system for further processing if necessary.

Examples of applications that can benefit from offloading large flows are:

- High Performance Computing (HPC) Research sites, where the threat defense device is deployed between storage and high compute stations. When one research site backs up using FTP file transfer or file sync over NFS, the large amount of data traffic affects all connections. Offloading FTP file transfer and file sync over NFS reduces the impact on other traffic.
- High Frequency Trading (HFT), where the threat defense device is deployed between workstations and the Exchange, mainly for compliance purposes. Security is usually not a concern, but latency is a major concern.

The following flows can be offloaded:

- (Static flow offload only.) Connections that are fastpathed by the prefilter policy.
- Standard or 802.1Q tagged Ethernet frames only.
- (Dynamic flow offload only):
  - Inspected flows that the inspection engine decides no longer need inspection. These flows include:
    - Flows handled by access control rules that apply the Trust action and are based on security zone, source and destination network and port matching only.
    - TLS/SSL flows that are not selected for decryption using a decryption policy.
    - Flows that are trusted by the Intelligent Application Bypass (IAB) policy either explicitly or due to exceeding flow bypass thresholds.
    - Flows that match file or intrusion policies that result in trusting the flow.
    - Any allowed flow that no longer needs to be inspected.
  - The following IPS preprocessor inspected flows:

- SSH and SMTP.
- FTP preprocessor secondary connections.
- Session Initiation Protocol (SIP) preprocessor secondary connections.
- Intrusion rules that use keywords (also referred to as *options*)
- Dynamic flow offload is *not* supported on the Secure Firewall 3100.

**Important** For details, exceptions, and limitations to the above, see [Flow Offload Limitations, on page 1994](#).

### Use Static Flow Offload

To offload eligible traffic to hardware, create a prefilter policy rule that applies the **Fastpath** action. Use prefilter rules for TCP/UDP, and tunnel rules for GRE.

(Not recommended.) To disable static flow offload and as a by-product, dynamic flow-offload, use FlexConfig to run the **no flow-offload enable** command. For information about this command, see the *Cisco ASA Series Command Reference*, available from <https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-command-reference-list.html>.

### Use Dynamic Flow Offload

Dynamic flow offload is enabled by default except on devices like the Secure Firewall 3100 that do not support it.

To disable dynamic offload:

```
> configure flow-offload dynamic whitelist disable
```

To re-enable dynamic offload:

```
> configure flow-offload dynamic whitelist enable
```

Note that dynamic offload occurs only if static flow offload is enabled, regardless of whether prefiltering is configured.

## Flow Offload Limitations

Not all flows can be offloaded. Even after offload, a flow can be removed from being offloaded under certain conditions. Following are some of the limitations:

### Device Limitations

The feature is supported on the following devices:

- Firepower 4100/9300 running FXOS 1.1.3 or higher.
- Secure Firewall 3100

### Flows that cannot be offloaded

The following types of flows cannot be offloaded.

- Any flows that do not use IPv4 addressing, such as IPv6 addressing.
- Flows for any protocol other than TCP, UDP, and GRE.

---

**Note** PPTP GRE connections cannot be offloaded.

---

- Flows on interfaces configured in passive, inline, or inline tap mode. Routed and switched interfaces are the only types supported.
- (Secure Firewall 3100.) Offload based on inner header for tunnelled flows.
- (Secure Firewall 3100.) Multi-instance offload.
- Flows that require inspection by Snort or other inspection engines. In some cases, such as FTP, the secondary data channel can be offloaded although the control channel cannot be offloaded.
- IPsec and TLS/DTLS VPN connections that terminate on the device.
- Flows that require encryption or decryption. For example, connections decrypted due to a decryption policy.
- Multicast flows in routed mode. They are supported in transparent mode if there are only two member interfaces in a bridge group.
- TCP Intercept flows.
- TCP state bypass flows. You cannot configure flow offload and TCP state bypass on the same traffic.
- Flows tagged with security groups.
- Reverse flows that are forwarded from a different cluster node, in the case of asymmetric flows in a cluster.
- Centralized flows in a cluster, if the flow owner is not the control unit.
- Flows that include IP options cannot be dynamically offloaded.

#### Additional Limitations

- Flow offload and Dead Connection Detection (DCD) are not compatible. Do not configure DCD on connections that can be offloaded.
- If more than one flow that matches flow offload conditions are queued to be offloaded at the same time to the same location on the hardware, only the first flow is offloaded. The other flows are processed normally. This is called a *collision*. Use the **show flow-offload flow** command in the CLI to display statistics for this situation.
- Dynamic flow offload disables all TCP normalizer checks.
- Although offloaded flows pass through FXOS interfaces, statistics for these flows do not appear on the logical device interface. Thus, logical device interface counters and packet rates do not reflect offloaded flows.

#### Dynamic flow offload not supported on certain devices

Dynamic flow offload is not supported on the Secure Firewall 3100.

**Conditions for reversing offload**

After a flow is offloaded, packets within the flow are returned to the threat defense for further processing if they meet the following conditions:

- They include TCP options other than Timestamp.
- They are fragmented.
- They are subject to Equal-Cost Multi-Path (ECMP) routing, and ingress packets move from one interface to another.

## CHAPTER 70

# Service Policies

You can use Threat Defense Service Policies to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. A service policy consists of multiple actions or rules applied to an interface or applied globally.

- [About Threat Defense Service Policies, on page 1997](#)
- [Requirements and Prerequisites for Service Policies, on page 1999](#)
- [Guidelines and Limitations for Service Policies, on page 1999](#)
- [Configure Threat Defense Service Policies, on page 2000](#)
- [Examples for Service Policy Rules, on page 2008](#)
- [Monitoring Service Policies, on page 2012](#)

## About Threat Defense Service Policies

You can use Threat Defense Service Policies to apply services to specific traffic classes. With service policies, you are not limited to applying the same services to all connections that enter the device or a given interface.

A traffic class is a combination of the interface and an extended access control list (ACL). The ACL “allow” rules determine which connections are part of the class. Any “denied” traffic in the ACL simply does not have the service applied to it: these connections are not actually dropped. You can use IP addresses and TCP/UDP ports to identify matching connections as precisely as you require.

There are two types of traffic class:

- **Interface-based rules**—If you specify a security zone or interface group in a service policy rule, the rule applies to the ACL “allowed” traffic that goes through any interface that is part of the interface objects.  
For a given feature, interface-based rules applied to the ingress interface always take precedence over global rules: if an ingress interface-based rule applies to a connection, any matching global rule is ignored. If no ingress interface or global rule applies, then an interface service rule on the egress interface is applied.
- **Global rules**—These rules apply to all interfaces. If an interface-based rule does not apply to a connection, the global rules are checked and applied to any connections that the ACL “allows.” If none apply, then the connections proceed without any services applied.

A given connection can match only one traffic class, either interface-based or global, for a given feature. There should be at most one rule for a given interface object/traffic flow combination.

Service policy rules are applied after access control rules. These services are configured only for connections you are allowing.

## How Service Policies Relate to FlexConfig and Other Features

Prior to version 6.3(0), you could configure connection-related service rules using the `TCP_Embryonic_Conn_Limit` and `TCP_Embryonic_Conn_Timeout` pre-defined FlexConfig objects. You should remove those objects and redo your rules using the Threat Defense Service Policy. If you created any custom FlexConfig objects to implement any of these connection-related features (that is, **set connection** commands), you should also remove those objects and implement the features through the service policy.

Because connection-related service policy features are treated as a separate feature group from other service-rule implemented features, you should not run into problems with overlapping traffic classes. However, please be mindful when configuring the following:

- QoS Policy rules are implemented using the service policy CLI. These rules are applied before connection-based service policy rules. However, both QoS and connection settings can be applied to the same or overlapping traffic classes.
- You can use FlexConfig policies to implement customized application inspections and NetFlow. Use the **show running-config** command to examine the CLI that already configures service rules, including the **policy-map**, **class-map**, and **service-policy** commands. Netflow and application inspection are compatible with QoS and connection settings, but you need to understand the existing configuration before implementing FlexConfig. Connection settings are applied before application inspections and Netflow.

---

**Note** Traffic classes that are created from the Threat Defense Service Policy are named **class\_map\_ACLname**, where *ACLname* is the name of the extended ACL object used in the service policy rule.

---

## What Are Connection Settings?

Connection settings comprise a variety of features related to managing traffic connections, such as a TCP flow through the threat defense. Some features are named components that you would configure to supply specific services.

Connection settings include the following:

- **Global timeouts for various protocols**—All global timeouts have default values, so you need to change them only if you are experiencing premature connection loss. You configure global timeouts in the Firepower Threat Defense Platform policy. Select **Devices > Platform Settings**.
- **Connection timeouts per traffic class**—You can override the global timeouts for specific types of traffic using service policies. All traffic class timeouts have default values, so you do not have to set them.
- **Connection limits and TCP Intercept**—By default, there are no limits on how many connections can go through (or to) the threat defense. You can set limits on particular traffic classes using service policy rules to protect servers from denial of service (DoS) attacks. Particularly, you can set limits on embryonic connections (those that have not finished the TCP handshake), which protects against SYN flooding attacks. When embryonic limits are exceeded, the TCP Intercept component gets involved to proxy connections and ensure that attacks are throttled.

- **Dead Connection Detection (DCD)**—If you have persistent connections that are valid but often idle, so that they get closed because they exceed idle timeout settings, you can enable Dead Connection Detection to identify idle but valid connections and keep them alive (by resetting their idle timers). Whenever idle times are exceeded, DCD probes both sides of the connection to see if both sides agree the connection is valid. The **show service-policy** command output includes counters to show the amount of activity from DCD. You can use the **show conn detail** command to get information about the initiator and responder and how often each has sent probes.
- **TCP sequence randomization**—Each TCP connection has two initial sequence numbers (ISN): one generated by the client and one generated by the server. By default, the threat defense randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions. Randomization prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session. However, TCP sequence randomization effectively breaks TCP SACK (Selective Acknowledgement), as the sequence numbers the client sees are different from what the server sees. You can disable randomization per traffic class if desired.
- **TCP Normalization**—The TCP Normalizer protects against abnormal packets. You can configure how some types of packet abnormalities are handled by traffic class. You can configure TCP Normalization using the FlexConfig policy.
- **TCP State Bypass**—You can bypass TCP state checking if you use asymmetrical routing in your network.

Network Admin

## Guidelines and Limitations for Service Policies

- Service policies apply to routed or switch interfaces only, in either routed or transparent mode. They do not apply to inline set or passive interfaces.
- You can have at most 25 traffic classes for a given interface or the global policy. Specifically, this means that you cannot have more than 25 service policy rules for the global policy for a given security zone or interface group. However, for interfaces, because the same interface can appear in both a security zone and interface group, be aware that the actual limitation is based on the interfaces, and not the zone/group. Thus, you might be prevented from having 25 rules per zone/group based on the membership of your zones/groups.

- You can have at most one rule for a given interface object/traffic flow combination.
- When you make service policy changes to the configuration, all new connections use the new service policy. Existing connections continue to use the policy that was configured at the time of the connection establishment. If you want all connections to immediately use the new policy, you need to disconnect the current connections so they can reconnect using the new policy. From an SSH or Console CLI session, enter the **clear conn** or **clear local-host** commands.

## Configure Threat Defense Service Policies

You can use Threat Defense Service Policies to apply services to specific traffic classes. For example, you can use a service policy to create a timeout configuration that is specific to a particular TCP application, as opposed to one that applies to all TCP applications. A service policy consists of multiple actions or rules applied to an interface or applied globally.

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, and click **Edit** (✎) for the access control policy whose Threat Defense Service Policy you want to edit.
- Step 2** Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.
- Step 3** Click **Edit** (✎) in the **Threat Defense Service Policy** group.
- A dialog box opens that shows the existing policy. The policy consists of an ordered list of rules, separated between global rules (which apply to all interfaces) and interface-based rules. The table shows the interface object and extended access control list name (which combined defines the traffic class for the rule), and the services applied.
- Step 4** Do any of the following:
- Click **Add Rule** to create a new rule. See [Configure a Service Policy Rule, on page 2000](#).
  - Click **Edit** (✎) to edit an existing rule. See [Configure a Service Policy Rule, on page 2000](#).
  - Click **Delete** (🗑) to delete a rule.
  - Click a rule and drag it to a new location to move it. You cannot drag rules between the interface and global lists, instead you must edit the rule to change the interface/global setting. The first rule in the list that matches a connection is applied to the connection.
- Step 5** Click **OK** when you are finished editing the policy.
- Step 6** Click **Save** on **Advanced** window. The changes are not saved until you click save.
- 

## Configure a Service Policy Rule

Configure service policy rules to apply services to specific traffic classes.

### Before you begin

Go to **Objects > Object Management > Access List > Extended** and create an the extended access list that defines the traffic to which the rule applies. The rule is applied to any connections that match Allow rules in the extended access list. Define the ACL rules precisely, so that your service policy rule applies to only the traffic that requires the service.

If you are creating an interface-based rule, you must also have configured the interfaces on the assigned devices and added them to security zones or interface groups.

### Procedure

---

**Step 1** If you are not already in the Threat Defense Service Policy dialog box, choose **Policies > Access Control**, edit the access control policy, select **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, then edit the **Threat Defense Service Policy**.

**Step 2** Do any of the following:

- Click **Add Rule** to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The service policy rule wizard opens to step you through the process of configuring the rule.

**Step 3** In the **Interface Object** step, select the option that defines the interfaces that will use the policy.

- **Apply Globally**—Select this option to create a global rule, which applies to all interfaces.
- **Select Interface Objects**—Select this option to create an interface-based rule. Then, select the security zones or interface objects that contain the desired interfaces, and click > to move them to the **Next** selected list. The service policy rule will be configured on each interface contained in the selected objects; it is not configured on the zone/group itself.

Click when the interface criteria is complete.

**Step 4** In the **Traffic Flow** step, select the extended ACL object that defines the connections to which the rule applies, then click **Next**.

**Step 5** In the **Connection Setting** step, configure the services to apply to this traffic class.

- **Enable TCP State Bypass** (TCP connections only)—Implement TCP State Bypass. Connections subject to TCP State Bypass are not inspected by any inspection engines, and they bypass all TCP state checking and TCP normalization. For detailed information, see [Bypass TCP State Checks for Asymmetrical Routing \(TCP State Bypass\)](#), on page 2003.

**Note** Use TCP State Bypass for troubleshooting purposes or when asymmetric routing cannot be resolved. This feature disables multiple security features, which can cause a high number of connections if you do not implement it properly with a narrowly-defined traffic class.

- **Randomize TCP Sequence Number** (TCP connections only)—Whether to enable or disable TCP sequence number randomization. Randomization is enabled by default. For more information, see [Disable TCP Sequence Randomization](#), on page 2007.

- **Enable Decrement TTL** (TCP connections only)—Decrement the time-to-live (TTL) on packets that match the class. If you decrement time to live, packets with a TTL of 1 will be dropped, but a connection

will be opened for the session on the assumption that the connection might contain packets with a greater TTL. Note that some packets, such as OSPF hello packets, are sent with TTL = 1, so decrementing time to live can have unexpected consequences.

**Note** If you want the threat defense device to appear on traceroutes, you must configure the decrement TTL option and also set the ICMP unreachable rate limit in the platform settings policy. See [Make the Threat Defense Device Appear on Traceroutes, on page 2011](#).

- **Connections**—Limits for the number of connections allowed for the entire class. You can configure these options:
  - **Maximum TCP and UDP** (TCP/UDP connections only)—The maximum number of simultaneous connections that are allowed, between 0 and 2000000, for the entire class. For TCP, this count applies to established connections only. The default is 0, which allows unlimited connections. Because the limit is applied to a class, one attacking host can consume all the connections and leave none for the rest of the hosts that are matched to the class. Set the per-client limit to ameliorate this problem.
  - **Maximum Embryonic** (TCP connections only)—The maximum number of simultaneous embryonic TCP connections (those that have not finished the TCP handshake) allowed, between 0 and 2000000. The default is 0, which allows unlimited connections. By setting a non-zero limit, you enable TCP Intercept, which protects inside systems from a DoS attack perpetrated by flooding an interface with TCP SYN packets. Also set the per-client options to protect against SYN flooding. For more information, see [Protect Servers from a SYN Flood DoS Attack \(TCP Intercept\), on page 2008](#).
- **Connections Per Client**—Limits for the number of connections allowed for a given client (source IP address). You can configure these options:
  - **Maximum TCP and UDP** (TCP/UDP connections only)—The maximum number of simultaneous connections allowed per client, between 0 and 2000000. For TCP, this includes established, half-open (embryonic), and half-closed connections. The default is 0, which allows unlimited connections. This option restricts the maximum number of simultaneous connections that are allowed for each host that is matched to the class.
  - **Maximum Embryonic** (TCP connections only)—The maximum number of simultaneous embryonic TCP connections allowed per client, between 0 and 2000000. The default is 0, which allows unlimited connections. For more information, see [Protect Servers from a SYN Flood DoS Attack \(TCP Intercept\), on page 2008](#).
- **Connections Syn Cookie MSS**—The server maximum segment size (MSS) for SYN-cookie generation for embryonic connections upon reaching the embryonic connections limit, from 48 to 65535. The default is 1380. This setting is meaningful only if you configure **Maximum Embryonic** for connections or per-client, or both.
- **Connections Timeout**—The timeout settings to apply to the traffic class. These timeouts override the global timeouts defined in the platform settings policy. You can configure the following:
  - **Embryonic** (TCP connections only)—The timeout period until a TCP embryonic (half-open) connection is closed, between 0:0:5 and 1193:00:00. The default is 0:0:30.
  - **Half Closed** (TCP connections only)—The idle timeout period until a half-closed connection is closed, between 0:0:30 and 1193:0:0. The default is 0:10:0. Half-closed connections are not affected by Dead Connection Detection (DCD). Also, the system does not send a reset when taking down half-closed connections.

- **Idle** (TCP, UDP, ICMP, IP connections)—The idle timeout period after which an established connection of any protocol closes, between 0:0:1 and 1193:0:0. The default is 1:0:0, unless you select the TCP State Bypass option, where the default is 0:2:0.
- **Reset Connection Upon Timeout** (TCP connections only)—Whether to send a TCP RST packet to both end systems after idle connections are removed.
- **Detect Dead Connections** (TCP connections only)—Whether to enable Dead Connection Detection (DCD). Before expiring an idle connection, the system probes the end hosts to determine if the connection is valid. If both hosts respond, the connection is preserved, otherwise the connection is freed. When operating in transparent firewall mode, you must configure static routes for the endpoints. You cannot configure DCD on connections that are also offloaded, so do not configure DCD on connections you are fast-pathing in the prefilter policy. Use the **show conn detail** command in the threat defense CLI to track how many DCD probes have been sent by the initiator and responder.

Configure the following options:

- **Detection Timeout**—The time duration in hh:mm:ss format to wait after each unresponsive DCD probe before sending another probe, between 0:0:1 and 24:0:0. The default is 0:0:15.  
For systems that are operating in a cluster or high-availability configuration, we recommend that you do not set the interval to less than one minute (0:1:0). If the connection needs to be moved between systems, the changes required take longer than 30 seconds, and the connection might be deleted before the change is accomplished.
- **Detection Retries**—The number of consecutive failed retries for DCD before declaring the connection dead, from 1 to 255. The default is 5.

**Step 6** Click **Finish** to save your changes.

The rule is added to the bottom of the appropriate list, either Interfaces or Global. Global rules are matched in top-down order. Rules in the Interfaces list are matched in top down order for each interface object. Place rules for narrowly-defined traffic classes above broader rules, to ensure the right services get applied. You can move rules within each list by using drag and drop. You cannot move rules between lists.

---

## Bypass TCP State Checks for Asymmetrical Routing (TCP State Bypass)

If you have an asymmetrical routing environment in your network, where the outbound and inbound flow for a given connection can go through two different threat defense devices, you need to implement TCP State Bypass on the affected traffic.

However, TCP State Bypass weakens the security of your network, so you should apply bypass on very specific, limited traffic classes.

The following topics explain the problem and solution in more detail.

### The Asymmetrical Routing Problem

By default, all traffic that goes through the threat defense is inspected using the Adaptive Security Algorithm and is either allowed through or dropped based on the security policy. The threat defense maximizes the firewall performance by checking the state of each packet (new connection or established connection) and

assigning it to either the session management path (a new connection SYN packet), the fast path (an established connection), or the control plane path (advanced inspection).

TCP packets that match existing connections in the fast path can pass through the threat defense without rechecking every aspect of the security policy. This feature maximizes performance. However, the method of establishing the session in the fast path using the SYN packet, and the checks that occur in the fast path (such as TCP sequence number), can stand in the way of asymmetrical routing solutions: both the outbound and inbound flow of a connection must pass through the same threat defense device.

For example, a new connection goes to Security Appliance 1. The SYN packet goes through the session management path, and an entry for the connection is added to the fast path table. If subsequent packets of this connection go through Security Appliance 1, then the packets match the entry in the fast path, and are passed through. But if subsequent packets go to Security Appliance 2, where there was not a SYN packet that went through the session management path, then there is no entry in the fast path for the connection, and the packets are dropped. The following figure shows an asymmetric routing example where the outbound traffic goes through a different threat defense than the inbound traffic:

**Figure 374: Asymmetric Routing**

If you have asymmetric routing configured on upstream routers, and traffic alternates between two threat defense devices, then you can configure TCP state bypass for specific traffic. TCP state bypass alters the way sessions are established in the fast path and disables the fast path checks. This feature treats TCP traffic much as it treats a UDP connection: when a non-SYN packet matching the specified networks enters the threat defense device, and there is not a fast path entry, then the packet goes through the session management path to establish the connection in the fast path. Once in the fast path, the traffic bypasses the fast path checks.

## Guidelines and Limitations for TCP State Bypass

### TCP State Bypass Unsupported Features

The following features are not supported when you use TCP state bypass:

- Application inspection—Inspection requires both inbound and outbound traffic to go through the same threat defense, so inspection is not applied to TCP state bypass traffic.

- Snort inspection—Inspection requires both inbound and outbound traffic to go through the same device. However, Snort inspection is not automatically bypassed for TCP state bypass traffic. You must also configure a prefilter fastpath rule for the same traffic class for which you configure TCP state bypass.
- TCP Intercept, maximum embryonic connection limit, TCP sequence number randomization—The threat defense does not keep track of the state of the connection, so these features are not applied.
- TCP normalization—The TCP normalizer is disabled.
- Stateful failover.

### TCP State Bypass NAT Guidelines

Because the translation session is established separately for each threat defense, be sure to configure static NAT on both devices for TCP state bypass traffic. If you use dynamic NAT, the address chosen for the session on Device 1 will differ from the address chosen for the session on Device 2.

## Configure TCP State Bypass

To bypass TCP state checking in asymmetrical routing environments, carefully define a traffic class that applies to the affected hosts or networks only, then enable TCP State Bypass on the traffic class using a service policy. You must also configure a corresponding prefilter fastpath policy for the same traffic to ensure the traffic also bypasses inspection.

Because bypass reduces the security of the network, limit its application as much as possible.

### Procedure

---

**Step 1** Create the extended ACL that defines the traffic class.

For example, to define a traffic class for TCP traffic from 10.1.1.1 to 10.2.2.2, do the following:

- Choose **Objects > Object Management**.
- Choose **Access List > Extended** from the table of contents.
- Click **Add Extended Access List**.
- Enter a **Name** for the object, for example, bypass.
- Click **Add** to add a rule.
- Keep **Allow** for the action.
- Enter 10.1.1.1 beneath the **Source** list and click **Add**, and 10.2.2.2 beneath the **Destination** list, and click **Add**.
- Click **Port**, select **TCP (6)** beneath the **Selected Source Ports** list, and click **Add**. Do not enter a port number, simply add TCP as the protocol, which will cover all ports.
- Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.
- Click **Save** on the Extended Access List Object dialog box to save the ACL object.

**Step 2** Configure the TCP state bypass service policy rule.

For example, to configure TCP state bypass for this traffic class globally, do the following:

- Choose **Policies > Access Control**, and edit the policy assigned to the devices that require this service.
- Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** (✎) for the **Threat Defense Service Policy**.

- c) Click **Add Rule**.
- d) Select **Apply Globally > Next**.
- e) Select the extended ACL object you created for this rule and click **Next**.
- f) Select **Enable TCP State Bypass**.
- g) (Optional.) Adjust the **Idle** timeout for bypassed connections. The default is 2 minutes.
- h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.
- i) Click **OK** to save the changes to the service policy.
- j) Click **Save** on **Advanced** to save the changes to the access control policy.

### Step 3 Configure a prefilter fastpath rule for the traffic class.

You cannot use the ACL object in the prefilter rule, so you need to recreate the traffic class either directly in the prefilter rule, or by first creating network objects that define the class.

The following procedure assumes that you already have a prefilter policy attached to the access control policy. If you have not created a prefilter policy yet, go to **Policies > Prefilter** and first create the policy. You can then follow this procedure to attach it to the access control policy and create the rule.

Keeping with our example, this procedure creates a fastpath rule for TCP traffic from 10.1.1.1 to 10.2.2.2.

- a) Choose **Policies > Access Control**, and edit the policy that has the TCP bypass service policy rule.
- b) Click the link for the **Prefilter Policy**, which is to the left immediately under the policy description.
- c) In the Prefilter Policy dialog box, select the policy to assign to the device if the correct one is not already selected. Do not click OK yet.

Because you cannot add rules to the default prefilter policy, you must choose a custom policy.

- d) In the Prefilter Policy dialog box, click the **Edit** (✎). This action opens a new browser window where you can edit the policy.
- e) Click **Add Prefilter Rule** and configure a rule with the following properties.
  - **Name**—Any name that you find meaningful will do, such as TCPBypass.
  - **Action**—Select **Fastpath**.
  - **Interface Objects**—If you configured TCP state bypass as a global rule, leave the default, any, for both source and destination. If you created an interface-based rule, select the same interface objects you used for rule in the **Source Interface Objects** list, and keep any as the destination.
  - **Networks**—Add 10.1.1.1 to the **Source Networks** list, and 10.2.2.2 to the **Destination Networks** list. You can either use network objects or manually add the addresses.
  - **Ports**—Under **Selected Source Ports**, select TCP(6), **do not enter a port**, and click **Add**. This will apply the rule to all (and only) TCP traffic, regardless of TCP port number.
- f) Click **Add** to add the rule to the prefilter policy.
- g) Click **Save** to save your changes to the prefilter policy.

You can now close the prefilter edit window and return to the access control policy edit window.

- h) In the access control policy edit window, the Prefilter Policy dialog box should still be open. Click **OK** to save your changes to the prefilter policy assignment.
- i) Click **Save** on the access control policy to save the changed prefilter policy assignment, if you changed it.

You can now deploy the changes to the affected devices.

---

## Disable TCP Sequence Randomization

Each TCP connection has two initial sequence numbers (ISN): one generated by the client and one generated by the server. The threat defense device randomizes the ISN of the TCP SYN passing in both the inbound and outbound directions.

Randomizing the ISN of the protected host prevents an attacker from predicting the next ISN for a new connection and potentially hijacking the new session. However, TCP sequence randomization effectively breaks TCP SACK (Selective Acknowledgement), as the sequence numbers the client sees are different from what the server sees.

You can disable TCP initial sequence number randomization if necessary, for example, because data is getting scrambled. Following are some situations where you might want to disable randomization.

- If another in-line firewall is also randomizing the initial sequence numbers, there is no need for both firewalls to be performing this action, even though this action does not affect the traffic.
- If you use eBGP multi-hop through the device, and the eBGP peers are using MD5. Randomization breaks the MD5 checksum.
- If you use a WAAS device that requires the threat defense device not to randomize the sequence numbers of connections.
- If you enable hardware bypass for the ISA 3000, and TCP connections are dropped when the ISA 3000 is no longer part of the data path.

### Procedure

---

**Step 1** Create the extended ACL that defines the traffic class.

For example, to define a traffic class for TCP traffic from any host to 10.2.2.2, do the following:

- a) Choose **Objects > Object Management**.
- b) Choose **Access List > Extended** from the table of contents.
- c) Click **Add Extended Access List**.
- d) Enter a **Name** for the object, for example, preserve-sq-no.
- e) Click **Add** to add a rule.
- f) Keep **Allow** for the action.
- g) Leave the **Source** list empty, enter 10.2.2.2 beneath the **Destination** list, and click **Add**.
- h) Click **Port**, select **TCP (6)** beneath the **Selected Source Ports** list, and click **Add**. Do not enter a port number, simply add TCP as the protocol, which will cover all ports.
- i) Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.
- j) Click **Save** on the Extended Access List Object dialog box to save the ACL object.

**Step 2** Configure the service policy rule that disables TCP sequence number randomization.

For example, to disable randomization for this traffic class globally, do the following:

- a) Choose **Policies > Access Control**, and edit the policy assigned to the devices that require this service.
- b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** (✎) for the **Threat Defense Service Policy**.
- c) Click **Add Rule**.
- d) Select **Apply Globally > Next**.
- e) Select the extended ACL object you created for this rule and click **Next**.
- f) Deselect **Randomize TCP Sequence Number**.
- g) (Optional.) Adjust the other connection options as needed.
- h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.
- i) Click **OK** to save the changes to the service policy.
- j) Click **Save** on **Advanced** to save the changes to the access control policy.

You can now deploy the changes to the affected devices.

---

## Examples for Service Policy Rules

The following topics provide examples of service policy rules.

### Protect Servers from a SYN Flood DoS Attack (TCP Intercept)

A SYN-flooding denial of service (DoS) attack occurs when an attacker sends a series of SYN packets to a host. These packets usually originate from spoofed IP addresses. The constant flood of SYN packets keeps the server SYN queue full, which prevents it from servicing connection requests from legitimate users.

You can limit the number of embryonic connections to help prevent SYN flooding attacks. An embryonic connection is a connection request that has not finished the necessary handshake between source and destination.

When the embryonic connection threshold of a connection is crossed, the threat defense acts as a proxy for the server and generates a SYN-ACK response to the client SYN request using the SYN cookie method, so that the connection is not added to the SYN queue of the targeted host. The SYN cookie is the initial sequence number returned in the SYN-ACK that is constructed from MSS, time stamp, and a mathematical hash of other items to essentially create a secret. If the threat defense receives an ACK back from the client with the correct sequence number and within the valid time window, it can then authenticate that the client is real and allow the connection to the server. The component that performs the proxy is called TCP Intercept.

Setting connection limits can protect a server from a SYN flood attack. You can optionally enable TCP Intercept statistics and monitor the results of your policy. The following procedure explains the end-to-end process.

#### Before you begin

- Ensure that you set the embryonic connection limit lower than the TCP SYN backlog queue on the server that you want to protect. Otherwise, valid clients can no longer access the server during a SYN attack. To determine reasonable values for embryonic limits, carefully analyze the capacity of the server, the network, and server usage.
- Depending on the number of CPU cores on your Secure Firewall Threat Defense device model, the maximum concurrent and embryonic connections can exceed the configured numbers due to the way

each core manages connections. In the worst case scenario, the device allows up to  $n-1$  extra connections and embryonic connections, where  $n$  is the number of cores. For example, if your model has 4 cores, if you configure 6 concurrent connections and 4 embryonic connections, you could have an additional 3 of each type. To determine the number of cores for your model, enter the **show cpu core** command in the device CLI.

## Procedure

- 
- Step 1** Create the extended ACL that defines the traffic class, which is the list of servers you want to protect. For example, to define a traffic class to protect the web servers with the IP addresses 10.1.1.5 and 10.1.1.6:
- Choose **Objects > Object Management**.
  - Choose **Access List > Extended** from the table of contents.
  - Click **Add Extended Access List**.
  - Enter a **Name** for the object, for example, protected-servers.
  - Click **Add** to add a rule.
  - Keep **Allow** for the action.
  - Leave the **Source** list empty, enter 10.1.1.5 beneath the **Destination** list, and click **Add**.
  - Also enter 10.1.1.6 beneath the **Destination** list and click **Add**.
  - Click **Port**, select **HTTP** in the available ports list, and click **Add to Destination**. If your server also support HTTPS connections, also add that port.
  - Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.
  - Click **Save** on the Extended Access List Object dialog box to save the ACL object.
- Step 2** Configure the service policy rule that sets embryonic connection limits. For example, to set the total concurrent embryonic limit to 1000 connections, and the per-client limit to 50 connections, do the following:
- Choose **Policies > Access Control**, and edit the policy assigned to the devices that require this service.
  - Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** (✎) for the **Threat Defense Service Policy**.
  - Click **Add Rule**.
  - Select **Apply Globally > Next**.
  - Select the extended ACL object you created for this rule and click **Next**.
  - Enter 1000 for **Connections > Maximum Embryonic**.
  - Enter 50 for **Connections Per Client > Maximum Embryonic**.
  - (Optional.) Adjust the other connection options as needed.
  - Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.
  - Click **OK** to save the changes to the service policy.
  - Click **Save** on **Advanced** to save the changes to the access control policy.
- Step 3** (Optional.) Configure the rates for TCP Intercept statistics. TCP Intercept uses the following options to determine the rate for collecting statistics. All options have default values, so if these rates suit your needs, you can skip this step.

- **Rate Interval**—The size of the history monitoring window, between 1 and 1440 minutes. The default is 30 minutes. During this interval, the system samples the number of attacks 30 times.
- **Burst Rate**—The threshold for syslog message generation, between 25 and 2147483647. The default is 400 per second. When the burst rate is exceeded, the device generates syslog message 733104.
- **Average Rate**—The average rate threshold for syslog message generation, between 25 and 2147483647. The default is 200 per second. When the average rate is exceeded, the device generates syslog message 733105.

If you want to adjust these options, do the following:

- Choose **Objects > Object Management**.
- Choose **FlexConfig > Text Object**.
- Click **Edit** (✎) for the threat\_defense\_statistics system-defined object.
- Although you can directly change the values, the recommended approach is to open the **Override** section and click **Add** to create a device override.
- Select the devices to which you will assign the service policy (through the access control policy assignment) and click **Add** to move them to the selected list.
- Click **Override**.
- The object must have 3 entries, so click **Count** as needed until you get 3.
- Enter the values you need, in order from 1-3, as rate interval, burst rate, and average rate. Consult the object description to verify you enter the values in the right order.
- Click **Add** in the Object Override dialog box.
- Click **Save** in the Edit Text Object dialog box.

#### Step 4 Enable TCP Intercept statistics.

You must configure a FlexConfig policy to enable TCP Intercept statistics.

- Choose **Devices > FlexConfig**.
- If you already have a policy assigned to the devices, edit it. Otherwise, create a new policy and assign it to the affected devices.
- Select the **Threat\_Detection\_Configure** object in the **Available FlexConfig** list and click >>. The object is added to the **Selected Append FlexConfigs** list.
- Click **Save**.
- (Optional.) You can verify that you have the right settings by clicking **Preview Config** and selecting one of the devices.

The system generates the CLI commands that will be written to the device during the next deployment. These commands will include those needed for the service policy as well as those needed for threat detection statistics. Scroll to the bottom of the preview to see the appended CLI. The TCP Intercept statistics command should look something like the following, if you use the default values (line break added for clarity):

```
###Flex-config Appended CLI ###

threat-detection statistics tcp-intercept rate-interval 30
burst-rate 400 average-rate 200
```

**Step 5** You can now deploy the changes to the affected devices.

**Step 6** Monitor the TCP Intercept statistics from the device CLI using the following commands:

- **show threat-detection statistics top tcp-intercept [all | detail]**—View the top 10 protected servers under attack. The **all** keyword shows the history data of all the traced servers. The **detail** keyword shows history sampling data. The system samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds.

**Note** You can use the **shun** command to block attacking host IP addresses. To remove the block, use the **no shun** command.

- **clear threat-detection statistics tcp-intercept**—Erases TCP Intercept statistics.

#### Example:

```
hostname(config)# show threat-detection statistics top tcp-intercept
Top 10 protected servers under attack (sorted by average rate)
Monitoring window size: 30 mins    Sampling interval: 30 secs
<Rank> <Server IP:Port> <Interface> <Ave Rate> <Cur Rate> <Total> <Source IP (Last Attack
Time)>
-----
1    10.1.1.5:80 inside 1249 9503 2249245 <various> Last: 10.0.0.3 (0 secs ago)
2    10.1.1.6:80 inside 10 10 6080 10.0.0.200 (0 secs ago)
```

## Make the Threat Defense Device Appear on Traceroutes

By default, the Threat Defense device does not appear on traceroutes as a hop. To make it appear, you need to decrement the time-to-live on packets that pass through the device, and increase the rate limit on ICMP unreachable messages. To accomplish this, you must configure a service policy rule and adjust the ICMP platform settings policy.

**Note** If you decrement time to live, packets with a TTL of 1 will be dropped, but a connection will be opened for the session on the assumption that the connection might contain packets with a greater TTL. Note that some packets, such as OSPF hello packets, are sent with TTL = 1, so decrementing time to live can have unexpected consequences. Keep these considerations in mind when defining your traffic class.

### Procedure

**Step 1** Create the extended ACL that defines the traffic class for which to enable traceroute reporting. For example, to define a traffic class for all addresses, but excluding OSPF traffic, do the following:

- Choose **Objects > Object Management**.
- Choose **Access List > Extended** from the table of contents.
- Click **Add Extended Access List**.
- Enter a **Name** for the object, for example, traceroute-enabled.
- Click **Add** to add a rule to exclude OSPF.
- Change the action to **Block**, click **Port**, select **OSPF (89)** as the protocol beneath the **Destination Ports** list, and click **Add** to add the protocol to the selected list.

- g) Click **Add** on the Extended Access List Entry dialog box to add the OSPF rule to the ACL.
- h) Click **Add** to add a rule to include all other connections.
- i) Keep **Allow** for the action, and leave both the Source and Destination lists empty.
- j) Click **Add** on the Extended Access List Entry dialog box to add the rule to the ACL.  
Ensure that the OSPF deny rule is above the Allow Any rule. Drag and drop to move the rules if necessary.
- k) Click **Save** on the Extended Access List Object dialog box to save the ACL object.

**Step 2** Configure the service policy rule that decrements the time-to-live value.

For example, to decrement time-to-live globally, do the following:

- a) Choose **Policies > Access Control**, and edit the policy assigned to the devices that require this service.
- b) Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line, and click **Edit** (✍) for the **Threat Defense Service Policy**.
- c) Click **Add Rule**.
- d) Select **Apply Globally** and click **Next**.
- e) Select the extended ACL object you created for this rule and click **Next**.
- f) Select **Enable Decrement TTL**.
- g) (Optional.) Adjust the other connection options as needed.
- h) Click **Finish** to add the rule. If necessary, drag and drop the rule to the desired position in the service policy.
- i) Click **OK** to save the changes to the service policy.
- j) Click **Save** on **Advanced** to save the changes to the access control policy.

You can now deploy the changes to the affected devices.

**Step 3** Increase the rate limit on ICMP unreachable messages.

- a) Choose **Devices > Platform Settings**.
- b) If you already have a policy assigned to the devices, edit it. Otherwise, create a new Threat Defense platform settings policy and assign it to the affected devices.
- c) Select **ICMP** from the table of contents.
- d) Increase the **Rate Limit**, for example, to 50. You might also want to increase the **Burst Size**, for example, to 10, to ensure enough responses are generated within the rate limit.

You can leave the ICMP rules table empty, it is not related to this task.

- e) Click **Save**.

**Step 4** You can now deploy the changes to the affected devices.

## Monitoring Service Policies

You can monitor service-policy related information using the device CLI. Following are some useful commands.

- **show conn [detail]**

Shows connection information. Detailed information uses flags to indicate special connection characteristics. For example, the “b” flag indicates traffic subject to TCP State Bypass.

When you use the **detail** keyword, you can see information about Dead Connection Detection (DCD) probing, which shows how often the connection was probed by the initiator and responder. For example, the connection details for a DCD-enabled connection would look like the following:

```
TCP dmz: 10.5.4.11/5555 inside: 10.5.4.10/40299,
      flags UO , idle 1s, uptime 32m10s, timeout 1m0s, bytes 11828,
cluster sent/rcvd bytes 0/0, owners (0,255)
  Traffic received at interface dmz
    Locally received: 0 (0 byte/s)
  Traffic received at interface inside
    Locally received: 11828 (6 byte/s)
  Initiator: 10.5.4.10, Responder: 10.5.4.11
  DCD probes sent: Initiator 5, Responder 5
```

- **show service-policy**

Shows service policy statistics, including Dead Connection Detection (DCD) statistics.

- **show threat-detection statistics top tcp-intercept [all | detail]**

View the top 10 protected servers under attack. The **all** keyword shows the history data of all the traced servers. The **detail** keyword shows history sampling data. The system samples the number of attacks 30 times during the rate interval, so for the default 30 minute period, statistics are collected every 60 seconds.

## CHAPTER 71

# Intelligent Application Bypass

The following topics describe how to configure access control policies to use Intelligent Application Bypass (IAB)

- [Introduction to IAB, on page 2015](#)
- [IAB Options, on page 2016](#)
- [Requirements and Prerequisites for Intelligent Application Bypass, on page 2018](#)
- [Configuring Intelligent Application Bypass, on page 2018](#)
- [IAB Logging and Analysis, on page 2019](#)

## Introduction to IAB

IAB identifies applications that you trust to traverse your network without further inspection if performance and flow thresholds are exceeded. For example, if a nightly backup significantly impacts system performance, you can configure thresholds that, if exceeded, trust traffic generated by your backup application. Optionally, you can configure IAB so that, when an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

The system implements IAB on traffic allowed by access control rules or the access control policy's default action, before the traffic is subject to deep inspection. A test mode allows you to determine whether thresholds are exceeded and, if so, to identify the application flows that would have been bypassed if you had actually enabled IAB (called *bypass mode*).

The following graphic illustrates the IAB decision-making process:

## IAB Options

### State

Enables or disables IAB.

### Performance Sample Interval

Specifies the time in seconds between IAB performance sampling scans, during which the system collects system performance metrics for comparison to IAB performance thresholds. A value of **0** disables IAB.

### Bypassable Applications and Filters

This feature provides two mutually exclusive options:

**Applications/Filters**

Provides an editor where you can specify bypassable applications and sets of applications (filters). See [Application Rule Conditions](#), on page 1065.

**All applications including unidentified applications**

When an inspection performance threshold is exceeded, trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.

**Performance and Flow Thresholds**

You must configure at least one inspection performance threshold and one flow bypass threshold. When a performance threshold is exceeded, the system examines flow thresholds and, if one threshold is exceeded, trusts the specified traffic. If you enable more than one of either, only one of each must be exceeded.

**Inspection performance thresholds** provide intrusion inspection performance limits that, if exceeded, trigger the inspection of flow thresholds. IAB does not use inspection performance thresholds set to 0. You can configure one or more of the following inspection performance thresholds:

**Drop Percentage**

Average packets dropped as a percentage of total packets, when packets are dropped because of performance overloads caused by expensive intrusion rules, file policies, decompression, and so on. This does not refer to packets dropped by normal configurations such as intrusion rules. Note that specifying an integer greater than 1 activates IAB when the specified percentage of packets is dropped. When you specify 1, any percentage from 0 through 1 activates IAB. This allows a small number of packets to activate IAB.

**Processor Utilization Percentage**

Average percentage of processor resources used.

**Packet Latency**

Average packet latency in microseconds.

**Flow Rate**

The rate at which the system processes flows, measured as the number of flows per second. Note that this option configures IAB to measure flow *rate*, not flow *count*.

**Flow bypass thresholds** provide flow limits that, if exceeded, trigger IAB to trust bypassable application traffic in bypass mode or allow application traffic subject to further inspection in test mode. IAB does not use flow bypass thresholds set to 0. You can configure one or more of the following flow bypass thresholds:

**Bytes per Flow**

The maximum number of kilobytes a flow can include.

**Packets per Flow**

The maximum number of packets a flow can include.

**Flow Duration**

The maximum number of seconds a flow can remain open.

**Flow Velocity**

The maximum transfer rate in kilobytes per second.

- Access Admin
- Network Admin

## Configuring Intelligent Application Bypass

---

**Caution** Not all deployments require IAB, and those that do might use it in a limited fashion. Do not enable IAB unless you have expert knowledge of your network traffic, especially application traffic, and system performance, including the causes of predictable performance issues. Before you run IAB in bypass mode, make sure that trusting the specified traffic does not expose you to risk.

---

### Before you begin

For Classic devices, you must have the Control license.

### Procedure

- 
- Step 1** In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** (✎) next to **Intelligent Application Bypass Settings**.
- Step 2** Configure IAB options:
- **State**—Turn IAB **Off** or **On**, or enable IAB in **Test** mode.
  - **Performance Sample Interval**—Enter the time in seconds between IAB performance-sampling scans. If you enable IAB, even in test mode, enter a non-zero value. Entering **0** disables IAB.
  - **Bypassable Applications and Filters**—Choose from:
    - Click the number of bypassed applications and filters and specify the applications whose traffic you want to bypass; see [Configuring Application Conditions and Filters, on page 1869](#).

- Click **All applications including unidentified applications** so that, when an inspection performance threshold is exceeded, IAB trusts all traffic that exceeds any flow bypass threshold, regardless of the application type.
- **Inspection Performance Thresholds**—Click **Configure** and enter at least one threshold value.
- **Flow Bypass Thresholds**—Click **Configure** and enter at least one threshold value.

You must specify at least one inspection performance threshold and one flow bypass threshold; both must be exceeded for IAB to trust traffic. If you enter more than one threshold of each type, only one of each type must be exceeded. For detailed information, see [IAB Options, on page 2016](#).

**Step 3** Click **OK** to save IAB settings.

**Step 4** Click **Save** to save the policy.

---

### What to do next

- Because some packets must be allowed to pass before an application can be detected, you must configure your system to examine those packets.  
See [Best Practices for Handling Packets That Pass Before Traffic Identification, on page 2750](#) and [Specify a Policy to Handle Packets That Pass Before Traffic Identification, on page 2750](#).
- Deploy configuration changes.

## IAB Logging and Analysis

IAB forces an end-of-connection event that logs bypassed flows and flows that would have been bypassed, regardless of whether you have enabled connection logging. Connection events indicate flows that are bypassed in bypass mode or that would have been bypassed in test mode. Custom dashboard widgets and reports based on connection events can display long-term statistics for bypassed and would-have-bypassed flows.

### IAB Connection Events

#### Action

When **Reason** includes `Intelligent App Bypass`:

#### **Allow -**

indicates that the applied IAB configuration was in test mode and traffic for the application specified by **Application Protocol** remains available for inspection.

#### **Trust -**

indicates that the applied IAB configuration was in bypass mode and traffic for the application specified by **Application Protocol** has been trusted to traverse the network without further inspection.

#### Reason

`Intelligent App Bypass` indicates that IAB triggered the event in bypass or test mode.

#### Application Protocol

This field displays the application protocol that triggered the event.

### Example

In the following truncated graphic, some fields are omitted. The graphic shows the **Action**, **Reason**, and **Application Protocol** fields for two connection events resulting from different IAB settings in two separate access control policies.

For the first event, the `Trust` action indicates that IAB was enabled in bypass mode and Bonjour protocol traffic was trusted to pass without further inspection.

For the second event, the `Allow` action indicates that IAB was enabled in test mode, so Ubuntu Update Manager traffic was subject to further inspection but would have been bypassed if IAB had been in bypass mode.

Action ×	Reason ×	Application × Protocol
Trust	Intelligent App Bypass	<input type="checkbox"/> Bonjour
Allow	Intelligent App Bypass	<input type="checkbox"/> Ubuntu Update Manager

404483

### Example

In the following truncated graphic, some fields are omitted. The flow in the second event was both bypassed (**Action:** `Trust`; **Reason:** `Intelligent App Bypass`) and inspected by an intrusion rule (**Reason:** `Intrusion Monitor`). The `Intrusion Monitor` reason indicates that an intrusion rule set to **Generate Events** detected but did not block an exploit during the connection. In the example, this happened before the application was detected. After the application was detected, IAB recognized the application as bypassable and trusted the flow.

Last Packet ×	Action ×	Reason ×	Application × Protocol
2015-06-12 10:53:09	Trust	Intelligent App Bypass	<input type="checkbox"/> Skype Probe
2015-06-12 10:53:08	Trust	Intelligent App Bypass, Intrusion Monitor	<input type="checkbox"/> HTTP

4044541

### IAB Custom Dashboard Widgets

You can create a Custom Analysis dashboard widget to display long-term IAB statistics based on connection events. Specify the following when creating the widget:

- **Preset:** None
- **Table:** Application Statistics
- **Field:** any
- **Aggregate:** either of:
  - IAB Bypassed Connections
  - IAB Would Bypass Connections
- **Filter:** any

## Examples

In the following Custom Analysis dashboard widget examples:

- The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.
- The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy.

## IAB Custom Reports

You can create a custom report to display long-term IAB statistics based on connection events. Specify the following when creating the report:

- **Table:** Application Statistics
- **Preset:** None
- **Filter:** any
- **X-Axis:** any
- **Y-Axis:** either of:
  - IAB Bypassed Connections
  - IAB Would Bypass Connections

## Examples

The following graphic shows two abbreviated report examples:

- The *Bypassed* example shows statistics for application traffic bypassed because the applications were specified as bypassable and IAB was enabled in bypass mode in the deployed access control policy.
- The *Would Have Bypassed* example shows statistics for application traffic that would have been bypassed because the applications were specified as bypassable and IAB was enabled in test mode in the deployed access control policy.

## CHAPTER 72

# Content Restriction

---

The following topics describe how to configure access control policies to use content restriction features:

- [About Content Restriction, on page 2023](#)
- [Requirements and Prerequisites for Content Restriction, on page 2024](#)
- [Guidelines and Limitations for Content Restriction, on page 2025](#)
- [Using Access Control Rules to Enforce Content Restriction, on page 2025](#)
- [Using a DNS Sinkhole to Enforce Content Restriction, on page 2026](#)

## About Content Restriction

Major search engines and content delivery services provide features that allow you to restrict search results and website content. For example, schools use content restriction features to comply with the Children's Internet Protection Act (CIPA).

When implemented by search engines and content delivery services, you can enforce content restriction features only for individual browsers or users. The system allows you to extend these features to your entire network.

The system allows you to enforce:

- *Safe Search*—Supported in many major search engines, this service filters out explicit and adult-oriented content that business, government, and education environments classify as objectionable. The system does not restrict a user's ability to access the home pages for supported search engines.

You can use two methods to configure the system to enforce these features:

### **Method: Access Control Rules**

Content restriction features communicate the restricted status of a search or content query via an element in the request URI, an associated cookie, or a custom HTTP header element. You can configure access control rules to modify these elements as the system processes traffic.

### **Method: DNS Sinkhole**

For Google searches, you can configure the system to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes filters for Safe Search.

The table below describes the differences between these enforcement methods.

Table 121: Comparison of Content Restriction Methods

Attribute	Method: Access Control Rules	Method: DNS Sinkhole
Supported devices	Any	Secure Firewall Threat Defense only
Search engines supported	Any tagged <code>safesearch</code> supported in the <b>Applications</b> tab of the rule editor	Google only
YouTube Restricted Mode supported	Yes	Yes
SSL policy required	Yes	No
Hosts must be using IPv4	No	Yes
Connection event logging	Yes	Yes

When determining which method to use, consider the following limitations:

- The access control rules method requires an SSL policy, which impacts performance.
- The Google SafeSearch VIP supports IPv4 traffic only. If you configure a DNS sinkhole to manage Google searches, any hosts on the affected network must be using IPv4.

The system logs different values for the **Reason** field in connection events, depending on the method:

- Access Control Rules—Content Restriction
- DNS Sinkhole—DNS Block

## Requirements and Prerequisites for Content Restriction

### Model Support

Any, or as indicated in the procedure.

### Supported Domains

Any

### User Roles

- Admin
- Access Admin
- Network Admin

# Guidelines and Limitations for Content Restriction

- Safe search is supported by Snort 2 only.
- YouTube and Google do not support the YouTubeEDU feature that was implemented in access control rules. Please remove any access control rules that configure YouTubeEDU as they are not truly functional. You can also remove associated decryption rules.

## Using Access Control Rules to Enforce Content Restriction

The following procedure explains how to configure access control rules to restrict content.”

**Note** When safe search is enabled in an access control rule, inline normalization is enabled automatically.

### Procedure

- 
- Step 1** Create a decryption policy.
- Step 2** Add rules for handling Safe Search traffic:
- Choose **Decrypt - Resign** as the **Action** for the rules.
  - In **Applications**, add selections to the **Selected Applications and Filters** list:
    - Safe Search—Add the `Category: search engine` filter.
- Step 3** Set rule positions for the rules you added. Click and drag, or use the right-click menu to cut and paste.
- Step 4** Create or edit an access control policy, and associate the decryption policy with the access control policy. For more information, see [Associating Other Policies with Access Control, on page 1844](#).
- Step 5** In the access control policy, add rules for handling Safe Search traffic:
- Choose **Allow** as the **Action** for the rules.
  - In **Applications**, click the icon for **Safe search** (🔒) and set related options.
    - [Safe Search Options for Access Control Rules, on page 2026](#)
  - In **Applications**, refine application selections in the **Selected Applications and Filters** list.

In most cases, enabling Safe Search populates the **Selected Applications and Filters** list with the appropriate values. The system does not automatically populate the list if a Safe Search application is already present in the list when you enable the feature. If applications do not populate as expected, manually add them as follows:

    - Safe Search—Add the `Category: search engine` filter.

For more information, see [Configuring Application Conditions and Filters, on page 1869](#).

- Step 6** Set rule positions for the access control rules you added. Click and drag, or use the right-click menu to cut and paste.
  - Step 7** Configure the HTTP response page that the system displays when it blocks restricted content; see [Choosing HTTP Response Pages, on page 1936](#).
  - Step 8** Deploy configuration changes.
- 

## Safe Search Options for Access Control Rules

The system supports Safe Search filtering for specific search engines only. For a list of supported search engines, see applications tagged `safesearch supported` in the **Applications** tab of the access control rule editor. For a list of unsupported search engines, see applications tagged `safesearch unsupported`.

When enabling Safe Search for an access control rule, set the following parameters:

### Enable Safe Search

Enables Safe Search filtering for traffic that matches this rule.

### Unsupported Search Traffic

Specifies the action you want the system to take when it processes traffic from unsupported search engines. If you choose **Block** or **Block with Reset**, you must also configure the HTTP response page that the system displays when it blocks restricted content; see [Choosing HTTP Response Pages, on page 1936](#).

## Using a DNS Sinkhole to Enforce Content Restriction

Typically, a DNS sinkhole directs traffic away from a particular target. This procedure describes how to configure a DNS sinkhole to redirect traffic to the Google SafeSearch Virtual IP Address (VIP), which imposes content filters on Google and YouTube search results.

Because Google SafeSearch uses a single IPv4 address for the VIP, hosts must use IPv4 addressing.

---

**Caution** If your network includes proxy servers, this content restriction method is not effective unless you position your threat defense devices between the proxy servers and the Internet.

---

This procedure describes enforcing content restriction for Google searches only. To enforce content restriction for other search engines, see [Using Access Control Rules to Enforce Content Restriction, on page 2025](#).

### Before you begin

This procedure applies to threat defense only, and requires the IPS license.

## Procedure

---

- Step 1** Obtain a list of supported Google domains via the following URL: [https://www.google.com/supported\\_domains](https://www.google.com/supported_domains).

- Step 2** Create a custom DNS list on your local computer, and add the following entries:
- To enforce Google SafeSearch, add an entry for each supported Google domain.
  - To enforce YouTube Restricted Mode, add a "youtube.com" entry.
- The custom DNS list must be in text file (.txt) format. Each line of the text file must specify an individual domain name, stripped of any leading periods. For example, the supported domain ".google.com" must appear as "google.com".
- Step 3** Upload the custom DNS list to the management center; see [Uploading New Security Intelligence Lists to the Secure Firewall Management Center, on page 1534](#).
- Step 4** Determine the IPv4 address for the Google SafeSearch VIP. For example, run `nslookup` on `forcesafesearch.google.com`.
- Step 5** Create a sinkhole object for the SafeSearch VIP; see [Creating Sinkhole Objects, on page 1535](#).
- Use the following values for this object:
- IPv4 Address—Enter the SafeSearch VIP address.
  - IPv6 Address—Enter the IPv6 loopback address (: :1).
  - Log Connections to Sinkhole—Click Log Connections.
  - Type—Choose **None**.
- Step 6** Create a basic DNS policy; see [Creating Basic DNS Policies, on page 1960](#).
- Step 7** Add a DNS rule for the sinkhole; see [Creating and Editing DNS Rules, on page 1962](#).
- For this rule:
- Check the **Enabled** check box.
  - Choose `sinkhole` from the **Action** drop-down list.
  - Choose the sinkhole object you created from the **Sinkhole** drop-down list.
  - Add the custom DNS list you created to the **Selected Items** list on **DNS**.
  - (Optional) Choose a network in **Networks** to limit content restriction to specific users. For example, if you want to limit content restriction to student users, assign students to a different subnet than faculty, and specify that subnet in this rule.
- Step 8** Associate the DNS policy with an access control policy; see [Associating Other Policies with Access Control, on page 1844](#).
- Step 9** Deploy configuration changes.
-

## CHAPTER 73

# Zero Trust Access

---

The following topics provide an overview of Zero Trust Application Policies and how to configure and deploy them.

- [About Zero Trust Access, on page 2029](#)
- [How Threat Defense Works with Zero Trust Access, on page 2030](#)
- [Why Use Zero Trust Access?, on page 2031](#)
- [Components of a Zero Trust Access Configuration, on page 2031](#)
- [Zero Trust Access Workflow, on page 2032](#)
- [Limitations for Zero Trust Access, on page 2033](#)
- [Prerequisites for Zero Trust Application Policy, on page 2034](#)
- [Manage Zero Trust Application Policies, on page 2034](#)
- [Create a Zero Trust Application Policy, on page 2035](#)
- [Create an Application Group, on page 2036](#)
- [Create an Application, on page 2037](#)
- [Set Targeted Devices for Zero Trust Access Policy, on page 2039](#)
- [Edit a Zero Trust Application Policy, on page 2040](#)
- [Monitor Zero Trust Sessions, on page 2041](#)
- [History for Zero Trust Access, on page 2042](#)

## About Zero Trust Access

The Zero Trust Access feature is based on Zero Trust Network Access (ZTNA) principles. ZTNA is a zero trust security model that eliminates implicit trust. The model grants the least privilege access after verifying the user, the context of the request, and after analyzing the risk if access is granted.

Zero Trust Access allows you to authenticate and authorize access to protected web based resources and applications from inside (on-premise) or outside (remote) the network using an external SAML Identity Provider (IdP) policy.

The features are:

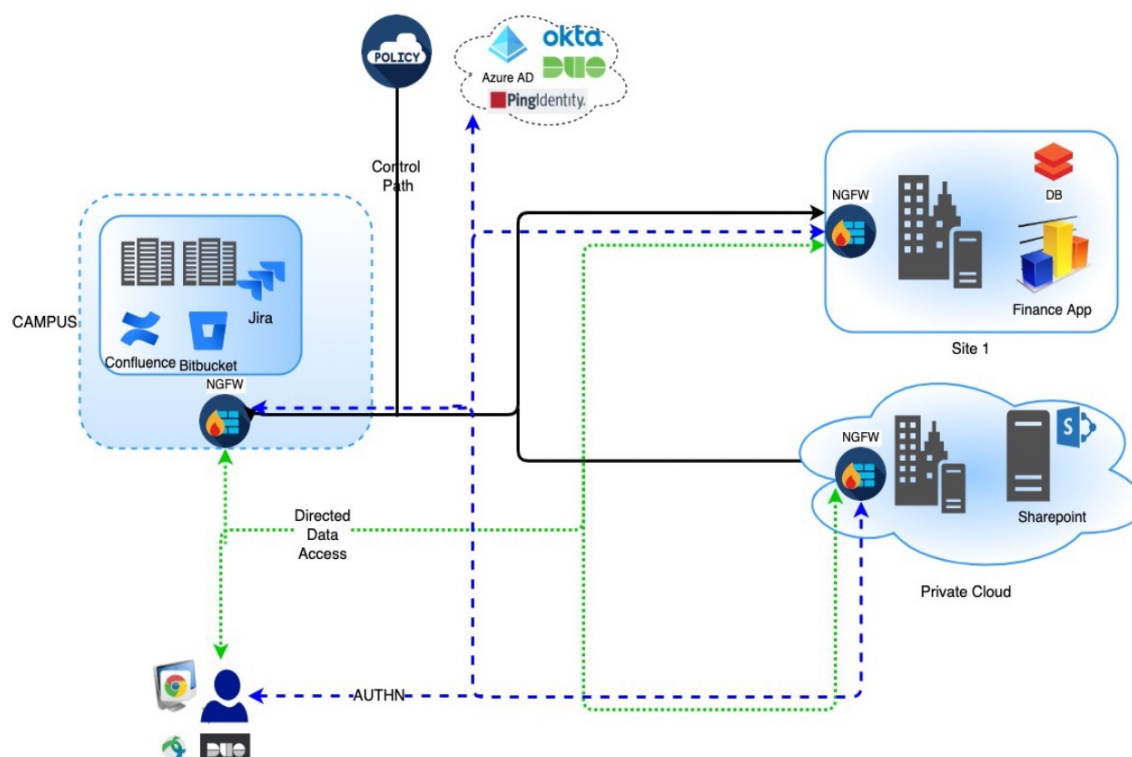

- Supports multiple SAML based identity providers such as Duo, Azure AD, Okta, and other identity providers.
- Client applications such as Cisco Secure Client are not required on the endpoint (client devices) for secure access.

- Access and authentication is through the browser.
- Supports only web applications (HTTPS).
- Client device posture is supported through agents such as Duo Health, using which the posture of the device can be evaluated against a policy in Duo, and access can be provided based on the same. The same functionality can be performed in conjunction with third-party identity providers that support posture evaluation with their agents such as Okta or PingID.
- Supports HTTP-Redirect SAML binding.
- Supports Application Groups that make it easier to enable zero trust protection on a set of applications.
- Leverages threat defense intrusion and malware protection on zero trust application traffic.

You can use the Secure Firewall Management Center web interface to create a Zero Trust Application Policy that allows you to define private applications and assign threat policies to them. The policy is application specific where the administrator decides the inspection levels based on the threat perception for that application.

## How Threat Defense Works with Zero Trust Access

Figure 375: Threat Defense Deployment

1. Using a browser, a remote or on-prem user sends a HTTPS request to connect to an application from an endpoint.

2. The HTTPS request is intercepted by the firewall that protects the application.
3. The firewall redirects the user to application's configured IdP for authentication.

---

**Note** In the figure, each firewall protects a set of web applications. The user can directly access the applications behind the firewall after authentication and authorization.

---

4. After the authentication and authorization process is complete, the firewall allows the user to access the application.

## Why Use Zero Trust Access?

Zero Trust Access leverages the existing deployment of threat defense as an enforcement point to application access. It allows for segmented access to a private application with per application authorization and per application tunnel for remote and on-premise users.

The feature hides the network from users and allows users to only access applications they are authorized for. Authorization for one application in the network does not give an implicit authorization for other applications on the network, thereby reducing the attack surface significantly. In other words, every access to an application must be explicitly authorized.

Adding the zero trust access functionality to threat defense enables migration to a more secure access model without having to install or manage yet another device in the network.

The feature is easy to manage as it does not require a client and is per application access.

## Components of a Zero Trust Access Configuration

A new configuration consists of a Zero Trust Application Policy, Application Group, and Applications.

- **Zero Trust Application Policy**— Consists of application groups, and grouped or ungrouped applications. Security Zones and Security Controls settings are associated at a global level for all the ungrouped applications and group of applications.

A global port pool is assigned to the policy, by default. A unique port is automatically assigned from this pool to each private application that is configured.

Zero Trust Application policy consists of application groups, and grouped or ungrouped applications.

- **Application Groups**—Consists of a logical group of applications that share SAML authentication settings and can optionally share Security Zones and Security Controls settings.

Application Groups inherit the Security Zones and Security Controls settings from the global policy and can override the values.

When an Application Group is created, the same SAML IdP configuration can be used for authenticating multiple applications. Applications that are part of an Application Group inherit the Application Group's SAML configuration. This eliminates the need to configure the SAML settings for each application. After the Application Group is created, new applications can be added to it without configuring the IdP for it.

When an end user tries to access an Application that is part of group, the user is authenticated to the Application Group for the first time. When the user tries to access other applications that are part of the same Application Group, the user is provided access without being redirected again to the IdP for authentication. This prevents overloading the IdP with requests for application access and optimizes the usage of the IdP if a limit is enabled.

- **Applications**—There are two types:
  - **Ungrouped Applications**— Are standalone applications. SAML settings must be configured for every application. The applications inherit the Security Zones and Security Controls settings from the global policy and can be overridden by the application.
  - **Grouped Applications**— Are multiple applications that are grouped under an Application Group. The SAML settings are inherited from the Application Group and cannot be overridden. However, the Security Zones and Security Controls settings can be overridden for each application.

The following certificates are required for the configuration:

- **Identity Certificate**—This certificate is used by threat defense to masquerade as the applications. Threat Defense behaves as a SAML Service Provider (SP). This certificate must be a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of the private applications. It is a common certificate for all applications protected by threat defense.
- **IdP Certificate**—The IdP provides a certificate for each defined Application or Application Group. This certificate must be configured so that threat defense can verify the IDP's signature on incoming SAML assertions.

---

**Note** IdP certificates are commonly included within the metadata file; otherwise, users are required to have the IdP certificate readily available during the configuration of applications.

---

- **Application Certificate**—The encrypted traffic from user to the application is decrypted by threat defense using this certificate for the purpose of inspection.

---

**Note** This certificate is required to verify the cookies in the header to authorize connections, even if we are not conducting an IPS/Malware inspection.

---

## Zero Trust Access Workflow

This figure depicts the Zero Trust Access workflow.

Figure 376: Zero Trust Access Workflow

The workflow is as follows:

1. User types the application URL in the browser.
  - If the HTTPS request is valid, the user is redirected to the mapped port (Step 6).
  - If the HTTPS request is invalid, the user is sent for authentication per application (Step 2).
2. The user is redirected to the configured identity provider (IdP).
3.
  - a. The user is redirected to the configured primary authentication source.
  - b. The user is challenged with the configured secondary multi-factor authentication, if any.
4. The IdP sends a SAML response to threat defense. The user ID and other necessary parameters are retrieved from the SAML response through the browser.
5. The user is redirected to the application.
6. The user is allowed access to the application after validation is successful.

## Limitations for Zero Trust Access

- Only web applications (HTTPS) are supported. Scenarios requiring decryption exemption are not supported.
- Supports only SAML IdPs.
- IPv6 is not supported. NAT66, NAT64, and NAT46 scenarios are not supported.
- The feature is available on threat defense only if Snort 3 is enabled.
- All hyperlinks in protected web applications must have a relative path and are not supported on individual mode clusters.

- Protected web applications running on a virtual host or behind internal load balancers must use the same external and internal URL.
- Not supported on individual mode clusters.
- Not supported on applications with strict HTTP Host Header validation enabled.
- If the application server hosts multiple applications and serves content based on the Server Name Indication (SNI) header in the TLS Client Hello, the external URL of the zero trust application configuration must match the SNI of that specific application.

## Prerequisites for Zero Trust Application Policy

Prerequisite Type	Description
Licensing	<ul style="list-style-type: none"> <li>• Smart license account with export-controlled features</li> <li>• (Optional) IPS and Threat licenses—It is required if security controls are used.</li> </ul>
Configurations	Create a wildcard or Subject Alternative Name (SAN) certificate that matches the FQDN of private applications. For more information, see <a href="#">Adding Certificate Enrollment Objects, on page 1511</a> .
	Create a security zone through which access to private applications are regulated. For more information, see <a href="#">Create Security Zone and Interface Group Objects, on page 910</a> .

## Manage Zero Trust Application Policies

You can create, edit, and delete zero trust application policies.

### Procedure

**Step 1** Choose **Policies > Access Control > Zero Trust Application**

**Step 2** Manage the zero trust access policies:

- Create—Click **New Policy**. See [Create a Zero Trust Application Policy, on page 2035](#)
- Edit—Click **Edit** (✎). See [Edit a Zero Trust Application Policy, on page 2040](#)
- Report—Click **Report** (📄).
- Delete—Click **Delete** (🗑).

**Step 3** Click **Save**.

---

#### What to do next

Ensure that there are no warnings before you deploy the configuration to threat defense. To deploy configuration changes, see Deploy Configuration Changes in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Create a Zero Trust Application Policy

This task configures a Zero Trust Application Policy.

#### Before you begin

Ensure that you complete all the prerequisites listed in [Prerequisites for Zero Trust Application Policy](#), on page 2034.

#### Procedure

---

**Step 1** Choose **Policies > Access Control > Zero Trust Application**.

**Step 2** Click **Add Policy**.

**Step 3** In the **General** section, enter the policy name in the **Name** field. The description field is optional.

**Step 4** Enter a domain name in the **Domain Name** field.

Ensure that the domain name is added to the DNS. The domain name resolves to the threat defense gateway interface from where the application is accessed. The domain name is used to generate the ACS URL for all private applications in an Application Group.

**Step 5** Choose an existing certificate from the **Identity Certificate** drop-down list.

Click the **Add (+)** icon to configure a certificate enrollment object. For more information, see [Adding Certificate Enrollment Objects](#), on page 1511.

**Step 6** Choose a security zone from the **Security Zones** drop-down list.

Click the **Add (+)** icon to add a new security zone.

To add security zones, see [Create Security Zone and Interface Group Objects](#), on page 910.

**Step 7** In the **Global Port Pool** section, a default port range is displayed. Modify, if required. Port values range from 1024 to 65535. A unique port from this pool is assigned to each private application.

**Note** This port range should avoid any conflicts with the existing NAT range.

**Step 8** (Optional) In the **Security Controls** section, you can add an Intrusion or Malware and File policy:

- **Intrusion Policy**—Choose a default policy from the drop-down list or click the **Add (+)** icon to create a new custom intrusion policy. For more information, see [Creating a Custom Snort 3 Intrusion Policy](#) topic in the latest version of the [Cisco Secure Firewall Management Center Snort 3 Configuration Guide](#).

- **Variable Set**—Choose a default variable set from the drop-down list or click the **Add (+)** icon to create a new variable set. For more information, see [Creating Variable Sets, on page 1553](#).

**Note** To use variable sets, you must have the Secure Firewall Threat Defense IPS license for your managed devices.

- **Malware and File Policy**—Choose an existing policy from the drop-down list. Click the **Add (+)** icon to create a new malware and file policy. For more information, see [Managing File Policies, on page 2281](#).

**Step 9** Click **Save** to save the policy.

---

### What to do next

1. Create an Application Group. See [Create an Application Group, on page 2036](#).
2. Create an Application. See [Create an Application, on page 2037](#).
3. Associate a Zero Trust Application Policy with a device. See [Set Targeted Devices for Zero Trust Access Policy, on page 2039](#)
4. Deploy configuration changes. See Deploy Configuration Changes in the [Cisco Secure Firewall Management Center Administration Guide](#).

# Create an Application Group

## Before you begin

[Create a Zero Trust Application Policy, on page 2035](#)

## Procedure

- 
- Step 1** Click **Add Application Group**.
- Step 2** In the **Application Group** section, type the name in the **Name** field and click **Next**.
- Step 3** In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the values of the **Entity ID** and **Assertion Consumer Service (ACS) URL** fields or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.
- Step 4** In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:
- **XML File Upload**—Choose a file or drag and drop the XML file.  
The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.
  - **Manual Configuration**—Perform these steps:
    - **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.
    - **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.

- **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

Click the **Add** (+) icon to configure a new certificate enrollment object. For more information, see [Add Certificate Enrollment, on page 1512](#).

- **Configure Later**—In the event you do not have the IdP metadata, you can configure it later.

Click **Next**.

**Step 5** In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**. The re-authentication interval allows you to provide a value that determines when a user must authenticate again.

**Step 6** In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy. You can override these settings. Click **Next**.

**Step 7** Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.

**Step 8** Click **Save**.

The Application Group is created and is displayed on the Zero Trust Application page.

---

#### What to do next

1. [Create an Application, on page 2037](#).
2. Deploy configuration changes. See Deploy Configuration Changes in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Create an Application

Use this task to create a Grouped or Ungrouped Application.

#### Before you begin

1. [Create a Zero Trust Application Policy, on page 2035](#).
2. [Create an Application Group, on page 2036](#) (required only for Grouped Applications).

#### Procedure

- 
- Step 1** Choose **Policies > Access Control > Zero Trust Application**
- Step 2** Choose the policy.
- Step 3** Click **Add Application**.
- Step 4** In the **Application Settings** section, complete the following fields.
- **Application Name**—Enter the application name.

- **External URL**—Enter the URL that is used by the user to access the application.
- **Application URL**—By default, the external URL is used as the Application URL. Uncheck the **Use External URL as Application URL** check box to specify a different URL.

If the threat defense uses an internal DNS, then the Application URL must align with an entry within that DNS, to ensure resolution to the application.

- **Application Certificate**—Choose the certificate for the private application. Click the **Add (+)** icon to configure an internal certificate object. For more information, see [Adding Internal Certificate Objects, on page 1509](#).
- **Application Group**—Choose the Application Group from the drop-down list. See [Create an Application Group, on page 2036](#).

**Note** This field is not applicable for an ungrouped application.

**Step 5** Click **Next**.

**Step 6** Based on the application type:

- For a Grouped Application, the **SAML Service Provider (SP) Metadata**, **SAML Identity Provider (IdP) Metadata**, and **Re-authentication Interval** are inherited from the Application Group and do not need to be configured by the user.

- For an Ungrouped Application, perform these steps:

**a.** In the **SAML Service Provider (SP) Metadata** section, the data is dynamically generated. Copy the **Entity ID** or **Assertion Consumer Service (ACS) URL** of the IdP or click **Download SP Metadata** to download this data in XML format for adding it to the IdP. Click **Next**.

**b.** In the **SAML Identity Provider (IdP) Metadata** section, add the metadata using any one of the methods:

- **XML File Upload**—Choose a file or drag and drop the XML file.

The details of the **Entity ID**, **Single Sign-On URL**, and **IdP Certificate** are displayed.

- **Manual Configuration**—Perform these steps:

- **Entity ID**—Enter the URL that is defined in the SAML IdP to identify a service provider uniquely.

- **Single Sign-On URL**—Enter the URL for signing into the SAML identity provider server.

- **IdP Certificate**—Choose the certificate of the IdP enrolled in threat defense to verify the messages signed by the IdP.

Click the **Add (+)** icon to configure a new certificate enrollment object. For more information, see [Add Certificate Enrollment, on page 1512](#).

- **Configure Later**—In the event you do not have the IdP metadata, you can configure it later.

Click **Next**.

**c.** In the **Re-authentication Interval** section, enter the value in the **Timeout Interval** field and click **Next**. The reauthentication interval allows you to provide a value that determines when a user must authenticate again.

- Step 7** In the **Security Zones and Security Controls** section, the security zones and threat settings are inherited from the parent policy or application group. You can override these settings. Click **Next**.
- Step 8** Review the configuration summary. Click **Edit** to modify the details in any of the sections. Click **Finish**.
- Step 9** Click **Save**.
- The Application is listed on the Zero Trust Application page and is enabled by default.

---

**What to do next**

1. [Set Targeted Devices for Zero Trust Access Policy, on page 2039.](#)
2. Deploy configuration changes. See Deploy Configuration Changes in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Set Targeted Devices for Zero Trust Access Policy

Each Zero Trust Application policy can target multiple devices; each device can have one deployed policy at a time.

**Before you begin**

1. [Create a Zero Trust Application Policy, on page 2035.](#)
2. [Create an Application Group, on page 2036.](#)
3. [Create an Application, on page 2037.](#)

**Procedure**

- 
- Step 1** Choose **Policies > Access Control > Zero Trust Application**
- Step 2** Choose the policy.
- Step 3** Click **Targeted Devices**.
- Step 4** Choose the devices where you want to deploy the policy using any one of the methods:
- Choose a device in the **Available Devices** list and click >> or the **Add (+)** icon.
  - To remove a device from the **Selected Devices** list, choose a device and click << or the **Delete (🗑)** icon.
- Step 5** Click **Apply** to save policy assignments.
- Step 6** Click **Save** to save the policy.
-

**What to do next**

Deploy configuration changes. See Deploy Configuration Changes in the [Cisco Secure Firewall Management Center Administration Guide](#).

# Edit a Zero Trust Application Policy

You can edit the settings of a Zero Trust Application Policy, Application Group, or Application.

**Procedure**

**Step 1** Choose **Policies > Access Control > Zero Trust Application**

**Step 2** Click **Edit** (✎) next to the Zero Trust Application Policy you want to edit.

**Step 3** Edit your Zero Trust Application Policy.

You can change the following settings or perform these actions:

- Name and Description—Click **Edit** (✎) next to the policy name, make your changes, and click **Apply**.
- To modify the policy settings:
  - Click **Settings**
  - Modify the settings as required.
    - Important** Editing the domain name for the SAML ACS URL interrupts application access.
  - Click **Save**.
- To modify the Application Group settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application Group you want to edit.
  - In each section, click **Edit** to modify the settings, as required
    - Important** Editing the Application Group name interrupts application access.
  - Click **Apply** after you modify the settings in a section.
  - Click **Finish**.
  - Click **Save**.
- To modify the Application settings:
  - Click **Applications**.
  - Click **Edit** (✎) next to the Application you want to edit.
  - In each section, click **Edit** to modify the settings, as required.

**Important** Editing the Application name interrupts application access.

- Click **Apply** after you modify the settings in a section.
  - Click **Finish**.
  - Click **Save**.
- To enable, disable, or delete multiple Applications, choose the Applications, click the required bulk action, and click **Save**.

**Note** These actions are also available in the right-click menu.

- To enable all Applications, click **Bulk Actions > Enable**.
  - To disable all Applications, click **Bulk Actions > Disable**.
  - To delete all Applications, click **Bulk Actions > Delete**.
- Click **Return to Zero Trust Application** to return to the policy page.

---

### What to do next

Deploy configuration changes. See Deploy Configuration Changes in the [Cisco Secure Firewall Management Center Administration Guide](#).

# Monitor Zero Trust Sessions

## Connection Events

After a Zero Trust Application Policy is deployed, new fields are available. To add the fields to the table view:

1. Choose **Analysis > Connections > Events**.
2. Go to the **Table View of Connection Events** tab.
3. In the table view of events, multiple fields are hidden by default. To change the fields that appear, click the **x** icon in any column name to display a field selector.
4. Choose the following fields:
  - Authentication Source
  - Zero Trust Application
  - Zero Trust Application Group
  - Zero Trust Application Policy
5. Click **Apply**.

See Connection and Security-Related Connection Events in the [Secure Firewall Management Center Administration Guide](#) for more information on the connection events.

### Zero Trust Dashboard

The Zero Trust dashboard allows you to monitor real-time data from active zero trust sessions on the devices.

The Zero Trust dashboard provides a summary of the top zero trust applications and zero trust users that are managed by the management center. Choose **Overview > Dashboards > Zero Trust** to access the dashboard.

The dashboard has the following widgets:

- Top Zero Trust Applications
- Top Zero Trust Users

### CLI Commands

Log in to the device CLI and use the following commands:

CLI Command	Description
<code>show running-config zero-trust</code>	To view the running configuration for a zero trust configuration
<code>show zero-trust</code>	To display the run-time zero trust statistics and session information
<code>show cluster zero-trust</code>	To display the summary of zero trust statistics across nodes in a cluster
<code>clear zero-trust</code>	To clear zero trust sessions and statistics
<code>show counters protocol zero_trust</code>	To view the counters that are hit for zero trust flow

## History for Zero Trust Access

Feature	Minimum Management Center	Minimum Threat Defense	Details
Zero Trust Access	7.4.0	7.4.0	You can allow users to access private applications without requiring additional software on their personal devices. This functionality leverages SAML-based authentication and supports Duo, as well as all other major identity providers.

- [Requirements and Prerequisites for Network Analysis and Intrusion Policies, on page 2057](#)
- [The Navigation Panel: Network Analysis and Intrusion Policies, on page 2057](#)
- [Conflicts and Changes: Network Analysis and Intrusion Policies, on page 2059](#)

## Network Analysis and Intrusion Policy Basics

Network analysis and intrusion policies work together as part of the system's intrusion detection and prevention feature.

- The term *intrusion detection* generally refers to the process of passively monitoring and analyzing network traffic for potential intrusions and storing attack data for security analysis. This is sometimes referred to as "IDS."
- The term *intrusion prevention* includes the concept of intrusion detection, but adds the ability to block or alter malicious traffic as it travels across your network. This is sometimes referred to as "IPS."

### Note

- You must configure Network Analysis Policy (NAP) in **Prevention** mode if you are using Snort 3 and SSL decryption or TLS Server Identity. The SSL functionality does not work when Snort 3 NAP is in detection mode.
- We strongly recommend that your intrusion policy (IPS) and network analysis policy (NAP) have the same settings. If IPS is in detection mode, set the NAP in detection mode, and conversely as well.

---

In an intrusion prevention deployment, when the system examines packets:

- A **network analysis policy** governs how traffic is *decoded* and *preprocessed* so it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt.
- An **intrusion policy** uses *intrusion and preprocessor rules* (sometimes referred to collectively as *intrusion rules*) to examine the decoded packets for attacks based on patterns. Intrusion policies are paired with *variable sets*, which allow you to use named values to accurately reflect your network environment.

Both network analysis and intrusion policies are invoked by a parent access control policy, but at different times. As the system analyzes traffic, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (additional preprocessing and intrusion rules) phase. Together, network analysis and intrusion policies provide broad and deep packet inspection. They can help you detect, alert on, and protect against network traffic that could threaten the availability, integrity, and confidentiality of hosts and their data.

The system is delivered with several similarly named network analysis and intrusion policies (for example, Balanced Security and Connectivity) that complement and work with each other. By using system-provided policies, you can take advantage of the experience of the Talos Intelligence Group. For these policies, Talos sets intrusion and preprocessor rule states, as well as provides the initial configurations for preprocessors and other advanced settings.

You can also create custom network analysis and intrusion policies. You can tune settings in custom policies to inspect traffic in the way that matters most to you so that you can improve both the performance of your managed devices and your ability to respond effectively to the events they generate.

You create, edit, save, and manage network analysis and intrusion policies using similar policy editors in the web interface. When you are editing either type of policy, a navigation panel appears on the left side of the web interface; the right side displays various configuration pages.

## How Policies Examine Traffic For Intrusions

When the system analyzes traffic as part of your access control deployment, the network analysis (decoding and preprocessing) phase occurs before and separately from the intrusion prevention (intrusion rules and advanced settings) phase.

The following diagram shows, in a simplified fashion, the order of traffic analysis in an inline, intrusion prevention and malware defense deployment. It illustrates how the access control policy invokes other policies to examine traffic, and in which order those policies are invoked. The network analysis and intrusion policy selection phases are highlighted.

In an inline deployment (that is, where relevant configurations are deployed to devices using routed, switched, or transparent interfaces, or inline interface pairs), the system can block traffic without further inspection at almost any step in the illustrated process. Security Intelligence, the SSL policy, network analysis policies, file

policies, and intrusion policies can all either drop or modify traffic. Only the network discovery policy, which passively inspects packets, cannot affect the flow of traffic.

Similarly, at each step of the process, a packet could cause the system to generate an event. Intrusion and preprocessor events (sometimes referred to collectively as *intrusion events*) are indications that a packet or its contents may represent a security risk.

---

**Tip** The diagram does not reflect that access control rules handle encrypted traffic when your SSL inspection configuration allows it to pass, or if you do not configure SSL inspection. By default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

---

Note that for a single connection, although the system selects a network analysis policy before an access control rule as shown in the diagram, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

## Decoding, Normalizing, and Preprocessing: Network Analysis Policies

Without decoding and preprocessing, the system could not appropriately evaluate traffic for intrusions because protocol differences would make pattern matching impossible. Network analysis policies govern these traffic-handling tasks:

- **after** traffic is filtered by Security Intelligence
- **after** encrypted traffic is decrypted by an optional SSL policy
- **before** traffic can be inspected by file or intrusion policies

A network analysis policy governs packet processing in phases. First the system decodes packets through the first three TCP/IP layers, then continues with normalizing, preprocessing, and detecting protocol anomalies:

- The packet decoder converts packet headers and payloads into a format that can be easily used by the preprocessors and later, intrusion rules. Each layer of the TCP/IP stack is decoded in turn, beginning with the data link layer and continuing through the network and transport layers. The packet decoder also detects various anomalous behaviors in packet headers.
- In inline deployments, the inline normalization preprocessor reformats (normalizes) traffic to minimize the chances of attackers evading detection. It prepares packets for examination by other preprocessors and intrusion rules, and helps ensure that the packets the system processes are the same as the packets received by the hosts on your network.

---

**Note** In a passive deployment, Cisco recommends that you enable adaptive profile updates at the access control policy level, instead of inline normalization at the network analysis level.

---

- Various network and transport layers preprocessors detect attacks that exploit IP fragmentation, perform checksum validation, and perform TCP and UDP session preprocessing.

Note that some advanced transport and network preprocessor settings apply globally to all traffic handled by the target devices of an access control policy. You configure these in the access control policy rather than in a network analysis policy.

- Various application-layer protocol decoders normalize specific types of packet data into formats that the intrusion rules engine can analyze. Normalizing application-layer protocol encodings allows the system to effectively apply the same content-related intrusion rules to packets whose data is represented differently, and to obtain meaningful results.
- The Modbus, DNP3, CIP, and s7commplus SCADA preprocessors detect traffic anomalies and provide data to intrusion rules. Supervisory Control and Data Acquisition (SCADA) protocols monitor, control, and acquire data from industrial, infrastructure, and facility processes such as manufacturing, production, water treatment, electric power distribution, airport and shipping systems, and so on.
- Several preprocessors allow you to detect specific threats, such as Back Orifice, portscans, SYN floods and other rate-based attacks.

Note that you configure the sensitive data preprocessor, which detects sensitive data such as credit card numbers and Social Security numbers in ASCII text, in intrusion policies.

In a newly created access control policy, one default network analysis policy governs preprocessing for *all* traffic for *all* intrusion policies invoked by the same parent access control policy. Initially, the system uses the Balanced Security and Connectivity network analysis policy as the default, but you can change it to another system-provided or custom network analysis policy. In a more complex deployment, advanced users can tailor traffic preprocessing options to specific security zones, networks, and VLANs by assigning different custom network analysis policies to preprocess matching traffic.

---

**Note** For an access control policy with rule action as **Trust** and a prefilter rule with action as **Fastpath** with logging options disabled, you will observe that the end-of-flow events are still generated in the system. The events are not visible on the management center event pages.

---

## Access Control Rules: Intrusion Policy Selection

After initial preprocessing, access control rules (when present) evaluate traffic. In most cases, the first access control rule that a packet matches is the rule that handles that traffic; you can monitor, trust, block, or allow matching traffic.

When you allow traffic with an access control rule, the system can inspect the traffic for discovery data, malware, prohibited files, and intrusions, in that order. Traffic not matching any access control rule is handled by the access control policy's default action, which can also inspect for discovery data and intrusions.

---

**Note** All packets, **regardless** of which network analysis policy preprocesses them, are matched to configured access control rules—and thus are potentially subject to inspection by intrusion policies—in top-down order.

---

The diagram in [How Policies Examine Traffic For Intrusions, on page 2046](#) shows the flow of traffic through a device in an inline, intrusion prevention and malware defense deployment, as follows:

- Access Control Rule A allows matching traffic to proceed. The traffic is then inspected for discovery data by the network discovery policy, for prohibited files and malware by File Policy A, and then for intrusions by Intrusion Policy A.
- Access Control Rule B also allows matching traffic. However, in this scenario, the traffic is not inspected for intrusions (or files or malware), so there are no intrusion or file policies associated with the rule. Note that by default, traffic that you allow to proceed is inspected by the network discovery policy; you do not need to configure this.
- In this scenario, the access control policy's default action allows matching traffic. The traffic is then inspected by the network discovery policy, and then by an intrusion policy. You can (but do not have to) use a different intrusion policy when you associate intrusion policies with access control rules or the default action.

The example in the diagram does not include any blocking or trusting rules because the system does not inspect blocked or trusted traffic.

## Intrusion Inspection: Intrusion Policies, Rules, and Variable Sets

You can use intrusion prevention as the system's last line of defense before traffic is allowed to proceed to its destination. Intrusion policies govern how the system inspects traffic for security violations and, in inline deployments, can block or alter malicious traffic. The main function of intrusion policies is to manage which intrusion and preprocessor rules are enabled and how they are configured.

### Intrusion and Preprocessor Rules

An intrusion rule is a specified set of keywords and arguments that detects attempts to exploit vulnerabilities on your network; the system uses an intrusion rule to analyze network traffic to check if it matches the criteria in the rule. The system compares packets against the conditions specified in each rule and, if the packet data matches all the conditions specified in a rule, the rule triggers.

The system includes the following types of rules created by Talos Intelligence Group:

- *shared object intrusion rules*, which are compiled and cannot be modified (except for rule header information such as source and destination ports and IP addresses)
- *standard text intrusion rules*, which can be saved and modified as new custom instances of the rule.
- *preprocessor rules*, which are rules associated with preprocessors and packet decoder detection options in the network analysis policy. You cannot copy or edit preprocessor rules. Most preprocessor rules are disabled by default; you must enable them to use preprocessors to generate events and, in an inline deployment, drop offending packets.

When the system processes packets according to an intrusion policy, first a rule optimizer classifies all activated rules in subsets based on criteria such as: transport layer, application protocol, direction to or from the protected network, and so on. Then, the intrusion rules engine selects the appropriate rule subsets to apply to each packet. Finally, a multi-rule search engine performs three different types of searches to determine if the traffic matches the rule:

- The protocol field search looks for matches in particular fields in an application protocol.
- The generic content search looks for ASCII or binary byte matches in the packet payload.
- The packet anomaly search looks for packet headers and payloads that, rather than containing specific content, violate well-established protocols.

In a custom intrusion policy, you can tune detection by enabling and disabling rules, as well as by writing and adding your own standard text rules. You can also use Cisco recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.

### Variable Sets

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated *variable set*. Most variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

The system provides a single default variable set, which is comprised of predefined default variables. Most system-provided shared object rules and standard text rules use these predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable `$HOME_NET` to specify the protected network and the variable `$EXTERNAL_NET` to specify the unprotected (or outside) network. In addition, specialized rules often use other predefined variables. For example, rules that detect exploits against web servers use the `$HTTP_SERVERS` and `$HTTP_PORTS` variables.

---

**Tip** Even if you use system-provided intrusion policies, Cisco **strongly** recommends that you modify key default variables in the default set. When you use variables that accurately reflect your network environment, processing is optimized and the system can monitor relevant systems for suspicious activity. Advanced users can create and use custom variable sets for pairing with one or more custom intrusion policies.

---

[Predefined Default Variables](#), on page 1543

## Intrusion Event Generation

When the system identifies a possible intrusion, it generates an *intrusion or preprocessor event* (sometimes collectively called *intrusion events*). Managed devices transmit their events to the management center, where you can view the aggregated data and gain a greater understanding of the attacks against your network assets. In an inline deployment, managed devices can also drop or replace packets that you know to be harmful.

Each intrusion event in the database includes an event header and contains information about the event name and classification; the source and destination IP addresses; ports; the process that generated the event; and the date and time of the event, as well as contextual information about the source of the attack and its target. For packet-based events, the system also logs a copy of the decoded packet header and payload for the packet or packets that triggered the event.

The packet decoder, the preprocessors, and the intrusion rules engine can all cause the system to generate an event. For example:

- If the packet decoder (configured in the network analysis policy) receives an IP packet that is less than 20 bytes, which is the size of an IP datagram without any options or payload, the decoder interprets this as anomalous traffic. If, later, the accompanying decoder rule in the intrusion policy that examines the packet is enabled, the system generates a preprocessor event.
- If the IP defragmentation preprocessor encounters a series of overlapping IP fragments, the preprocessor interprets this as a possible attack and, when the accompanying preprocessor rule is enabled, the system generates a preprocessor event.

- Within the intrusion rules engine, most standard text rules and shared object rules are written so that they generate intrusion events when triggered by packets.

As the database accumulates intrusion events, you can begin your analysis of potential attacks. The system provides you with the tools you need to review intrusion events and evaluate whether they are important in the context of your network environment and your security policies.

## System-Provided and Custom Network Analysis and Intrusion Policies

Creating a new access control policy is one of the first steps in managing traffic flow using the system. By default, a newly created access control policy invokes system-provided network analysis and intrusion policies to examine traffic.

The following diagram shows how a newly created access control policy in an inline, intrusion-prevention deployment initially handles traffic. The preprocessing and intrusion prevention phases are highlighted.

**Figure 377: New Access Control Policy: Intrusion Prevention**

Note how:

- A default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided *Balanced Security and Connectivity network analysis policy* is the default.
- The default action of the access control policy allows all non-malicious traffic, as determined by the system-provided *Balanced Security and Connectivity intrusion policy*. Because the default action allows traffic to pass, the discovery feature can examine it for host, application, and user data before the intrusion policy can examine and potentially block malicious traffic.
- The policy uses default Security Intelligence options (global Block and Do Not Block lists only), does not decrypt encrypted traffic with an SSL policy, and does not perform special handling and inspection of network traffic using access control rules.

A simple step you can take to tune your intrusion prevention deployment is to use a different set of system-provided network analysis and intrusion policies as your defaults. Cisco delivers several pairs of these policies with the system.

Or, you can tailor your intrusion prevention deployment by creating and using custom policies. You may find that the preprocessor options, intrusion rule, and other advanced settings configured in those policies do not address the security needs of your network. By tuning your network analysis and intrusion policies you can configure, at a very granular level, how the system processes and inspects the traffic on your network for intrusions.

## System-Provided Network Analysis and Intrusion Policies

Cisco delivers several pairs of network analysis and intrusion policies with the system. By using system-provided network analysis and intrusion policies, you can take advantage of the experience of the

Talos Intelligence Group. For these policies, Talos provides intrusion and preprocessor rule states as well as initial configurations for preprocessors and other advanced settings.

No system-provided policy covers every network profile, traffic mix, or defensive posture. Each covers common cases and network setups that provide a starting point for a well-tuned defensive policy. Although you can use system-provided policies as-is, Cisco strongly recommends that you use them as the base for custom policies that you tune to suit your network.

---

**Tip** Even if you use system-provided network analysis and intrusion policies, you should configure the system's intrusion variables to accurately reflect your network environment. At a minimum, modify key default variables in the default set.

---

As new vulnerabilities become known, Talos releases intrusion rule updates (also known as *Snort Rule Updates*). These rule updates can modify any system-provided network analysis or intrusion policy, and can provide new and updated intrusion rules and preprocessor rules, modified states for existing rules, and modified default policy settings. Rule updates may also delete rules from system-provided policies and provide new rule categories, as well as modify the default variable set.

If a rule update affects your deployment, the web interface marks affected intrusion and network analysis policies as out of date, as well as their parent access control policies. You must re-deploy an updated policy for its changes to take effect.

For your convenience, you can configure rule updates to automatically re-deploy affected intrusion policies, either alone or in combination with affected access control policies. This allows you to easily and automatically keep your deployment up-to-date to protect against recently discovered exploits and intrusions.

To ensure up-to-date preprocessing settings, you **must** re-deploy access control policies, which also deploys any associated SSL, network analysis, and file policies that are different from those currently running, and can also update default values for advanced preprocessing and performance options.

Cisco delivers the following network analysis and intrusion policies with the system:

#### **Balanced Security and Connectivity network analysis and intrusion policies**

These policies are built for both speed and detection. Used together, they serve as a good starting point for most organizations and deployment types. The system uses the Balanced Security and Connectivity policies and settings as defaults in most cases.

#### **Connectivity Over Security network analysis and intrusion policies**

These policies are built for organizations where connectivity (being able to get to all resources) takes precedence over network infrastructure security. The intrusion policy enables far fewer rules than those enabled in the Security over Connectivity policy. Only the most critical rules that block traffic are enabled.

#### **Security Over Connectivity network analysis and intrusion policies**

These policies are built for organizations where network infrastructure security takes precedence over user convenience. The intrusion policy enables numerous network anomaly intrusion rules that could alert on or drop legitimate traffic.

#### **Maximum Detection network analysis and intrusion policies**

These policies are built for organizations where network infrastructure security is given even more emphasis than is given by the Security Over Connectivity policies, with the potential for even greater operational impact. For example, the intrusion policy enables rules in a large number of threat categories including malware, exploit kit, old and common vulnerabilities, and known in-the-wild exploits.

### No Rules Active intrusion policy

In the No Rules Active intrusion policy, all intrusion rules, and all advanced settings except intrusion rule thresholds, are disabled. This policy provides a starting point if you want to create your own intrusion policy instead of basing it on the enabled rules in one of the other system-provided policies.

**Note** Depending on the system-provided base policy that is selected, the settings of the policy vary. To view the policy settings, click the **Edit** icon next to the policy and then click the **Manage Base Policy** link.

## Benefits of Custom Network Analysis and Intrusion Policies

You may find that the preprocessor options, intrusion rules, and other advanced settings configured in the system-provided network analysis and intrusion policies do not fully address the security needs of your organization.

Building custom policies can improve the performance of the system in your environment and can provide a focused view of the malicious traffic and policy violations occurring on your network. By creating and tuning custom policies you can configure, at a very granular level, how the system processes and inspects the traffic on your network for intrusions.

All custom policies have a base policy, also called a base layer, which defines the default settings for all configurations in the policy. A layer is a building block that you can use to efficiently manage multiple network analysis or intrusion policies.

In most cases, you base custom policies on system-provided policies, but you can use another custom policy. However, all custom policies have a system-provided policy as the eventual base in a policy chain. Because rule updates can modify system-provided policies, importing a rule update may affect you even if you are using a custom policy as your base. If a rule update affects your deployment, the web interface marks affected policies as out of date.

## Benefits of Custom Network Analysis Policies

By default, one network analysis policy preprocessors all unencrypted traffic handled by the access control policy. That means that all packets are decoded and preprocessed according to the same settings, regardless of the intrusion policy (and therefore intrusion rule set) that later examines them.

Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default. A simple way to tune preprocessing is to create and use a custom network analysis policy as the default.

Tuning options available vary by preprocessor, but some of the ways you can tune preprocessors and decoders include:

- You can disable preprocessors that do not apply to the traffic you are monitoring. For example, the HTTP Inspect preprocessor normalizes HTTP traffic. If you are confident that your network does not include any web servers using Microsoft Internet Information Services (IIS), you can disable the preprocessor option that looks for IIS-specific traffic and thereby reduce system processing overhead.

---

**Note** If you disable a preprocessor in a custom network analysis policy, but the system needs to use that preprocessor to later evaluate packets against an enabled intrusion or preprocessor rule, the system automatically enables and uses the preprocessor although the preprocessor remains disabled in the network analysis policy web interface.

---

- Specify ports, where appropriate, to focus the activity of certain preprocessors. For example, you can identify additional ports to monitor for DNS server responses or encrypted SSL sessions, or ports on which you decode telnet, HTTP, and RPC traffic.

For advanced users with complex deployments, you can create multiple network analysis policies, each tailored to preprocess traffic differently. Then, you can configure the system to use those policies to govern the preprocessing of traffic using different security zones, networks, or VLANs.

---

**Note** Tailoring preprocessing using custom network analysis policies—especially multiple network analysis policies—is an advanced task. Because preprocessing and intrusion inspection are so closely related, you **must** be careful to allow the network analysis and intrusion policies examining a single packet to complement each other.

---

## Benefits of Custom Intrusion Policies

In a newly created access control policy initially configured to perform intrusion prevention, the default action allows all traffic, but first inspects it with the system-provided Balanced Security and Connectivity intrusion policy. Unless you add access control rules or change the default action, all traffic is inspected by that intrusion policy.

To customize your intrusion prevention deployment, you can create multiple intrusion policies, each tailored to inspect traffic differently. Then, configure an access control policy with rules that specify which policy inspects which traffic. Access control rules can be simple or complex, matching and inspecting traffic using multiple criteria including security zone, network or geographical location, VLAN, port, application, requested URL, or user.

The main function of intrusion policies is to manage which intrusion and preprocessor rules are enabled and how they are configured, as follows:

- Within each intrusion policy, you should verify that all rules applicable to your environment are enabled, and improve performance by disabling rules that are not applicable to your environment. In an inline deployment, you can specify which rules should drop or modify malicious packets.
- Cisco recommendations allow you to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.
- You can modify existing rules and write new standard text rules as needed to catch new exploits or to enforce your security policies.

Other customizations you might make to an intrusion policy include:

- The sensitive data preprocessor detects sensitive data such as credit card numbers and Social Security numbers in ASCII text. Note that other preprocessors that detect specific threats (back orifice attacks,

several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic) are configured in network analysis policies.

- Global thresholds cause the system to generate events based on how many times traffic matching an intrusion rule originates from or is targeted to a specific address or address range within a specified time period. This helps prevent the system from being overwhelmed with a large number of events.
- Suppressing intrusion event notifications and setting thresholds for individual rules or entire intrusion policies can also prevent the system from being overwhelmed with a large number of events.
- In addition to the various views of intrusion events within the web interface, you can enable logging to syslog facilities or send event data to an SNMP trap server. Per policy, you can specify intrusion event notification limits, set up intrusion event notification to external logging facilities, and configure external responses to intrusion events. Note that in addition to these per-policy alerting configurations, you can globally enable or disable email alerting on intrusion events for each rule or rule group. Your email alert settings are used regardless of which intrusion policy processes a packet.

## Limitations of Custom Policies

Because preprocessing and intrusion inspection are so closely related, you **must** be careful that your configuration allows the network analysis and intrusion policies processing and examining a single packet to complement each other.

By default, the system uses one network analysis policy to preprocess all traffic handled by managed devices using a single access control policy. The following diagram shows how a newly created access control policy in an inline, intrusion-prevention deployment initially handles traffic. The preprocessing and intrusion prevention phases are highlighted.

**Figure 378: New Access Control Policy: Intrusion Prevention**

Notice how a default network analysis policy governs the preprocessing of *all* traffic handled by the access control policy. Initially, the system-provided Balanced Security and Connectivity network analysis policy is the default.

A simple way to tune preprocessing is to create and use a custom network analysis policy as the default. However, if you disable a preprocessor in a custom network analysis policy but the system needs to evaluate preprocessed packets against an enabled intrusion or preprocessor rule, the system automatically enables and uses the preprocessor although it remains disabled in the network analysis policy web interface.

**Note** In order to get the performance benefits of disabling a preprocessor, you **must** make sure that none of your intrusion policies have enabled rules that require that preprocessor.

An additional challenge arises if you use multiple custom network analysis policies. For advanced users with complex deployments, you can tailor preprocessing to specific security zones, networks, and VLANs by assigning custom network analysis policies to preprocess matching traffic. To accomplish this, you add custom *network analysis rules* to your access control policy. Each rule has an associated network analysis policy that governs the preprocessing of traffic that matches the rule.

**Tip** You configure network analysis rules as an advanced setting in an access control policy. Unlike other types of rules in the system, network analysis rules invoke—rather than being contained by—network analysis policies.

The system matches packets to any configured network analysis rules in top-down order by rule number. Traffic that does not match any network analysis rule is preprocessed by the default network analysis policy. While this allows you a great deal of flexibility in preprocessing traffic, keep in mind that all packets, **regardless** of which network analysis policy preprocessed them, are subsequently matched to access control rules—and thus to potential inspection by intrusion policies—in their own process. In other words, preprocessing a packet with a particular network analysis policy does **not** guarantee that the packet will be examined with any particular intrusion policy. You **must** carefully configure your access control policy so it invokes the correct network analysis and intrusion policies to evaluate a particular packet.

The following diagram shows in focused detail how the network analysis policy (preprocessing) selection phase occurs before and separately from the intrusion prevention (rules) phase. For simplicity, the diagram eliminates the discovery and file/malware inspection phases. It also highlights the default network analysis and default-action intrusion policies.

In this scenario, an access control policy is configured with two network analysis rules and a default network analysis policy:

- Network Analysis Rule A preprocesses matching traffic with Network Analysis Policy A. Later, you want this traffic to be inspected by Intrusion Policy A.
- Network Analysis Rule B preprocesses matching traffic with Network Analysis Policy B. Later, you want this traffic to be inspected by Intrusion Policy B.
- All remaining traffic is preprocessed with the default network analysis policy. Later, you want this traffic to be inspected by the intrusion policy associated with the access control policy's default action.

After the system preprocesses traffic, it can examine the traffic for intrusions. The diagram shows an access control policy with two access control rules and a default action:

- Access Control Rule A allows matching traffic. The traffic is then inspected by Intrusion Policy A.
- Access Control Rule B allows matching traffic. The traffic is then inspected by Intrusion Policy B.
- The access control policy's default action allows matching traffic. The traffic is then inspected by the default action's intrusion policy.

Each packet's handling is governed by a network analysis policy and intrusion policy pair, but the system does **not** coordinate the pair for you. Consider a scenario where you misconfigure your access control policy so that Network Analysis Rule A and Access Control Rule A do not process the same traffic. For example, you could intend the paired policies to govern the handling of traffic on a particular security zone, but you mistakenly use different zones in the two rules' conditions. This could cause traffic to be incorrectly preprocessed. For this reason, tailoring preprocessing using network analysis rules and custom policies is an **advanced** task.

Note that for a single connection, although the system selects a network analysis policy before an access control rule, some preprocessing (notably application layer preprocessing) occurs after access control rule selection. This does **not** affect how you configure preprocessing in custom network analysis policies.

## License Requirements for Network Analysis and Intrusion Policies

## The Navigation Panel: Network Analysis and Intrusion Policies

Network analysis and intrusion policies use similar web interfaces to edit and save changes to their configurations.

A navigation panel appears on the left side of the web interface when you are editing either type of policy. The following graphic shows the navigation panel for the network analysis policy (left) and the intrusion policy (right).

A dividing line separates the navigation panel into links to policy settings you can configure with (below) or without (above) direct interaction with policy layers. To navigate to any settings page, click its name in the navigation panel. Dark shading of an item in the navigation panel highlights your current settings page. For example, in the illustration above the Policy Information page would be displayed to the right of the navigation panel.

### Policy Information

The Policy Information page provides configuration options for commonly used settings. As shown in the illustration for the network analysis policy panel above, a **Policy Change icon** appears next to **Policy Information** in the navigation panel when the policy contains unsaved changes. The icon disappears when you save your changes.

### Rules (intrusion policy only)

The Rules page in an intrusion policy allows you to configure rule states and other settings for shared object rules, standard text rules, and preprocessor rules.

### Cisco Recommendations (intrusion policy only)

The Cisco Recommendations page in an intrusion policy allows you to associate the operating systems, servers, and client application protocols detected on your network with intrusion rules specifically written to protect those assets. This allows you to tailor your intrusion policy to the specific needs of your monitored network.

### Settings (network analysis policy) and Advanced Settings (intrusion policy)

The Settings page in a network analysis policy allows you to enable or disable preprocessors and access preprocessor configuration pages. Expanding the **Settings** link displays sublinks to individual configuration pages for all enabled preprocessors in the policy.

The Advanced Settings page in an intrusion policy allows you to enable or disable advanced settings and access configuration pages for those advanced settings. Expanding the **Advanced Settings** link displays sublinks to individual configuration pages for all enabled advanced settings in the policy.

### Policy Layers

The Policy Layers page displays a summary of the layers that comprise your network analysis or intrusion policy. Expanding the Policy Layers link displays sublinks to summary pages for the layers in your policy. Expanding each layer sublink displays further sublinks to the configuration pages for all rules, preprocessors, or advanced settings that are enabled in the layer.

## Conflicts and Changes: Network Analysis and Intrusion Policies

When you edit a network analysis or intrusion policy, a **Policy Change icon** appears next to **Policy Information** in the navigation panel to indicate that the policy contains unsaved changes. You must save (or *commit*) your changes before the system recognizes them.

---

**Note** After you save, you must deploy the network analysis or intrusion policy for your changes to take effect. If you deploy a policy without saving, the system uses the most recently saved configuration.

---

### Resolving Editing Conflicts

The Network Analysis Policy page (**Policies > Access Control**, then click **Network Analysis Policy or Policies > Access Control > Intrusion**, then click **Network Analysis Policies**) and Intrusion Policy page (**Policies > Access Control > Intrusion**) display whether each policy has unsaved changes, as well as information about who is currently editing the policy. Cisco recommends that only one person edit a policy at a time. If you are performing simultaneous editing, the consequences are as follows:

- If you are editing a network analysis or intrusion policy at the same time another user is editing the same policy, and the other user saves their changes to the policy, you are warned when you commit the policy that you will overwrite the other user's changes.
- If you are editing the same network analysis or intrusion policy via multiple web interface instances as the same user, and you save your changes for one instance, you cannot save your changes for the other instance.

### Resolving Configuration Dependencies

To perform their particular analysis, many preprocessors and intrusion rules require that traffic first be decoded or preprocessed in a certain way, or have other dependencies. When you save a network analysis or intrusion policy, the system either automatically enables required settings, or warns you that disabled settings will have no effect on traffic, as follows:

- You cannot save an intrusion policy if you added an SNMP rule alert but did not configure SNMP alerting. You must either configure SNMP alerting or disable the rule alert, then save again.
- You cannot save an intrusion policy if it includes enabled sensitive data rules but you have not enabled the sensitive data preprocessor. You must either allow the system to enable the preprocessor and save the policy, or disable the rules and save again.
- If you disable a required preprocessor in a network analysis policy, you can still save the policy. However, the system automatically uses the disabled preprocessor with its current settings, even though the preprocessor remains disabled in the web interface.

- If you disable inline mode in a network analysis policy but enable the Inline Normalization preprocessor, you can still save the policy. However, the system warns you that normalization settings will be ignored. Disabling inline mode also causes the system to ignore other settings that allow preprocessors to modify or block traffic, including checksum verification and rate-based attack prevention.

### Committing, Discarding, and Caching Policy Changes

While editing a network analysis or intrusion policy, if you exit the policy editor without saving your changes, the system caches those changes. Your changes are cached even when you log out of the system or experience a system crash. The system cache can store unsaved changes for one network analysis and one intrusion policy per user; you must commit or discard your changes before editing another policy of the same type. The system discards the cached changes when you edit another policy without saving your changes to the first policy, or when you import an intrusion rule update.

You can commit or discard policy changes on the Policy Information page of either the network analysis or intrusion policy editor.

In the Secure Firewall Management Center configuration, you can control:

- whether you are prompted (or required) to comment on your network analysis or intrusion policy changes when you commit them
- whether changes and comments are recorded in the audit log

## Exiting a Network Analysis or Intrusion Policy

### Procedure

---

If you want to exit the network analysis or intrusion policy advanced editor, you have the following choices:

- **Cache** — To exit the policy and cache changes, choose any menu or other path to another page. On exiting, click **Leave page** when prompted, or click **Stay on page** to remain in the advanced editor.
  - **Discard** — To discard unsaved changes, click **Discard Changes** on the Policy Information page, then click **OK**.
  - **Save** — To save changes to the policy, click **Commit Changes** on the Policy Information page. If prompted, enter a comment, and then click **OK**.
-

## CHAPTER 75

# Getting Started with Intrusion Policies

---

The following topics explain how to get started with intrusion policies:

- [Intrusion Policy Basics, on page 2061](#)
- [License Requirements for Intrusion Policies, on page 2062](#)
- [Requirements and Prerequisites for Intrusion Policies, on page 2063](#)
- [Managing Intrusion Policies, on page 2063](#)
- [Custom Intrusion Policy Creation, on page 2064](#)
- [Editing Snort 2 Intrusion Policies, on page 2065](#)
- [Access Control Rule Configuration to Perform Intrusion Prevention, on page 2066](#)
- [Drop Behavior in an Inline Deployment, on page 2067](#)
- [Drop Behavior in a Dual System Deployment, on page 2069](#)
- [Intrusion Policy Advanced Settings, on page 2069](#)
- [Optimizing Performance for Intrusion Detection and Prevention, on page 2070](#)

## Intrusion Policy Basics

*Intrusion policies* are defined sets of intrusion detection and prevention configurations that inspect traffic for security violations and, in inline deployments, can block or alter malicious traffic. Intrusion policies are invoked by your access control policy and are the system's last line of defense before traffic is allowed to its destination.

At the heart of each intrusion policy are the intrusion rules. An enabled rule causes the system to generate intrusion events for (and optionally block) traffic matching the rule. Disabling a rule stops processing of the rule.

The system delivers several base intrusion policies, which enable you to take advantage of the experience of the Talos Intelligence Group. For these policies, Talos sets intrusion and preprocessor rule states (enabled or disabled), as well as provides the initial configurations for other advanced settings.

---

**Tip** System-provided intrusion and network analysis policies are similarly named but contain different configurations. For example, the Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules.

---

If you create a custom intrusion policy, you can:

- Tune detection by enabling and disabling rules, as well as by writing and adding your own rules.
- Use Cisco recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets.
- Configure various advanced settings such as external alerting, sensitive data preprocessing, and global rule thresholding.
- Use layers as building blocks to efficiently manage multiple intrusion policies.

In an inline deployment, an intrusion policy can block and modify traffic:

- *Drop rules* can drop matching packets and generate intrusion events. To configure an intrusion or preprocessor drop rule, set its state to Drop and Generate Events.
- Intrusion rules can use the `replace` keyword to replace malicious content.

For intrusion rules to affect traffic, you must correctly configure drop rules and rules that replace content, as well as correctly deploy managed devices inline, that is, with inline interface sets. Finally, you must enable the intrusion policy's *drop behavior*, or **Drop when Inline** setting.

When tailoring your intrusion policy, especially when enabling and adding rules, keep in mind that some intrusion rules require that traffic first be decoded or preprocessed in a certain way. Before an intrusion policy examines a packet, the packet is preprocessed according to configurations in a network analysis policy. If you disable a required preprocessor, the system automatically uses it with its current settings, although the preprocessor remains disabled in the network analysis policy web interface.

---

**Caution** Because preprocessing and intrusion inspection are so closely related, the network analysis and intrusion policies examining a single packet **must** complement each other. Tailoring preprocessing, especially using multiple custom network analysis policies, is an **advanced** task.

---

After you configure a custom intrusion policy, you can use it as part of your access control configuration by associating the intrusion policy with one or more access control rules or an access control policy's default action. This forces the system to use the intrusion policy to examine certain allowed traffic before the traffic passes to its final destination. A variable set that you pair with the intrusion policy allows you to accurately reflect your home and external networks and, as appropriate, the servers on your network.

Note that by default, the system disables intrusion inspection of encrypted payloads. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has intrusion inspection configured.

# Managing Intrusion Policies

On the Intrusion Policy page (**Policies > Access Control > Intrusion**) you can view your current custom intrusion policies, along with the following information:

- the time and date the policy was last modified (in local time) and the user who modified it
- whether the **Drop when Inline** setting is enabled, which allows you to drop and modify traffic in an inline deployment. An inline deployment could be configurations that are deployed to devices using routed, switched, or transparent interfaces, or inline interface pairs.
- which access control policies and devices are using the intrusion policy to inspect traffic
- whether a policy has unsaved changes, as well as information about who (if anyone) is currently editing the policy

## Procedure

---

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Manage your intrusion policy:

- Compare—Click **Compare Policies**; see [Compare Policies](#).
- Create — Click **Create Policy**; see:
  - [Creating a Custom Snort 2 Intrusion Policy, on page 2064](#) for Snort 2 policies.
  - [Creating a Custom Snort 3 Intrusion Policy](#) topic in the latest version of the [Cisco Secure Firewall Management Center Snort 3 Configuration Guide](#) for Snort 3 policies.
- Delete — Click **Delete** (  ) next to the policy you want to delete. The system prompts you to confirm and informs you if another user has unsaved changes in the policy. Click **OK** to confirm.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Edit — Choose:
  - **Snort 2 Version**; see [Editing Snort 2 Intrusion Policies, on page 2065](#).
  - **Snort 3 Version**; see *Editing Snort 3 Intrusion Policies* topic in the latest version of the [Cisco Secure Firewall Management Center Snort 3 Configuration Guide](#).

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Export — If you want to export an intrusion policy to import on another Secure Firewall Management Center, click **YouTube EDU** (📺); see *Exporting Configurations* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- Deploy—Choose **Deploy > Deployment**; see [Deploy Configuration Changes, on page 240](#).
- Report—Click **Report** (📄); see [Generate Current Policy Reports, on page 253](#).

## Custom Intrusion Policy Creation

When you create a new intrusion policy you must give it a unique name, specify a base policy, and specify drop behavior.

The base policy defines the intrusion policy's default settings. Modifying a setting in the new policy overrides—but does not change—the settings in the base policy. You can use either a system-provided or custom policy as your base policy.

## Creating a Custom Snort 2 Intrusion Policy

### Procedure

- Step 1** Choose **Policies > Access Control > Intrusion**.
- Step 2** Click **Create Policy**. If you have unsaved changes in another policy, click **Cancel** when prompted to return to the Intrusion Policy page.  
Ensure the **Intrusion Policies** tab is selected.
- Step 3** Enter a unique **Name** and, optionally, a **Description**.
- Step 4** Choose the **Inspection Mode**.  
The selected action determines whether intrusion rules block and alert (**Prevention mode**) or only alert (**Detection mode**).
- Step 5** Choose the initial **Base Policy**.

You can use either a system-provided or another custom policy as your base policy.

**Step 6** Click **Save**.

The new policy has the same settings as its base policy.

---

### Related Topics

[Intrusion Rules in Layers](#), on page 2217

[Conflicts and Changes: Network Analysis and Intrusion Policies](#), on page 2059

## Editing Snort 2 Intrusion Policies

### Procedure

---

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Ensure the **Intrusion Policies** tab is selected.

**Step 3** Click **Snort 2 Version** next to the intrusion policy you want to configure.

**Step 4** Edit your policy:

- Change the base policy—Choose a base policy from the **Base Policy** drop-down list; see [Changing the Base Policy, on page 2213](#).
- Configure advanced settings—Click **Advanced Settings** in the navigation panel; see [Intrusion Policy Advanced Settings, on page 2069](#).
- Configure Cisco recommended intrusion rules—Click **Cisco Recommendations** in the navigation panel; see [Generating and Applying Cisco Recommendations, on page 2228](#).
- Drop behavior in an inline deployment—Check or clear **Drop when Inline**; see [Setting Drop Behavior in an Inline Deployment, on page 2068](#).
- Filter rules by recommended rule state—After you generate recommendations, click **View** next to each recommendation type. Click **View Recommended Changes** to view all recommendations.
- Filter rules by current rule state—Click **View** next to each rule state type (generate events, drop and generate events); see [Intrusion Rule Filters in an Intrusion Policy, on page 2078](#).
- Manage policy layers—Click **Policy Layers** in the navigation panel; see [Layer Management, on page 2214](#).
- Manage intrusion rules—Click **Manage Rules**; see [Viewing Intrusion Rules in an Intrusion Policy, on page 2073](#).
- View settings in base policy—Click **Manage Base Policy**; see [The Base Layer, on page 2211](#).

**Step 5** To save changes you made in this policy since the last policy commit, choose **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

**What to do next**

- Deploy configuration changes.

**Related Topics**

[Generating and Applying Cisco Recommendations](#), on page 2228

[Configuring Intrusion Rules in Layers](#), on page 2218

[Conflicts and Changes: Network Analysis and Intrusion Policies](#), on page 2059

## Intrusion Policy Changes

When you create a new intrusion policy, it has the same intrusion rule and advanced settings as its base policy.

The system caches one intrusion policy per user. While editing an intrusion policy, if you choose any menu or other path to another page, your changes stay in the system cache even if you leave the page.

# Access Control Rule Configuration to Perform Intrusion Prevention

An access control policy can have multiple access control rules associated with intrusion policies. You can configure intrusion inspection for any Allow or Interactive Block access control rule, which permits you to match different intrusion inspection profiles against different types of traffic on your network before it reaches its final destination.

Whenever the system uses an intrusion policy to evaluate traffic, it uses an associated *variable set*. Variables in a set represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions and dynamic rule states.

---

**Tip** Even if you use system-provided intrusion policies, Cisco **strongly** recommends you configure the system's intrusion variables to accurately reflect your network environment. At a minimum, modify default variables in the default set.

---

### Understanding System-Provided and Custom Intrusion Policies

Cisco delivers several intrusion policies with the system. By using system-provided intrusion policies, you can take advantage of the experience of the Talos Intelligence Group. For these policies, Talos sets intrusion and preprocessor rule states, as well as provides the initial configurations for advanced settings. You can use system-provided policies as-is, or you can use them as the base for custom policies. Building custom policies can improve the performance of the system in your environment and provide a focused view of the malicious traffic and policy violations occurring on your network.

### Connection and Intrusion Event Logging

When an intrusion policy invoked by an access control rule detects an intrusion and generates an intrusion event, it saves that event to the Secure Firewall Management Center. The system also automatically logs the end of the connection where the intrusion occurred to the Secure Firewall Management Center database, regardless of the logging configuration of the access control rule.

**Related Topics**

[Predefined Default Variables](#), on page 1543

## Access Control Rule Configuration and Intrusion Policies

The number of unique intrusion policies you can use in a single access control policy depends on the model of the target devices; more powerful devices can handle more. Every unique **pair** of intrusion policy and variable set counts as one policy. Although you can associate a different intrusion policy-variable set pair with each Allow and Interactive Block rule (as well as with the default action), you cannot deploy an access control policy if the target devices have insufficient resources to perform inspection as configured.

## Configuring an Access Control Rule to Perform Intrusion Prevention

You must be an Admin, Access Admin, or Network Admin to perform this task.

**Procedure**

- 
- Step 1** In the access control policy editor, create a new rule or edit an existing rule; see [Access Control Rule Components](#), on page 1856.
  - Step 2** Ensure the rule action is set to **Allow**, **Interactive Block**, or **Interactive Block with reset**.
  - Step 3** Click **Inspection**.
  - Step 4** Choose a system-provided or custom **Intrusion Policy**, or choose **None** to disable intrusion inspection for traffic that matches the access control rule.
  - Step 5** If you want to change the variable set associated with the intrusion policy, choose a value from the **Variable Set** drop-down list.
  - Step 6** Click **Save** to save the rule.
  - Step 7** Click **Save** to save the policy.
- 

**What to do next**

- Deploy configuration changes.

**Related Topics**

[Variable Set](#), on page 1541

[Snort Restart Scenarios](#), on page 232

## Drop Behavior in an Inline Deployment

If you want to assess how your configuration would function in an inline deployment (that is, where relevant configurations are deployed to devices using routed, switched, or transparent interfaces, or inline interface pairs) without actually affecting traffic, you can disable drop behavior. In this case, the system generates intrusion events but does not drop packets that trigger the drop rules. When you are satisfied with the results, you can enable drop behavior.

Note that in passive or inline deployments in tap mode, the system cannot affect traffic regardless of the drop behavior. In a passive deployment, rules set to **Drop and Generate Events** behave identically to rules set to **Generate Events**. The system generates intrusion events but cannot drop packets.

**Note** Suppose a file Block action causes a Block or Pending file policy verdict on a packet, and later, an IPS event is generated on the same packet. In that case, the IPS event is marked as Dropped instead of Would have dropped even if the IPS policy is in detection mode (IDS).

**Note** To block the transfer of malware over FTP, you must not only correctly configure malware defense, but also enable **Drop when Inline** in your access control policy's default intrusion policy.

When you view intrusion events, workflows can include the *inline result*, which indicates whether traffic was actually dropped, or whether it only would have dropped.

## Setting Drop Behavior in an Inline Deployment

### Procedure

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Set the policy's drop behavior:

- Check the **Drop when Inline** check box to allow intrusion rules to affect traffic and generate events.
- Clear the **Drop when Inline** check box to prevent intrusion rules from affecting traffic while still generating events.

**Step 4** Click **Commit Changes** to save changes you made in this policy since the last policy commit.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

### What to do next

- Deploy configuration changes.

## Drop Behavior in a Dual System Deployment

When there are two systems connected back to back in a network, it is normal to see the first system drop events and still record a drop or "would have dropped" event on the second system. The first system decides to drop the packets by the time it scans the last packet of the file, while the second system also investigates and identifies the traffic as "to be dropped".

For example, a 5 packet HTTP GET request whose first packet triggers a rule is blocked by the first system and only the last packet is dropped. The second system receives only 4 packets and the connection gets dropped, but when the second system finally flushes the partial GET request while it is pruning the session, it triggers the same rule with "would have dropped" as the inline result.

## Intrusion Policy Advanced Settings

An intrusion policy's *advanced settings* require specific expertise to configure. The base policy for your intrusion policy determines which advanced settings are enabled by default and the default configuration for each.

When you choose **Advanced Settings** in the navigation panel of an intrusion policy, the policy lists its advanced settings by type. On the Advanced Settings page, you can enable or disable advanced settings in your intrusion policy, as well as access advanced setting configuration pages. An advanced setting must be enabled for you to configure it.

When you disable an advanced setting, the sublink and **Edit** link no longer appear, but your configurations are retained. Note that some intrusion policy configurations (sensitive data rules, SNMP alerts for intrusion rules) require enabled and correctly configured advanced settings.

Modifying the configuration of an advanced setting requires an understanding of the configuration you are modifying and its potential impact on your network.

### Specific Threat Detection

The sensitive data preprocessor detects sensitive data such as credit card numbers and Social Security numbers in ASCII text.

Note that other preprocessors that detect specific threats (back orifice attacks, several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic) are configured in network analysis policies.

### Intrusion Rule Thresholds

Global rule thresholding can prevent your system from being overwhelmed with a large number of events by allowing you to use thresholds to limit the number of times the system logs and displays intrusion events.

### External Responses

In addition to the various views of intrusion events in the web interface, you can enable logging to system log (syslog) facilities or send event data to an SNMP trap server. Per policy, you can specify intrusion event notification limits, set up intrusion event notification to external logging facilities, and configure external responses to intrusion events.

Note that in addition to these per-policy alerting configurations, you can globally enable or disable email alerting on intrusion events for each rule or rule group. Your email alert settings are used regardless of which intrusion policy processes a packet.

**Related Topics**

- [Sensitive Data Detection Basics](#), on page 2231

# Optimizing Performance for Intrusion Detection and Prevention

If you want the system to perform intrusion detection and prevention but do not need to take advantage of discovery data, you can optimize performance by disabling new discovery as described below.

**Before you begin**

To perform this task, you must have one of the following user roles:

- Admin, Access Admin, or Network Admin for access control.
- Admin or Discovery Admin for network discovery.

**Procedure**

- 
- |               |                                                                                                                                                                                                                                                                                      |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Modify or delete rules associated with the access control policy deployed at the target device. None of the access control rules associated with that device can have user, application, or URL conditions; see <a href="#">Create and Edit Access Control Rules</a> , on page 1863. |
| <b>Step 2</b> | Delete all rules from the network discovery policy for the target device; see <a href="#">Configuring Network Discovery Rules</a> , on page 2682.                                                                                                                                    |
| <b>Step 3</b> | Deploy the changed configuration to the target device; see <a href="#">Deploy Configuration Changes</a> , on page 240.                                                                                                                                                               |
-

## CHAPTER 76

# Tuning Intrusion Policies Using Rules

The following topics explain how to use rules to tune intrusion policies:

- [Intrusion Rule Tuning Basics, on page 2071](#)
- [Intrusion Rule Types, on page 2071](#)
- [License Requirements for Intrusion Rules, on page 2072](#)
- [Requirements and Prerequisites for Intrusion Rules, on page 2073](#)
- [Viewing Intrusion Rules in an Intrusion Policy, on page 2073](#)
- [Intrusion Rule Filters in an Intrusion Policy, on page 2078](#)
- [Intrusion Rule States, on page 2085](#)
- [Intrusion Event Notification Filters in an Intrusion Policy, on page 2087](#)
- [Dynamic Intrusion Rule States, on page 2092](#)
- [Adding Intrusion Rule Comments, on page 2095](#)

## Intrusion Rule Tuning Basics

You can use the Rules page in an intrusion policy to configure rule states and other settings for shared object rules, standard text rules, and preprocessor rules.

You enable a rule by setting its rule state to Generate Events or to Drop and Generate Events. Enabling a rule causes the system to generate events on traffic matching the rule. Disabling a rule stops processing of the rule. You can also set your intrusion policy so that a rule set to Drop and Generate Events in an inline deployment generates events on, and drops, matching traffic. In a passive deployment, a rule set to Drop and Generate Events just generates events on matching traffic.

You can filter rules to display a subset of rules, enabling you to select the exact set of rules where you want to change rule states or rule settings.

When an intrusion rule or rule argument requires a disabled preprocessor, the system automatically uses it with its current configuration even though it remains disabled in the network analysis policy's web interface.

## Intrusion Rule Types

An intrusion rule is a specified set of keywords and arguments that the system uses to detect attempts to exploit vulnerabilities in your network. As the system analyzes network traffic, it compares packets against the conditions specified in each rule, and triggers the rule if the data packet meets all the conditions specified in the rule.

An intrusion policy contains:

- *intrusion rules*, which are subdivided into *shared object rules* and *standard text rules*
- *preprocessor rules*, which are associated with a detection option of the packet decoder or with one of the preprocessors included with the system

The following table summarizes attributes of these rule types:

**Table 122: Intrusion Rule Types**

Type	Generator ID (GID)	Snort ID (SID)	Source	Can Copy?	Can Edit?
shared object rule	3	lower than 1000000	Talos Intelligence Group	yes	limited
standard text rule	1 (Global domain or legacy GID)	lower than 1000000	Talos	yes	limited
	1000 - 2000 (descendant domain)	1000000 or higher	Created or imported by user	yes	yes
preprocessor rule	decoder- or preprocessor-specific	lower than 1000000	Talos	no	no
		1000000 or higher	Generated by the system during option configuration	no	no

You cannot save changes to any rule created by Talos, but you can save a copy of a modified rule as a custom rule. You can modify either variables used in the rule or rule header information (such as source and destination ports and IP addresses).

For the rules it creates, Talos assigns default rule states in each default intrusion policy. Most preprocessor rules are disabled by default and must be enabled if you want the system to generate events for preprocessor rules and, in an inline deployment, drop offending packets.

## Viewing Intrusion Rules in an Intrusion Policy

You can adjust how rules are displayed in the intrusion policy, and can sort rules by several criteria. You can also display the details for a specific rule to see rule settings, rule documentation, and other rule specifics.

### Procedure

---

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Click **Rules** under **Policy Information** in the navigation panel.

**Step 4** While viewing the rules, you can:

- Filter the rules as described in [Setting a Rule Filter in an Intrusion Policy, on page 2084](#).
  - Sort the rules by clicking the title in the top of the column you want to sort by.
  - View an intrusion rule's details as described in [Viewing Intrusion Rule Details, on page 2075](#).
  - View rules in different policy layers by choosing a layer from the **Policy** drop-down list.
- 

## Intrusion Rules Page Columns

The Intrusion Rules page uses the same icons in its menu bar and column headers. For example, the Rule State menu uses the same **Generate Events** as the Rule State column in the rule listing.

Table 123: Rules Page Columns

Heading	Description
GID	Integer that indicates the Generator ID (GID) for the rule.
SID	Integer that indicates the Snort ID (SID), which acts a unique identifier for the rule. For custom rules, the SID is 1000000 or higher.
Message	Message included in events generated by this rule, which also acts as the name of the rule.
Generate Events	The rule state for the rule: <ul style="list-style-type: none"> <li>• Drop and Generate Events</li> <li>• Generate Events</li> <li>• Disabled</li> </ul> <p>Note the icon for a disabled rule is a dimmed version of the icon for a rule that is set to generate events without dropping traffic. Also, clicking the rule state icon for a rule allows you to change the rule state.</p>
Cisco Recommended rule state	Cisco recommended rule state for the rule.
Event Filter	Event filter, including event thresholds and event suppression, applied to the rule.
Dynamic state	Dynamic rule state for the rule, which goes into effect if specified rate anomalies occur.
Errors (✖)	Alerts configured for the rule (currently SNMP alerts only).
Comment (🗨)	Comments added to the rule.

You can also use the layer drop-down list to switch to the Rules page for other layers in your policy. Note that, unless you add layers to your policy, the only editable views listed in the drop-down list are the policy Rules page and the Rules page for a policy layer that is originally named *My Changes*; note also that making changes in one of these views is the same as making the changes in the other. The drop-down list also lists the Rules page for the read-only base policy.

## Intrusion Rule Details

You can view rule documentation, Cisco recommendations, and rule overhead from the Rule Detail view. You can also view and add rule-specific features.

Table 124: Rule Details

Item	Description
Summary	The rule summary. For rule-based events, this row appears when the rule documentation contains summary information.
Rule State	The current rule state for the rule. Also indicates the layer where the rule state is set.

Item	Description
Cisco Recommendation	If Cisco recommendations have been generated, an icon that represents the recommended rule state; see <a href="#">Intrusion Rules Page Columns, on page 2073</a> . If the recommendation is to enable the rule, the system also indicates the network assets or configurations that triggered the recommendation.
Rule Overhead	The rule's potential impact on system performance and the likelihood that the rule might generate false positives. Local rules do not have an assigned overhead, unless they are mapped to a vulnerability.
Thresholds	Thresholds currently set for this rule, as well as the facility to add a threshold for the rule.
Suppressions	Suppression settings currently set for this rule, as well as the facility to add suppressions for the rule.
Dynamic State	Rate-based rule states currently set for this rule, as well as the facility to add dynamic rule states for the rule.
Alerts	SNMP alerts set for this rule, as well as the facility to add an alert for the rule.
Comments	Comments added to this rule, as well as the facility to add comments for the rule.
Documentation	The rule documentation for the current rule, supplied by the Talos Intelligence Group. Optionally, click <b>Rule Documentation</b> to view more-specific rule details.

## Viewing Intrusion Rule Details

### Procedure

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** On the navigation pane, click **Rules**.

**Step 4** Click the rule whose rule details you want to view, then click **Show details** at the bottom of the page. Rule details appear, as described in [Intrusion Rule Details, on page 2074](#).

**Step 5** From the rule details, you can configure:

- Alerts—See [Setting an SNMP Alert for an Intrusion Rule, on page 2078](#).
- Comments—See [Adding a Comment to an Intrusion Rule, on page 2078](#).
- Dynamic rule states—See [Setting a Dynamic Rule State from the Rule Details Page, on page 2077](#).
- Thresholds—See [Setting a Threshold for an Intrusion Rule, on page 2076](#).
- Suppressions—See [Setting Suppression for an Intrusion Rule, on page 2076](#).

## Setting a Threshold for an Intrusion Rule

You can set a single threshold for a rule from the Rule Detail page. Adding a threshold overwrites any existing threshold for the rule.

Note that a **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

### Procedure

- 
- Step 1** From an intrusion rule's details, click **Add** next to **Thresholds**.
- Step 2** From the **Type** drop-down list, choose the type of threshold you want to set:
- Choose **Limit** to limit notification to the specified number of event instances per time period.
  - Choose **Threshold** to provide notification for each specified number of event instances per time period.
  - Choose **Both** to provide notification once per time period after a specified number of event instances.
- Step 3** From the **Track By** drop-down list, choose **Source** or **Destination** to indicate whether you want the event instances tracked by source or destination IP address.
- Step 4** In the **Count** field, enter the number of event instances you want to use as your threshold.
- Step 5** In the **Seconds** field, enter a number that specifies the time period, in seconds, for which event instances are tracked.
- Step 6** Click **OK**.
- Tip** The system displays an **Event Filter** next to the rule in the Event Filtering column. If you add multiple event filters to a rule, the system includes an indication of the number of event filters.
- 

## Setting Suppression for an Intrusion Rule

You can set one or more suppressions for a rule in your intrusion policy.

Note that a **Revert** appears in a field when you type an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

### Procedure

- 
- Step 1** From an intrusion rule's details, click **Add** next to **Suppressions**.
- Step 2** From the **Suppression Type** drop-down list, choose one of the following options:
- Choose **Rule** to completely suppress events for a selected rule.
  - Choose **Source** to suppress events generated by packets originating from a specified source IP address.
  - Choose **Destination** to suppress events generated by packets going to a specified destination IP address.
- Step 3** If you chose **Source** or **Destination** for the suppression type, in the **Network** field enter the IP address, an address block, or a comma-separated list comprised of any combination of these.

If the intrusion policy is associated with the default action of an access control policy, you can also specify or list a network variable in the default action variable set.

**Step 4** Click **OK**.

**Tip** The system displays an **Event Filter** next to the rule in the Event Filtering column next to the suppressed rule. If you add multiple event filters to a rule, a number over the filter indicates the number of filters.

---

## Setting a Dynamic Rule State from the Rule Details Page

You can set one or more dynamic rule states for a rule. The first dynamic rule state listed has the highest priority. When two dynamic rule states conflict, the action of the first is carried out.

Dynamic rule states are policy-specific.

Note that a **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

### Procedure

---

**Step 1** From an intrusion rule's details, click **Add** next to **Dynamic State**.

**Step 2** From the **Track By** drop-down list, choose an option to indicate how you want the rule matches tracked:

- Choose **Source** to track the number of hits for that rule from a specific source or set of sources.
- Choose **Destination** to track the number of hits for that rule to a specific destination or set of destinations.
- Choose **Rule** to track all matches for that rule.

**Step 3** If you set **Track By** to **Source** or **Destination**, enter the IP address of each host you want to track in the **Network** field.

**Step 4** Next to **Rate**, specify the number of rule matches per time period to set the attack rate:

- In the **Count** field, specify the number of rule matches you want to use as your threshold.
- In the **Seconds** field, specify the number of seconds that make up the time period for which attacks are tracked.

**Step 5** From the **New State** drop-down list, choose the new action to be taken when the conditions are met.

**Step 6** Enter a value in the **Timeout** field.

After the timeout occurs, the rule reverts to its original state. Enter 0 to prevent the new action from timing out.

**Step 7** Click **OK**.

**Tip** The system displays a dynamic state (🔍) next to the rule in the Dynamic State column. If you add multiple dynamic rule state filters to a rule, a number over the filters indicates the number of filters.

## Setting an SNMP Alert for an Intrusion Rule

You can set an SNMP alert for a rule from the Rule Detail page.

### Procedure

---

From an intrusion rule's details, click **Add SNMP Alert** next to **Alerts**.

**Tip** The system displays an alert **Errors** (✖) next to the rule in the Alerting column. If you add multiple alerts to a rule, the system includes an indication of the number of alerts.

---

## Adding a Comment to an Intrusion Rule

### Procedure

---

**Step 1** From an intrusion rule's details, click **Add** next to **Comments**.

**Step 2** In the **Comment** field, enter the rule comment.

**Step 3** Click **OK**.

**Tip** The system displays a **Comment** (🗨) next to the rule in the Comments column. If you add multiple comments to a rule, a number over the comment indicates the number of comments.

**Step 4** To delete a rule comment, click **Delete** in the rule comments section. You can only delete a comment if the comment is cached with uncommitted intrusion policy changes.

---

### What to do next

- Deploy configuration changes.

## Intrusion Rule Filters in an Intrusion Policy

You can filter the rules you display on the Rules page by a single criteria, or a combination of one or more criteria.

Rule filter keywords help you find the rules for which you want to apply rule settings, such as rule states or event filters. You can filter by a keyword and simultaneously select the argument for the keyword by selecting the argument you want from the Rules page filter panel.

## Intrusion Rule Filters Notes

The filter you construct is shown in the Filter text box. You can click keywords and keyword arguments in the filter panel to construct a filter. When you choose multiple keywords, the system combines them using AND logic to create a compound search filter. For example, if you choose **preprocessor** under **Category** and then choose **Rule Content > GID** and enter 116, you get a filter of `Category: "preprocessor" GID: "116"`, which retrieves all rules that are preprocessor rules **and** have a GID of 116.

The Category, Microsoft Vulnerabilities, Microsoft Worms, Platform Specific, Preprocessor, and Priority filter groups allow you to submit more than one argument for a keyword, separated by commas. For example, you can choose **os-linux** and **os-windows** from **Category** to produce the filter

`Category: "os-windows, os-linux"`, which retrieves any rules in the `os-linux` category or in the `os-windows` category.

To show the filter panel, click the **Show icon**.

To hide the filter panel, click the **Hide icon**.

## Intrusion Policy Rule Filters Construction Guidelines

In most cases, when you are building a filter, you can use the filter panel to the left of the Rules page in the intrusion policy to choose the keywords/arguments you want to use.

Rule filters are grouped into rule filter groups in the filter panel. Many rule filter groups contain sub-criteria so that you can more easily find the specific rules you are looking for. Some rule filters have multiple levels that you can expand to drill down to individual rules.

Items in the filter panel sometimes represent filter type groups, sometimes represent keywords, and sometimes represent the argument to a keyword. Note the following:

- When you choose a filter type group heading that is not a keyword (Rule Configuration, Rule Content, Platform Specific, and Priority), it expands to list the available keywords.

When you choose a keyword by clicking on a node in the criteria list, a pop-up window appears, where you supply the argument you want to filter by.

If that keyword is already used in the filter, the argument you supply replaces the existing argument for that keyword.

For example, if you click **Drop and Generate Events** under **Rule Configuration > Recommendation** in the filter panel, `Recommendation: "Drop and Generate Events"` is added to the filter text box. If you then click **Generate Events** under **Rule Configuration > Recommendation**, the filter changes to `Recommendation: "Generate Events"`.

- When you choose a filter type group heading that is a keyword (Category, Classifications, Microsoft Vulnerabilities, Microsoft Worms, Priority, and Rule Update), it lists the available arguments.

When you choose an item from this type of group, the argument and the keyword it applies to are immediately added to the filter. If the keyword is already in the filter, it replaces the existing argument for the keyword that corresponds to that group.

For example, if you click **os-linux** under **Category** in the filter panel, `Category: "os-linux"` is added to the filter text box. If you then click **os-windows** under **Category**, the filter changes to `Category: "os-windows"`.

- Reference under Rule Content is a keyword, and so are the specific reference ID types listed below it. When you choose any of the reference keywords, a pop-up window appears, where you supply an

argument and the keyword is added to the existing filter. If the keyword is already in use in the filter, the new argument you supply replaces the existing argument.

For example, if you click **Rule Content** > **Reference** > **CVE ID** in the filter panel, a pop-up window prompts you to supply the CVE ID. If you enter 2007, then `CVE:"2007"` is added to the filter text box. In another example, if you click **Rule Content** > **Reference** in the filter panel, a pop-up window prompts you to supply the reference. If you enter 2007, then `Reference:"2007"` is added to the filter text box.

- When you choose rule filter keywords from different groups, each filter keyword is added to the filter and any existing keywords are maintained (unless overridden by a new value for the same keyword).

For example, if you click **os-linux** under **Category** in the filter panel, `Category:"os-linux"` is added to the filter text box. If you then click **MS00-006** under **Microsoft Vulnerabilities**, the filter changes to `Category:"os-linux" MicrosoftVulnerabilities:"MS00-006"`.

- When you choose multiple keywords, the system combines them using AND logic to create a compound search filter. For example, if you choose **preprocessor** under **Category** and then choose **Rule Content** > **GID** and enter 116, you get a filter of `Category: "preprocessor" GID:"116"`, which retrieves all rules that are preprocessor rules **and** have a GID of 116.
- The Category, Microsoft Vulnerabilities, Microsoft Worms, Platform Specific, and Priority filter groups allow you to submit more than one argument for a keyword, separated by commas. For example, you can choose **os-linux** and **os-windows** from **Category** to produce the filter `Category:"os-windows, app-detect"`, which retrieves any rules in the `os-linux` category or in the `os-windows` category.

The same rule may be retrieved by more than one filter keyword/argument pair. For example, the DOS Cisco attempt rule (SID 1545) appears if rules are filtered by the **dos** category, and also if you filter by the **High** priority.

**Note** The Talos Intelligence Group may use the rule update mechanism to add and remove rule filters.

Note that the rules on the Rules page may be either shared object rules (generator ID 3) or standard text rules (generator ID 1, Global domain or legacy GID; 1000 - 2000, descendant domains). The following table describes the different rule filters.

**Table 125: Rule Filter Groups**

Filter Group	Description	Multiple Argument Support?	Heading is...	Items in List are...
Rule Configuration	Finds rules according to the configuration of the rule.	No	A grouping	keywords
Rule Content	Finds rules according to the content of the rule.	No	A grouping	keywords
Category	Finds rules according to the rule categories used by the rule editor. Note that local rules appear in the local sub-group.	Yes	A keyword	arguments
Classifications	Finds rules according to the attack classification that appears in the packet display of an event generated by the rule.	No	A keyword	arguments

Filter Group	Description	Multiple Argument Support?	Heading is...	Items in List are...
Microsoft Vulnerabilities	Finds rules according to Microsoft bulletin number.	Yes	A keyword	arguments
Microsoft Worms	Finds rules based on specific worms that affect Microsoft Windows hosts.	Yes	A keyword	arguments
Platform Specific	Finds rules according to their relevance to specific versions of operating systems.  Note that a rule may affect more than one operating system or more than one version of an operating system. For example, enabling SID 2260 affects multiple versions of Mac OS X, IBM AIX, and other operating systems.	Yes	A keyword	arguments  Note that if you pick one of the items from the sub-list, it adds a modifier to the argument.
Preprocessors	Finds rules for individual preprocessors.  Note that you must enable preprocessor rules associated with a preprocessor option to generate events and, in an inline deployment, drop offending packets for the option when the preprocessor is enabled.	Yes	A grouping	sub-groupings
Priority	Finds rules according to high, medium, and low priorities.  The classification assigned to a rule determines its priority. These groups are further grouped into rule categories. Note that local rules (that is, rules that you import or create) do not appear in the priority groups.	Yes	A keyword	arguments  Note that if you pick one of the items from the sub-list, it adds a modifier to the argument.
Rule Update	Finds rules added or modified through a specific rule update. For each rule update, view all rules in the update, only new rules imported in the update, or only existing rules changed by the update.	No	A keyword	arguments

## Intrusion Rule Configuration Filters

You can filter the rules listed in the Rules page by several rule configuration settings. For example, if you want to view the set of rules whose rule state does not match the recommended rule state, you can filter on rule state by selecting **Does not match recommendation**.

When you choose a keyword by clicking on a node in the criteria list, you can supply the argument you want to filter by. If that keyword is already used in the filter, the argument you supply replaces the existing argument for that keyword.

For example, if you click **Drop and Generate Events** under **Rule Configuration > Recommendation** in the filter panel, `Recommendation:"Drop and Generate Events"` is added to the filter text box. If you then click **Generate Events** under **Rule Configuration > Recommendation**, the filter changes to `Recommendation:"Generate Events"`.

## Intrusion Rule Content Filters

You can filter the rules listed in the Rules page by several rule content items. For example, you can quickly retrieve a rule by searching for the rule's SID. You can also find all rules that inspect traffic going to a specific destination port.

When you select a keyword by clicking on a node in the criteria list, you can supply the argument you want to filter by. If that keyword is already used in the filter, the argument you supply replaces the existing argument for that keyword.

For example, if you click **SID** under **Rule Content** in the filter panel, a pop-up window appears, prompting you to supply a SID. If you type 1045, then `SID:"1045"` is added to the filter text box. If you then click **SID** again and change the SID filter to 1044, the filter changes to `SID:"1044"`.

**Table 126: Rule Content Filters**

This filter...	Finds rules that...
Message	contain the supplied string in the message field.
SID	have the specified SID.
GID	have the specified GID.
Reference	contain the supplied string in the reference field. You can also filter by a specific type of reference and supplied string.
Action	start with <code>alert</code> or <code>pass</code> .
Protocol	include the selected protocol.
Direction	are based on whether the rule includes the indicated directional setting.
Source IP	use the specified addresses or variables for the source IP address designation in the rule. You can filter by a valid IP address, a CIDR block/prefix length, or using variables such as <code>\$HOME_NET</code> or <code>\$EXTERNAL_NET</code> .
Destination IP	use the specified addresses or variables for the source IP address designation in the rule. You can filter by a valid IP address, a CIDR block/prefix length, or using variables such as <code>\$HOME_NET</code> or <code>\$EXTERNAL_NET</code> .
Source port	include the specified source port. The port value must be an integer between 1 and 65535 or a port variable.
Destination port	include the specified destination port. The port value must be an integer between 1 and 65535 or a port variable.
Rule Overhead	have the selected rule overhead.
Metadata	have metadata containing the matching <i>key value</i> pair. For example, type <code>metadata:"service http"</code> to locate rules with metadata relating to the HTTP application protocol.

## Intrusion Rule Categories

The system places rules in categories based on the type of traffic the rule detects. On the Rules page, you can filter by rule category, so you can set a rule attribute for all rules in a category. For example, if you do not have Linux hosts on your network, you could filter by the **os-linux** category, then disable all the rules showing to disable the entire **os-linux** category.

You can hover your pointer over a category name to display the number of rules in that category.

---

**Note** The Talos Intelligence Group may use the rule update mechanism to add and remove rule categories.

---

## Intrusion Rule Filter Components

You can edit your filter to modify the special keywords and their arguments that are supplied when you click on a filter in the filter panel. Custom filters on the Rules page function like those used in the rule editor, but you can also use any of the keywords supplied in the Rules page filter, using the syntax displayed when you select the filter through the filter panel. To determine a keyword for future use, click on the appropriate argument in the filter panel on the right. The filter keyword and argument syntax appear in the filter text box. Remember that comma-separated multiple arguments for a keyword are only supported for the Category and Priority filter types.

You can use keywords and arguments, character strings, and literal character strings in quotes, with spaces separating multiple filter conditions. A filter cannot include regular expressions, wild card characters, or any special operator such as a negation character (!), a greater than symbol (>), less than symbol (<), and so on. When you type in search terms without a keyword, without initial capitalization of the keyword, or without quotes around the argument, the search is treated as a string search and the category, message, and SID fields are searched for the specified terms.

Except for the `gid` and `sid` keywords, all arguments and strings are treated as partial strings. Arguments for `gid` and `sid` return only exact matches.

Each rule filter can include one or more keywords in the format:

```
keyword:"argument"
```

where `keyword` is one of the keywords in the intrusion rule filter groups and `argument` is enclosed in double quotes and is a single, case-insensitive, alphanumeric string to search for in the specific field or fields relevant to the keyword. Note that keywords should be typed with initial capitalization.

Arguments for all keywords except `gid` and `sid` are treated as partial strings. For example, the argument `123` returns `"12345"`, `"41235"`, `"45123"`, and so on. The arguments for `gid` and `sid` return only exact matches; for example, `sid:3080` returns only `SID 3080`.

Each rule filter can also include one or more alphanumeric character strings. Character strings search the rule Message field, Snort ID (SID), and Generator ID (GID). For example, the string `123` returns the strings `"Lotus123"`, `"123mania"`, and so on in the rule message, and also returns `SID 6123`, `SID 12375`, and so on. You can search for a partial SID by filtering with one or more character strings.

All character strings are case-insensitive and are treated as partial strings. For example, any of the strings `ADMIN`, `admin`, or `Admin` return `"admin"`, `"CFADMIN"`, `"Administrator"` and so on.

You can enclose character strings in quotes to return exact matches. For example, the literal string `"overflow attempt"` in quotes returns only that exact string, whereas a filter comprised of the two strings `overflow` and

attempt without quotes returns "overflow attempt", "overflow multipacket attempt", "overflow with evasion attempt", and so on.

You can narrow filter results by entering any combination of keywords, character strings, or both, separated by spaces. The result includes any rule that matches all the filter conditions.

You can enter multiple filter conditions in any order. For example, each of the following filters returns the same rules:

- url:at login attempt cve:200
- login attempt cve:200 url:at
- login cve:200 attempt url:at

## Intrusion Rule Filter Usage

You can select predefined filter keywords from the filter panel on the left side of the Rules page in the intrusion policy. When you select a filter, the page displays all matching rules, or indicates when no rules match.

You can add keywords to a filter to further constrain it. Any filter you enter searches the entire rules database and returns all matching rules. When you enter a filter while the page still displays the result of a previous filter, the page clears and returns the result of the new filter instead.

You can also type a filter using the same keyword and argument syntax supplied when you select a filter, or modify argument values in a filter after you select it. When you type in search terms without a keyword, without initial capitalization of the keyword, or without quotes around the argument, the search is treated as a string search and the category, message, and SID fields are searched for the specified terms.

## Setting a Rule Filter in an Intrusion Policy

You can filter the rules on the Rules page to display a subset of rules. You can then use any of the page features, including choosing any of the features available in the context menu. This can be useful, for example, when you want to set a threshold for all the rules in a specific category. You can use the same features with rules in a filtered or unfiltered list. For example, you can apply new rule states to rules in a filtered or unfiltered list.

All filter keywords, keyword arguments, and character strings are case-insensitive. If you click an argument for a keyword already in the filter, it replaces the existing argument.

### Procedure

---

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Construct a filter using any of the following methods, separately or in combination:

- Enter a value in the **Filter** text box, and press Enter.
- Expand any of the predefined keywords. For example, click **Rule Configuration**.

- Click a keyword, and specify an argument value if prompted. For example:
    - Under **Rule Configuration**, you could click **Rule State**, choose `Generate Events` from the drop-down-list, and click **OK**.
    - Under **Rule Configuration**, you could click **Comment**, enter the string of comment text to filter by, and click **OK**.
    - Under **Category**, you could click **app-detect**, which the system uses as the argument value.
  - Expand a keyword, and click an argument value. For example, expand **Rule State** and click **Generate Events**.
- 

## Intrusion Rule States

Intrusion rule states allow you to enable or disable the rule within an individual intrusion policy, as well as specify which action the system takes if monitored conditions trigger the rule.

The Talos Intelligence Group sets the default state of each intrusion and preprocessor rule in each default policy. For example, a rule may be enabled in the Security over Connectivity default policy and disabled in the Connectivity over Security default policy. Talos sometimes uses a rule update to change the default state of one or more rules in a default policy. If you allow rule updates to update your base policy, you also allow the rule update to change the default state of a rule in your policy when the default state changes in the default policy you used to create your policy (or in the default policy it is based on). Note, however, that if you have changed the rule state, the rule update does not override your change.

When you create an intrusion rule, it inherits the default states of the rules in the default policy you use to create your policy.

## Intrusion Rule State Options

In an intrusion policy, you can set a rule's state to the following values:

### Generate Events

You want the system to detect a specific intrusion attempt and generate an intrusion event when it finds matching traffic. When a malicious packet crosses your network and triggers the rule, the packet is sent to its destination and the system generates an intrusion event. The malicious packet reaches its target, but you are notified via the event logging.

### Drop and Generate Events

You want the system to detect a specific intrusion attempt, drop the packet containing the attack, and generate an intrusion event when it finds matching traffic. The malicious packet never reaches its target, and you are notified via the event logging.

Note that rules set to this rule state generate events but do not drop packets in a passive deployment. For the system to drop packets, **Drop when Inline** must also be enabled (the default setting) in your intrusion policy and you must deploy your device inline.

### Disable

You do not want the system to evaluate matching traffic.

**Note** Choosing either the **Generate Events** or **Drop and Generate Events** options enables the rule. Choosing **Disable** disables the rule.

Cisco **strongly** recommends that you **do not** enable all the intrusion rules in an intrusion policy. The performance of your managed device is likely to degrade if all rules are enabled. Instead, tune your rule set to match your network environment as closely as possible.

## Setting Intrusion Rule States

Intrusion rule states are policy-specific.

### Procedure

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Tip** This page indicates the total number of enabled rules, the total number of enabled rules set to Generate Events, and the total number set to Drop and Generate Events. Note also that in a passive deployment, rules set to Drop and Generate Events only generate events.

**Step 3** Click **Rules** immediately under **Policy Information** in the navigation panel.

**Step 4** Choose the rule or rules where you want to set the rule state.

**Step 5** Choose one of the following:

- **Rule State > Generate Events**
- **Rule State > Drop and Generate Events**
- **Rule State > Disable**

**Step 6** To save changes you made in this policy since the last policy commit, click **Policy Information** in the navigation panel, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

### What to do next

- Deploy configuration changes.

# Intrusion Event Notification Filters in an Intrusion Policy

The importance of an intrusion event can be based on frequency of occurrence, or on source or destination IP address. In some cases you may not care about an event until it has occurred a certain number of times. For example, you may not be concerned if someone attempts to log into a server until they fail a certain number of times. In other cases, you may only need to see a few occurrences to know there is a widespread problem. For example, if a DoS attack is launched against your web server, you may only need to see a few occurrences of an intrusion event to know that you need to address the situation. Seeing hundreds of the same event only overwhelms your system.

## Intrusion Event Thresholds

You can set thresholds for individual rules, per intrusion policy, to limit the number of times the system logs and displays an intrusion event based on how many times the event is generated within a specified time period. This can prevent you from being overwhelmed with a large number of identical events. You can set thresholds per shared object rule, standard text rule, or preprocessor rule.

## Intrusion Event Thresholds Configuration

To set a threshold, first specify the thresholding type.

**Table 127: Thresholding Options**

Option	Description
Limit	Logs and displays events for the specified number of packets (specified by the <b>Count</b> argument) that trigger the rule during the specified time period. For example, if you set the type to <b>Limit</b> , the <b>Count</b> to 10, and the <b>Seconds</b> to 60, and 14 packets trigger the rule, the system stops logging events for the rule after displaying the first 10 that occur within the same minute.
Threshold	Logs and displays a single event when the specified number of packets (specified by the <b>Count</b> argument) trigger the rule during the specified time period. Note that the counter for the time restarts after you hit the threshold count of events and the system logs that event. For example, you set the type to <b>Threshold</b> , <b>Count</b> to 10, and <b>Seconds</b> to 60, and the rule triggers 10 times by second 33. The system generates one event, then resets the <b>Seconds</b> and <b>Count</b> counters to 0. The rule then triggers another 10 times in the next 25 seconds. Because the counters reset to 0 at second 33, the system logs another event.
Both	Logs and displays an event once per specified time period, after the specified number (count) of packets trigger the rule. For example, if you set the type to <b>Both</b> , <b>Count</b> to two, and <b>Seconds</b> to 10, the following event counts result: <ul style="list-style-type: none"> <li>• If the rule is triggered once in 10 seconds, the system does not generate any events (the threshold is not met)</li> <li>• If the rule is triggered twice in 10 seconds, the system generates one event (the threshold is met when the rule triggers the second time)</li> <li>• If the rule is triggered four times in 10 seconds, the system generates one event (the threshold is met when the rule triggers the second time, and following events are ignored)</li> </ul>

Next, specify tracking, which determines whether the event threshold is calculated per source or destination IP address.

**Table 128: Thresholding IP Options**

Option	Description
Source	Calculates event instance count per source IP address.
Destination	Calculates event instance count per destination IP address.

Finally, specify the number of instances and time period that define the threshold.

**Table 129: Thresholding Instance/Time Options**

Option	Description
Count	The number of event instances per specified time period per tracking IP address required to meet the threshold.
Seconds	The number of seconds that elapse before the count resets. If you set the threshold type to <b>limit</b> , the tracking to <b>Source IP</b> , the <b>count</b> to 10, and the <b>seconds</b> to 10, the system logs and displays the first 10 events that occur in 10 seconds from a given source port. If only 7 events occur in the first 10 seconds, the system logs and displays those; if 40 events occur in the first 10 seconds, the system logs and displays 10, then begins counting again when the 10-second time period elapses.

Note that you can use intrusion event thresholding alone or in any combination with rate-based attack prevention, the `detection_filter` keyword, and intrusion event suppression.

---

**Tip** You can also add thresholds from within the packet view of an intrusion event.

---

#### Related Topics

[The `detection\_filter` Keyword](#), on page 2194

## Adding and Modifying Intrusion Event Thresholds

You can set a threshold for one or more specific rules in an intrusion policy. You can also separately or simultaneously modify existing threshold settings. You can set a single threshold for each. Adding a threshold overwrites any existing threshold for the rule.

You can also modify the global threshold that applies by default to all rules and preprocessor-generated events associated with the intrusion policy.

A **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

---

**Tip** A global or individual threshold on a managed device with multiple CPUs may result in a higher number of events than expected.

---

## Procedure

- 
- Step 1** Choose **Policies > Access Control > Intrusion**.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 3** Click **Rules** immediately under **Policy Information** in the navigation pane.
- Step 4** Choose the rule or rules where you want to set a threshold.
- Step 5** Choose **Event Filtering > Threshold**.
- Step 6** Choose a threshold type from the **Type** drop-down list.
- Step 7** From the **Track By** drop-down list, choose whether you want the event instances tracked by **Source** or **Destination** IP address.
- Step 8** Enter a value in the **Count** field.
- Step 9** Enter a value in the **Seconds** field.
- Step 10** Click **OK**.
- Tip** The system displays an **Event Filter** next to the rule in the Event Filtering column. If you add multiple event filters to a rule, a number over the filter indicates the number of event filters.
- Step 11** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- Deploy configuration changes.

### Related Topics

[Global Rule Thresholding Basics](#), on page 2243

## Viewing and Deleting Intrusion Event Thresholds

You may want to view or delete an existing threshold setting for a rule. You can use the Rules Details view to display the configured settings for a threshold to see if they are appropriate for your system. If they are not, you can add a new threshold to overwrite the existing values.

Note that you can also modify the global threshold that applies by default to all rules and preprocessor-generated events logged by the intrusion policy.

## Procedure

- 
- Step 1** Choose **Policies > Access Control > Intrusion**.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 3** Click **Rules** immediately under **Policy Information** in the navigation pane.
- Step 4** Choose the rule or rules with a configured threshold you want to view or delete.
- Step 5** To remove the threshold for each selected rule, choose **Event Filtering > Remove Thresholds**.
- Step 6** Click **OK**.
- Step 7** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- Deploy configuration changes.

### Related Topics

[Global Rule Thresholding Basics](#), on page 2243

## Intrusion Policy Suppression Configuration

You can suppress intrusion event notification when a specific IP address or range of IP addresses triggers a specific rule or preprocessor. This is useful for eliminating false positives. For example, if you have a mail server that transmits packets that look like a specific exploit, you might suppress event notification for that event when it is triggered by your mail server. The rule triggers for all packets, but you only see events for legitimate attacks.

## Intrusion Policy Suppression Types

Note that you can use intrusion event suppression alone or in any combination with rate-based attack prevention, the `detection_filter` keyword, and intrusion event thresholding.

---

**Tip** You can add suppressions from within the packet view of an intrusion event. You can also access suppression settings by using the right-click context menu on the intrusion rules editor page (**Objects > Intrusion Rules**) and on any intrusion event page (if the event was triggered by an intrusion rule).

---

### Related Topics

[The `detection\_filter` Keyword](#), on page 2194

## Suppressing Intrusion Events for a Specific Rule

You can suppress intrusion event notification for a rule or rules in your intrusion policy. When notification is suppressed for a rule, the rule triggers but events are not generated. You can set one or more suppressions for a rule. The first suppression listed has the highest priority. When two suppressions conflict, the action of the first is carried out.

Note that a **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

### Procedure

- 
- Step 1** Choose **Policies > Access Control > Intrusion**.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 3** Click **Rules** immediately under **Policy Information** in the navigation panel.
- Step 4** Choose the rule or rules for which you want to configure suppression conditions.
- Step 5** Choose **Event Filtering > Suppression**.
- Step 6** Choose a **Suppression Type**.
- Step 7** If you chose **Source** or **Destination** for the suppression type, in the **Network** field enter the IP address, address block, or variable you want to specify as the source or destination IP address, or a comma-separated list comprised of any combination of these.
- Step 8** Click **OK**.
- Tip** The system displays an **Event Filter** next to the rule in the Event Filtering column next the suppressed rule. If you add multiple event filters to a rule, a number over the filter indicates the number of event filters.
- Step 9** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
- 

### What to do next

- Deploy configuration changes.

## Viewing and Deleting Suppression Conditions

You may want to view or delete an existing suppression condition. For example, you can suppress event notification for packets originating from a mail server IP address because the mail server normally transmits packets that look like exploits. If you then decommission that mail server and reassign the IP address to another host, you should delete the suppression conditions for that source IP address.

## Procedure

- 
- Step 1** Choose **Policies > Access Control > Intrusion**.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 3** Click **Rules** immediately under **Policy Information** in the navigation panel.
- Step 4** Choose the rule or rules for which you want to view or delete suppressions.
- Step 5** You have the following choices:
- To remove all suppression for a rule, choose **Event Filtering > Remove Suppressions**.
  - To remove a specific suppression setting, click the rule, then click **Show details**. Expand the suppression settings and click **Delete** next to the suppression settings you want to remove.
- Step 6** Click **OK**.
- Step 7** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
- 

### What to do next

- Deploy configuration changes.

## Dynamic Intrusion Rule States

Rate-based attacks attempt to overwhelm a network or host by sending excessive traffic toward the network or host, causing it to slow down or deny legitimate requests. You can use rate-based prevention to change the action of a rule in response to excessive rule matches for specific rules.

You can configure your intrusion policies to include a rate-based filter that detects when too many matches for a rule occur in a given time period. You can use this feature on managed devices deployed inline to block rate-based attacks for a specified time, then revert to a rule state where rule matches only generate events and do not drop traffic.

Rate-based attack prevention identifies abnormal traffic patterns and attempts to minimize the impact of that traffic on legitimate requests. You can identify excessive rule matches in traffic going to a particular destination IP address or addresses or coming from a particular source IP address or addresses. You can also respond to excessive matches for a particular rule across all detected traffic.

In some cases, you may not want to set a rule to the Drop and Generate Events state because you do not want to drop every packet that matches the rule, but you do want to drop packets matching the rule if a particular rate of matches occurs in a specified time. Dynamic rule states let you configure the rate that should trigger

a change in the action for a rule, what the action should change to when the rate is met, and how long the new action should persist.

The following diagram shows an example where an attacker is attempting to access a host. Repeated attempts to find a password trigger a rule which has rate-based attack prevention configured. The rate-based settings change the rule attribute to Drop and Generate Events after rule matches occur five times in a 10-second span. The new rule attribute times out after 15 seconds.

After the timeout, note that packets are still dropped in the rate-based sampling period that follows. If the sampled rate is above the threshold in the current or previous sampling period, the new action continues. The new action reverts to Generate Events only after a sampling period completes where the sampled rate was below the threshold rate.

## Dynamic Intrusion Rule State Configuration

In the intrusion policy, you can configure a rate-based filter for any intrusion or preprocessor rule. The rate-based filter contains three components:

- the rule matching rate, which you configure as a count of rule matches within a specific number of seconds
- a new action to be taken when the rate is exceeded, with three available actions: Generate Events, Drop and Generate Events, and Disable
- the duration of the action, which you configure as a timeout value

Note that when started, the new action occurs until the timeout is reached, even if the rate falls below the configured rate during that time period. When the timeout is reached, if the rate has fallen below the threshold, the action for the rule reverts to the action initially configured for the rule.

You can configure rate-based attack prevention in an inline deployment to block attacks, either temporarily or permanently. Without rate-based configuration, rules set to Generate Events do generate events, but the system does not drop packets for those rules. However, if the attack traffic matches rules that have rate-based criteria configured, the rate action may cause packet dropping to occur for the period of time that the rate action is active, even if those rules are not initially set to Drop and Generate Events.

---

**Note** Rate-based actions cannot enable disabled rules or drop traffic that matches disabled rules.

---

You can define multiple rate-based filters on the same rule. The first filter listed in the intrusion policy has the highest priority. Note that when two rate-based filter actions conflict, the action of the first rate-based filter is carried out.

## Setting a Dynamic Rule State from the Rules Page

You can set one or more dynamic rule states for a rule. The first dynamic rule state listed has the highest priority. When two dynamic rule states conflict, the action of the first is carried out.

Dynamic rule states are policy-specific.

A **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

---

**Note** Dynamic rule states cannot enable disabled rules or drop traffic that matches disabled rules.

---

### Procedure

- 
- Step 1** Choose **Policies > Access Control > Intrusion**.
  - Step 2** Click **Snort 2 Version** next to the policy you want to edit.  
If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
  - Step 3** Click **Rules** immediately under **Policy Information** in the navigation pane.
  - Step 4** Choose the rule or rules where you want to add a dynamic rule state.
  - Step 5** Choose **Dynamic State > Add Rate-Based Rule State**.
  - Step 6** Choose a value from the **Track By** drop-down list.
  - Step 7** If you set **Track By** to **Source** or **Destination**, enter the address of each host you want to track in the **Network** field. You can specify a single IP address, address block, variable, or a comma-separated list comprised of any combination of these.
  - Step 8** Next to **Rate**, specify the number of rule matches per time period to set the attack rate:
    - Enter a value in the **Count** field.
    - Enter a value in the **Seconds** field.
  - Step 9** From the **New State** drop-down list, specify the new action to be taken when the conditions are met.
  - Step 10** Enter a value in the **Timeout** field.  
After the timeout occurs, the rule reverts to its original state. Specify 0 or leave the **Timeout** field blank to prevent the new action from timing out.

- Step 11** Click **OK**.
- Tip** The system displays a **Dynamic State** next to the rule in the Dynamic State column. If you add multiple dynamic rule state filters to a rule, a number over the filter indicates the number of filters.
- Tip** To delete all dynamic rule settings for a set of rules, choose the rules on the Rules page, then choose **Dynamic State > Remove Rate-Based States**. You can also delete individual rate-based rule state filters from the rule details for the rule by choosing the rule, clicking **Show details**, then clicking **Delete** by the rate-based filter you want to remove.
- Step 12** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

**What to do next**

- Deploy configuration changes.

## Adding Intrusion Rule Comments

You can add comments to rules in your intrusion policy. Comments added this way are policy-specific; that is, comments you add to a rule in one intrusion policy are not visible in other intrusion policies. Any comments you add can be seen in the Rule Details view on the Rules page for the intrusion policy.

After you commit the intrusion policy changes containing the comment, you can also view the comment by clicking **Rule Comment** on the rule Edit page.

### Procedure

- 
- Step 1** Choose **Policies > Access Control > Intrusion**.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 3** Click **Rules** immediately under **Policy Information** in the navigation panel.
- Step 4** Choose the rule or rules where you want to add a comment.
- Step 5** Choose **Comments > Add Rule Comment**.
- Step 6** In the **Comment** field, enter the rule comment.
- Step 7** Click **OK**.
- Tip** The system displays a **Comment** (🗨) next to the rule in the Comments column. If you add multiple comments to a rule, a number over the comment indicates the number of comments.

**Step 8** Optionally, delete a rule comment by clicking **Delete** next to the comment.

You can only delete a comment if the comment is cached with uncommitted intrusion policy changes. After intrusion policy changes are committed, the rule comment is permanent.

**Step 9** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

#### What to do next

- Deploy configuration changes.

## CHAPTER 77

# Custom Intrusion Rules

The following topics describe how to use the intrusion rules editor:

- [Custom Intrusion Rules Overview, on page 2097](#)
- [License Requirements for the Intrusion Rule Editor, on page 2098](#)
- [Requirements and Prerequisites for the Intrusion Rule Editor, on page 2098](#)
- [Rule Anatomy, on page 2098](#)
- [Custom Rule Creation, on page 2109](#)
- [Searching for Rules, on page 2113](#)
- [Rule Filtering on the Intrusion Rules Editor Page, on page 2115](#)
- [Keywords and Arguments in Intrusion Rules, on page 2118](#)

## Custom Intrusion Rules Overview

An *intrusion rule* is a set of keywords and arguments that the system uses to detect attempts to exploit vulnerabilities on your network. As the system analyzes network traffic, it compares packets against the conditions specified in each rule. If the packet data matches all the conditions specified in a rule, the rule triggers. If a rule is an *alert rule*, it generates an intrusion event. If it is a *pass rule*, it ignores the traffic. For a *drop* rule in an inline deployment, the system drops the packet and generates an event. You can view and evaluate intrusion events from the Secure Firewall Management Center web interface.

The system provides two types of intrusion rules: shared object rules and standard text rules. The Talos Intelligence Group can use shared object rules to detect attacks against vulnerabilities in ways that traditional standard text rules cannot. You cannot create shared object rules. When you write your own intrusion rule, you create a standard text rule.

You can write custom standard text rules to tune the types of events you are likely to see. Note that while this documentation sometimes discusses rules targeted to detect specific exploits, the most successful rules target traffic that may attempt to exploit known vulnerabilities rather than specific known exploits. By writing rules and specifying the rule's event message, you can more easily identify traffic that indicates attacks and policy evasions.

When you enable a custom standard text rule in a custom intrusion policy, keep in mind that some rule keywords and arguments require that traffic first be decoded or preprocessed in a certain way. This chapter explains the options you must configure in your network analysis policy, which governs preprocessing. Note that if you disable a required preprocessor, the system automatically uses it with its current settings, although the preprocessor remains disabled in the network analysis policy web interface.

**Caution**

Make sure you use a controlled network environment to test any intrusion rules that you write before you use the rules in a production environment. Poorly written intrusion rules may seriously affect the performance of the system.

**Note**

You can create custom intrusion rules using Snort. However, support for tuning and troubleshooting these rules is not available currently.

## Rule Anatomy

All standard text rules contain two logical sections: the rule header and the rule options. The rule header contains:

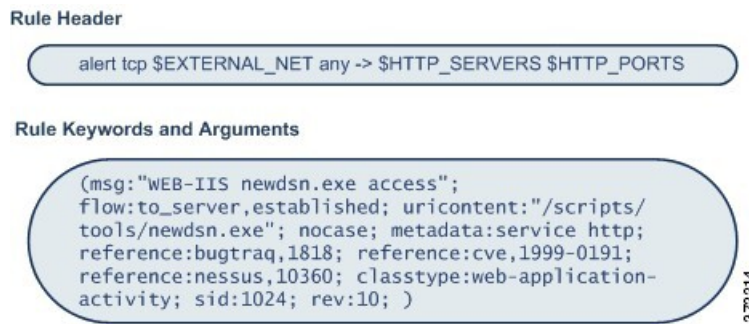

- the rule's action or type
- the protocol
- the source and destination IP addresses and netmasks

- direction indicators showing the flow of traffic from source to destination
- the source and destination ports

The rule options section contains:

- event messages
- keywords and their parameters and arguments
- patterns that a packet’s payload must match to trigger the rule
- specifications of which parts of the packet the rules engine should inspect

The following diagram illustrates the parts of a rule:

Note that the options section of a rule is the section enclosed in parentheses. The intrusion rules editor provides an easy-to-use interface to help you build standard text rules.

## The Intrusion Rule Header

Every standard text rule and shared object rule has a rule header containing parameters and arguments. The following illustrates parts of a rule header:

The following table describes each part of the rule header shown above.

**Table 130: Rule Header Values**

Rule Header Component	Example Value	This Value...
Action	alert	Generates an intrusion event when triggered.
Protocol	tcp	Tests TCP traffic only.
Source IP Address	\$EXTERNAL_NET	Tests traffic coming from any host that is not on your internal network.

Rule Header Component	Example Value	This Value...
Source Ports	any	Tests traffic coming from any port on the originating host.
Operator	->	Tests external traffic (destined for the web servers on your network).
Destination IP Address	\$HTTP_SERVERS	Tests traffic to be delivered to any host specified as a web server on your internal network.
Destination Ports	\$HTTP_PORTS	Tests traffic delivered to an HTTP port on your internal network.

**Note** The previous example uses default variables, as do most intrusion rules.

#### Related Topics

[Variable Set](#), on page 1541

## Intrusion Rule Header Action

Each rule header includes a parameter that specifies the action the system takes when a packet triggers a rule. Rules with the action set to *alert* generate an intrusion event against the packet that triggered the rule and log the details of that packet. Rules with the action set to *pass* do not generate an event against, or log the details of, the packet that triggered the rule.

**Note** In an inline deployment, rules with the rule state set to *Drop and Generate Events* generate an intrusion event against the packet that triggered the rule. Also, if you apply a drop rule in a passive deployment, the rule acts as an alert rule.

By default, pass rules override alert rules. You can create pass rules to prevent packets that meet criteria defined in the pass rule from triggering the alert rule in specific situations, rather than disabling the alert rule. For example, you might want a rule that looks for attempts to log into an FTP server as the user “anonymous” to remain active. However, if your network has one or more legitimate anonymous FTP servers, you could write and activate a pass rule that specifies that, for those specific servers, anonymous users do not trigger the original rule.

Within the intrusion rules editor, you select the rule type from the **Action** list.

## Intrusion Rule Header Protocol

In each rule header, you must specify the protocol of the traffic the rule inspects. You can specify the following network protocols for analysis:

- ICMP (Internet Control Message Protocol)
- IP (Internet Protocol)

---

**Note** The system ignores port definitions in an intrusion rule header when the protocol is set to `ip`.

---

- TCP (Transmission Control Protocol)
- UDP (User Datagram Protocol)

Use **IP** as the protocol type to examine all protocols assigned by IANA, including TCP, UDP, ICMP, IGMP, and many more.

---

**Note** You cannot currently write rules that match patterns in the next header (for example, the TCP header) in an IP payload. Instead, content matches begin with the last decoded protocol. As a workaround, you can match patterns in TCP headers by using rule options.

---

Within the Intrusion Rules editor, you select the protocol type from the **Protocol** list.

#### Related Topics

[Intrusion Rule Header Protocol](#), on page 2100

## Intrusion Rule Header Direction

Within the rule header, you can specify the direction that the packet must travel for the rule to inspect it. The following table describes these options.

*Table 131: Directional Options in Rule Headers*

Use...	To Test...
Directional	only traffic from the specified source IP address to the specified destination IP address
Bidirectional	all traffic traveling between the specified source and destination IP addresses

## Intrusion Rule Header Source and Destination IP Addresses

Restricting packet inspection to the packets originating from specific IP addresses or destined to a specific IP address reduces the amount of packet inspection the system must perform. This also reduces false positives by making the rule more specific and removing the possibility of the rule triggering against packets whose source and destination IP addresses do not indicate suspicious behavior.

---

**Tip** The system recognizes only IP addresses and does not accept host names for source or destination IP addresses.

---

Within the intrusion rules editor, you specify source and destination IP addresses in the **Source IPs** and **Destination IPs** fields.

When writing standard text rules, you can specify IPv4 and IPv6 addresses in a variety of ways, depending on your needs. You can specify a single IP address, `any`, IP address lists, CIDR notation, prefix lengths, or a

network variable. Additionally, you can indicate that you want to exclude a specific IP address or set of IP addresses. When specifying IPv6 addresses, you can use any addressing convention defined in RFC 4291.

## IP Address Syntax in Intrusion Rules

The following table summarizes the various ways you can specify source and destination IP addresses.

**Table 132: Source/Destination IP Address Syntax**

To Specify...	Use...	Example
any IP address	any	any
a specific IP address	the IP address  Note that you would not mix IPv4 and IPv6 source and destination addresses in the same rule.	192.168.1.1  2001:db8::abcd
a list of IP addresses	brackets ([]) to enclose the IP addresses and commas to separate them	[192.168.1.1,192.168.1.15]  [2001:db8::b3ff, 2001:db8::0202]
a block of IP addresses	IPv4 CIDR block or IPv6 address prefix notation	192.168.1.0/24  2001:db8::/32
anything except a specific IP address or set of addresses	the ! character before the IP address or addresses you want to negate	!192.168.1.15  !2001:db8::0202:b3ff:fe1e
anything in a block of IP addresses except one or more specific IP addresses	a block of addresses followed by a list of negated addresses or blocks	[10.0.0/8, !10.2.3.4, !10.1.0.0/16]  [2001:db8::/32, !2001:db8::8329, !2001:db8::0202]
IP addresses defined by a network variable	the variable name, in uppercase letters, preceded by \$  Note that preprocessor rules can trigger events regardless of the hosts defined by network variables used in intrusion rules.	\$HOME_NET
all IP addresses except addresses defined by an IP address variable	the variable name, in uppercase letters, preceded by !\$	!\$HOME_NET

The following descriptions provide additional information on some of the IP address entry methods.

### Any IP Address

You can specify the word `any` as a rule source or destination IP address to indicate any IPv4 or IPv6 address.

For example, the following rule uses the argument **any** in the **Source IPs** and **Destination IPs** fields and evaluates packets with any IPv4 or IPv6 source or destination address:

```
alert tcp any any -> any any
```

You can also specify `::` to indicate any IPv6 address.

### Multiple IP Addresses

You can list individual IP addresses by separating the IP addresses with commas and, optionally, by surrounding non-negated lists with brackets, as shown in the following example:

```
[192.168.1.100,192.168.1.103,192.168.1.105]
```

You can list IPv4 and IPv6 addresses alone or in any combination, as shown in the following example:

```
[192.168.1.100,2001:db8::1234,192.168.1.105]
```

Note that surrounding an IP address list with brackets, which was required in earlier software releases, is not required. Note also that, optionally, you can enter lists with a space before or after each comma.

---

**Note** You must surround negated lists with brackets.

---

You can also use IPv4 Classless Inter-Domain Routing (CIDR) notation or IPv6 prefix lengths to specify address blocks. For example:

- 192.168.1.0/24 specifies the IPv4 addresses in the 192.168.1.0 network with a subnet mask of 255.255.255.0, that is, 192.168.1.0 through 192.168.1.255.
- 2001:db8::/32 specifies the IPv6 addresses in the 2001:db8:: network with a prefix length of 32 bits, that is, 2001:db8:: through 2001:db8:fff:fff:fff:fff:fff:fff.

---

**Tip** If you need to specify a block of IP addresses but cannot express it using CIDR or prefix length notation alone, you can use CIDR blocks and prefix lengths in an IP address list.

---

### IP Addresses Negation

You can use an exclamation point (!) to negate a specified IP address. That is, you can match any IP address with the exception of the specified IP address or addresses. For example, `!192.168.1.1` specifies any IP address other than 192.168.1.1, and `!2001:db8:ca2e::fa4c` specifies any IP address other than 2001:db8:ca2e::fa4c.

To negate a list of IP addresses, place ! before a bracketed list of IP addresses. For example, `![192.168.1.1,192.168.1.5]` would define any IP address other than 192.168.1.1 or 192.168.1.5.

---

**Note** You must use brackets to negate a list of IP addresses.

---

Be careful when using the negation character with IP address lists. For example, if you use `![192.168.1.1,!192.168.1.5]` to match any address that is not 192.168.1.1 or 192.168.1.5, the system interprets this syntax as “anything that is not 192.168.1.1, **or** anything that is not 192.168.1.5.”

Because 192.168.1.5 is not 192.168.1.1, and 192.168.1.1 is not 192.168.1.5, both IP addresses match the IP address value of `![192.168.1.1,!192.168.1.5]`, and it is essentially the same as using “any.”

Instead, use `![192.168.1.1,192.168.1.5]`. The system interprets this as “**not** 192.168.1.1 **and not** 192.168.1.5,” which matches any IP address other than those listed between brackets.

Note that you cannot logically use negation with `any` which, if negated, would indicate no address.

## Intrusion Rule Header Source and Destination Ports

Within the intrusion rules editor, you specify source and destination ports in the **Source Port** and **Destination Port** fields.

### Port Syntax in Intrusion Rules

The system uses a specific type of syntax to define the port numbers used in rule headers.

**Note** The system ignores port definitions in an intrusion rule header when the protocol is set to `ip`.

You can list ports by separating the ports with commas, as shown in the following example:

```
80, 8080, 8138, 8600-9000, !8650-8675
```

Optionally, the following example shows how you can surround a port list with brackets, which was required in previous software versions but is no longer required:

```
[80, 8080, 8138, 8600-9000, !8650-8675]
```

Note that you **must** surround negated port lists in brackets, as shown in the following example:

```
![20, 22, 23]
```

The following table summarizes the syntax you can use:

**Table 133: Source/Destination Port Syntax**

To Specify...	Use	Example
any port	<code>any</code>	<code>any</code>
a specific port	the port number	<code>80</code>
a range of ports	a dash between the first and last port number in the range	<code>80-443</code>
all ports less than or equal to a specific port	a dash before the port number	<code>-21</code>
all ports greater than or equal to a specific port	a dash after the port number	<code>80-</code>
all ports except a specific port or range of ports	the <code>!</code> character before the port, port list, or range of ports you want to negate  Note that you can logically use negation with all port designations except <code>any</code> , which if negated would indicate <i>no port</i> .	<code>!20</code>
all ports defined by a port variable	the variable name, in uppercase letter, preceded by <code>\$</code>	<code>\$HTTP_PORTS</code>

To Specify...	Use	Example
all ports except ports defined by a port variable	the variable name, in uppercase letter, preceded by !\$	!\$HTTP_PORTS

## Intrusion Event Details

As you construct a standard text rule, you can include contextual information that describes the vulnerability that the rule detects in exploit attempts. You can also include external references to vulnerability databases and define the priority that the event holds in your organization. When analysts see the event, they then have information about the priority, exploit, and known mitigation readily available.

### Message

You can specify meaningful text that appears as a message when the rule triggers. The message gives immediate insight into the nature of the vulnerability that the rule detects attempts to exploit. You can use any printable standard ASCII characters except curly braces ({}). The system strips quotes that completely surround the message.

**Tip** You must specify a rule message. Also, the message cannot consist of white space only, one or more quotation marks only, one or more apostrophes only, or any combination of just white space, quotation marks, or apostrophes.

To define the event message in the intrusion rules editor, you enter the event message in the **Message** field.

### Classification

For each rule, you can specify an attack classification that appears in the packet display of the event. The following table lists the name and number for each classification.

**Table 134: Rule Classifications**

Number	Classification Name	Description
1	not-suspicious	Not Suspicious Traffic
2	unknown	Unknown Traffic
3	bad-unknown	Potentially Bad Traffic
4	attempted-recon	Attempted Information Leak
5	successful-recon-limited	Information Leak
6	successful-recon-largescale	Large Scale Information Leak
7	attempted-dos	Attempted Denial of Service
8	successful-dos	Denial of Service
9	attempted-user	Attempted User Privilege Gain

Number	Classification Name	Description
10	unsuccessful-user	Unsuccessful User Privilege Gain
11	successful-user	Successful User Privilege Gain
12	attempted-admin	Attempted Administrator Privilege Gain
13	successful-admin	Successful Administrator Privilege Gain
14	rpc-portmap-decode	Decode of an RPC Query
15	shellcode-detect	Executable Code was Detected
16	string-detect	A Suspicious String was Detected
17	suspicious-filename-detect	A Suspicious Filename was Detected
18	suspicious-login	An Attempted Login Using a Suspicious Username was Detected
19	system-call-detect	A System Call was Detected
20	tcp-connection	A TCP Connection was Detected
21	trojan-activity	A Network Trojan was Detected
22	unusual-client-port-connection	A Client was Using an Unusual Port
23	network-scan	Detection of a Network Scan
24	denial-of-service	Detection of a Denial of Service Attack
25	non-standard-protocol	Detection of a Non-Standard Protocol or Event
26	protocol-command-decode	Generic Protocol Command Decode
27	web-application-activity	Access to a Potentially Vulnerable Web Application
28	web-application-attack	Web Application Attack
29	misc-activity	Misc Activity
30	misc-attack	Misc Attack
31	icmp-event	Generic ICMP Event
32	inappropriate-content	Inappropriate Content was Detected
33	policy-violation	Potential Corporate Privacy Violation
34	default-login-attempt	Attempt to Login By a Default Username and Password
35	sdf	Sensitive Data
36	malware-cnc	Known malware command and control traffic

Number	Classification Name	Description
37	client-side-exploit	Known client side exploit attempt
38	file-format	Known malicious file or file based exploit

### Custom Classification

If you want more customized content for the packet display description of the events generated by a rule you define, you can create a custom classification.

Argument	Description
Classification Name	The name of the classification. The page is difficult to read if you use more than 40 characters. The following characters are not supported: <> ( ) \ ' " & \$ ; and the space character.
Classification Description	A description of the classification. You can use alphanumeric characters and spaces. The following characters are not supported: <> ( ) \ ' " & \$ ;
Priority	High, medium, or low.

### Custom Priority

By default, the priority of a rule derives from the event classification for the rule. However, you can override the classification priority for a rule by adding the `priority` keyword to the rule and selecting a high, medium, or low priority. For example, to assign a high priority for a rule that detects web application attacks, add the `priority` keyword to the rule and select **high** as the priority.

### Custom Reference

You can use the `reference` keyword to add references to external web sites and additional information about the event. Adding a reference provides analysts with an immediately available resource to help them identify why the packet triggered a rule. The following table lists some of the external systems that can provide data on known exploits and attacks.

**Table 135: External Attack Identification Systems**

System ID	Description	Example ID
bugtraq	Bugtraq page	8550
cve	Common Vulnerabilities and Exposure ID	2020-9607
mcafee	McAfee page	98574
url	Website reference	www.example.com?exploit=14
msb	Microsoft security bulletin	MS11-082

System ID	Description	Example ID
nessus	Nessus page	10039
secure-url	Secure Website Reference (https://...)	intranet/exploits/exploit=14 Note that you can use <code>secure-url</code> with any secure website.

You specify a reference by entering a reference value, as follows:

```
id_system,id
```

where `id_system` is the system being used as a prefix, and `id` is the CVE ID number, Arachnids ID, or URL (without `http://`).

For example, to specify the Adobe Acrobat and Reader issue documented in CVE-2020-9607, enter the value:

```
cve,2020-9607
```

Note the following when adding references to a rule:

- Do not use a space after the comma.
- Do not use uppercase letters in the system ID.

## Adding a Custom Classification

### Procedure

- 
- Step 1** While creating or editing a rule, choose **Edit Classifications** from the **Classification** drop-down list (**Objects > Intrusion Rules > Create Rules > Edit Classifications**).
- If **View Classifications** displays instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 2** Enter a **Classification Name** and **Classification Description** as described in [Intrusion Event Details](#), on page 2105.
- Step 3** Choose a priority for the classification from the **Priority** drop-down list.
- Step 4** Click **Add**.
- Step 5** Click **Done**.
- 

#### Related Topics

  - Step 3** Enter a value in the **reference** field as described in [Intrusion Event Details, on page 2105](#).
  - Step 4** Click **Save**.

---

#### Related Topics

[Custom Rule Creation](#), on page 2109

## Custom Rule Creation

You can create a custom intrusion rule by:

- creating your own standard text rules
- saving existing standard text rules as new
- saving system-provided shared object rules as new
- importing a local rule file

The system saves the custom rule in the local rule category, regardless of the method you used to create it.

When you create a custom intrusion rule, the system assigns it a unique rule number, which has the format `GID:SID:Rev`. The elements of this number are:

#### **GID**

Generator ID. For all standard text rules, this value is 1 (Global domain or legacy GID) or 1000 - 2000 (descendant domains). For all shared object rules you save as new, this value is 1.

**SID**

Snort ID. Indicates whether the rule is a local rule of a system rule. When you create a new rule, the system assigns the next available SID for a local rule.

SID numbers for local rules start at 1000000, and the SID for each new local rule is incremented by one.

**Rev**

The revision number. For a new rule, the revision number is one. Each time you modify a custom rule the revision number increments by one.

In a custom standard text rule, you set the rule header settings and the rule keywords and arguments. You can use the rule header settings to focus the rule to only match traffic using a specific protocol and traveling to or from specific IP addresses or ports.

In a custom system-provided standard text rule or shared object rule, you are limited to modifying rule header information such as the source and destination ports and IP addresses. You cannot modify the rule keywords or arguments.

Modifying header information for a shared object rule and saving your changes creates a new instance of the rule with a generator ID (GID) of 1 (Global domain) or 1000 - 2000 (descendant domains) and the next available SID for a custom rule. The system links the new instance of the shared object rule to the reserved `soid` keyword, which maps the rule you create to the rule created by the Talos Intelligence Group. You can delete instances of a shared object rule that you create, but you cannot delete shared object rules created by Talos.

## Writing New Rules

### Procedure

- 
- Step 1** Choose **Objects > Intrusion Rules**.
- Step 2** Click **Create Rule**.
- Step 3** Enter a value in the **Message** field.
- Step 4** Choose a value from each of the following drop-down lists:
- **Classification**
  - **Action**
  - **Protocol**
  - **Direction**
- Step 5** Enter values in the following fields:
- **Source IPs**
  - **Destination IPs**
  - **Source Port**
  - **Destination Port**
- The system uses the value `any` if you do not specify a value for these fields.
- Step 6** Choose a value from the **Detection Options** drop-down list.
- Step 7** Click **Add Option**.

- Step 8** Enter any arguments for the keyword you added.
- Step 9** Optionally, repeat steps 6 to 8.
- Step 10** If you added multiple keywords, you can:
- Reorder keywords — Click the up or down arrow next to the keyword you want to move.
  - Delete a keyword — Click the **X** next to that keyword.
- Step 11** Click **Save As New**.
- 

#### What to do next

- Enable your new or changed rules within the appropriate intrusion policy; see [Viewing Intrusion Rules in an Intrusion Policy, on page 2073](#).
- Deploy configuration changes.

## Modifying Existing Rules

You can save system-provided rules and rules belonging to ancestor domains as new custom rules in the local rule category, which you can then modify.

### Procedure

---

- Step 1** Access the intrusion rules using either of the following methods:
- Choose **Policies > Access Control > Intrusion**.  
Click **Snort 2 Version** next to the policy you want to edit and click **Rules**.
  - Choose **Objects > Intrusion Rules**.
- Step 2** Locate the rule you want to modify. You have the following choices:
- Navigate through the folders to the rule.
  - Search for the rule; see [Searching for Rules, on page 2113](#).
  - Filter for the group to which the rule belongs; see [Filtering Rules, on page 2117](#).
- Step 3** Click **Edit** () next to the rule or, in the case of search results, click the rule message.
- If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Modify the rule as appropriate for the rule type.
- Note** Do not modify the protocol for a shared object rule; doing so would render the rule ineffective.
- Step 5** You have the following choices:
- Click **Save** if you are editing a custom rule and want to overwrite the current version of that rule.

- Click **Save As New** if you are editing a system-provided rule or any rule belonging to an ancestor domain, or if you are editing a custom rule and want to save the changes as a new rule.
- 

### What to do next

- If you want to use the local modification of the rule instead of the system-provided rule, deactivate the system-provided rule by using the procedures at [Intrusion Rule States, on page 2085](#) and activate the local rule.
- Deploy configuration changes.

[Rule Filtering on the Intrusion Rules Editor Page](#), on page 2115

## Adding Comments to Intrusion Rules

You can add comments to any intrusion rule. Such comments can be helpful to provide context and additional information about the rule and the exploit or policy violation it identifies.

### Procedure

---

- Step 1** Access the intrusion rules using either of the following methods:
- Choose **Policies > Access Control > Intrusion**.  
Click **Snort 2 Version** next to the policy you want to edit and click **Rules**.
  - Choose **Objects > Intrusion Rules**.
- Step 2** Locate the rule you want to annotate. You have the following choices:
- Navigate through the folders to the rule.
  - Search for the rule; see [Searching for Rules, on page 2113](#).
  - Filter for the group where the rule belongs; see [Filtering Rules, on page 2117](#).
- Step 3** Click **Edit** () next to the rule or, in the case of search results, click the rule message.  
If **View** () appears next to a rule instead, the rule belongs to an ancestor policy, or you do not have permission to modify the rule.
- Step 4** Click **Rule Comment**.
- Step 5** Enter your comment in the text box.
- Step 6** Click **Add Comment**.

**Tip** You can also add and view rule comments in an intrusion event's packet view.

---

**Related Topics**

[Searching for Rules](#), on page 2113

## Deleting Custom Rules

You can delete custom rules if the rules are not currently enabled in an intrusion policy. You cannot delete either standard text rules or shared object rules provided by the system.

The system stores deleted rules in the deleted category, and you can use a deleted rule as the basis for a new rule. The Rules page in an intrusion policy does not display the deleted category, so you cannot enable deleted custom rules.

---

**Tip** Custom rules include shared object rules that you save with modified header information. The system also saves these in the local rule category and lists them with a GID of 1 (Global domain or legacy GID) or 1000 - 2000 (descendant domains). You can delete your modified version of a shared object rule, but you cannot delete the original shared object rule.

---

**Procedure**

- 
- Step 1** Access the intrusion rules using either of the following methods:
- Choose **Policies > Access Control > Intrusion**.  
Click **Snort 2 Version** next to the policy you want to edit and click **Rules**.
  - Choose **Objects > Intrusion Rules**.
- Step 2** You have two choices:
- Delete all local rules — Click **Delete Local Rules**, then click **OK**.
  - Delete a single rule — Choose `Local Rules` from the **Group Rules By** drop-down, click **Delete** (  ) next to a rule you want to delete, and click **OK** to confirm the deletion.
- 

**Related Topics**

[Intrusion Rule States](#), on page 2085

## Searching for Rules

The system provides thousands of standard text rules, and the Talos Intelligence Group continues to add rules as new vulnerabilities and exploits are discovered. You can easily search for specific rules so that you can activate, deactivate, or edit them.

## Procedure

- 
- Step 1** Access the intrusion rules using either of the following methods:
- Choose **Policies > Access Control > Intrusion**.  
Click **Snort 2 Version** next to the policy you want to edit and click **Rules**.
  - Choose **Objects > Intrusion Rules**.
- Step 2** Click **Search** on the toolbar.
- Step 3** Add search criteria.
- Step 4** Click **Search**.
- 

## Search Criteria for Intrusion Rules

The following table describes the available search options:

**Table 136: Rule Search Criteria**

Option	Description
Signature ID	To search for a single rule based on Snort ID (SID), enter an SID number. To search for multiple rules, enter a comma-separated list of SID numbers. This field has an 80-character limit.
Generator ID	To search for standard text rules, select <b>1</b> . To search for shared object rules, select <b>3</b> .
Message	To search for a rule with a specific message, enter a single word from the rule message in the <b>Message</b> field. For example, to search for DNS exploits, you would enter <code>DNS</code> , or to search for buffer overflow exploits, enter <code>overflow</code> .
Protocol	To search rules that evaluate traffic of a specific protocol, select the protocol. If you do not select a protocol, search results contain rules for all protocols.
Source Port	To search for rules that inspect packets originating from a specified port, enter a source port number or a port-related variable.
Destination Port	To search for rules that inspect packets destined for a specific port, enter a destination port number or a port-related variable.
Source IP	To search for rules that inspect packets originating from a specified IP address, enter a source IP address or an IP address-related variable.
Destination IP	To search for rules that inspect packets destined for a specified IP address, enter a destination IP address or an IP address-related variable.
Keyword	To search for specific keywords, you can use the keyword search options. You select a keyword and enter a keyword value for which to search. You can also precede the keyword value with an exclamation point (!) to match any value other than the specified value.

Option	Description
Category	To search for rules in a specific category, select the category from the <b>Category</b> list.
Classification	To search for rules that have a specific classification, select the classification name from the <b>Classification</b> list.
Rule State	To search for rules within a specific policy and a specific rule state, select the policy from the first <b>Rule State</b> list, and choose a state from the second list to search for rules set to <b>Generate Events, Drop and Generate Events</b> , or <b>Disabled</b> .

## Rule Filtering on the Intrusion Rules Editor Page

You can filter the rules on the intrusion rules editor page to display a subset of rules. This can be useful, for example, when you want to modify a rule or change its state but have difficulty finding it among the thousands of rules available.

When you enter a filter, the page displays any folder that includes at least one matching rule, or a message when no rule matches.

### Filtering Guidelines

Your filter can include special keywords and their arguments, character strings, and literal character strings in quotes, with spaces separating multiple filter conditions. A filter cannot include regular expressions, wild card characters, or any special operator such as a negation character (!), a greater than symbol (>), less than symbol (<), and so on.

All keywords, keyword arguments, and character strings are case-insensitive. Except for the `gid` and `sid` keywords, all arguments and strings are treated as partial strings. Arguments for `gid` and `sid` return only exact matches.

You can expand a folder on the original, unfiltered page and the folder remains expanded when the subsequent filter returns matches in that folder. This can be useful when the rule you want to find is in a folder that contains a large number of rules.

You cannot constrain a filter with a subsequent filter. Any filter you enter searches the entire rules database and returns all matching rules. When you enter a filter while the page still displays the result of a previous filter, the page clears and returns the result of the new filter instead.

You can use the same features with rules in a filtered or unfiltered list. For example, you can edit rules in a filtered or unfiltered list on the intrusion rules editor page. You can also use any of the options in the context menu for the page.

**Tip** Filtering may take significantly longer when the combined total of rules in all sub-groups is large because rules appear in multiple categories, even when the total number of unique rules is much smaller.

## Keyword Filtering

Each rule filter can include one or more keywords in the format:

```
keyword:argument
```

where keyword is one of the keywords in the following table and argument is a single, case-insensitive, alphanumeric string to search for in the specific field or fields relevant to the keyword.

Arguments for all keywords except `gid` and `sid` are treated as partial strings. For example, the argument `123` returns "12345", "41235", "45123", and so on. The arguments for `gid` and `sid` return only exact matches; for example, `sid:3080` returns only SID 3080.

**Tip** You can search for a partial SID by filtering with one or more character strings.

The following table describes the specific filtering keywords and arguments you can use to filter rules.

**Table 137: Rule Filter Keywords**

Keyword	Description	Example
arachnids	Returns one or more rules based on all or part of the Arachnids ID in a rule reference.	arachnids:181
bugtraq	Returns one or more rules based on all or part of the Bugtraq ID in a rule reference.	bugtraq:2120
cve	Returns one or more rules based on all or part of the CVE number in a rule reference.	cve:2003-0109
gid	The argument 1 returns standard text rules. The argument 3 returns shared object rules.	gid:3
mcafee	Returns one or more rules based on all or part of the McAfee ID in a rule reference.	mcafee:10566
msg	Returns one or more rules based on all or part of the rule Message field, also known as the event message.	msg:chat
nessus	Returns one or more rules based on all or part of the Nessus ID in a rule reference.	nessus:10737
ref	Returns one or more rules based on all or part of a single alphanumeric string in a rule reference or in the rule Message field.	ref:MS03-039
sid	Returns the rule with the exact Snort ID.	sid:235
url	Returns one or more rules based on all or part of the URL in a rule reference.	url:faqs.org

### Related Topics

[Defining an Event Reference](#), on page 2109

[Intrusion Event Details](#), on page 2105

## Character String Filtering

Each rule filter can include one or more alphanumeric character strings. Character strings search the rule **Message** field, Snort ID (SID), and Generator ID (GID). For example, the string `123` returns the strings `"Lotus123"`, `"123mania"`, and so on in the rule message, and also returns SID 6123, SID 12375, and so on.

All character strings are case-insensitive and are treated as partial strings. For example, any of the strings `ADMIN`, `admin`, or `Admin` return `"admin"`, `"CFADMIN"`, `"Administrator"` and so on.

You can enclose character strings in quotes to return exact matches. For example, the literal string `"overflow attempt"` in quotes returns only that exact string, whereas a filter comprised of the two strings `overflow` and `attempt` without quotes returns `"overflow attempt"`, `"overflow multipacket attempt"`, `"overflow with evasion attempt"`, and so on.

### Related Topics

[Intrusion Event Details](#), on page 2105

## Combination Keyword and Character String Filtering

You can narrow filter results by entering any combination of keywords, character strings, or both, separated by spaces. The result includes any rule that matches all the filter conditions.

You can enter multiple filter conditions in any order. For example, each of the following filters returns the same rules:

- `url:at login attempt cve:200`
- `login attempt cve:200 url:at`
- `login cve:200 attempt url:at`

## Filtering Rules

On the Intrusion Rules page, you can filter rules into subsets so you can more easily find specific rules. You can then use any of the page features, including choosing any of the features available in the context menu.

Rule filtering can be particularly useful to locate a specific rule to edit.

### Procedure

- 
- Step 1** Access the intrusion rules using either of the following methods:
- Choose **Policies > Access Control > Intrusion**.  
Click **Snort 2 Version** next to the policy you want to edit and click **Rules**.
  - Choose **Objects > Intrusion Rules**.
- Step 2** Prior to filtering, you have the following choices:
- Expand any rule group you want to expand. Some rule groups also have sub-groups that you can expand.

Expanding a group on the original, unfiltered page can be useful when you expect that a rule might be in that group. The group remains expanded when the subsequent filter results in a match in that folder, and when you return to the original, unfiltered page by clicking filter **Clear** (X).

- Choose a different grouping method from the **Group Rules By** drop-down list.

**Step 3** Enter filter constraints in the text box next to **Filter** (Q) under the **Group Rules By** list.

**Step 4** Press Enter.

**Note** Clear the current filtered list by clicking filter **Clear** (X).

## Keywords and Arguments in Intrusion Rules

Using the rules language, you can specify the behavior of a rule by combining keywords. Keywords and their associated values (called *arguments*) dictate how the system evaluates packets and packet-related values that the rules engine tests. The system currently supports keywords that allow you to perform inspection functions, such as content matching, protocol-specific pattern matching, and state-specific matching. You can define up to 100 arguments per keyword, and combine any number of compatible keywords to create highly specific rules. This helps decrease the chance of false positives and false negatives and focus the intrusion information you receive.

Note that you can also use adaptive profile updates in passive deployments to dynamically adapt active rule processing for specific packets based on rule metadata and host information.

Keywords described in this section are listed under Detection Options in the rules editor.

### Related Topics

[About Adaptive Profiles](#), on page 2937

## The content and protected\_content Keywords

Use the `content` keyword or the `protected_content` keyword to specify content that you want to detect in a packet.

You should almost always follow a `content` or `protected_content` keyword by modifiers that indicate where the content should be searched for, whether the search is case sensitive, and other options.

Note that all content matches must be true for the rule to trigger an event, that is, each content match has an AND relationship with the others.

Note also that, in an inline deployment, you can set up rules that match malicious content and then replace it with your own text string of equal length.

### content

When you use the `content` keyword, the rules engine searches the packet payload or stream for that string. For example, if you enter `/bin/sh` as the value for one of the `content` keywords, the rules engine searches the packet payload for the string `/bin/sh`.

Match content using either an ASCII string, hexadecimal content (binary byte code), or a combination of both. Surround hexadecimal content with pipe characters (|) in the keyword value. For example, you can mix hexadecimal content and ASCII content using something that looks like `|90C8 C0FF FFFF|bin/sh`.

You can specify multiple content matches in a single rule. To do this, use additional instances of the `content` keyword. For each content match, you can indicate that content matches must be found in the packet payload or stream for the rule to trigger.

**Caution** You may invalidate your intrusion policy if you create a rule that includes only one `content` keyword and that keyword has the **Not** option selected.

### protected\_content

The `protected_content` keyword allows you to encode your search content string before configuring the rule argument. The original rule author uses a hash function (SHA-512, SHA-256, or MD5) to encode the string before configuring the keyword.

When you use the `protected_content` keyword instead of the `content` keyword, there is no change to how the rules engine searches the packet payload or stream for that string and most of the keyword options function as expected. The following table summarizes the exceptions, where the `protected_content` keyword options differ from the `content` keyword options.

*Table 138: protected\_content Option Exceptions*

Option	Description
Hash Type	New option for the <code>protected_content</code> rule keyword.
Case Insensitive	Not supported
Within	Not supported
Depth	Not supported
Length	New option for the <code>protected_content</code> rule keyword.
Use Fast Pattern Matcher	Not supported
Fast Pattern Matcher Only	Not supported
Fast Pattern Matcher Offset and Length	Not supported

Cisco recommends that you include at least one `content` keyword in rules that include a `protected_content` keyword to ensure that the rules engine uses the fast pattern matcher, which increases processing speed and improves performance. Position the `content` keyword before the `protected_content` keyword in the rule.

Note that the rules engine uses the fast pattern matcher when a rule includes at least one `content` keyword, regardless of whether you enable the `content` keyword Use Fast Pattern Matcher argument.

**Caution** You may invalidate your intrusion policy if you create a rule that includes only one `protected_content` keyword and that keyword has the **Not** option selected.

**Related Topics**

[Custom Rule Creation](#), on page 2109

[Basic content and protected\\_content Keyword Arguments](#), on page 2120

[The replace Keyword](#), on page 2129

**Basic content and protected\_content Keyword Arguments**

You can constrain the location and case-sensitivity of content searches with parameters that modify the `content` or `protected_content` keyword. Configure options that modify the `content` or `protected_content` keyword to specify the content for which you want to search.

**Case Insensitive**

---

**Note** This option is **not** supported when configuring the `protected_content` keyword.

---

You can instruct the rules engine to ignore case when searching for content matches in ASCII strings. To make your search case-insensitive, check **Case Insensitive** when specifying a content search.

**Hash Type**

---

**Note** This option is **only** configurable with the `protected_content` keyword.

---

Use the **Hash Type** drop-down to identify the hash function you used to encode your search string. The system supports SHA-512, SHA-256, and MD5 hashing for `protected_content` search strings. If the length of your hashed content does not match the selected hash type, the system does **not** save the rule.

The system automatically selects the Cisco-set default value. When **Default** is selected, no specific hash function is written into the rule and the system assumes SHA-512 for the hash function.

**Raw Data**

The **Raw Data** option instructs the rules engine to analyze the original packet payload before analyzing the normalized payload data (decoded by a network analysis policy) and does not use an argument value. You can use this keyword when analyzing telnet traffic to check the telnet negotiation options in the payload before normalization.

You cannot use the **Raw Data** option together in the same `content` or `protected_content` keyword with any HTTP content option.

---

**Tip** You can configure the HTTP Inspect preprocessor **Client Flow Depth** and **Server Flow Depth** options to determine whether raw data is inspected in HTTP traffic, and how much raw data is inspected.

---

**Not**

Select the **Not** option to search for content that does not match the specified content. If you create a rule that includes a `content` or `protected_content` keyword with the **Not** option selected, you must also include in the rule at least one other `content` or `protected_content` keyword without the **Not** option selected.

**Caution** Do not create a rule that includes only one `content` or `protected_content` keyword if that keyword has the **Not** option selected. You may invalidate your intrusion policy.

For example, SMTP rule 1:2541:9 includes three `content` keywords, one of which has the **Not** option selected. A custom rule based on this rule would be invalid if you removed all of the `content` keywords except the one with the **Not** option selected. Adding such a rule to your intrusion policy could invalidate the policy.

**Tip** You cannot select the **Not** check box and the **Use Fast Pattern Matcher** check box with the same `content` keyword.

## content and protected\_content Keyword Search Locations

You can use search location options to specify where to begin searching for the specified content and how far to continue searching.

### Permitted Combinations: content Search Location Arguments

You can use either of two `content` location pairs to specify where to begin searching for the specified content and how far to continue searching, as follows:

- Use **Offset** and **Depth** together to search relative to the beginning of the packet payload.
- Use **Distance** and **Within** together to search relative to the current search location.

When you specify only one of a pair, the default for the other option in the pair is assumed.

You cannot mix the **Offset** and **Depth** options with the **Distance** and **Within** options. For example, you cannot pair **Offset** and **Within**. You can use any number of location options in a rule.

When no location is specified, the defaults for **Offset** and **Depth** are assumed; that is, the content search starts at the beginning of the packet payload and continues to the end of the packet.

You can also use an existing `byte_extract` variable to specify the value for a location option.

**Tip** You can use any number of location options in a rule.

### Related Topics

[The `byte\_extract` Keyword](#), on page 2135

### Permitted Combinations: protected\_content Search Location Arguments

Use the required **Length** `protected_content` location option in combination with either the **Offset** or **Distance** location option to specify where to begin searching for the specified content and how far to continue searching, as follows:

- Use **Length** and **Offset** together to search for the protected string relative to the beginning of the packet payload.
- Use **Length** and **Distance** together to search for the protected string relative to the current search location.

---

**Tip** You cannot mix the **Offset** and **Distance** options within a single keyword configuration, but you can use any number of location options in a rule.

---

When no location is specified, the defaults are assumed; that is, the content search starts at the beginning of the packet payload and continues to the end of the packet.

You can also use an existing `byte_extract` variable to specify the value for a location option.

### Related Topics

[The `byte\_extract` Keyword](#), on page 2135

## content and protected\_content Search Location Arguments

### Depth

---

**Note** This option is **only** supported when configuring the `content` keyword.

---

Specifies the maximum content search depth, in bytes, from the beginning of the offset value, or if no offset is configured, from the beginning of the packet payload.

For example, in a rule with a `content` value of `cgi-bin/phf`, and `offset` value of 3, and a `depth` value of 22, the rule starts searching for a match to the `cgi-bin/phf` string at byte 3, and stops after processing 22 bytes (byte 25) in packets that meet the parameters specified by the rule header.

You must specify a value that is greater than or equal to the length of the specified content, up to a maximum of 65535 bytes. You cannot specify a value of 0.

The default depth is to search to the end of the packet.

### Distance

Instructs the rules engine to identify subsequent content matches that occur a specified number of bytes after the previous successful content match.

Because the distance counter starts at byte 0, specify one less than the number of bytes you want to move forward from the last successful content match. For example, if you specify 4, the search begins at the fifth byte.

You can specify a value of -65535 to 65535 bytes. If you specify a negative `Distance` value, the byte you start searching on may fall outside the beginning of a packet. Any calculations will take into account the bytes outside the packet, even though the search actually starts on the first byte in the packet. For example, if the current location in the packet is the fifth byte, and the next content rule option specifies a `Distance` value of -10 and a `Within` value of 20, the search starts at the beginning of the payload and the `Within` option is adjusted to 15.

The default distance is 0, meaning the current location in the packet subsequent to the last content match.

### Length

---

**Note** This option is **only** supported when configuring the `protected_content` keyword.

---

The **Length** `protected_content` keyword option indicates the length, in bytes, of the unlashd search string. For example, if you used the content `sample1` to generate a secure hash, use 7 for the **Length** value. You **must** enter a value in this field.

### Offset

Specifies in bytes where in the packet payload to start searching for content relative to the beginning of the packet payload. You can specify a value of 65535 to 65535 bytes.

Because the offset counter starts at byte 0, specify one less than the number of bytes you want to move forward from the beginning of the packet payload. For example, if you specify 7, the search begins at the eighth byte.

The default offset is 0, meaning the beginning of the packet.

### Within

---

**Note** This option is **only** supported when configuring the `content` keyword.

---

The **Within** option indicates that, to trigger the rule, the next content match must occur within the specified number of bytes after the end of the last successful content match. For example, if you specify a **Within** value of 8, the next content match must occur within the next eight bytes of the packet payload or it does not meet the criteria that triggers the rule.

You can specify a value that is greater than or equal to the length of the specified content, up to a maximum of 65535 bytes.

The default for **Within** is to search to the end of the packet.

## Overview: HTTP content and protected\_content Keyword Arguments

HTTP `content` or `protected_content` keyword options let you specify where to search for content matches within an HTTP message decoded by the HTTP Inspect preprocessor.

Two options search status fields in HTTP responses:

- **HTTP Status Code**
- **HTTP Status Message**

Note that although the rules engine searches the raw, unnormalized status fields, these options are listed here separately to simplify explanation below of the restrictions to consider when combining other raw HTTP fields and normalized HTTP fields.

Five options search normalized fields in HTTP requests, responses, or both, as appropriate :

- **HTTP URI**
- **HTTP Method**

- **HTTP Header**
- **HTTP Cookie**
- **HTTP Client Body**

Three options search raw (unnormalized) non-status fields in HTTP requests, responses, or both, as appropriate:

- **HTTP Raw URI**
- **HTTP Raw Header**
- **HTTP Raw Cookie**

Use the following guidelines when selecting HTTP `content` options:

- HTTP `content` options apply only to TCP traffic.
- To avoid a negative impact on performance, select only those parts of the message where the specified content might appear.  
For example, when traffic is likely to include large cookies such as those in shopping cart messages, you might search for the specified content in the HTTP header but not in HTTP cookies.
- To take advantage of HTTP Inspect preprocessor normalization, and to improve performance, any HTTP-related rule you create should at a minimum include at least one `content` or `protected_content` keyword with an **HTTP URI**, **HTTP Method**, **HTTP Header**, or **HTTP Client Body** option selected.
- You cannot use the `replace` keyword in conjunction with HTTP `content` or `protected_content` keyword options.

You can specify a single normalized HTTP option or status field, or use normalized HTTP options and status fields in any combination to target a content area to match. However, note the following restrictions when using HTTP field options:

- You cannot use the **Raw Data** option together in the same `content` or `protected_content` keyword with any HTTP option.
- You cannot use a raw HTTP field option (**HTTP Raw URI**, **HTTP Raw Header**, or **HTTP Raw Cookie**) together in the same `content` or `protected_content` keyword with its normalized counterpart (**HTTP URI**, **HTTP Header**, or **HTTP Cookie**, respectively).
- You cannot select **Use Fast Pattern Matcher** in combination with one or more of the following HTTP field options:

**HTTP Raw URI**, **HTTP Raw Header**, **HTTP Raw Cookie**, **HTTP Cookie**, **HTTP Method**, **HTTP Status Message**, or **HTTP Status Code**

However, you can include the options above in a `content` or `protected_content` keyword that also uses the fast pattern matcher to search one of the following normalized fields:

**HTTP URI**, **HTTP Header**, or **HTTP Client Body**

For example, if you select **HTTP Cookie**, **HTTP Header**, and **Use Fast Pattern Matcher**, the rules engine searches for content in both the HTTP cookie and the HTTP header, but the fast pattern matcher is applied only to the HTTP header, not to the HTTP cookie.

- When you combine restricted and unrestricted options, the fast pattern matcher searches only the unrestricted fields you specify to test whether to pass the rule to the intrusion rules editor for complete evaluation, including evaluation of the restricted fields.

### Related Topics

[content Keyword Fast Pattern Matcher Arguments](#), on page 2127

## HTTP content and protected\_content Keyword Arguments

### HTTP URI

Select this option to search for content matches in the normalized request URI field.

Note that you cannot use this option in combination with the `pcr` keyword HTTP URI (U) option to search the same content.

---

**Note** A pipelined HTTP request packet contains multiple URIs. When **HTTP URI** is selected and the rules engine detects a pipelined HTTP request packet, the rules engine searches all URIs in the packet for a content match.

---

### HTTP Raw URI

Select this option to search for content matches in the normalized request URI field.

Note that you cannot use this option in combination with the `pcr` keyword HTTP URI (U) option to search the same content.

---

**Note** A pipelined HTTP request packet contains multiple URIs. When **HTTP URI** is selected and the rules engine detects a pipelined HTTP request packet, the rules engine searches all URIs in the packet for a content match.

---

### HTTP Method

Select this option to search for content matches in the request method field, which identifies the action such as GET and POST to take on the resource identified in the URI.

### HTTP Header

Select this option to search for content matches in the normalized header field, except for cookies, in HTTP requests; also in responses when the HTTP Inspect preprocessor **Inspect HTTP Responses** option is enabled.

Note that you cannot use this option in combination with the `pcr` keyword HTTP header (H) option to search the same content.

### HTTP Raw Header

Select this option to search for content matches in the raw header field, except for cookies, in HTTP requests; also in responses when the HTTP Inspect preprocessor **Inspect HTTP Responses** option is enabled.

Note that you cannot use this option in combination with the `pcr` keyword HTTP raw header (D) option to search the same content.

### HTTP Cookie

Select this option to search for content matches in any cookie identified in a normalized HTTP client request header; also in response set-cookie data when the HTTP Inspect preprocessor **Inspect HTTP Responses** option is enabled. Note that the system treats cookies included in the message body as body content.

You must enable the HTTP Inspect preprocessor **Inspect HTTP Cookies** option to search only the cookie for a match; otherwise, the rules engine searches the entire header, including the cookie.

Note the following:

- You cannot use this option in combination with the `pcrc` keyword HTTP cookie (C) option to search the same content.
- The `Cookie:` and `Set-Cookie:` header names, leading spaces on the header line, and the `CRLF` that terminates the header line are inspected as part of the header and not as part of the cookie.

### HTTP Raw Cookie

Select this option to search for content matches in any cookie identified in a raw HTTP client request header; also in response set-cookie data when the HTTP Inspect preprocessor **Inspect HTTP Responses** option is enabled; note that the system treats cookies included in the message body as body content.

You must enable the HTTP Inspect preprocessor **Inspect HTTP Cookies** option to search only the cookie for a match; otherwise, the rules engine searches the entire header, including the cookie.

Note the following:

- You cannot use this option in combination with the `pcrc` keyword HTTP raw cookie (K) option to search the same content.
- The `Cookie:` and `Set-Cookie:` header names, leading spaces on the header line, and the `CRLF` that terminates the header line are inspected as part of the header and not as part of the cookie.

### HTTP Client Body

Select this option to search for content matches in the message body in an HTTP client request.

Note that for this option to function, you must specify a value of 0 to 65535 for the HTTP Inspect preprocessor **HTTP Client Body Extraction Depth** option.

### HTTP Status Code

Select this option to search for content matches in the 3-digit status code in an HTTP response.

You must enable the HTTP Inspect preprocessor **Inspect HTTP Responses** option for this option to return a match.

### HTTP Status Message

Select this option to search for content matches in the textual description that accompanies the status code in an HTTP response.

You must enable the HTTP Inspect preprocessor **Inspect HTTP Responses** option for this option to return a match.

## Overview: content Keyword Fast Pattern Matcher

**Note** These options are **not** supported when configuring the `protected_content` keyword.

The fast pattern matcher quickly determines which rules to evaluate before passing a packet to the rules engine. This initial determination improves performance by significantly reducing the number of rules used in packet evaluation.

By default, the fast pattern matcher searches packets for the longest content specified in a rule; this is to eliminate as much as possible needless evaluation of a rule. Consider the following example rule fragment:

```
alert tcp any any -> any 80 (msg:"Exploit"; content:"GET";
http_method; nocase; content:"/exploit.cgi"; http_uri;
nocase;)
```

Almost all HTTP client requests contain the content `GET`, but few will contain the content `/exploit.cgi`. Using `GET` as the fast pattern content would cause the rules engine to evaluate this rule in most cases and would rarely result in a match. However, most client `GET` requests would not be evaluated using `/exploit.cgi`, thus increasing performance.

The rules engine evaluates the packet against the rule only when the fast pattern matcher detects the specified content. For example, if one `content` keyword in a rule specifies the content `short`, another specifies `longer`, and a third specifies `longest`, the fast pattern matcher will use the content `longest` and the rule will be evaluated only if the rules engine finds `longest` in the payload.

### content Keyword Fast Pattern Matcher Arguments

#### Use Fast Pattern Matcher

Use this option to specify a shorter search pattern for the fast pattern matcher to use. Ideally, the pattern you specify is less likely to be found in the packet than the longest pattern and, therefore, more specifically identifies the targeted exploit.

Note the following restrictions when selecting **Use Fast Pattern Matcher** and other options in the same `content` keyword:

- You can specify **Use Fast Pattern Matcher** only one time per rule.
- You cannot use **Distance**, **Within**, **Offset**, or **Depth** when you select **Use Fast Pattern Matcher** in combination with **Not**.
- You cannot select Use Fast Pattern Matcher in combination with any of the following HTTP field options: **HTTP Raw URI**, **HTTP Raw Header**, **HTTP Raw Cookie**, **HTTP Cookie**, **HTTP Method**, **HTTP Status Message**, or **HTTP Status Code**

However, you can include the options above in a `content` keyword that also uses the fast pattern matcher to search one of the following normalized fields:

**HTTP URI**, **HTTP Header**, or **HTTP Client Body**

For example, if you select **HTTP Cookie**, **HTTP Header**, and **Use Fast Pattern Matcher**, the rules engine searches for content in both the HTTP cookie and the HTTP header, but the fast pattern matcher is applied only to the HTTP header, not to the HTTP cookie.

Note that you cannot use a raw HTTP field option (**HTTP Raw URI**, **HTTP Raw Header**, or **HTTP Raw Cookie**) together in the same `content` keyword with its normalized counterpart (**HTTP URI**, **HTTP Header**, or **HTTP Cookie**, respectively).

When you combine restricted and unrestricted options, the fast pattern matcher searches only the unrestricted fields you specify to test whether to pass the packet to the rules engine for complete evaluation, including evaluation of the restricted fields.

- Optionally, when you select **Use Fast Pattern Matcher** you can also select **Fast Pattern Matcher Only** or **Fast Pattern Matcher Offset and Length**, but not both.
- You cannot use the fast pattern matcher when inspecting Base64 data.

### Fast Pattern Matcher Only

This option allows you to use the `content` keyword only as a fast pattern matcher option and not as a rule option. You can use this option to conserve resources when rules engine evaluation of the specified content is not necessary. For example, consider a case where a rule requires only that the content `12345` be anywhere in the payload. When the fast pattern matcher detects the pattern, the packet can be evaluated against additional keywords in the rule. There is no need for the rules engine to reevaluate the packet to determine if it includes the pattern `12345`.

You would not use this option when the rule contains other conditions relative to the specified content. For example, you would not use this option to search for the content `1234` if another rule condition sought to determine if `abcd` occurs before `1234`. In this case, the rules engine could not determine the relative location because specifying **Fast Pattern Matcher Only** instructs the rules engine not to search for the specified content.

Note the following conditions when using this option:

- The specified content is location-independent; that is, it may occur anywhere in the payload; thus, you cannot use positional options (**Distance**, **Within**, **Offset**, **Depth**, or **Fast Pattern Matcher Offset and Length**).
- You cannot use this option in combination with **Not**.
- You cannot use this option in combination with **Fast Pattern Matcher Offset and Length**.
- The specified content will be treated as case-insensitive, because all patterns are inserted into the fast pattern matcher in a case-insensitive manner; this is handled automatically, so it is not necessary to select **Case Insensitive** when you select this option.
- You should not immediately follow a `content` keyword that uses the **Fast Pattern Matcher Only** option with the following keywords, which set the search location relative to the current search location:
  - `isdataat`
  - `pcre`
  - `content` when **Distance** or **Within** is selected
  - `content` when **HTTP URI** is selected

- `asn1`
- `byte_jump`
- `byte_test`
- `byte_math`
- `byte_extract`
- `base64_decode`

### Fast Pattern Matcher Offset and Length

The **Fast Pattern Matcher Offset and Length** option allows you to specify a portion of the content to search. This can reduce memory consumption in cases where the pattern is very long and only a portion of the pattern is sufficient to identify the rule as a likely match. When a rule is selected by the fast pattern matcher, the entire pattern is evaluated against the rule.

You determine the portion for the fast pattern matcher to use by specifying in bytes where to begin the search (offset) and how far into the content (length) to search, using the syntax:

```
offset,length
```

For example, for the content:

```
1234567
```

if you specify the number of offset and length bytes as:

```
1,5
```

the fast pattern matcher searches only for the content `23456`.

Note that you cannot use this option together with **Fast Pattern Matcher Only**.

[The base64\\_decode and base64\\_data Keywords](#), on page 2207

## The replace Keyword

You can use the `replace` keyword in an inline deployment to replace specified content or to replace content in SSL traffic detected by the Cisco SSL Appliance.

To use the `replace` keyword, construct a custom standard text rule that uses the `content` keyword to look for a specific string. Then use the `replace` keyword to specify a string to replace the content. The replace value and content value must be the same length.

---

**Note** You **cannot** use the `replace` keyword to replace hashed content in a `protected_content` keyword.

---

Optionally, you can enclose the replacement string in quotation marks for backward compatibility with previous software versions. If you do not include quotation marks, they are added to the rule automatically so the rule

is syntactically correct. To include a leading or trailing quotation mark as part of the replacement text, you must use a backslash to escape it, as shown in the following example:

```
"replacement text plus \"quotation\" marks"
```

A rule can contain multiple `replace` keywords, but only one per `content` keyword. Only the first instance of the content found by the rule is replaced.

The following are example uses of the `replace` keyword:

- If the system detects an incoming packet that contains an exploit, you can replace the malicious string with a harmless one. Sometimes this technique is more successful than simply dropping the offending packet. In some attack scenarios, the attacker simply resends the dropped packet until it bypasses your network defenses or floods your network. By substituting one string for another rather than dropping the packet, you may trick the attacker into believing that the attack was launched against a target that was not vulnerable.
- If you are concerned about reconnaissance attacks that try to learn whether you are running a vulnerable version of, for example, a web server, then you can detect the outgoing packet and replace the banner with your own text.

---

**Note** Make sure that you set the rule state to Generate Events in the inline intrusion policy where you want to use the replace rule; setting the rule to Drop and Generate events would cause the packet to drop, which would prevent replacing the content.

---

As part of the string replacement process, the system automatically updates the packet checksums so that the destination host can receive the packet without error.

Note that you cannot use the `replace` keyword in combination with HTTP request message `content` keyword options.

[Overview: HTTP content and protected\\_content Keyword Arguments](#), on page 2123

## The byte\_jump Keyword

The `byte_jump` keyword calculates the number of bytes defined in a specified byte segment, and then skips that number of bytes within the packet, either forward from the end of the specified byte segment, or from the beginning or end of the packet payload, or from a point relative to the last content match, depending on the options you specify. This is useful in packets where a specific segment of bytes describe the number of bytes included in variable data within the packet.

The following table describes the arguments required by the `byte_jump` keyword.

Table 139: Required `byte_jump` Arguments

Argument	Description
Bytes	<p>The number of bytes to pick up from the packet.</p> <p>If used without DCE/RPC, the allowed values are 0 to 10, with the following restrictions:</p> <ul style="list-style-type: none"> <li>• If used with the <code>From End</code> argument, bytes can be 0. If Bytes is 0, the extracted value is 0.</li> <li>• If you specify a number of bytes other than 1, 2, or 4, you must specify a Number Type (hexadecimal, octal, or decimal.)</li> </ul> <p>If used with DCE/RPC, allowed values are 1, 2, and 4.</p>
Offset	<p>The number of bytes into the payload to start processing. The <code>offset</code> counter starts at byte 0, so calculate the <code>offset</code> value by subtracting 1 from the number of bytes you want to jump forward from the beginning of the packet payload or the last successful content match.</p> <p>You can specify -65535 to 65535 bytes.</p> <p>You can also use an existing <code>byte_extract</code> variable or <code>byte_math</code> result to specify the value for this argument.</p>

The following table describes options you can use to define how the system interprets the values you specified for the required arguments.

Table 140: Additional Optional `byte_jump` Arguments

Argument	Description
Relative	Makes the offset relative to the last pattern found in the last successful content match.
Align	Rounds the number of converted bytes up to the next 32-bit boundary.
Multiplier	<p>Indicates the value by which the rules engine should multiply the <code>byte_jump</code> value obtained from the packet to get the final <code>byte_jump</code> value.</p> <p>That is, instead of skipping the number of bytes defined in a specified byte segment, the rules engine skips that number of bytes multiplied by an integer you specify with the Multiplier argument.</p>
Post Jump Offset	<p>The number of bytes -65535 through 65535 to skip forward or backward after applying other <code>byte_jump</code> arguments. A positive value skips forward and a negative value skips backward. Leave the field blank or enter 0 to disable.</p> <p>Note that some <code>byte_jump</code> arguments do not apply when you select the <b>DCE/RPC</b> argument.</p>
From Beginning	Indicates that the rules engine should skip the specified number of bytes in the payload starting from the beginning of the packet payload, instead of from the current position in the packet.
From End	The jump will originate from the byte that follows the last byte of the buffer.

Argument	Description
Bitmask	Applies the specified hexadecimal bitmask using the AND operator to the bytes extracted from the Bytes argument.  A bitmask can be 1 to 4 bytes.  The result will be right-shifted by the number of bits equal to the number of trailing zeros in the mask.

You can specify only one of **DCE/RPC**, **Endian**, or **Number Type**.

If you want to define how the `byte_jump` keyword calculates the bytes, you can choose from the arguments described in the following table. If you do not select a byte-ordering argument, the rules engine uses big endian byte order.

**Table 141: Byte-Ordering `byte_jump` Arguments**

Argument	Description
Big Endian	Processes data in big endian byte order, which is the default network byte order.
Little Endian	Processes data in little endian byte order.
DCE/RPC	Specifies a <code>byte_jump</code> keyword for traffic processed by the DCE/RPC preprocessor. The DCE/RPC preprocessor determines big endian or little endian byte order, and the <b>Number Type</b> and <b>Endian</b> arguments do not apply.  When you enable this argument, you can also use <code>byte_jump</code> in conjunction with other specific DCE/RPC keywords.

Define how the system views string data in a packet by using one of the arguments in the following table.

**Table 142: Number Type Arguments**

Argument	Description
Hexadecimal String	Represents converted string data in hexadecimal format.
Decimal String	Represents converted string data in decimal format.
Octal String	Represents converted string data in octal format.

For example, if the values you set for `byte_jump` are as follows:

- Bytes = 4
- Offset = 12
- Relative enabled
- Align enabled

the rules engine calculates the number described in the four bytes that appear 13 bytes after the last successful content match, and skips ahead that number of bytes in the packet. For instance, if the four calculated bytes in a specific packet were `00 00 00 1F`, the rules engine would convert this to 31. Because `align` is specified

(which instructs the engine to move to the next 32-bit boundary), the rules engine skips ahead 32 bytes in the packet.

Alternately, if the values you set for `byte_jump` are as follows:

- Bytes = 4
- Offset = 12
- From Beginning enabled
- Multiplier = 2

the rules engine calculates the number described in the four bytes that appear 13 bytes after the beginning of the packet. Then, the engine multiplies that number by two to obtain the total number of bytes to skip. For instance, if the four calculated bytes in a specific packet were `00 00 00 1F`, the rules engine would convert this to 31, then multiply it by two to get 62. Because From Beginning is enabled, the rules engine skips the first 63 bytes in the packet.

## The `byte_test` Keyword

The `byte_test` keyword tests the specified byte segment against the Value argument and its operator.

The following table describes the required arguments for the `byte_test` keyword.

**Table 143: Required `byte_test` Arguments**

Argument	Description
Bytes	<p>The number of bytes to calculate from the packet.</p> <p>If used without DCE/RPC, the allowed values are 1 to 10. However, if you specify a number of bytes other than 1, 2, or 4, you must specify a Number Type (hexadecimal, octal, or decimal.).</p> <p>If used with DCE/RPC, allowed values are 1, 2, and 4.</p>
Value	<p>Value to test, including its operator.</p> <p>Supported operators: <code>&lt;</code>, <code>&gt;</code>, <code>=</code>, <code>!</code>, <code>&amp;</code>, <code>^</code>, <code>!&gt;</code>, <code>!&lt;</code>, <code>!&lt;=</code>, <code>!&amp;</code>, or <code>!^</code>.</p> <p>For example, if you specify <code>!1024</code>, <code>byte_test</code> would convert the specified number, and if it did not equal 1024, it would generate an event (if all other keyword parameters matched).</p> <p>Note that <code>!</code> and <code>!&lt;=</code> are equivalent.</p> <p>You can also use an existing <code>byte_extract</code> variable or <code>byte_math</code> result to specify the value for this argument.</p>

Argument	Description
Offset	<p>The number of bytes into the payload to start processing. The <code>offset</code> counter starts at byte 0, so calculate the <code>offset</code> value by subtracting 1 from the number of bytes you want to count forward from the beginning of the packet payload or the last successful content match.</p> <p>You can use an existing <code>byte_extract</code> variable or <code>byte_math</code> result to specify the value for this argument.</p>

You can further define how the system uses `byte_test` arguments with the arguments described in the following table.

**Table 144: Additional Optional `byte_test` Arguments**

Argument	Description
Bitmask	<p>Applies the specified hexadecimal bitmask using the AND operator to the bytes extracted from the Bytes argument.</p> <p>A bitmask can be 1 to 4 bytes.</p> <p>The result will be right-shifted by the number of bits equal to the number of trailing zeros in the mask.</p>
Relative	Makes the offset relative to the last successful pattern match.

You can specify only one of **DCE/RPC**, **Endian**, or **Number Type**.

To define how the `byte_test` keyword calculates the bytes it tests, choose from the arguments in the following table. If you do not select a byte-ordering argument, the rules engine uses big endian byte order.

**Table 145: Byte-Ordering `byte_test` Arguments**

Argument	Description
Big Endian	Processes data in big endian byte order, which is the default network byte order.
Little Endian	Processes data in little endian byte order.
DCE/RPC	<p>Specifies a <code>byte_test</code> keyword for traffic processed by the DCE/RPC preprocessor. The DCE/RPC preprocessor determines big endian or little endian byte order, and the <b>Number Type</b> and <b>Endian</b> arguments do not apply.</p> <p>When you enable this argument, you can also use <code>byte_test</code> in conjunction with other specific DCE/RPC keywords.</p>

You can define how the system views string data in a packet by using one of the arguments in the following table.

**Table 146: Number Type `byte-test` Arguments**

Argument	Description
Hexadecimal String	Represents converted string data in hexadecimal format.

Argument	Description
Decimal String	Represents converted string data in decimal format.
Octal String	Represents converted string data in octal format.

For example, if the value for `byte_test` is specified as the following:

- Bytes = 4
- Operator and Value > 128
- Offset = 8
- Relative enabled

The rules engine calculates the number described in the four bytes that appear 9 bytes away from (relative to) the last successful content match, and, if the calculated number is larger than 128 bytes, the rule is triggered.

[DCE/RPC Keywords](#), on page 2167

## The `byte_extract` Keyword

You can use the `byte_extract` keyword to read a specified number of bytes from a packet into a variable. You can then use the variable later in the same rule as the value for specific arguments in certain other detection keywords.

This is useful, for example, for extracting data size from packets where a specific segment of bytes describes the number of bytes included in data within the packet. For example, a specific segment of bytes might say that subsequent data is comprised of four bytes; you can extract the data size of four bytes to use as your variable value.

You can use `byte_extract` to create up to two separate variables in a rule concurrently. You can redefine a `byte_extract` variable any number of times; entering a new `byte_extract` keyword with the same variable name and a different variable definition overwrites the previous definition of that variable.

The following table describes the arguments required by the `byte_extract` keyword.

**Table 147: Required `byte_extract` Arguments**

Argument	Description
Bytes to Extract	The number of bytes to pick up from the packet.  If you specify a number of bytes other than 1, 2, or 4, you must specify a Number Type (hexadecimal, octal, or decimal.)

Argument	Description
Offset	The number of bytes into the payload to begin extracting data. You can specify -65535 to 65535 bytes. The offset counter starts at byte 0, so calculate the offset value by subtracting 1 from the number of bytes you want to count forward. For example, specify 7 to count forward 8 bytes. The rules engine counts forward from the beginning of the packet payload or, if you also specify <b>Relative</b> , after the last successful content match. Note that you can specify negative numbers only when you also specify <b>Relative</b> .  You can use an existing <code>byte_math</code> result to specify the value for this argument.
Variable Name	The variable name to use in arguments for other detection keywords. You can specify an alphanumeric string that must begin with a letter.

To further define how the system locates the data to extract, you can use the arguments described in the following table.

**Table 148: Additional Optional `byte_extract` Arguments**

Argument	Description
Multiplier	A multiplier for the value extracted from the packet. You can specify 0 to 65535. If you do not specify a multiplier, the default value is 1.
Align	Rounds the extracted value to the nearest 2-byte or 4-byte boundary. When you also select <b>Multiplier</b> , the system applies the multiplier before the alignment.
Relative	Makes <b>Offset</b> relative to the end of the last successful content match instead of the beginning of the payload.
Bitmask	Applies the specified hexadecimal bitmask using the AND operator to the bytes extracted from the Bytes to Extract argument.  A bitmask can be 1 to 4 bytes.  The result will be right-shifted by the number of bits equal to the number of trailing zeros in the mask.

You can specify only one of **DCE/RPC**, **Endian**, or **Number Type**.

To define how the `byte_extract` keyword calculates the bytes it tests, you can choose from the arguments in the following table. If you do not select a byte-ordering argument, the rules engine uses big endian byte order.

**Table 149: Byte-Ordering `byte_extract` Arguments**

Argument	Description
Big Endian	Processes data in big endian byte order, which is the default network byte order.
Little Endian	Processes data in little endian byte order.

Argument	Description
DCE/RPC	Specifies a <code>byte_extract</code> keyword for traffic processed by the DCE/RPC preprocessor. The DCE/RPC preprocessor determines big endian or little endian byte order, and the <b>Number Type</b> and <b>Endian</b> arguments do not apply.  When you enable this argument, you can also use <code>byte_extract</code> in conjunction with other specific DCE/RPC keywords.

You can specify a number type to read data as an ASCII string. To define how the system views string data in a packet, you can select one of the arguments in the following table.

**Table 150: Number Type `byte_extract` arguments**

Argument	Description
Hexadecimal String	Reads extracted string data in hexadecimal format.
Decimal String	Reads extracted string data in decimal format.
Octal String	Reads extracted string data in octal format.

For example, if the value for `byte_extract` is specified as the following:

- Bytes to Extract = 4
- Variable Name = var
- Offset = 8
- Relative = enabled

the rules engine reads the number described in the four bytes that appear 9 bytes away from (relative to) the last successful content match into a variable named `var`, which you can specify later in the rule as the value for certain keyword arguments.

The following table lists the keyword arguments where you can specify a variable defined in the `byte_extract` keyword.

**Table 151: Arguments Accepting a `byte_extract` Variable**

Keyword	Argument
content	Depth, Offset, Distance, Within
byte_jump	Offset
byte_test	Offset, Value
byte_math	RValue, Offset
isdataat	Offset

## The byte\_math Keyword

The `byte_math` keyword performs a mathematical operation on an extracted value and a specified value or existing variable, and stores the outcome in a new resulting variable. You can then use the resulting variable as an argument in other keywords.

You can use multiple `byte_math` keywords in a rule to perform multiple `byte_math` operations.

The following table describes the arguments required by the `byte_math` keyword.

**Table 152: Required byte\_math Arguments**

Argument	Description
Bytes	<p>The number of bytes to calculate from the packet.</p> <p>If used without DCE/RPC, the allowed values are 1 to 10:</p> <ul style="list-style-type: none"> <li>• Bytes can be 1 to 10 when the operator is +, -, *, or /.</li> <li>• Bytes can be 1 to 4 when the operator is &lt;&lt; or &gt;&gt;.</li> <li>• If you specify a number of bytes other than 1, 2, or 4, you must specify a Number Type (hexadecimal, octal, or decimal.)</li> </ul> <p>If used with DCE/RPC, allowed values are 1, 2, and 4.</p>
Offset	<p>The number of bytes into the payload to start processing. The <code>offset</code> counter starts at byte 0, so calculate the <code>offset</code> value by subtracting 1 from the number of bytes you want to jump forward from the beginning of the packet payload or (if you specified Relative) from the last successful content match.</p> <p>You can specify -65535 to 65535 bytes.</p> <p>You can also specify the <code>byte_extract</code> variable here.</p>
Operator	+ , - , * , / , << , or >>
RValue	The value following the operator. This can be an unsigned integer or a variable passed from <code>byte_extract</code> .

Argument	Description
Result Variable	<p>The name of the variable into which the result of the <code>byte_math</code> calculation will be stored. You can use this variable as an argument in other keywords.</p> <p>This value is stored as an unsigned integer.</p> <p>This variable name:</p> <ul style="list-style-type: none"> <li>• Must use alphanumeric characters</li> <li>• Must not begin with a number</li> <li>• May include special characters supported by the Microsoft filename/variable name convention</li> <li>• Cannot consist entirely of special characters</li> </ul>

The following table describes options you can use to define how the system interprets the values you specified for the required arguments.

**Table 153: Additional Optional `byte_math` Arguments**

Argument	Description
Relative	Makes the offset relative to the last pattern found in the last successful content match instead of the beginning of the payload.
Bitmask	<p>Applies the specified hexadecimal bitmask using the AND operator to the bytes extracted from the Bytes argument.</p> <p>A bitmask can be 1 to 4 bytes.</p> <p>The result will be right-shifted by the number of bits equal to the number of trailing zeros in the mask.</p>

You can specify only one of **DCE/RPC**, **Endian**, or **Number Type**.

If you want to define how the `byte_math` keyword calculates the bytes, you can choose from the arguments described in the following table. If you do not select a byte-ordering argument, the rules engine uses big endian byte order.

**Table 154: Byte-Ordering `byte_math` Arguments**

Argument	Description
Big Endian	Processes data in big endian byte order, which is the default network byte order.
Little Endian	Processes data in little endian byte order.
DCE/RPC	<p>Specifies a <code>byte_math</code> keyword for traffic processed by the DCE/RPC preprocessor.</p> <p>The DCE/RPC preprocessor determines big endian or little endian byte order, and the <b>Number Type</b> and <b>Endian</b> arguments do not apply.</p> <p>When you enable this argument, you can also use <code>byte_math</code> in conjunction with other specific DCE/RPC keywords.</p>

Define how the system views string data in a packet by using one of the arguments in the following table.

**Table 155: Number Type Arguments**

Argument	Description
Hexadecimal String	Represents string data in hexadecimal format.
Decimal String	Represents string data in decimal format.
Octal String	Represents string data in octal format.

For example, if the values you set for `byte_math` are as follows:

- Bytes = 2
- Offset = 0
- Operator = \*
- RValue = height
- Result Variable = area

the rules engine extracts the number described in the first two bytes in the packet and multiplies it by the RValue (which uses the existing variable, `height`) to create the new variable, `area`.

**Table 156: Arguments Accepting a byte\_math Variable**

Keyword	Argument
<code>byte_jump</code>	Offset
<code>byte_test</code>	Offset, Value
<code>byte_extract</code>	Offset
<code>isdataat</code>	Offset

## Overview: The pcre Keyword

The `pcre` keyword allows you to use Perl-compatible regular expressions (PCRE) to inspect packet payloads for specified content. You can use PCRE to avoid writing multiple rules to match slight variations of the same content.

Regular expressions are useful when searching for content that could be displayed in a variety of ways. The content may have different attributes that you want to account for in your attempt to locate it within a packet's payload.

Note that the regular expression syntax used in intrusion rules is a subset of the full regular expression library and varies in some ways from the syntax used in commands in the full library. When adding a `pcre` keyword using the intrusion rules editor, enter the full value in the following format:

```
!/pcre/ ismxAEGRBUIPHDMCKSY
```

where:

- `!` is an optional negation (use this if you want to match patterns that **do not** match the regular expression).
- `/pcre/` is a Perl-compatible regular expression.
- `ismxAEGRBUIPHDMCKSY` is any combination of modifier options.

Also note that you must escape the characters listed in the following table for the rules engine to interpret them correctly when you use them in a PCRE to search for specific content in a packet payload.

**Table 157: Escaped PCRE Characters**

You must escape...	with a backslash...	or Hex code...
# (hash mark)	\#	\x23
;(semicolon)	\;	\x3B
(vertical bar)	\	\x7C
:(colon)	\:	\x3A

You can also use `m?regex?`, where `?` is a delimiter other than `/`. You may want to use this in situations where you need to match a forward slash within a regular expression and do not want to escape it with a backslash. For example, you might use `m?regex? ismxAEGRBUIPHDMCKSY` where `regex` is your Perl-compatible regular expression and `ismxAEGRBUIPHDMCKSY` is any combination of modifier options.

**Tip** Optionally, you can surround your Perl-compatible regular expression with quote characters, for example, `pcre_expression` or `"pcre_expression"`. The option of using quotes accommodates experienced users accustomed to previous versions when quotes were required instead of optional. The intrusion rules editor does not display quotation marks when you display a rule after saving it.

## pcre Syntax

The `pcre` keyword accepts standard Perl-compatible regular expression (PCRE) syntax. The following sections describe that syntax.

**Tip** While this section describes the basic syntax you may use for PCRE, you may want to consult an online reference or book dedicated to Perl and PCRE for more advanced information.

### Metacharacters

Metacharacters are literal characters that have special meaning within regular expressions. When you use them within a regular expression, you must “escape” them by preceding them with a backslash.

The following table describes the metacharacters you can use with PCRE and gives examples of each.

Table 158: PCRE Metacharacters

Metacharacter	Description	Example
.	Matches any character except newlines. If <code>s</code> is used as a modifying option, it also includes newline characters.	<code>abc.</code> matches <code>abcd</code> , <code>abc1</code> , <code>abc#</code> , and so on.
*	Matches zero or more occurrences of a character or expression.	<code>abc*</code> matches <code>abc</code> , <code>abcc</code> , <code>abccc</code> , <code>abccccc</code> , and so on.
?	Matches zero or one occurrence of a character or expression.	<code>abc?</code> matches <code>abc</code> .
+	Matches one or more occurrences of a character or expression.	<code>abc+</code> matches <code>abc</code> , <code>abcc</code> , <code>abccc</code> , <code>abccccc</code> , and so on.
()	Groups expressions.	<code>(abc)+</code> matches <code>abc</code> , <code>abcabc</code> , <code>abcabcabc</code> and so on.
{}	Specifies a limit for the number of matches for a character or expression. If you want to set a lower and upper limit, separate the lower limit and upper limit with a comma.	<code>a{4,6}</code> matches <code>aaaa</code> , <code>aaaaa</code> , or <code>aaaaaa</code> . <code>(ab){2}</code> matches <code>abab</code> .
[]	Allows you to define character classes, and matches any character or combination of characters described in the set.	<code>[abc123]</code> matches <code>a</code> or <code>b</code> or <code>c</code> , and so on.
^	Matches content at the beginning of a string. Also used for negation, if used within a character class.	<code>^in</code> matches the “in” in <code>info</code> , but not in <code>bin</code> . <code>[^a]</code> matches anything that does not contain <code>a</code> .
\$	Matches content at the end of a string.	<code>ce\$</code> matches the “ce” in <code>announce</code> , but not <code>cent</code> .
	Indicates an OR expression.	<code>(MAILTO HELP)</code> matches <code>MAILTO</code> or <code>HELP</code> .
\	Allows you to use metacharacters as actual characters and is also used to specify a predefined character class.	<code>\.</code> matches a period, <code>\*</code> matches an asterisk, <code>\\</code> matches a backslash and so on. <code>\d</code> matches the numeric characters, <code>\w</code> matches alphanumeric characters, and so on.

### Character Classes

Character classes include alphabetic characters, numeric characters, alphanumeric characters, and white space characters. While you can create your own character classes within brackets, you can use the predefined classes as shortcuts for different types of character types. When used without additional qualifiers, a character class matches a single digit or character.

The following table describes and provides examples of the predefined character classes accepted by PCRE.

Table 159: PCRE Character Classes

Character Class	Description	Character Class Definition
<code>\d</code>	Matches a numeric character (“digit”).	<code>[0-9]</code>
<code>\D</code>	Matches anything that is not a numeric character.	<code>[^0-9]</code>

Character Class	Description	Character Class Definition
\w	Matches an alphanumeric character (“word”).	[a-zA-Z0-9_]
\W	Matches anything that is not an alphanumeric character.	[^a-zA-Z0-9_]
\s	Matches white space characters, including spaces, carriage returns, tabs, newlines, and form feeds.	[\r\t\n\f]
\S	Matches anything that is not a white space character.	[^\r\t\n\f]

## pcre Modifier Options

You can use modifying options after you specify regular expression syntax in the `pcre` keyword’s value. These modifiers perform Perl, PCRE, and Snort-specific processing functions. Modifiers always appear at the end of the PCRE value, and appear in the following format:

```
/pcre/ismxAEGRBUIPHDMCKSY
```

where `ismxAEGRBUPHMC` can include any of the modifying options that appear in the following tables.

**Tip** Optionally, you can surround the regular expression and any modifying options with quotes, for example, `"/pcre/ismxAEGRBUIPHDMCKSY"`. The option of using quotes accommodates experienced users accustomed to previous versions when quotes were required instead of optional. The intrusion rules editor does not display quotation marks when you display a rule after saving it.

The following table describes options you can use to perform Perl processing functions.

**Table 160: Perl-Related Post Regular Expression Options**

Option	Description
i	Makes the regular expression case-insensitive.
s	The dot character (.) describes all characters except the newline or <code>\n</code> character. You can use "s" as an option to override this and have the dot character match all characters, including the newline character.
m	By default, a string is treated as a single line of characters, and <code>^</code> and <code>\$</code> match the beginning and ending of a specific string. When you use "m" as an option, <code>^</code> and <code>\$</code> match content immediately before or after any newline character in the buffer, as well as at the beginning or end of the buffer.
x	Ignores white space data characters that may appear within the pattern, except when escaped (preceded by a backslash) or included inside a character class.

The following table describes the PCRE modifiers you can use after the regular expression.

Table 161: PCRE-Related Post Regular Expression Options

Option	Description
A	The pattern must match at the beginning of the string (same as using <code>^</code> in a regular expression).
E	Sets <code>\$</code> to match only at the end of the subject string. (Without <code>E</code> , <code>\$</code> also matches immediately before the final character if it is a newline, but not before any other newline characters).
G	By default, <code>*</code> , <code>+</code> and <code>?</code> are “greedy,” which means that if two or more matches are found, they will choose the longest match. Use the <code>G</code> character to change this so that these characters always choose the first match unless followed by a question mark character ( <code>?</code> ). For example, <code>*?+?</code> and <code>??</code> would be greedy in a construct using the <code>G</code> modifier, and any incidences of <code>*</code> , <code>+</code> , or <code>?</code> without the additional question mark will not be greedy.

The following table describes the Snort-specific modifiers that you can use after the regular expression.

Table 162: Snort-Specific Post Regular Expression Modifiers

Option	Description
R	Searches for matching content relative to the end of the last match found by the rules engine.
B	Searches for the content within data before it is decoded by a preprocessor (this option is similar to using the <code>Raw Data</code> argument with the <code>content</code> or <code>protected_content</code> keyword).
U	Searches for the content within the URI of a normalized HTTP request message decoded by the HTTP Inspect preprocessor. Note that you cannot use this option in combination with the <code>content</code> or <code>protected_content</code> keyword <b>HTTP URI</b> option to search the same content.  Note that a pipelined HTTP request packet contains multiple URIs. A PCRE expression that includes the <code>U</code> option causes the rules engine to search for a content match only in the first URI in a pipelined HTTP request packet. To search all URIs in the packet, use the <code>content</code> or <code>protected_content</code> keyword with <b>HTTP URI</b> selected, either with or without an accompanying PCRE expression that uses the <code>U</code> option.
I	Searches for the content within the URI of a raw HTTP request message decoded by the HTTP Inspect preprocessor. Note that you cannot use this option in combination with the <code>content</code> or <code>protected_content</code> keyword <b>HTTP Raw URI</b> option to search the same content
P	Searches for the content within the body of a normalized HTTP request message decoded by the HTTP Inspect preprocessor.

Option	Description
H	Searches for the content within the header, excluding cookies, of an HTTP request or response message decoded by the HTTP Inspect preprocessor. Note that you cannot use this option in combination with the <code>content</code> or <code>protected_content</code> keyword <b>HTTP Header</b> option to search the same content.
D	Searches for the content within the header, excluding cookies, of a raw HTTP request or response message decoded by the HTTP Inspect preprocessor. Note that you cannot use this option in combination with the <code>content</code> or <code>protected_content</code> keyword <b>HTTP Raw Header</b> option to search the same content.
M	Searches for the content within the method field of a normalized HTTP request message decoded by the HTTP Inspect preprocessor; the method field identifies the action such as GET, PUT, CONNECT, and so on to take on the resource identified in the URI.
C	<p>When the HTTP Inspect preprocessor <b>Inspect HTTP Cookies</b> option is enabled, searches for the normalized content within any cookie in an HTTP request header, and also within any set-cookie in an HTTP response header when the preprocessor <b>Inspect HTTP Responses</b> option is enabled. When <b>Inspect HTTP Cookies</b> is not enabled, searches the entire header, including the cookie or set-cookie data.</p> <p>Note the following:</p> <ul style="list-style-type: none"> <li>• Cookies included in the message body are treated as body content.</li> <li>• You cannot use this option in combination with the <code>content</code> or <code>protected_content</code> keyword <b>HTTP Cookie</b> option to search the same content.</li> <li>• The <code>Cookie:</code> and <code>Set-Cookie:</code> header names, leading spaces on the header line, and the <code>CRLF</code> that terminates the header line are inspected as part of the header and not as part of the cookie.</li> </ul>
K	<p>When the HTTP Inspect preprocessor <b>Inspect HTTP Cookies</b> option is enabled, searches for the raw content within any cookie in an HTTP request header, and also within any set-cookie in an HTTP response header when the preprocessor <b>Inspect HTTP Responses</b> option is enabled. When <b>Inspect HTTP Cookies</b> is not enabled, searches the entire header, including the cookie or set-cookie data.</p> <p>Note the following:</p> <ul style="list-style-type: none"> <li>• Cookies included in the message body are treated as body content.</li> <li>• You cannot use this option in combination with the <code>content</code> or <code>protected_content</code> keyword <b>HTTP Raw Cookie</b> option to search the same content.</li> <li>• The <code>Cookie:</code> and <code>Set-Cookie:</code> header names, leading spaces on the header line, and the <code>CRLF</code> that terminates the header line are inspected as part of the header and not as part of the cookie.</li> </ul>
S	Searches the 3-digit status code in an HTTP response.
Y	Searches the textual description that accompanies the status code in an HTTP response.

**Note** Do not use the U option in combination with the R option. This could cause performance problems. Also, do not use the U option in combination with any other HTTP content option (I, P, H, D, M, C, K, S, or Y).

## pcre Example Keyword Values

The following examples show values that you could enter for `pcre`, with descriptions of what each example would match.

- `/feedback[ (\d{0,1}) ]?\.cgi/U`

This example searches packet payload for `feedback`, followed by zero or one numeric character, followed by `.cgi`, and located only in URI data.

This example would match:

- `feedback.cgi`
- `feedback1.cgi`
- `feedback2.cgi`
- `feedback3.cgi`

This example would **not** match:

- `feedbacka.cgi`
- `feedback11.cgi`
- `feedback21.cgi`
- `feedbackzb.cgi`
- `/^ez (\w{3,5}) \.cgi/iU`

This example searches packet payload for `ez` at the beginning of a string, followed by a word of 3 to 5 letters, followed by `.cgi`. The search is case-insensitive and only searches URI data.

This example would match:

- `EZBoard.cgi`
- `ezman.cgi`
- `ezadmin.cgi`
- `EZAdmin.cgi`

This example would **not** match:

- `ezez.cgi`
- `fez.cgi`

- abcezboard.cgi
- ezboardman.cgi
- **/mail (file|seek) \.cgi/U**

This example searches packet payload for `mail`, followed by either `file` or `seek`, in URI data.

This example would match:

- mailfile.cgi
- mailseek.cgi

This example would **not** match:

- MailFile.cgi
- mailfilefile.cgi
- **m?http\\x3a\\x2f\\x2f.\* (\n|\t)+?U**

This example searches packet payload for URI content for a tab or newline character in an HTTP request, after any number of characters. This example uses `m?regex?` to avoid using `http:\\/\\/` in the expression. Note that the colon is preceded by a backslash.

This example would match:

- http://www.example.com?scriptvar=x&othervar=\n\...\
- http://www.example.com?scriptvar=\t

This example would **not** match:

- ftp://ftp.example.com?scriptvar=&othervar=\n\...\
- http://www.example.com?scriptvar=|/bin/sh -i|
- **m?http\\x3a\\x2f\\x2f.\*=\\.|.\*\|+?sU**

This example searches packet payload for a URL with any number of characters, including newlines, followed by an equal sign, and pipe characters that contain any number of characters or white space. This example uses `m?regex?` to avoid using `http:\\/\\/` in the expression.

This example would match:

- http://www.example.com?value=|/bin/sh/ -i|
- http://www.example.com?input=|cat /etc/passwd|

This example would **not** match:

- ftp://ftp.example.com?value=|/bin/sh/ -i|
- http://www.example.com?value=x&input?|cat /etc/passwd|
- **/[0-9a-f]{2}\:[0-9a-f]{2}\:[0-9a-f]{2}\:[0-9a-f]{2}\:[0-9a-f]{2}\:[0-9a-f]{2}/i**

This example searches packet payload for any MAC address. Note that it escapes the colon characters with backslashes.

## The metadata Keyword

You can use the `metadata` keyword to add your own descriptive information to a rule. You can also use the `metadata` keyword with `service` arguments to identify applications and ports in network traffic. You can use the information you add to organize or identify rules in ways that suit your needs, and you can search rules for information you add and for `service` arguments.

The system validates metadata based on the argument format:

*key value*

where *key* and *value* provide a combined description separated by a space. This is the format used by the Talos Intelligence Group for adding metadata to rules provided by Cisco.

Alternatively, you can also use the format:

*key = value*

For example, you could use the *key value* format to identify rules by author and date, using a category and sub-category as follows:

```
author SnortGuru_20050406
```

You can use multiple `metadata` keywords in a rule. You can also use commas to separate multiple *key value* arguments in a single `metadata` keyword, as seen in the following example:

```
author SnortGuru_20050406, revised_by SnortUser1_20050707,
revised_by SnortUser2_20061003,
revised_by SnortUser1_20070123
```

You are not limited to using a *key value* or *key=value* format; however, you should be aware of limitations resulting from validation based on these formats.

### Restricted Characters to Avoid

Note the following character restrictions:

- Do not use a semicolon (;) or colon (:).
- The system interprets a comma as a separator for multiple *key value* or *key=value* arguments. For example:  
*key value, key value, key value*
- The system interprets the equal to (=) character or space character as separators between *key* and *value*. For example:

*key value*

*key=value*

All other characters are permitted.

### Reserved Metadata to Avoid

Avoid using the following words in a `metadata` keyword, either as a single argument or as the *key* in a *key value* argument; these are reserved for use by Talos:

```
application
engine
impact_flag
os
policy
rule-type
rule-flushing
soid
```

---

**Note** Contact Support for assistance in adding restricted metadata to local rules that might not otherwise function as expected.

---

### Impact Level 1

You can use the following reserved *key value* argument in a `metadata` keyword:

```
impact_flag red
```

This *key value* argument sets the impact flag to red (level 1) for a local rule you import or a custom rule you create using the intrusion rules editor.

Note that when Talos includes the `impact_flag red` argument in a rule provided by Cisco, Talos has determined that a packet triggering the rule indicates that the source or destination host is potentially compromised by a virus, trojan, or other piece of malicious software.

## Service Metadata

The system detects applications running on the hosts in your network and inserts application protocol information into your network traffic; it does this regardless of the configuration of your discovery policy. You can use `metadata` keyword `service` arguments in a TCP or UDP rule to match application protocols and ports in your network traffic. You can combine one or more `service` application arguments in a rule with a single port argument.

### Service Applications

You can use the `metadata` keyword with `service` as the *key* and an application as the *value* to match packets with the identified application protocol. For example, the following *key value* argument in a `metadata` keyword associates the rule with HTTP traffic:

```
service http
```

You can identify multiple applications separated by commas. For example:

```
service http, service smtp, service ftp
```

---

**Caution** Adaptive profiling **must** be enabled (its default state) as described in [Configuring Adaptive Profiles, on page 2940](#) for intrusion rules to use service metadata.

---

The following table describes the most common application values used with the `service` keyword.

**Note** Contact Support for assistance if you have difficulty identifying applications not in the table.

**Table 163: service Values**

Value	Description
cvs	Concurrent Versions System
dcerpc	Distributed Computing Environment/Remote Procedure Calls System
dns	Domain Name System
finger	Finger user information protocol
ftp	File Transfer Protocol
ftp-data	File Transfer Protocol (Data Channel)
http	Hypertext Transfer Protocol
imap	Internet Message Access Protocol
isakmp	Internet Security Association and Key Management Protocol
mysql	My Structured Query Language
netbios-dgm	NETBIOS Datagram Service
netbios-ns	NETBIOS Name Service
netbios-ssn	NETBIOS Session Service
nntp	Network News Transfer Protocol
oracle	Oracle Net Services
shell	OS Shell
pop2	Post Office Protocol, version 2
pop3	Post Office Protocol, version 3
smtp	Simple Mail Transfer Protocol
snmp	Simple Network Management Protocol
ssh	Secure Shell network protocol
sunrpc	Sun Remote Procedure Call Protocol
telnet	Telnet network protocol

Value	Description
tftp	Trivial File Transfer Protocol
x11	X Window System

### Service Ports

You can use the `metadata` keyword with `service` as the *key* and a specified port argument as the *value* to define how the rule matches ports in combination with applications.

You can specify any of the port values in the table below, one value per rule.

**Table 164: service Port Values**

Value	Description
<code>else-ports</code> or <code>unknown</code>	<p>The system applies the rule if either of the following conditions is met:</p> <ul style="list-style-type: none"> <li>• The packet application is known and matches the rule application.</li> <li>• The packet application is unknown and packet ports match the rule ports.</li> </ul> <p>The <code>else-ports</code> and <code>unknown</code> values produce the default behavior that the system uses when <code>service</code> specifies an application protocol with no port modifier.</p>
<code>and-ports</code>	<p>The system applies the rule if the packet application is known and matches the rule application, and the packet port matches the ports in the rule header. You cannot use <code>and-ports</code> in a rule that does not specify an application.</p>
<code>or-ports</code>	<p>The system applies the rule if any of the following conditions are met:</p> <ul style="list-style-type: none"> <li>• The packet application is known and matches the rule application.</li> <li>• The packet application is unknown and packet port matches the rule ports.</li> <li>• The packet application does not match the rule application and packet ports match the rule ports.</li> <li>• The rule does not specify an application and packet ports match the rule ports.</li> </ul>

Note the following:

- You must include a `service` application argument with the `service and-ports` argument.
- If a rule specifies more than one of the values in the table above, the system applies the last one that appears in the rule.
- Port and application arguments can be in any order.

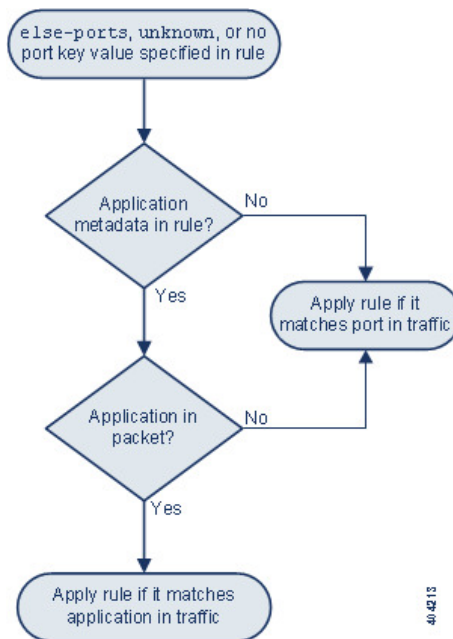

Except for the `and-ports` value, you can include a `service` port argument with or without one or more `service` application arguments. For example:

```
service or-ports, service http, service smtp
```

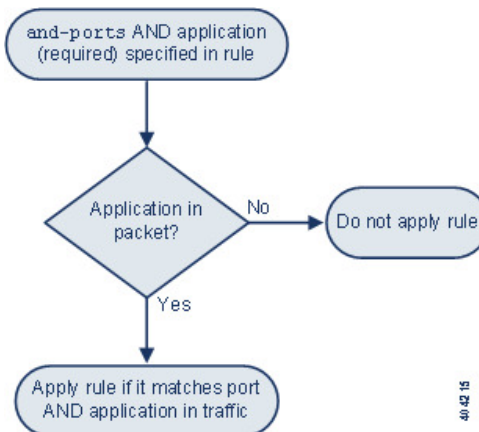

### Applications and Ports in Traffic

The diagrams below illustrate the application and port combinations that intrusion rules support, and the results of applying these rule constraints to packet data.

#### Host application protocol else source/destination ports:

#### Host application protocol and source/destination ports:

**Host application protocol or source/destination ports:**

**Example Matches**

The following sample rules using the `metadata` keyword with `service` arguments are shown with examples of data they match and do not match:

- `alert tcp any any -> any [80,8080] (metadata:service and-ports, service http, service smtp;)`

Example Matches	Example Non-Matches
<ul style="list-style-type: none"> <li>• HTTP traffic over TCP port 80</li> <li>• HTTP traffic over TCP port 8080</li> <li>• SMTP traffic over TCP port 80</li> <li>• SMTP traffic over TCP port 8080</li> </ul>	<ul style="list-style-type: none"> <li>• POP3 traffic on ports 80 or 8080</li> <li>• Traffic of unknown application on ports 80 or 8080</li> <li>• HTTP traffic on port 9999</li> </ul>

- `alert tcp any any -> any [80,8080] (metadata:service or-ports, service http;)`

Example Matches	Example Non-Matches
<ul style="list-style-type: none"> <li>• HTTP traffic on any port</li> <li>• SMTP traffic on port 80</li> <li>• SMTP traffic on port 8080</li> <li>• Traffic of unknown application on port 80 and 8080</li> </ul>	<ul style="list-style-type: none"> <li>• Non-HTTP and non-SMTP traffic on ports other than 80 or 8080</li> </ul>

- Any of the following rules:

- `alert tcp any any -> any [80,8080] metadata:service else-ports, service http;)`
- `alert tcp any any -> any [80,8080] metadata:service unknown, service http;)`
- `alert tcp any any -> any [80,8080] metadata:service http;)`

Example Matches	Example Non-Matches
<ul style="list-style-type: none"> <li>• HTTP traffic on any port</li> <li>• port 80 if packet application is unknown</li> <li>• port 8080 if packet application is unknown</li> </ul>	<ul style="list-style-type: none"> <li>• SMTP traffic on ports 80 or 8080</li> <li>• POP3 traffic on ports 80 or 8080</li> </ul>

## Metadata Search Guidelines

To search for rules that use the `metadata` keyword, select the `metadata` keyword on the rules Search page and, optionally, type any portion of the metadata. For example, you can type:

- `search` to display all rules where you have used `search` for *key*.
- `search http` to display all rules where you have used `search` for *key* and `http` for *value*.
- `author snortguru` to display all rules where you have used `author` for *key* and `SnortGuru` for *value*.
- `author s` to display all rules where you have used `author` for *key* and any terms such as `SnortGuru` or `SnortUser1` or `SnortUser2` for *value*.

**Tip** When you search for both *key* and *value*, use the same connecting operator (equal to [=] or a space character) in searches that is used in the *key value* argument in the rule; searches return different results depending on whether you follow *key* with equal to (=) or a space character.

Note that regardless of the format you use to add metadata, the system interprets your metadata search term as all or part of a *key value* or *key=value* argument. For example, the following would be valid metadata that does not follow a *key value* or *key=value* format:

```
ab cd ef gh
```

However, the system would interpret each space in the example as a separator between a *key* and *value*. Thus, you could successfully locate a rule containing the example metadata using any of the following searches for juxtaposed and single terms:

```
cd ef
ef gh
ef
```

but you would not locate the rule using the following search, which the system would interpret as a single *key value* argument:

ab ef

[Searching for Rules](#), on page 2113

## IP Header Values

You can use keywords to identify possible attacks or security policy violations in the IP headers of packets.

### fragbits

The `fragbits` keyword inspects the fragment and reserved bits in the IP header. You can check each packet for the Reserved Bit, the More Fragments bit, and the Don't Fragment bit in any combination.

**Table 165: Fragbits Argument Values**

Argument	Description
R	Reserved bit
M	More Fragments bit
D	Don't Fragment bit

To further refine a rule using the `fragbits` keyword, you can specify any operator described in the following table after the argument value in the rule.

**Table 166: Fragbit Operators**

Operator	Description
plus sign (+)	The packet must match against all specified bits.
asterisk (*)	The packet can match against any of the specified bits.
exclamation point (!)	The packet meets the criteria if none of the specified bits are set.

For example, to generate an event against packets that have the Reserved Bit set (and possibly any other bits), use `R+` as the `fragbits` value.

### id

The `id` keyword tests the IP header fragment identification field against the value you specify in the keyword's argument. Some denial-of-service tools and scanners set this field to a specific number that is easy to detect. For example, in SID 630, which detects a Synscan portscan, the `id` value is set to `39426`, the static value used as the ID number in packets transmitted by the scanner.

**Note** `id` argument values must be numeric.

**ipopts**

The `IPopts` keyword allows you to search packets for specified IP header options. The following table lists the available argument values.

**Table 167: IPoption Arguments**

Argument	Description
rr	record route
eol	end of list
nop	no operation
ts	time stamp
sec	IP security option
lsrr	loose source routing
ssrr	strict source routing
satid	stream identifier

Analysts most frequently watch for strict and loose source routing because these options may be an indication of a spoofed source IP address.

**ip\_proto**

The `ip_proto` keyword allows you to identify packets with the IP protocol specified as the keyword's value. You can specify the IP protocols as a number, 0 through 255. You can combine these numbers with the following operators: `<`, `>`, or `!`. For example, to inspect traffic with any protocol that is not ICMP, use `!1` as a value to the `ip_proto` keyword. You can also use the `ip_proto` keyword multiple times in a single rule; note, however, that the rules engine interprets multiple instances of the keyword as having a Boolean AND relationship. For example, if you create a rule containing `ip_proto:!3; ip_proto:!6`, the rule ignores traffic using the GGP protocol AND the TCP protocol.

**tos**

Some networks use the type of service (ToS) value to set precedence for packets traveling on that network. The `tos` keyword allows you to test the packet's IP header ToS value against the value you specify as the keyword's argument. Rules using the `tos` keyword will trigger on packets whose ToS is set to the specified value and that meet the rest of the criteria set forth in the rule.

---

**Note** Argument values for `tos` must be numeric.

---

The ToS field has been deprecated in the IP header protocol and replaced with the Differentiated Services Code Point (DSCP) field.

**ttl**

A packet's time-to-live (ttl) value indicates how many hops it can make before it is dropped. You can use the `ttl` keyword to test the packet's IP header ttl value against the value, or range of values, you specify as the keyword's argument. It may be helpful to set the `ttl` keyword parameter to a low value such as 0 or 1, as low time-to-live values are sometimes indicative of a traceroute or intrusion evasion attempt. (Note, though, that the appropriate value for this keyword depends on your managed device placement and network topology.) Use syntax as follows:

- Use an integer from 0 to 255 to set a specific value for the TTL value. You can also precede the value with an equal (=) sign (for example, you can specify `5` or `=5`).
- Use a hyphen (-) to specify a range of TTL values (for example, `0-2` specifies all values 0 through 2, `-5` specifies all values 0 through 5, and `5-` specifies all values 5 through 255).
- Use the greater than (>) sign to specify TTL values greater than a specific value (for example, `>3` specifies all values greater than 3).
- Use the greater than and equal to signs (>=) to specify TTL values greater than or equal to a specific value (for example, `>=3` specifies all values greater than or equal to 3).
- Use the less than (<) sign to specify TTL values less than a specific value (for example, `<3` specifies all values less than 3).
- Use the less than and equal to signs (<=) to specify TTL values less than or equal to a specific value (for example, `<=3` specifies all values less than or equal to 3).

## ICMP Header Values

The system supports keywords that you can use to identify attacks and security policy violations in the headers of ICMP packets. Note, however, that predefined rules exist that detect most ICMP types and codes. Consider enabling an existing rule or creating a local rule based on an existing rule; you may be able to find a rule that meets your needs more quickly than if you build an ICMP rule from scratch.

**icmp\_id and icmp\_seq**

The ICMP identification and sequence numbers help associate ICMP replies with ICMP requests. In normal traffic, these values are dynamically assigned to packets. Some covert channel and Distributed Denial of Server (DDoS) programs use static ICMP ID and sequence values. The following keywords allow you to identify ICMP packets with static values.

Keyword	Definition
<code>icmp_id</code>	Inspects an ICMP echo request or reply packet's ICMP ID number. Use a numeric value that corresponds with the ICMP ID number as the argument for the <code>icmp_id</code> keyword.
<code>icmp_seq</code>	The <code>icmp_seq</code> keyword inspects an ICMP echo request or reply packet's ICMP sequence. Use a numeric value that corresponds with the ICMP sequence number as the argument for the <code>icmp_seq</code> keyword.

### itype

Use the `itype` keyword to look for packets with specific ICMP message type values. You can specify either a valid ICMP type value or an invalid ICMP type value to test for different types of traffic. For example, attackers may set ICMP type values out of range to cause denial of service and flooding attacks.

You can specify a range for the `itype` argument value using less than (<) and greater than (>).

For example:

- <35
- >36
- 3<>55

### icode

ICMP messages sometimes include a code value that provides details when a destination is unreachable.

You can use the `icode` keyword to identify packets with specific ICMP code values. You can choose to specify either a valid ICMP code value or an invalid ICMP code value to test for different types of traffic.

You can specify a range for the `icode` argument value using less than (<) and greater than (>).

For example:

- to find values less than 35, specify <35.
- to find values greater than 36, specify >36.
- to find values between 3 and 55, specify 3<>55.

---

**Tip** You can use the `icode` and `itype` keywords together to identify traffic that matches both. For example, to identify ICMP traffic that contains an ICMP Destination Unreachable code type with an ICMP Port Unreachable code type, specify an `itype` keyword with a value of 3 (for Destination Unreachable) and an `icode` keyword with a value of 3 (for Port Unreachable).

---

## TCP Header Values and Stream Size

The system supports keywords that are designed to identify attacks attempted using TCP headers of packets and TCP stream size.

### ack

You can use the `ack` keyword to compare a value against a packet's TCP acknowledgment number. The rule triggers if a packet's TCP acknowledgment number matches the value specified for the `ack` keyword.

Argument values for `ack` must be numeric.

### flags

You can use the `flags` keyword to specify any combination of TCP flags that, when set in an inspected packet, cause the rule to trigger.

**Note** In situations where you would traditionally use `A+` as the value for `flags`, you should instead use the `flow` keyword with a value of `established`. Generally, you should use the `flow` keyword with a value of `stateless` when using flags to ensure that all combinations of flags are detected.

You can either check for or ignore the values described in the following table for the `flag` keyword.

**Table 168: flag Arguments**

Argument	TCP Flag
Ack	Acknowledges data.
Psh	Data should be sent in this packet.
Syn	A new connection.
Urg	Packet contains urgent data.
Fin	A closed connection.
Rst	An aborted connection.
CWR	An ECN congestion window has been reduced. This was formerly the R1 argument, which is still supported for backward compatibility.
ECE	ECN echo. This was formerly the R2 argument, which is still supported for backward compatibility.

When using the `flags` keyword, you can use an operator to indicate how the system performs matches against multiple flags. The following table describes these operators.

**Table 169: Operators Used with flags**

Operator	Description	Example
all	The packet must contain all specified flags.	Select <code>Urg</code> and <code>all</code> to specify that a packet must contain the Urgent flag and may contain any other flags.
any	The packet can contain any of the specified flags.	Select <code>Ack</code> , <code>Psh</code> , and <code>any</code> to specify that either or both the <code>Ack</code> and <code>Psh</code> flags must be set to trigger the rule, and that other flags may also be set on a packet.
not	The packet must <b>not</b> contain the specified flag set.	Select <code>Urg</code> and <code>not</code> to specify that the Urgent flag is <b>not</b> set on packets that trigger this rule.

## flow

You can use the `flow` keyword to select packets for inspection by a rule based on session characteristics. The `flow` keyword allows you to specify the direction of the traffic flow to which a rule applies, applying rules to either the client flow or server flow. To specify how the `flow` keyword inspects your packets, you can set the

direction of traffic you want analyzed, the state of packets inspected, and whether the packets are part of a rebuilt stream.

Stateful inspection of packets occurs when rules are processed. If you want a TCP rule to ignore stateless traffic (traffic without an established session context), you must add the `flow` keyword to the rule and select the **Established** argument for the keyword. If you want a UDP rule to ignore stateless traffic, you must add the `flow` keyword to the rule and select either the **Established** argument or a directional argument, or both. This causes the TCP or UDP rule to perform stateful inspection of a packet.

When you add a directional argument, the rules engine inspects only those packets that have an established state with a flow that matches the direction specified. For example, if you add the `flow` keyword with the `established` argument and the `From Client` argument to a rule that triggers when a TCP or UDP connection is detected, the rules engine only inspects packets that are sent from the client.

**Tip** For maximum performance, always include a `flow` keyword in a TCP rule or a UDP session rule.

The following table describes the stream-related arguments you can specify for the `flow` keyword:

**Table 170: State-Related flow Arguments**

Argument	Description
Established	Triggers on established connections.
Stateless	Triggers regardless of the state of the stream processor.

The following table describes the directional options you can specify for the `flow` keyword:

**Table 171: flow Directional Arguments**

Argument	Description
To Client	Triggers on server responses.
To Server	Triggers on client responses.
From Client	Triggers on client responses.
From Server	Triggers on server responses.

Notice that `From Server` and `To Client` perform the same function, as do `To Server` and `From Client`. These options exist to add context and readability to the rule. For example, if you create a rule designed to detect an attack from a server to a client, use `From Server`. But, if you create a rule designed to detect an attack from the client to the server, use `From Client`.

The following table describes the stream-related arguments you can specify for the `flow` keyword:

**Table 172: Stream-Related flow Arguments**

Argument	Description
Ignore Stream Traffic	Does not trigger on rebuilt stream packets.
Only Stream Traffic	Triggers only on rebuilt stream packets.

For example, you can use `To Server, Established, Only Stream Traffic` as the value for the `flow` keyword to detect traffic, traveling from a client to the server in an established session, that has been reassembled by the stream preprocessor.

### seq

The `seq` keyword allows you to specify a static sequence number value. Packets whose sequence number matches the specified argument trigger the rule containing the keyword. While this keyword is used rarely, it is helpful in identifying attacks and network scans that use generated packets with static sequence numbers.

### window

You can use the `window` keyword to specify the TCP window size you are interested in. A rule containing this keyword triggers whenever it encounters a packet with the specified TCP window size. While this keyword is used rarely, it is helpful in identifying attacks and network scans that use generated packets with static TCP window sizes.

### stream\_size

You can use the `stream_size` keyword in conjunction with the stream preprocessor to determine the size in bytes of a TCP stream, using the format:

```
direction,operator,bytes
```

where `bytes` is number of bytes. You must separate each option in the argument with a comma (,).

The following table describes the case-insensitive directional options you can specify for the `stream_size` keyword:

**Table 173: stream\_size Keyword Directional Arguments**

Argument	Description
client	triggers on a stream from the client matching the specified stream size.
server	triggers on a stream from the server matching the specified stream size.
both	triggers on traffic from the client and traffic from the server both matching the specified stream size.  For example, the argument <code>both, &gt;, 200</code> would trigger when traffic from the client is greater than 200 bytes AND traffic from the server is greater than 200 bytes.
either	triggers on traffic from either the client or the server matching the specified stream size, whichever occurs first.  For example, the argument <code>either, &gt;, 200</code> would trigger when traffic from the client is greater than 200 bytes OR traffic from the server is greater than 200 bytes.

The following table describes the operators you can use with the `stream_size` keyword:

Table 174: stream\_size Keyword Argument Operators

Operator	Description
=	equal to
!=	not equal to
>	greater than
<	less than
>=	greater than or equal to
<=	less than or equal to

For example, you could use `client, >=, 5001216` as the argument for the `stream_size` keyword to detect a TCP stream traveling from a client to a server and greater than or equal to 5001216 bytes.

## The stream\_reassembly Keyword

You can use the `stream_reassemble` keyword to enable or disable TCP stream reassembly for a single connection when inspected traffic on the connection matches the conditions of the rule. Optionally, you can use this keyword multiple times in a rule.

Use the following syntax to enable or disable stream reassembly:

```
enable|disable, server|client|both, option, option
```

The following table describes the optional arguments you can use with the `stream_reassemble` keyword.

Table 175: stream\_reassemble Optional Arguments

Argument	Description
noalert	Generate no events regardless of any other detection options specified in the rule.
fastpath	Ignore the rest of the connection traffic when there is a match.

For example, the following rule disables TCP client-side stream reassembly without generating an event on the connection where a 200 OK status code is detected in an HTTP response:

```
alert tcp any 80 -> any any (flow:to_client, established; content: "200 OK";
stream_reassemble:disable, client, noalert
```

## SSL Keywords

You can use SSL rule keywords to invoke the Secure Sockets Layer (SSL) preprocessor and extract information about SSL version and session state from packets in an encrypted session.

When a client and server communicate to establish an encrypted session using SSL or Transport Layer Security (TLS), they exchange handshake messages. Although the data transmitted in the session is encrypted, the handshake messages are not.

The SSL preprocessor extracts state and version information from specific handshake fields. Two fields within the handshake indicate the version of SSL or TLS used to encrypt the session and the stage of the handshake.

### ssl\_state

The `ssl_state` keyword can be used to match against state information for an encrypted session. To check for two or more SSL versions used simultaneously, use multiple `ssl_version` keywords in a rule.

When a rule uses the `ssl_state` keyword, the rules engine invokes the SSL preprocessor to check traffic for SSL state information.

For example, to detect an attacker's attempt to cause a buffer overflow on a server by sending a `ClientHello` message with an overly long challenge length and too much data, you could use the `ssl_state` keyword with `client_hello` as an argument then check for abnormally large packets.

Use a comma-separated list to specify multiple arguments for the SSL state. When you list multiple arguments, the system evaluates them using the OR operator. For example, if you specify `client_hello` and `server_hello` as arguments, the system evaluates the rule against traffic that has a `client_hello` OR a `server_hello`.

You can also negate any argument; for example:

```
!client_hello, !unknown
```

To ensure the connection has reached each of a set of states, multiple rules using the `ssl_state` rule option should be used. The `ssl_state` keyword takes the following identifiers as arguments:

**Table 176: ssl\_state Arguments**

Argument	Purpose
<code>client_hello</code>	Matches against a handshake message with <code>ClientHello</code> as the message type, where the client requests an encrypted session.
<code>server_hello</code>	Matches against a handshake message with <code>ServerHello</code> as the message type, where the server responds to the client's request for an encrypted session.
<code>client_keyx</code>	Matches against a handshake message with <code>ClientKeyExchange</code> as the message type, where the client transmits a key to the server to confirm receipt of a key from the server.
<code>server_keyx</code>	Matches against a handshake message with <code>ServerKeyExchange</code> as the message type, where the client transmits a key to the server to confirm receipt of a key from the server.
<code>unknown</code>	Matches against any handshake message type.

### ssl\_version

The `ssl_version` keyword can be used to match against version information for an encrypted session. When a rule uses the `ssl_version` keyword, the rules engine invokes the SSL preprocessor to check traffic for SSL version information.

For example, if you know there is a buffer overflow vulnerability in SSL version 2, you could use the `ssl_version` keyword with the `ssl_v2` argument to identify traffic using that version of SSL.

Use a comma-separated list to specify multiple arguments for the SSL version. When you list multiple arguments, the system evaluates them using the OR operator. For example, if you wanted to identify any encrypted traffic that was not using SSLv2, you could add `ssl_version:ssl_v3,tls1.0,tls1.1,tls1.2` to a rule. The rule would evaluate any traffic using SSL Version 3, TLS Version 1.0, TLS Version 1.1, or TLS Version 1.2.

The `ssl_version` keyword takes the following SSL/TLS version identifiers as arguments:

**Table 177: `ssl_version` Arguments**

Argument	Purpose
<code>sslv2</code>	Matches against traffic encoded using Secure Sockets Layer (SSL) Version 2.
<code>sslv3</code>	Matches against traffic encoded using Secure Sockets Layer (SSL) Version 3.
<code>tls1.0</code>	Matches against traffic encoded using Transport Layer Security (TLS) Version 1.0.
<code>tls1.1</code>	Matches against traffic encoded using Transport Layer Security (TLS) Version 1.1.
<code>tls1.2</code>	Matches against traffic encoded using Transport Layer Security (TLS) Version 1.2.

## The appid Keyword

You can use the `appid` keyword to identify the application protocol, client application, or web application in a packet. For example, you could target a specific application that you know is susceptible to a specific vulnerability.

Within the `appid` keyword of an intrusion rule, click **Configure AppID** to select one or more applications that you want to detect.

### Browsing the Available Applications

When you first start to build the condition, the **Available Applications** list is unconstrained and displays every application the system detects, 100 per page:

- To page through the applications, click the arrows underneath the list.
- To display a pop-up window with summary information about the application's characteristics, as well as Internet search links that you can follow, click **Information** (i) next to an application.

### Using Application Filters

To help you find the applications you want to match, you can constrain the **Available Applications** list in the following ways:

- To search for applications, click the **Search by name** prompt above the list, then type a name. The list updates as you type to display matching applications.
- To constrain the applications by applying a filter, use the **Application Filters** list. The **Available Applications** list updates as you apply filters. For your convenience, the system uses an **Unlock icon** to mark applications that the system can identify only in decrypted traffic—not encrypted or unencrypted.

**Note** If you select one or more filters in the Application Filters list and also search the **Available Applications** list, your selections and the search-filtered **Available Applications** list are combined using an AND operation.

### Selecting Applications

To select a single application, select it and click **Add to Rule**. To select all applications in the current constrained view, right-click and select **Select All**.

## Application Layer Protocol Values

Although preprocessors perform most of the normalization and inspection of application layer protocol values, you can continue to inspect application layer values using various preprocessor options.

### The RPC Keyword

The `rpc` keyword identifies Open Network Computing Remote Procedure Call (ONC RPC) services in TCP or UDP packets. This allows you to detect attempts to identify the RPC programs on a host. Intruders can use an RPC portmapper to determine if any of the RPC services running on your network can be exploited. They can also attempt to access other ports running RPC without using portmapper. The following table lists the arguments that the `rpc` keyword accepts.

**Table 178: rpc Keyword Arguments**

Argument	Description
application	The RPC application number
procedure	The RPC procedure invoked
version	The RPC version

To specify the arguments for the `rpc` keyword, use the following syntax:

```
application,procedure,version
```

where `application` is the RPC application number, `procedure` is the RPC procedure number, and `version` is the RPC version number. You must specify all arguments for the `rpc` keyword — if you are not able to specify one of the arguments, replace it with an asterisk (\*).

For example, to search for RPC portmapper (which is the RPC application indicated by the number 100000), with any procedure or version, use `100000,*,*` as the arguments.

### The ASN.1 Keyword

The `asn1` keyword allows you to decode a packet or a portion of a packet, looking for various malicious encodings.

The following table describes the arguments for the `asn1` keyword.

Table 179: asn.1 Keyword Arguments

Argument	Description
Bitstring Overflow	Detects invalid, remotely exploitable bitstring encodings.
Double Overflow	Detects a double ASCII encoding that is larger than a standard buffer. This is known to be an exploitable function in Microsoft Windows, but it is unknown at this time which services may be exploitable.
Oversize Length	Detects ASN.1 type lengths greater than the supplied argument. For example, if you set the Oversize Length to 500, any ASN.1 type greater than 500 triggers the rule.
Absolute Offset	Sets an absolute offset from the beginning of the packet payload. (Remember that the offset counter starts at byte 0.) For example, if you want to decode SNMP packets, set Absolute Offset to 0 and do not set a Relative Offset. Absolute Offset may be positive or negative.
Relative Offset	This is the relative offset from the last successful content match, <code>pcre</code> , or <code>byte_jump</code> . To decode an ASN.1 sequence right after the content "foo", set Relative Offset to 0, and do not set an Absolute Offset. Relative Offset may be positive or negative. (Remember that the offset counter starts at 0.)

For example, there is a known vulnerability in the Microsoft ASN.1 Library that creates a buffer overflow, allowing an attacker to exploit the condition with a specially crafted authentication packet. When the system decodes the asn.1 data, exploit code in the packet could execute on the host with system-level privileges or could cause a DoS condition. The following rule uses the `asn1` keyword to detect attempts to exploit this vulnerability:

```
alert tcp $EXTERNAL_NET any -> $HOME_NET 445
(flow:to_server, established; content:"|FF|SMB|73|";
nocase; offset:4; depth:5;
asn1:bitstring_overflow,double_overflow,oversize_length 100,
relative_offset 54;)
```

The above rule generates an event against TCP traffic traveling from any IP address defined in the `$EXTERNAL_NET` variable, from any port, to any IP address defined in the `$HOME_NET` variable using port 445. In addition, it only executes the rule on established TCP connections to servers. The rule then tests for specific content in specific locations. Finally, the rule uses the `asn1` keyword to detect bitstring encodings and double ASCII encodings and to identify asn.1 type lengths over 100 bytes in length starting 55 bytes from the end of the last successful content match. (Remember that the `offset` counter starts at byte 0.)

## The urilen Keyword

You can use the `urilen` keyword in conjunction with the HTTP Inspect preprocessor to inspect HTTP traffic for URIs of a specific length, less than a maximum length, greater than a minimum length, or within a specified range.

After the HTTP Inspect preprocessor normalizes and inspects the packet, the rules engine evaluates the packet against the rule and determines whether the URI matches the length condition specified by the `urilen` keyword. You can use this keyword to detect exploits that attempt to take advantage of URI length vulnerabilities, for example, by creating a buffer overflow that allows the attacker to cause a DoS condition or execute code on the host with system-level privileges.

Note the following when using the `urilen` keyword in a rule:

- In practice, you always use the `urilen` keyword in combination with the `flow:established` keyword and one or more other keywords.
- The rule protocol is always TCP.
- Target ports are always HTTP ports.

You specify the URI length using a decimal number of bytes, less than (<) and greater than (>).

For example:

- specify `5` to detect a URI 5 bytes long.
- specify `< 5` (separated by one space character) to detect a URI less than 5 bytes long.
- specify `> 5` (separated by one space character) to detect a URI greater than 5 bytes long.
- specify `3 <> 5` (with one space character before and after <>) to detect a URI between 3 and 5 bytes long inclusive.

For example, there is a known vulnerability in Novell's server monitoring and diagnostics utility iMonitor version 2.4, which comes with eDirectory version 8.8. A packet containing an excessively long URI creates a buffer overflow, allowing an attacker to exploit the condition with a specially crafted packet that could execute on the host with system-level privileges or could cause a DoS condition. The following rule uses the `urilen` keyword to detect attempts to exploit this vulnerability:

```
alert tcp $EXTERNAL_NET any -> $HOME_NET $HTTP_PORTS
(msg:"EXPLOIT eDirectory 8.8 Long URI iMonitor buffer
overflow attempt"; flow:to_server,established;
urilen:> 8192; uricontent:"/nds/"; nocase;
classtype:attempted-admin; sid:x; rev:1;)
```

The above rule generates an event against TCP traffic traveling from any IP address defined in the `$EXTERNAL_NET` variable, from any port, to any IP address defined in the `$HOME_NET` variable using the ports defined in the `$HTTP_PORTS` variable. In addition, packets are evaluated against the rule only on established TCP connections to servers. The rule uses the `urilen` keyword to detect any URI over 8192 bytes in length. Finally, the rule searches the URI for the specific case-insensitive content `/nds/`.

## DCE/RPC Keywords

The three DCE/RPC keywords described in the following table allow you to monitor DCE/RPC session traffic for exploits. When the system processes rules with these keywords, it invokes the DCE/RPC preprocessor.

**Table 180: DCE/RPC Keywords**

Use...	In this way...	To detect...
<code>dce_iface</code>	alone	packets identifying a specific DCE/RPC service

Use...	In this way...	To detect...
dce_opnum	preceded by dce_iface	packets identifying specific DCE/RPC service operations
dce_stub_data	preceded by dce_iface + dce_opnum	stub data defining a specific operation request or response

Note in the table that you should always precede `dce_opnum` with `dce_iface`, and you should always precede `dce_stub_data` with `dce_iface + dce_opnum`.

You can also use these DCE/RPC keywords in combination with other rule keywords. Note that for DCE/RPC rules, you use the `byte_jump`, `byte_test`, and `byte_extract` keywords with their **DCE/RPC** arguments selected.

Cisco recommends that you include at least one `content` keyword in rules that include DCE/RPC keywords to ensure that the rules engine uses the fast pattern matcher, which increases processing speed and improves performance. Note that the rules engine uses the fast pattern matcher when a rule includes at least one `content` keyword, regardless of whether you enable the `content` keyword **Use Fast Pattern Matcher** argument.

You can use the DCE/RPC version and adjoining header information as the matching content in the following cases:

- the rule does not include another `content` keyword
- the rule contains another `content` keyword, but the DCE/RPC version and adjoining information represent a more unique pattern than the other content

For example, the DCE/RPC version and adjoining information are more likely to be unique than a single byte of content.

You should end qualifying rules with one of the following version and adjoining information content matches:

- For connection-oriented DCE/RPC rules, use the content `|05 00 00|` (for major version 05, minor version 00, and the request PDU (protocol data unit) type 00).
- For connectionless DCE/RPC rules, use the content `|04 00|` (for version 04, and the request PDU type 00).

In either case, position the `content` keyword for version and adjoining information as the last keyword in the rule to invoke the fast pattern matcher without repeating processing already completed by the DCE/RPC preprocessor. Note that placing the `content` keyword at the end of the rule applies to version content used as a device to invoke the fast pattern matcher, and not necessarily to other content matches in the rule.

## dce\_iface

You can use the `dce_iface` keyword to identify a specific DCE/RPC service.

Optionally, you can also use `dce_iface` in combination with the `dce_opnum` and `dce_stub_data` keywords to further limit the DCE/RPC traffic to inspect.

A fixed, sixteen-byte Universally Unique Identifier (UUID) identifies the application interface assigned to each DCE/RPC service. For example, the UUID 4b324fc8-670-01d3-1278-5a47bf6ee188 identifies the DCE/RPC lanmanserver service, also known as the `srvsvc` service, which provides numerous management functions for sharing peer-to-peer printers, files, and SMB named pipes. The DCE/RPC preprocessor uses the UUID and associated header values to track DCE/RPC sessions.

The interface UUID is comprised of five hexadecimal strings separated by hyphens:

```
<4hexbytes>-<2hexbytes>-<2hexbytes>-<2hexbytes>-<6hexbytes>
```

You specify the interface by entering the entire UUID including hyphens, as seen in the following UUID for the netlogon interface:

```
12345678-1234-abcd-ef00-01234567cffb
```

Note that you must specify the first three strings in the UUID in big endian byte order. Although published interface listings and protocol analyzers typically display UUIDs in the correct byte order, you might encounter a need to rearrange the UUID byte order before entering it. Consider the following messenger service UUID shown as it might sometimes be displayed in raw ASCII text with the first three strings in little endian byte order:

```
f8 91 7b 5a 00 ff d0 11 a9 b2 00 c0 4f b6 e6 fc
```

You would specify the same UUID for the `dce_iface` keyword by inserting hyphens and putting the first three strings in big endian byte order as follows:

```
5a7b91f8-ff00-11d0-a9b2-00c04fb6e6fc
```

Although a DCE/RPC session can include requests to multiple interfaces, you should include only one `dce_iface` keyword in a rule. Create additional rules to detect additional interfaces.

DCE/RPC application interfaces also have interface version numbers. You can optionally specify an interface version with an operator indicating that the version equals, does not equal, is less than, or greater than the specified value.

Both connection-oriented and connectionless DCE/RPC can be fragmented in addition to any TCP segmentation or IP fragmentation. Typically, it is not useful to associate any DCE/RPC fragment other than the first with the specified interface, and doing so may result in a large number of false positives. However, for flexibility you can optionally evaluate all fragments against the specified interface.

The following table summarizes the `dce_iface` keyword arguments.

**Table 181: `dce_iface` Arguments**

Argument	Description
Interface UUID	The UUID, including hyphens, that identifies the application interface of the specific service that you want to detect in DCE/RPC traffic. Any request associated with the specified interface would match the interface UUID.
Version	Optionally, the application interface version number 0 to 65535 and an operator indicating whether to detect a version greater than (>), less than (<), equal to (=), or not equal to (!) the specified value.

Argument	Description
All Fragments	Optionally, enable to match against the interface in all associated DCE/RPC fragments and, if specified, on the interface version. This argument is disabled by default, indicating that the keyword matches only if the first fragment or the entire unfragmented packet is associated with the specified interface. Note that enabling this argument may result in false positives.

### The dce\_opnum Keyword

You can use the `dce_opnum` keyword in conjunction with the DCE/RPC preprocessor to detect packets that identify one or more specific operations that a DCE/RPC service provides.

Client function calls request specific service functions, which are referred to in DCE/RPC specifications as *operations*. An operation number (opnum) identifies a specific operation in the DCE/RPC header. It is likely that an exploit would target a specific operation.

For example, the UUID 12345678-1234-abcd-ef00-01234567effb identifies the interface for the netlogon service, which provides several dozen different operations. One of these is operation 6, the NetrServerPasswordSet operation.

You should precede a `dce_opnum` keyword with a `dce_iface` keyword to identify the service for the operation.

You can specify a single decimal value 0 to 65535 for a specific operation, a range of operations separated by a hyphen, or a comma-separated list of operations and ranges in any order.

Any of the following examples would specify valid netlogon operation numbers:

```
15
15-18
15, 18-20
15, 20-22, 17
15, 18-20, 22, 24-26
```

### The dce\_stub\_data Keyword

You can use the `dce_stub_data` keyword in conjunction with the DCE/RPC preprocessor to specify that the rules engine should start inspection at the beginning of the stub data, regardless of any other rule options. Packet payload rule options that follow the `dce_stub_data` keyword are applied relative to the stub data buffer.

DCE/RPC stub data provides the interface between a client procedure call and the DCE/RPC run-time system, the mechanism that provides the routines and services central to DCE/RPC. DCE/RPC exploits are identified in the stub data portion of the DCE/RPC packet. Because stub data is associated with a specific operation or function call, you should always precede `dce_stub_data` with `dce_iface` and `dce_opnum` to identify the related service and operation.

The `dce_stub_data` keyword has no arguments.

## SIP Keywords

Four SIP keywords allow you to monitor SIP session traffic for exploits.

Note that the SIP protocol is vulnerable to denial of service (DoS) attacks. Rules addressing these attacks can benefit from rate-based attack prevention.

## The sip\_header Keyword

You can use the `sip_header` keyword to start inspection at the beginning of the extracted SIP request or response header and restrict inspection to header fields.

The `sip_header` keyword has no arguments.

The following example rule fragment points to the SIP header and matches the CSeq header field:

```
alert udp any any -> any 5060 ( sip_header; content:"CSeq"; )
```

### Related Topics

[Dynamic Intrusion Rule States](#), on page 2092

[Rate-Based Attack Prevention](#), on page 2927

## The sip\_body Keyword

You can use the `sip_body` keyword to start inspection at the beginning of the extracted SIP request or response message body and restrict inspection to the message body.

The `sip_body` keyword has no arguments.

The following example rule fragment points to the SIP message body and matches a specific IP address in the `c` (connection information) field in extracted SDP data:

```
alert udp any any -> any 5060 ( sip_body; content:"c=IN 192.168.12.14"; )
```

Note that rules are not limited to searching for SDP content. The SIP preprocessor extracts the entire message body and makes it available to the rules engine.

## The sip\_method Keyword

A *method* field in each SIP request identifies the purpose of the request. You can use the `sip_method` keyword to test SIP requests for specific methods. Separate multiple methods with commas.

You can specify any of the following currently defined SIP methods:

```
ack, benotify, bye, cancel, do, info, invite, join, message, notify, options, prack,  
publish, quath, refer, register, service, sprack, subscribe, unsubscribe, update
```

Methods are case-insensitive. You can separate multiple methods with commas.

Because new SIP methods might be defined in the future, you can also specify a custom method, that is, a method that is not a currently defined SIP method. Accepted field values are defined in RFC 2616, which allows all characters except control characters and separators such as `=`, `(`, and `)`. See RFC 2616 for the complete list of excluded separators. When the system encounters a specified custom method in traffic, it will inspect the packet header but not the message.

The system supports up to 32 methods, including the 21 currently defined methods and an additional 11 methods. The system ignores any undefined methods that you might configure. Note that the 32 total methods includes methods specified using the **Methods to Check** SIP preprocessor option.

You can specify only one method when you use negation. For example:

```
!invite
```

Note, however, that multiple `sip_method` keywords in a rule are linked with an **AND** operation. For example, to test for all extracted methods except `invite` and `cancel`, you would use two negated `sip_method` keywords:

```

sip_method: !invite
sip_method: !cancel

```

Cisco recommends that you include at least one `content` keyword in rules that include the `sip_method` keyword to ensure that the rules engine uses the fast pattern matcher, which increases processing speed and improves performance. Note that the rules engine uses the fast pattern matcher when a rule includes at least one `content` keyword, regardless of whether you enable the `content` keyword **Use Fast Pattern Matcher** argument.

## The sip\_stat\_code Keyword

A three-digit status code in each SIP response indicates the outcome of the requested action. You can use the `sip_stat_code` keyword to test SIP responses for specific status codes.

You can specify a one-digit response-type number 1-9, a specific three-digit number 100-999, or a comma-separated list of any combination of either. A list matches if any single number in the list matches the code in the SIP response.

The following table describes the SIP status code values you can specify.

**Table 182: sip\_stat\_code Values**

To detect...	Specify...	For example...	Detects...
a specific status code	the three-digit status code	189	189
any three-digit code that begins with a specified single digit	the single digit	1	1xx; that is, 100, 101, 102, and so on
a list of values	any comma-separated combination of specific codes and single digits	222, 3	222 plus 300, 301, 302, and so on

Note also that the rules engine does not use the fast pattern matcher to search for the value specify using the `sip_stat_code` keyword, regardless of whether your rule includes a `content` keyword.

## GTP Keywords

Three GSRP Tunneling Protocol (GTP) keywords allow you to inspect the GTP command channel for GTP version, message type, and information elements. You cannot use GTP keywords in combination with other intrusion rule keywords such as `content` or `byte_jump`. You **must** use the `gtp_version` keyword in each rule that uses the `gtp_info` or `gtp_type` keyword.

### The gtp\_version Keyword

You can use the `gtp_version` keyword to inspect GTP control messages for GTP version 0, 1, or 2.

Because different GTP versions define different message types and information elements, you must use `gtp_version` when you use the `gtp_type` or `gtp_info` keyword. You can specify the value 0, 1, or 2.

## The gtp\_type Keyword

Each GTP message is identified by a message type, which is comprised of both a numeric value and a string. You can use the `gtp_type` keyword to inspect traffic for specific GTP message types. Because different GTP versions define different message types and information elements, you must also use `gtp_version` when you use the `gtp_type` or `gtp_info` keyword.

You can specify a defined decimal value for a message type, a defined string, or a comma-separated list of either or both in any combination, as seen in the following example:

```
10, 11, echo_request
```

The system uses an OR operation to match each value or string that you list. The order in which you list values and strings does not matter. Any single value or string in the list matches the keyword. You receive an error if you attempt to save a rule that includes an unrecognized string or an out-of-range value.

Note in the table that different GTP versions sometimes use different values for the same message type. For example, the `sgsn_context_request` message type has a value of 50 in GTPv0 and GTPv1, but a value of 130 in GTPv2.

The `gtp_type` keyword matches different values depending on the version number in the packet. In the example above, the keyword matches the message type value 50 in a GTPv0 or GTPv1 packet and the value 130 in a GTPv2 packet. The keyword does not match a packet when the message type value in the packet is not a known value for the version specified in the packet.

If you specify an integer for the message type, the keyword matches if the message type in the keyword matches the value in the GTP packet, regardless of the version specified in the packet.

The following table lists the defined values and strings recognized by the system for each GTP message type.

**Table 183: GTP Message Types**

Value	Version 0	Version 1	Version 2
1	echo_request	echo_request	echo_request
2	echo_response	echo_response	echo_response

## The gtp\_info Keyword

A GTP message can include multiple information elements, each of which is identified by both a defined numeric value and a defined string. You can use the `gtp_info` keyword to start inspection at the beginning of a specified information element, and restrict inspection to the specified information element. Because different GTP versions define different message types and information elements, you must also use `gtp_version` when you use this keyword.

You can specify either the defined decimal value or the defined string for an information element. You can specify a single value or string, and you can use multiple `gtp_info` keywords in a rule to inspect multiple information elements.

When a message includes multiple information elements of the same type, all are inspected for a match. When information elements occur in an invalid order, only the last instance is inspected.

Note that different GTP versions sometimes use different values for the same information element. For example, the `cause` information element has a value of 1 in GTPv0 and GTPv1, but a value of 2 in GTPv2.

The `gtp_info` keyword matches different values depending on the version number in the packet. In the example above, the keyword matches the information element value 1 in a GTPv0 or GTPv1 packet and the value 2 in a GTPv2 packet. The keyword does not match a packet when the information element value in the packet is not a known value for the version specified in the packet.

If you specify an integer for the information element, the keyword matches if the message type in the keyword matches the value in the GTP packet, regardless of the version specified in the packet.

The following table lists the values and strings recognized by the system for each GTP information element.

**Table 184: GTP Information Elements**

Value	Version 0	Version 1	Version 2

## SCADA Keywords

The rules engine uses Modbus, DNP3, CIP, and S7Commplus rules to access certain protocol fields.

### Modbus Keywords

You can use Modbus keywords alone or in combination with other keywords such as `content` and `byte_jump`.

#### **modbus\_data**

You can use the `modbus_data` keyword to point to the beginning of the Data field in a Modbus request or response.

#### **modbus\_func**

You can use the `modbus_func` keyword to match against the Function Code field in a Modbus application layer request or response header. You can specify either a single defined decimal value or a single defined string for a Modbus function code.

The following table lists the defined values and strings recognized by the system for Modbus function codes.

**Table 185: Modbus Function Codes**

Value	String
1	read_coils
2	read_discrete_inputs

Value	String
3	read_holding_registers
4	read_input_registers
5	write_single_coil
6	write_single_register
7	read_exception_status
8	diagnostics
11	get_comm_event_counter
12	get_comm_event_log
15	write_multiple_coils
16	write_multiple_registers
17	report_slave_id
20	read_file_record
21	write_file_record
22	mask_write_register
23	read_write_multiple_registers
24	read_fifo_queue
43	encapsulated_interface_transport

### modbus\_unit

You can use the `modbus_unit` keyword to match a single decimal value against the Unit ID field in a Modbus request or response header.

## DNP3 Keywords

You can use DNP3 keywords alone or in combination with other keywords such as `content` and `byte_jump`.

### dnp3\_data

You can use the `dnp3_data` keyword to point to the beginning of reassembled DNP3 application layer fragments.

The DNP3 preprocessor reassembles link layer frames into application layer fragments. The `dnp3_data` keyword points to the beginning of each application layer fragment; other rule options can match against the reassembled data within fragments without separating the data and adding checksums every 16 bytes.

**dnp3\_func**

You can use the `dnp3_func` keyword to match against the Function Code field in a DNP3 application layer request or response header. You can specify either a single defined decimal value or a single defined string for a DNP3 function code.

The following table lists the defined values and strings recognized by the system for DNP3 function codes.

**Table 186: DNP3 Function Codes**

Value	String
0	confirm
1	read
2	write
3	select
4	operate
5	direct_operate
6	direct_operate_nr
7	immed_freeze
8	immed_freeze_nr
9	freeze_clear
10	freeze_clear_nr
11	freeze_at_time
12	freeze_at_time_nr
13	cold_restart
14	warm_restart
15	initialize_data
16	initialize_appl
17	start_appl
18	stop_appl
19	save_config
20	enable_unsolicited
21	disable_unsolicited
22	assign_class

Value	String
23	delay_measure
24	record_current_time
25	open_file
26	close_file
27	delete_file
28	get_file_info
29	authenticate_file
30	abort_file
31	activate_config
32	authenticate_req
33	authenticate_err
129	response
130	unsolicited_response
131	authenticate_resp

### dnp3\_ind

You can use the `dnp3_ind` keyword to match against flags in the Internal Indications field in a DNP3 application layer response header.

You can specify the string for a single known flag or a comma-separated list of flags, as seen in the following example:

```
class_1_events, class_2_events
```

When you specify multiple flags, the keyword matches against any flag in the list. To detect a combination of flags, use the `dnp3_ind` keyword multiple times in a rule.

The following list provides the string syntax recognized by the system for defined DNP3 internal indications flags.

```
class_1_events
class_2_events
class_3_events
need_time
local_control
device_trouble
device_restart
no_func_code_support
object_unknown
parameter_error
event_buffer_overflow
```

```

already_executing
config_corrupt
reserved_2
reserved_1

```

### **dnp3\_obj**

You can use the `dnp3_obj` keyword to match against DNP3 object headers in a request or response.

DNP3 data is comprised of a series of DNP3 objects of different types such as analog input, binary input, and so on. Each type is identified with a *group* such as analog input group, binary input group, and so on, each of which can be identified by a decimal value. The objects in each group are further identified by an *object variation* such as 16-bit integers, 32-bit integers, short floating point, and so on, each of which specifies the data format of the object. Each type of object variation can also be identified by a decimal value.

You identify object headers by specifying the decimal number for the type of object header group and the decimal number for the type of object variation. The combination of the two defines a specific type of DNP3 object.

## **CIP and ENIP Keywords**

You can use the following keywords alone or in combination to create custom intrusion rules that identify attacks against CIP and ENIP traffic detected by the CIP preprocessor. For configurable keywords, specify a single integer within the allowed range. See [The CIP Preprocessor, on page 2874](#) for more information.

**Table 187:**

<b>This keyword...</b>	<b>Matches against...</b>	<b>Range</b>
<code>cip_attribute</code>	the Object Class/Instance Attribute field in a CIP message. Specify a single defined integer value.	0 - 65535
<code>cip_class</code>	the Object Class field in a CIP message. Specify a single defined integer value.	0 - 65535
<code>cip_conn_path_class</code>	the Object Class in Connection Path. Specify a single integer value.	0 - 65535
<code>cip_instance</code>	the Instance ID field in a CIP message. Specify a single integer value.	0 - 4284927295
<code>cip_req</code>	the service request message.	N/A
<code>cip_rsp</code>	the service response message.	N/A
<code>cip_service</code>	the Service field in a CIP service request message. Specify a single integer value.	0 - 127
<code>cip_status</code>	the Status field in a CIP service response message. Specify a single integer value.	0 - 255
<code>enip_command</code>	the Command Code in EthNet/IP header. Specify a single integer value.	0 - 65535
<code>enip_req</code>	the EthNet/IP request message.	N/A

This keyword...	Matches against...	Range
enip_rsp	the EthNet/IP response message.	N/A

## S7Commplus Keywords

You can use the S7Commplus keywords alone or in combination to create custom intrusion rules that identify attacks against traffic detected by the S7Commplus preprocessor. For configurable keywords, specify a single known value or a single integer within the allowed range. See [The S7Commplus Preprocessor, on page 2878](#) for more information.

Note the following:

- Multiple S7commplus keywords in the same rule are AND-ed.
- Using multiple `s7commplus_func` or `s7commplus_opcode` keywords in the same rule negates the rule and it will never match traffic. To search for multiple values with these keywords, create multiple rules.

### s7commplus\_content

Before using a `content` or `protected_content` keyword in an S7Commplus intrusion rule, use the `s7commplus_content` keyword to position the cursor to the beginning of the packet payload. See [The content and protected\\_content Keywords, on page 2118](#) for more information.

### s7commplus\_func

Use the `s7commplus_func` keyword to match against one of the following values in an S7Commplus header:

- explore
- createobject
- deleteobject
- setvariable
- getlink
- setmultivar
- getmultivar
- beginsequence
- endsequence
- invoke
- getvarsubstr
- 0x0 through 0xFFF

Note that numeric expressions allow for additional values.

### s7commplus\_opcode

Use the `s7commplus_opcode` keyword to match against one of the following values in an S7Commplus header:

- request
- response
- notification
- response2
- 0x0 through 0xFF

Note that numeric expressions allow for additional values.

## Packet Characteristics

You can write rules that only generate events against packets with specific packet characteristics.

### **dsize**

The `dsize` keyword tests the packet payload size. With it, you can use the greater than and less than operators (< and >) to specify a range of values. You can use the following syntax to specify ranges:

```
>number_of_bytes
<number_of_bytes
number_of_bytes<>number_of_bytes
```

For example, to indicate a packet size greater than 400 bytes, use `>400` as the `dtype` value. To indicate a packet size of less than 500 bytes, use `<500`. To specify that the rule trigger against any packet between 400 and 500 bytes inclusive, use `400<>500`.

---

**Caution** The `dsize` keyword tests packets before they are decoded by any preprocessors.

---

### **isdataat**

The `isdataat` keyword instructs the rules engine to verify that data resides at a specific location in the payload.

The following table lists the arguments you can use with the `isdataat` keyword.

**Table 188: isdataat Arguments**

Argument	Type	Description
Offset	Required	The specific location in the payload. For example, to test that data appears at byte 50 in the packet payload, you would specify <code>50</code> as the offset value. A <code>!</code> modifier negates the results of the <code>isdataat</code> test; it alerts if a certain amount of data is not present within the payload.  You can also use an existing <code>byte_extract</code> variable or <code>byte_math</code> result to specify the value for this argument.
Relative	Optional	Makes the location relative to the last successful content match. If you specify a relative location, note that the counter starts at byte 0, so calculate the location by subtracting 1 from the number of bytes you want to move forward from the last successful content match. For example, to specify that the data must appear at the ninth byte after the last successful content match, you would specify a relative offset of <code>8</code> .

Argument	Type	Description
Raw Data	Optional	Specifies that the data is located in the original packet payload before decoding or application layer normalization by any Firepower System preprocessor. You can use this argument with <b>Relative</b> if the previous content match was in the raw packet data.

For example, in a rule searching for the content `foo`, if the value for `isdataat` is specified as the following:

- Offset = !10
- Relative = enabled

The system alerts if the rules engine does not detect 10 bytes after `foo` before the payload ends.

### sameip

The `sameip` keyword tests that a packet's source and destination IP addresses are the same. It does not take an argument.

### fragoffset

The `fragoffset` keyword tests the offset of a fragmented packet. This is useful because some exploits (such as WinNuke denial-of-service attacks) use hand-generated packet fragments that have specific offsets.

For example, to test whether the offset of a fragmented packet is 31337 bytes, specify `31337` as the `fragoffset` value.

You can use the following operators when specifying arguments for the `fragoffset` keyword.

**Table 189: fragoffset Keyword Argument Operators**

Operator	Description
!	not
>	greater than
<	less than

Note that you cannot use the not (!) operator in combination with < or >.

### cvsv

The `cvsv` keyword tests Concurrent Versions System (CVS) traffic for malformed CVS entries. An attacker can use a malformed entry to force a heap overflow and execute malicious code on the CVS server. This keyword can be used to identify attacks against two known CVS vulnerabilities: CVE-2004-0396 (CVS 1.11.x up to 1.11.15, and 1.12.x up to 1.12.7) and CVE-2004-0414 (CVS 1.12.x through 1.12.8, and 1.11.x through 1.11.16). The `cvsv` keyword checks for a well-formed entry, and generates alerts when a malformed entry is detected.

Your rule should include the ports where CVS runs. In addition, any ports where traffic may occur should be added to the list of ports for stream reassembly in your TCP policies so state can be maintained for CVS sessions. The TCP ports 2401 (`pserver`) and 514 (`rsh`) are included in the list of client ports where stream reassembly occurs. However, note that if your server runs as an `xinetd` server (i.e., `pserver`), it can run on any TCP port. Add any non-standard ports to the stream reassembly **Client Ports** list.

**Related Topics**

[The `byte\_extract` Keyword](#), on page 2135

[TCP Stream Preprocessing Options](#), on page 2905

## Active Response Keywords

The **resp** and **react** keywords provide two approaches to initiating active responses. An intrusion rule that contains either keyword initiates a single active response when a packet triggers the rule. Active response keywords initiate active responses to close TCP connections in response to triggered TCP rules or UDP sessions in response to triggered UDP rules. See [Active Responses in Intrusion Drop Rules, on page 2882](#). Active responses are not intended to take the place of a firewall for a number of reasons, including that an attacker may have chosen to ignore or circumvent active responses.

Active responses are supported in inline, including routed or transparent, deployments. For example, in response to the `react` keyword in an inline deployment, the system can insert a TCP reset (RST) packet directly into the traffic for each end of the connection, which normally should close the connection. Active responses are not supported or suited for passive deployments.

Because active responses can be routed back, the system does not allow TCP resets to initiate TCP resets; this prevents an unending sequence of active responses. The system also does not allow ICMP unreachable packets to initiate ICMP unreachable packets in keeping with standard practice.

You can configure the TCP stream preprocessor to detect additional traffic on a TCP connection after an intrusion rule has triggered an active response. When the preprocessor detects additional traffic, it sends additional active responses up to a specified maximum to both ends of the connection or session. See **Maximum Active Responses** and **Minimum Response Seconds** in [Advanced Transport/Network Preprocessor Options, on page 2883](#).

**Related Topics**

[Active Responses in Intrusion Drop Rules](#), on page 2882

## The `resp` Keyword

You can use the `resp` keyword to actively respond to TCP connections or UDP sessions, depending on whether you specify the TCP or UDP protocol in the rule header.

Keyword arguments allow you to specify the packet direction and whether to use TCP reset (RST) packets or ICMP unreachable packets as active responses.

You can use any of the TCP reset or ICMP unreachable arguments to close TCP connections. You should use only ICMP unreachable arguments to close UDP sessions.

Different TCP reset arguments also allow you to target active responses to the packet source, destination, or both. All ICMP unreachable arguments target the packet source and allow you to specify whether to use an ICMP network, host, or port unreachable packet, or all three.

The following table lists the arguments you can use with the `resp` keyword to specify exactly what you want the system to do when the rule triggers.

**Table 190: `resp` Arguments**

Argument	Description
<code>reset_source</code>	Directs a TCP reset packet to the endpoint that sent the packet that triggered the rule. Alternatively, you can specify <code>rst_snd</code> , which is supported for backward compatibility.

Argument	Description
reset_dest	Directs a TCP reset packet to the intended destination endpoint of the packet that triggered the rule. Alternatively, you can specify <code>rst_rcv</code> , which is supported for backward compatibility.
reset_both	Directs a TCP reset packet to both the sending and receiving endpoints. Alternatively, you can specify <code>rst_all</code> , which is supported for backward compatibility.
icmp_net	Directs an ICMP network unreachable message to the sender.
icmp_host	Directs an ICMP host unreachable message to the sender.
icmp_port	Directs an ICMP port unreachable message to the sender. This argument is used to terminate UDP traffic.
icmp_all	Directs the following ICMP messages to the sender: <ul style="list-style-type: none"> <li>• network unreachable</li> <li>• host unreachable</li> <li>• port unreachable</li> </ul>

For example, to configure a rule to reset both sides of a connection when a rule is triggered, use `reset_both` as the value for the `resp` keyword.

You can use a comma-separated list to specify multiple arguments as follows:

```
argument,argument,argument
```

## The react Keyword

You can use the `react` keyword to send a default HTML page to the TCP connection client when a packet triggers the rule; after sending the HTML page, the system uses TCP reset packets to initiate active responses to both ends of the connection. The `react` keyword does not trigger active responses for UDP traffic.

Optionally, you can specify the following argument:

```
msg
```

When a packet triggers a `react` rule that uses the `msg` argument, the HTML page includes the rule event message.

If you do not specify the `msg` argument, the HTML page includes the following message:

```
You are attempting to access a forbidden site.
Consult your system administrator for details.
```

**Note** Because active responses can be routed back, ensure that the HTML response page does not trigger a `react` rule; this could result in an unending sequence of active responses. Cisco recommends that you test `react` rules extensively before activating them in a production environment.

## The `detection_filter` Keyword

You can use the `detection_filter` keyword to prevent a rule from generating events unless a specified number of packets trigger the rule within a specified time. This can stop the rule from prematurely generating events. For example, two or three failed login attempts within a few seconds could be expected behavior, but a large number of attempts within the same time could indicate a brute force attack.

The `detection_filter` keyword requires arguments that define whether the system tracks the source or destination IP address, the number of times the detection criteria must be met before triggering an event, and how long to continue the count.

Use the following syntax to delay the triggering of events:

```
track by_src/by_dst, count count, seconds number_of_seconds
```

The `track` argument specifies whether to use the packet's source or destination IP address when counting the number of packets that meet the rule's detection criteria. Select from the argument values described in the following table to specify how the system tracks event instances.

**Table 191: `detection_filter` Track Arguments**

Argument	Description
<code>by_src</code>	Detection criteria count by source IP address.
<code>by_dst</code>	Detection criteria count by destination IP address.

The `count` argument specifies the number of packets that must trigger the rule for the specified IP address within the specified time before the rule generates an event.

The `seconds` argument specifies the number of seconds within which the specified number of packets must trigger the rule before the rule generates an event.

Consider the case of a rule that searches packets for the content `foo` and uses the `detection_filter` keyword with the following arguments:

```
track by_src, count 10, seconds 20
```

In the example, the rule will not generate an event until it has detected `foo` in 10 packets within 20 seconds from a given source IP address. If the system detects only 7 packets containing `foo` within the first 20 seconds, no event is generated. However, if `foo` occurs 40 times in the first 20 seconds, the rule generates 30 events and the count begins again when 20 seconds have elapsed.

### Comparing the `threshold` and `detection_filter` Keywords

The `detection_filter` keyword replaces the deprecated `threshold` keyword. The `threshold` keyword is still supported for backward compatibility and operates the same as thresholds that you set within an intrusion policy.

The `detection_filter` keyword is a detection feature that is applied before a packet triggers a rule. The rule does not generate an event for triggering packets detected before the specified packet count and, in an inline deployment, does not drop those packets if the rule is set to drop packets. Conversely, the rule does generate events for packets that trigger the rule and occur after the specified packet count and, in an inline deployment, drops those packets if the rule is set to drop packets.

Thresholding is an event notification feature that does not result in a detection action. It is applied after a packet triggers an event. In an inline deployment, a rule that is set to drop packets drops all packets that trigger the rule, independent of the rule threshold.

Note that you can use the `detection_filter` keyword in any combination with the intrusion event thresholding, intrusion event suppression, and rate-based attack prevention features in an intrusion policy. Note also that policy validation fails if you enable an imported local rule that uses the deprecated `threshold` keyword in combination with the intrusion event thresholding feature in an intrusion policy.

## The tag Keyword

Use the `tag` keyword to tell the system to log additional traffic for the host or session. Use the following syntax when specifying the type and amount of traffic you want to capture using the `tag` keyword:

```
tagging_type, count, metric, optional_direction
```

The next three tables describe the other available arguments.

You can choose from two types of tagging. The following table describes the two types of tagging. Note that the session tag argument type causes the system to log packets from the same session as if they came from different sessions if you configure only rule header options in the intrusion rule. To group packets from the same session together, configure one or more rule options (such as a `flag` keyword or `content` keyword) within the same intrusion rule.

**Table 192: Tag Arguments**

Argument	Description
session	Logs packets in the session that triggered the rule.
host	Logs packets from the host that sent the packet that triggered the rule. You can add a directional modifier to log only the traffic coming from the host ( <code>src</code> ) or going to the host ( <code>dst</code> ).

To indicate how much traffic you want to log, use the following argument:

**Table 193: Count Argument**

Argument	Description
count	The number of packets or seconds you want to log after the rule triggers.  This unit of measure is specified with the metric argument, which follows the count argument.

Select the metric you want to use to log by time or volume of traffic from those described in the following table.

**Caution** High-bandwidth networks can see thousands of packets per second, and tagging a large number of packets may seriously affect performance, so make sure you tune this setting for your network environment.

**Table 194: Logging Metrics Arguments**

Argument	Description
packets	Logs the number of packets specified by the count after the rule triggers.
seconds	Logs traffic for the number of seconds specified by the count after the rule triggers.

For example, when a rule with the following `tag` keyword value triggers:

```
host, 30, seconds, dst
```

all packets that are transmitted from the client to the host for the next 30 seconds are logged.

## The flowbits Keyword

Use the `flowbits` keyword to assign state names to sessions. By analyzing subsequent packets in a session according to the previously named state, the system can detect and alert on exploits that span multiple packets in a single session.

The `flowbits` state name is a user-defined label assigned to packets in a specific part of a session. You can label packets with state names based on packet content to help distinguish malicious packets from those you do not want to alert on. You can define up to 1024 state names per managed device. For example, if you want to alert on malicious packets that you know only occur after a successful login, you can use the `flowbits` keyword to filter out the packets that constitute an initial login attempt so you can focus only on the malicious packets. You can do this by first creating a rule that labels all packets in the session that have an established login with a `logged_in` state, then creating a second rule where `flowbits` checks for packets with the state you set in the first rule and acts only on those packets.

An optional *group name* allows you to include a state name in a group of states. A state name can belong to several groups. States not associated with a group are not mutually exclusive, so a rule that triggers and sets a state that is not associated with a group does not affect other currently set states.

## flowbits Keyword Options

The following table describes the various combinations of operators, states, and groups available to the `flowbits` keyword. Note that state names can contain alphanumeric characters, periods (`.`), underscores (`_`), and dashes (`-`).

**Table 195: flowbits Options**

Operator	State Option	Group	Description
<code>set</code>	<code>state_name</code>	optional	Sets the specified state for a packet. Sets the state in the specified group if a group is defined.
<code>set</code>	<code>state_name&amp;state_name</code>	optional	Sets the specified states for a packet. Sets the states in the specified group if a group is defined.

Operator	State Option	Group	Description
setx	state_name	mandatory	Sets the specified state in the specified group for a packet, and unsets all other states in the group.
setx	state_name&state_name	mandatory	Sets the specified states in the specified group for a packet, and unsets all other states in the group.
unset	state_name	no group	Unsets the specified state for a packet.
unset	state_name&state_name	no group	Unsets the specified states for a packet.
unset	all	mandatory	Unsets all the states in the specified group.
toggle	state_name	no group	Unsets the specified state if it is set, and sets the specified state if it is unset.
toggle	state_name&state_name	no group	Unsets the specified states if they are set, and sets the specified states if they are unset.
toggle	all	mandatory	Unsets all states set in the specified group, and sets all states unset in the specified group.
isset	state_name	no group	Determines if the specified state is set in the packet.
isset	state_name&state_name	no group	Determines if the specified states are set in the packet.
isset	state_name state_name	no group	Determines if any of the specified states are set in the packet.
isset	any	mandatory	Determines if any state is set in the specified group.
isset	all	mandatory	Determines if all states are set in the specified group.
isnotset	state_name	no group	Determines if the specified state is not set in the packet.
isnotset	state_name&state_name	no group	Determines if the specified states are not set in the packet.
isnotset	state_name state_name	no group	Determines if any of the specified states is not set in the packet.
isnotset	any	mandatory	Determines if any state is not set in the packet.
isnotset	all	mandatory	Determines if all states are not set in the packet.
reset	(no state)	optional	Unsets all states for all packets. Unsets all states in a group if a group is specified.

Operator	State Option	Group	Description
noalert	(no state)	no group	Use this in conjunction with any other operator to suppress event generation.

## Guidelines for Using the flowbits Keyword

Note the following when using the `flowbits` keyword:

- When using the `setx` operator, the specified state can only belong to the specified group, and not to any other group.
- You can define the `setx` operator multiple times, specifying different states and the same group with each instance.
- When you use the `setx` operator and specify a group, you cannot use the `set`, `toggle`, or `unset` operators on that specified group.
- The `isset` and `isnotset` operators evaluate for the specified state regardless of whether the state is in a group.
- During intrusion policy saves, intrusion policy reapplies, and access control policy applies (regardless of whether the access control policy references one intrusion policy or multiple intrusion policies), if you enable a rule that contains the `isset` or `isnotset` operator **without** a specified group, and you do not enable at least one rule that affects `flowbits` assignment (`set`, `setx`, `unset`, `toggle`) for the corresponding state name and protocol, all rules that affect `flowbits` assignment for the corresponding state name are enabled.
- During intrusion policy saves, intrusion policy reapplies, and access control policy applies (regardless of whether the access control policy references one intrusion policy or multiple intrusion policies), if you enable a rule that contains the `isset` or `isnotset` operator **with** a specified group, all rules that affect `flowbits` assignment (`set`, `setx`, `unset`, `toggle`) and define a corresponding group name are also enabled.

## flowbits Keyword Examples

This section provides three examples that use the `flowbits` keyword.

### flowbits Keyword Example: A Configuration Using `state_name`

This is an example of a `flowbits` configuration using `state_name`.

Consider the IMAP vulnerability described in CVE ID 2000-0284. This vulnerability exists in an implementation of IMAP, specifically in the LIST, LSUB, RENAME, FIND, and COPY commands. However, to take advantage of the vulnerability, the attacker must be logged into the IMAP server. Because the LOGIN confirmation from the IMAP server and the exploit that follows are necessarily in different packets, it is difficult to construct non-flow-based rules that catch this exploit. Using the `flowbits` keyword, you can construct a series of rules that track whether the user is logged into the IMAP server and, if so, generate an event if one of the attacks is detected. If the user is not logged in, the attack cannot exploit the vulnerability and no event is generated.

The two rule fragments that follow illustrate this example. The first rule fragment looks for an IMAP login confirmation from the IMAP server:

```
alert tcp any 143 -> any any (msg:"IMAP login"; content:"OK
```

```
LOGIN"; flowbits:set,logged_in; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

371863

Note that `flowbits:set` sets a state of `logged_in`, while `flowbits:noalert` suppresses the alert because you are likely to see many innocuous login sessions on an IMAP server.

The next rule fragment looks for a `LIST` string, but does not generate an event unless the `logged_in` state has been set as a result of some previous packet in the session:

```
alert tcp any any -> any 143 (msg:"IMAP LIST";
content:"LIST"; flowbits:isset,logged_in;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

371863

In this case, if a previous packet has caused a rule containing the first fragment to trigger, then a rule containing the second fragment triggers and generates an event.

### flowbits Keyword Example: A Configuration Resulting in False Positive Events

Including different state names that are set in different rules in a group can prevent false positive events that might otherwise occur when content in a subsequent packet matches a rule whose state is no longer valid. The following example illustrates how you can get false positives when you do not include multiple state names in a group.

Consider the case where the following three rule fragments trigger in the order shown during a single session:

```
(msg:"JPEG transfer";
content:"image/";pcre:"/^Content-?Type\x3a(\s*|\s*\r?\n\s+)image\x2fp?jpe?g/smi";
?flowbits:set,http.jpeg; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

The `content` and `pcr` keywords in the first rule fragment match a JPEG file download, `flowbits:set,http.jpeg` sets the `http.jpeg` flowbits state, and `flowbits:noalert` stops the rule from generating events. No event is generated because the rule's purpose is to detect the file download and set the `flowbits` state so one or more companion rules can test for the state name in combination with malicious content and generate events when malicious content is detected.

The next rule fragment detects a GIF file download subsequent to the JPEG file download above:

```
(msg:"GIF transfer"; content:"image/";
pcr:"/^Content-Type\x3a(\s*|\s*\r?\n\s+)image\x2fgif/smi";
?flowbits:set,http.jpg,image_downloads; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

The `content` and `pcr` keywords in the second rule match the GIF file download, `flowbits:set,http.jpg` sets the `http.jpg` flowbit state, and `flowbits:noalert` stops the rule from generating an event. Note that the `http.jpeg` state set by the first rule fragment is still set even though it is no longer needed; this is because the JPEG download must have ended if a subsequent GIF download has been detected.

The third rule fragment is a companion to the first rule fragment:

```
(msg:"JPEG exploit";?flowbits:isset,http.jpeg;content:"|FF|";
pcr:"?/\xFF[\xE1\xE2\xED\xFE]\x00[\x00\x01]/");)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

In the third rule fragment, `flowbits:isset,http.jpeg` determines that the now-irrelevant `http.jpeg` state is set, and `content` and `pcr` match content that would be malicious in a JPEG file but not in a GIF file. The third rule fragment results in a false positive event for a nonexistent exploit in a JPEG file.

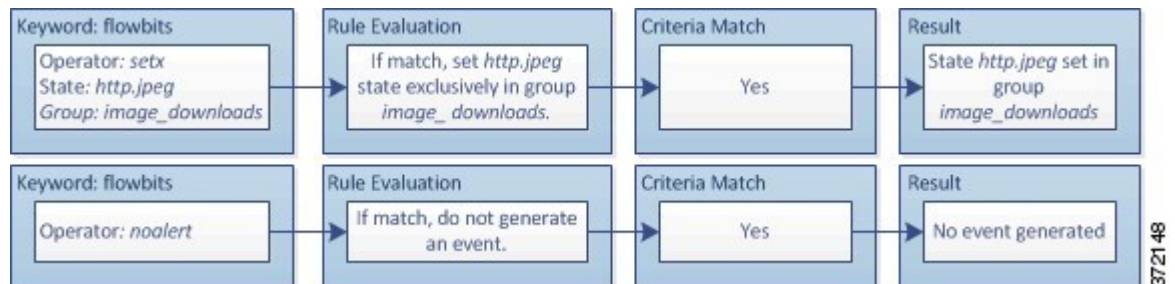

## flowbits Keyword Example: A Configuration for Preventing False Positive Events

The following example illustrates how including state names in a group and using the `setx` operator can prevent false positives.

Consider the same case as the previous example, except that the first two rules now include their two different state names in the same state group.

```
(msg:"JPEG transfer";
content:"image/";pcr:"/^Content-Type\x3a(\s*|\s*\r?\n\s+)image\x2fp?jpe?g/smi";
?flowbits:setx,http.jpeg,image_downloads; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

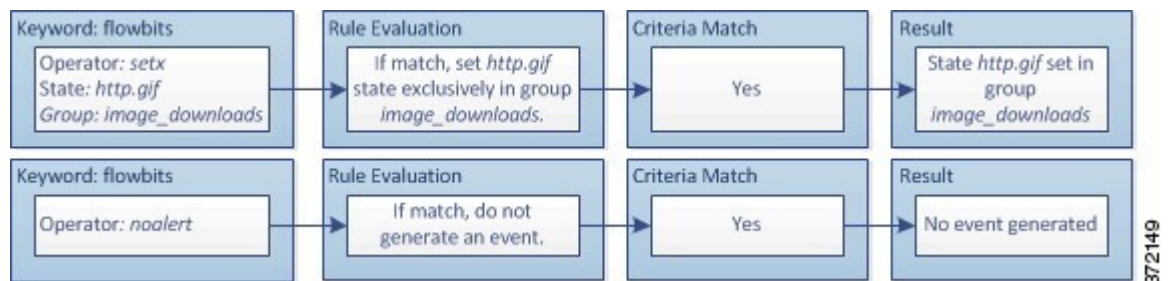

When the first rule fragment detects a JPEG file download, the `flowbits:setx,http.jpeg,image_downloads` keyword sets the `flowbits` state to `http.jpeg` and includes the state in the `image_downloads` group.

The next rule then detects a subsequent GIF file download:

```
(msg:"GIF transfer"; content:"image/";
pcr:"/^Content-Type\x3a(\s*|\s*\r?\n\s+)image\x2fgif/smi";
?flowbits:setx,http.jpg,image_downloads; flowbits:noalert;)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

When the second rule fragment matches the GIF download, the `flowbits:setx,http.jpg,image_downloads` keyword sets the `http.jpg` `flowbits` state and unsets `http.jpeg`, the other state in the group.

The third rule fragment does not result in a false positive:

```
(msg:"JPEG exploit"; ?flowbits:isset,http.jpeg;content:"|FF|";
pcr:"/?\xFF[\xE1\xE2\xED\xFE]\x00[\x00\x01]/");)
```

The following diagram illustrates the effect of the `flowbits` keyword in the preceding rule fragment:

Because `flowbits:isset,http.jpeg` is false, the rules engine stops processing the rule and no event is generated, thus avoiding a false positive even in a case where content in the GIF file matches exploit content for a JPEG file.

## The http\_encode Keyword

You can use the `http_encode` keyword to generate events on the type of encoding in an HTTP request or response before normalization, either in the HTTP URI, in non-cookie data in an HTTP header, in cookies in HTTP requests headers, or set-cookie data in HTTP responses.

You must configure the HTTP Inspect preprocessor to inspect HTTP responses and HTTP cookies to return matches for rules using the `http_encode` keyword.

Also, you must enable both the decoding and alerting option for each specific encoding type in your HTTP Inspect preprocessor configuration so the `http_encode` keyword in an intrusion rule can trigger events on that encoding type.

The following table describes the encoding types this option can generate events for in HTTP URIs, headers, cookies, and set-cookies:

**Table 196: http\_encode Encoding Types**

Encoding Type	Description
utf8	Detects UTF-8 encoding in the specified location when this encoding type is enabled for decoding by the HTTP Inspect preprocessor.
double_encode	Detects double encoding in the specified location when this encoding type is enabled for decoding by the HTTP Inspect preprocessor.
non_ascii	Detects non-ASCII characters in the specified location when non-ASCII characters are detected but the detected encoding type is not enabled.
uencode	Detects Microsoft %u encoding in the specified location when this encoding type is enabled for decoding by the HTTP Inspect preprocessor.
bare_byte	Detects bare byte encoding in the specified location when this encoding type is enabled for decoding by the HTTP Inspect preprocessor.

### Related Topics

[The HTTP Inspect Preprocessor](#), on page 2824

[Server-Level HTTP Normalization Options](#), on page 2825

## http\_encode Keyword Syntax

### Encoding Location

Specifies whether to search for the specified encoding type in an HTTP URI, header, or cookie, including a set-cookie.

### Encoding Type

Specifies one or more encoding types using one of the following formats:

```
encode_type
encode_type|encode_type|encode_type...
```

where `encode_type` is one of the following:

```
utf8
double_encode
non_ascii
uencode
bare_byte.
```

Note that you cannot use the negation (!) and OR (|) operators together.

## http\_encode Keyword example: Using Two http\_encode Keywords to Search for Two Encodings

The following example uses two `http_encode` keywords in the same rule to search the HTTP URI for UTF-8 AND Microsoft IIS %u encoding:

First, the `http_encode` keyword:

- **Encoding Location:** HTTP URI
- **Encoding Type:** utf8

Then, the additional `http_encode` keyword:

- **Encoding Location:** HTTP URI
- **Encoding Type:** uencode

## Overview: The file\_type and file\_group Keywords

The `file_type` and `file_group` keywords allow you to detect files transmitted via FTP, HTTP, SMTP, IMAP, POP3, and NetBIOS-ssn (SMB) based on their type and version. Do **not** use more than one `file_type` or `file_group` keyword in a single intrusion rule.

---

**Tip** Updating your vulnerability database (VDB) populates the intrusion rules editor with the most up-to-date file types, versions, and groups.

---

**Note** The system does not automatically enable preprocessors to accommodate the `file_type` and `file_group` keywords.

You **must** enable specific preprocessors if you want to generate events and, in an inline deployment, drop offending packets for traffic matching your `file_type` or `file_group` keywords.

**Table 197: file\_type and file\_group Intrusion Event Generation**

Protocol	Required Preprocessor or Preprocessor Option
FTP	FTP/Telnet preprocessor and the <b>Normalize TCP Payload</b> inline normalization preprocessor option
HTTP	HTTP Inspect preprocessor to generate intrusion events in HTTP traffic
SMTP	SMTP preprocessor to generate intrusion events in HTTP traffic
IMAP	IMAP preprocessor
POP3	POP preprocessor
Netbios-ssn (SMB)	The DCE/RPC preprocessor and the <b>SMB File Inspection</b> DCE/RPC preprocessor option

## The file\_type and file\_group Keywords

### file\_type

The `file_type` keyword allows you to specify the file type and version of a file detected in traffic. File type arguments (for example, **JPEG** and **PDF**) identify the format of the file you want to find in traffic.

**Note** Do **not** use the `file_type` keyword with another `file_type` or `file_group` keyword in the same intrusion rule.

The system selects **Any Version** by default, but some file types allow you to select version options (for example, PDF version **1.7**) to identify specific file type versions you want to find in traffic.

**file\_group**

The `file_group` keyword allows you to select a Cisco-defined group of similar file types to find in traffic (for example, **multimedia** or **audio**). File groups also include Cisco-defined versions for each file type in the group.

---

**Note** Do **not** use the `file_group` keyword with another `file_group` or `file_type` keyword in the same intrusion rule.

---

## The file\_data Keyword

The `file_data` keyword provides a pointer that serves as a reference for the positional arguments available for other keywords such as `content`, `byte_jump`, `byte_test`, and `pcre`. The detected traffic determines the type of data the `file_data` keyword points to. You can use the `file_data` keyword to point to the beginning of the following payload types:

- HTTP response body

To inspect HTTP response packets, the HTTP Inspect preprocessor must be enabled and you must configure the preprocessor to inspect HTTP responses. The `file_data` keyword matches if the HTTP Inspect preprocessor detects HTTP response body data.

- Uncompressed gzip file data

To inspect uncompressed gzip files in the HTTP response body, the HTTP Inspect preprocessor must be enabled and you must configure the preprocessor to inspect HTTP responses and to decompress gzip-compressed files in the HTTP response body. For more information, see the **Inspect HTTP Responses** and **Inspect Compressed Data** Server-Level HTTP Normalization options. The `file_data` keyword matches if the HTTP Inspect preprocessor detects uncompressed gzip data in the HTTP response body.

- Normalized JavaScript

To inspect normalized JavaScript data, the HTTP Inspect preprocessor must be enabled and you must configure the preprocessor to inspect HTTP responses. The `file_data` keyword matches if the HTTP Inspect preprocessor detects JavaScript in response body data.

- SMTP payload

To inspect the SMTP payload, the SMTP preprocessor must be enabled. The `file_data` keyword matches if the SMTP preprocessor detects SMTP data.

- Encoded email attachments in SMTP, POP, or IMAP traffic

To inspect email attachments in SMTP, POP, or IMAP traffic, the SMTP, POP, or IMAP preprocessor, respectively, must be enabled, alone or in any combination. Then, for each enabled preprocessor, you must ensure that the preprocessor is configured to decode each attachment encoding type that you want decoded. The attachment decoding options that you can configure for each preprocessor are: **Base64 Decoding Depth**, **7-Bit/8-Bit/Binary Decoding Depth**, **Quoted-Printable Decoding Depth**, and **Unix-to-Unix Decoding Depth**.

You can use multiple `file_data` keywords in a rule.

### Related Topics

- [The HTTP Inspect Preprocessor](#), on page 2824
- [Server-Level HTTP Normalization Options](#), on page 2825
- [The SMTP Preprocessor](#), on page 2853
- [The IMAP Preprocessor](#), on page 2847

## The `pkt_data` Keyword

The `pkt_data` keyword provides a pointer that serves as a reference for the positional arguments available for other keywords such as `content`, `byte_jump`, `byte_test`, and `pcr`.

When normalized FTP, telnet, or SMTP traffic is detected, the `pkt_data` keyword points to the beginning of the normalized packet payload. When other traffic is detected, the `pkt_data` keyword points to the beginning of the raw TCP or UDP payload.

The following normalization options must be enabled for the system to normalize the corresponding traffic for inspection by intrusion rules:

- Enable the FTP & Telnet preprocessor **Detect Telnet Escape codes within FTP commands** option to normalize FTP traffic for inspection.
- Enable the FTP & Telnet preprocessor **Normalize telnet** option to normalize telnet traffic for inspection.
- Enable the SMTP preprocessor **Normalize** option to normalize SMTP traffic for inspection.

You can use multiple `pkt_data` keywords in a rule.

## The `base64_decode` and `base64_data` Keywords

You can use the `base64_decode` and `base64_data` keywords in combination to instruct the rules engine to decode and inspect specified data as Base64 data. This can be useful, for example, for inspecting Base64-encoded HTTP Authentication request headers and Base64-encoded data in HTTP PUT and POST requests.

These keywords are particularly useful for decoding and inspecting Base64 data in HTTP requests. However, you can also use them with any protocol such as SMTP that uses the space and tab characters the same way HTTP uses these characters to extend a lengthy header line over multiple lines. When this line extension, which is known as folding, is not present in a protocol that uses it, inspection ends at any carriage return or line feed that is not followed with a space or tab.

### `base64_decode`

The `base64_decode` keyword instructs the rules engine to decode packet data as Base64 data. Optional arguments let you specify the number of bytes to decode and where in the data to begin decoding.

You can use the `base64_decode` keyword once in a rule; it must precede at least one instance of the `base64_data` keyword.

Before decoding Base64 data, the rules engine unfolds lengthy headers that are folded across multiple lines. Decoding ends when the rules engine encounters any the following:

- the end of a header line
- the specified number of bytes to decode
- the end of the packet

The following table describes the arguments you can use with the `base64_decode` keyword.

**Table 198: Optional base64\_decode Arguments**

Argument	Description
Bytes	Specifies the number of bytes to decode. When not specified, decoding continues to the end of a header line or the end of the packet payload, whichever comes first. You can specify a positive, non-zero value.
Offset	Determines the offset relative to the start of the packet payload or, when you also specify <b>Relative</b> , relative to the current inspection location. You can specify a positive, non-zero value.
Relative	Specifies inspection relative to the current inspection location.

### base64\_data

The `base64_data` keyword provides a reference for inspecting Base64 data decoded using the `base64_decode` keyword. The `base64_data` keyword sets inspection to begin at the start of the decoded Base64 data. Optionally, you can then use the positional arguments available for other keywords such as `content` or `byte_test` to further specify the location to inspect.

You must use the `base64_data` keyword at least once after using the `base64_decode` keyword; optionally, you can use `base64_data` multiple times to return to the beginning of the decoded Base64 data.

Note the following when inspecting Base64 data:

- You cannot use the fast pattern matcher.
- If you interrupt Base64 inspection in a rule with an intervening HTTP content argument, you must insert another `base64_data` keyword in the rule before further inspecting Base64 data.

# Layers in Intrusion and Network Analysis Policies

---

The following topics explain how to use layers in intrusion and network analysis policies:

- [Layer Basics, on page 2209](#)
- [License Requirements for Network Analysis and Intrusion Policy Layers, on page 2209](#)
- [Requirements and Prerequisites for Network Analysis and Intrusion Policy Layers, on page 2210](#)
- [The Layer Stack, on page 2210](#)
- [Layer Management, on page 2214](#)

## Layer Basics

Larger organizations with many managed devices may have many intrusion policies and network analysis policies to support the unique needs of different departments, business units or, in some instances, different companies. Configurations in both policy types are contained in building blocks called *layers*, which you can use to efficiently manage multiple policies.

Layers in intrusion and network analysis policies work in essentially the same way. You can create and edit either policy type without consciously using layers. You can modify your policy configurations and, if you have not added user layers to your policy, the system automatically includes your changes in a single configurable layer that is initially named *My Changes*. You can also add up to 200 layers where you can configure any combination of settings. You can copy, merge, move, and delete user layers and, most important, share individual user layers with other policies of the same type.

## The Layer Stack

Layer stacks are composed of the following:

### User Layers

User-configurable layers. You can copy, merge, move, or delete any user-configurable layer and set any user-configurable layer to be shared by other policies of the same type. This layer includes the automatically-generated layer initially named My Changes.

### Built-in Layers

The read-only base policy layer. The policy in this layer can be either a system-provided policy or a custom policy you created.

By default, a network analysis or intrusion policy includes a base policy layer and a My Changes layer. You can add user layers as necessary.

Each policy layer contains complete configurations for either all preprocessors in a network analysis policy or all intrusion rules and advanced settings in an intrusion policy. The lowest, base policy layer includes all the settings from the base policy you selected when you created the policy. A setting in a higher layer takes precedence over the same setting in a lower layer. Features not explicitly set in a layer *inherit* their settings from the next highest layer where they are explicitly set. The system *flattens* the layers, that is, it applies only the cumulative effect of all settings, when it handles network traffic.

---

**Tip** You can create an intrusion or network analysis policy based solely on the default settings in the base policy. In the case of an intrusion policy, you can also use Firepower rule state recommendations if you want to tailor your intrusion policy to the specific needs of your monitored network.

---

The following figure shows an example layer stack that, in addition to the base policy layer and the initial My Changes layer, also includes two additional user-configurable layers, *User Layer 1* and *User Layer 2*. Note

in the figure that each user-configurable layer that you add is initially positioned as the highest layer in the stack; thus, User Layer 2 in the figure was added last and is highest in the stack.

Regardless of whether you allow rule updates to modify your policy, changes in a rule update never override changes you make in a layer. This is because changes in a rule update are made in the base policy, which determines the default settings in your base policy layer; your changes are always made in a higher layer, so they override any changes that a rule update makes to your base policy.

## The Base Layer

The base layer, also referred to as the base policy, of an intrusion or network analysis policy defines the default settings for all configurations in the policy, and is the lowest layer in the policy. When you create a new policy and change a setting without adding new layers, the change is stored in the My Changes layer, and overrides—but does not change—the setting in the base policy.

## System-Provided Base Policies

The system provides several pairs of network analysis and intrusion policies. By using system-provided network analysis and intrusion policies, you can take advantage of the experience of the Talos Intelligence Group. For these policies, Talos sets intrusion and preprocessor rule states, as well as provides the initial configurations for preprocessors and other advanced settings. You can use these system-provided policies as-is, or you can use them as the base for custom policies.

If you use a system-provided policy as your base, importing rule updates may modify settings in your base policy. However, you can configure a custom policy so that the system does not automatically make these changes to its system-provided base policy. This allows you to update system-provided base policies manually, on a schedule independent of rule updates. In either case, changes that a rule update makes to your base policy do not change or override settings in your My Changes or any other layer.

System-provided intrusion and network analysis policies are similarly named but contain different configurations. For example, the Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates.

## Custom Base Policies

You can use a custom policy as your base. You can tune settings in custom policies to inspect traffic in ways that matter most to you so you can improve both the performance of your managed devices and your ability to respond effectively to the events they generate.

If you change the custom policy that you use as the base for another policy, those changes are automatically used as the default settings of the policy that uses the base.

In addition, a rule update may affect your policy even if you use a custom base policy, because all policies have a system-provided policy as the eventual base in a policy chain. If the first custom policy in a chain (the one that uses the system-provided policy as its base) allows rule updates to modify its base policy, your policy may be affected.

Regardless of how changes are made to your base policy—whether by a rule update or when you modify a custom policy that you use as a base policy—they do not change or override settings in your My Changes or any other layer.

## The Effect of Rule Updates on Base Policies

When you import rule updates, the system modifies system-provided intrusion, access control, and network analysis policies. Rule updates can include:

- modified network analysis preprocessor settings
- modified advanced settings in intrusion and access control policies
- new and updated intrusion rules
- modified states for existing rules
- new rule categories and default variables

Rule updates can also delete existing rules from system-provided policies.

Changes to default variables and rule categories are handled at the system level.

When you use a system-provided policy as your intrusion or network analysis base policy, you can allow rule updates to modify your base policy which, in this case, is a copy of the system-provided policy. If you allow rule updates to update your base policy, a new rule update makes the same changes in your base policy that it makes to the system-provided policy that you use as your base policy. If you have not modified the corresponding setting, a setting in your base policy determines the setting in your policy. However, rule updates do not override changes you make in your policy.

If you do not allow rule updates to modify your base policy, you can manually update your base policy after importing one or more rule updates.

Rule updates always delete intrusion rules that Talos deletes, regardless of the rule state in your intrusion policy or whether you allow rule updates to modify your base intrusion policy.

Until you re-deploy your changes to network traffic, rules in your currently deployed intrusion policies behave as follows:

- Disabled intrusion rules remain disabled.
- Rules set to **Generate Events** continue to generate events when triggered.
- Rules set to **Drop and Generate Events** continue to generate events and drop offending packets when triggered.

Rule updates do not modify a custom base policy unless both of the following conditions are met:

- You allow rule updates to modify the system-provided base policy of the parent policy, that is, the policy that originated the custom base policy.
- You have not made changes in the parent policy that override the corresponding settings in the parent's base policy.

When both conditions are met, changes in the rule update are passed to the child policy, that is, the policy using the custom base policy, when you save the parent policy.

For example, if a rule update enables a previously disabled intrusion rule, and you have not modified the rule's state in the parent intrusion policy, the modified rule state is passed to the base policy when you save the parent policy.

Likewise, if a rule update modifies a default preprocessor setting and you have not modified the setting in the parent network analysis policy, the modified setting is passed to the base policy when you save the parent policy.

## Changing the Base Policy

You can choose a different system-provided or custom policy as your base policy.

You can chain up to five custom policies, with four of the five using one of the other four previously created policies as its base policy; the fifth must use a system-provided policy as its base.

### Procedure

---

**Step 1** Choose **Policies > Access Control > Intrusion**.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Click **Edit** (✎) in the required intrusion policy row.

**Step 4** Choose a base policy from the **Base Policy** drop-down list.

**Step 5** Click **Save**.

---

### What to do next

- Deploy configuration changes.

### Related Topics

[Conflicts and Changes: Network Analysis and Intrusion Policies](#), on page 2059

## The Cisco Recommendations Layer

When you generate rule state recommendations in an intrusion policy, you can choose whether to automatically modify rule states based on the recommendations.

As seen in the following figure, using recommended rule states inserts a read-only, built-in Cisco Recommendations layer immediately above the base layer.

Layer: User Layer 2

Layer: User Layer 1

Layer: User Layer (My Changes)

Layer: Cisco Recommendations Layer

Layer: Base Policy Layer

Note that this layer is unique to intrusion policies.

If you subsequently choose not to use recommended rule states, the system removes the Cisco Recommendations layer. You cannot manually delete this layer, but you can add and remove it by choosing to use or not use recommended rule states.

Adding the Cisco Recommendations layer adds a Cisco Recommendations link under Policy Layers in the navigation panel. This link leads you to a read-only view of the Cisco Recommendations layer page where you can access a recommendation-filtered view of the Rules page in read-only mode.

Using recommended rule states also adds a Rules sublink beneath the Cisco Recommendations link in the navigation panel. The Rules sublink provides access to a read-only display of the Rules page in the Cisco Recommendations layer. Note the following in this view:

- When there is no rule state icon in the state column, the state is inherited from the base policy.
- When there is no rule state icon in the Cisco Recommendation column in this or other Rules page views, there is no recommendation for this rule.

### Related Topics

[Tailoring Intrusion Protection to Your Network Assets](#), on page 2225

## Layer Management

The Policy Layers page provides a single-page summary of the complete layer stack for your network analysis or intrusion policy. On this page you can add shared and unshared layers, copy, merge, move, and delete layers, access the summary page for each layer, and access configuration pages for enabled, disabled, and overridden configurations within each layer.

For each layer, you can view the following information:

- whether the layer is a built-in, shared user, or unshared user layer
- which layers contain the highest, that is the effective, preprocessor or advanced setting configurations, by feature name
- in an intrusion policy, the number of intrusion rules whose states are set in the layer, and the number of rules set to each rule state.

The Policy Layers page also provides a summary of the net effect of all enabled preprocessors (network analysis) or advanced settings (intrusion) and, for intrusion policies, intrusion rules.

The feature name in the summary for each layer indicates which configurations are enabled, disabled, overridden, or inherited in the layer, as follows:

When the feature is...	The feature name is...
enabled in the layer	written in plain text
disabled in the layer	struck out
overridden by the configuration in a higher layer	written in italic text
inherited from a lower layer	not present

You can add up to 200 layers to a network analysis or intrusion policy. When you add a layer, it appears as the highest layer in your policy. The initial state is Inherit for all features and, in an intrusion policy, no event filtering, dynamic state, or alerting rule actions are set.

You give a user-configurable layer a unique name when you add the layer to your policy. Later, you can change the name and, optionally, add or modify a description that is visible when you edit the layer.

You can copy a layer, move a layer up or down within the User Layers page area, or delete a user layer, including the initial My Changes layer. Note the following considerations:

- When you copy a layer, the copy appears as the highest layer.
- Copying a shared layer creates a layer that is initially unshared and which you can then share if you choose.
- You cannot delete a shared layer; a layer with sharing enabled that you have not shared with another policy is not a shared layer.

You can merge a user-configurable layer with another user-configurable layer immediately beneath it. A merged layer retains all settings that were unique to either layer, and accepts the settings from the higher layer if both layers included settings for the same preprocessor, intrusion rule, or advanced setting. The merged layer retains the name of the lower layer. In the policy where you create a sharable layer that you can add to other policies, you can merge an unshared layer immediately above the sharable layer with the sharable layer, but you cannot merge the sharable layer with an unshared layer beneath it. In a policy where you add a shared layer that you created in another policy, you can merge the shared layer into an unshared layer immediately beneath it and the resulting layer is no longer shared; you cannot merge an unshared layer into a shared layer beneath it.

## Shared Layers

A *shared layer* is a layer you add to your policy after creating the layer in another policy where you allow it to be shared. A *sharable layer* is a layer you allow to be shared.

The following figure shows an example primary policy where you create the company-wide layer and site-specific layers for sites A and B, and allow these to be shared. You then add these as shared layers to the policies for sites A and B.

The company-wide layer in the primary policy includes settings applicable to sites A and B. The site-specific layers include settings specific to each site. For example, in the case of a network analysis policy Site A might not have web servers on the monitored network and would not require the protection or processing overhead of the HTTP Inspect preprocessor, but both sites would likely require TCP stream preprocessing. You could enable TCP stream processing in the company-wide layer that you share with both sites, disable the HTTP Inspect preprocessor in the site-specific layer that you share with Site A, and enable the HTTP Inspect preprocessor in the site-specific layer that you share with Site B. By editing configurations in a higher layer in the site-specific policies, you could also further tune the policy for each site if necessary with any configuration adjustments.

It is unlikely that the flattened net settings in the example primary policy would be useful for monitoring traffic, but the time saved in configuring and updating the site-specific policies makes this a useful application of policy layers.

Many other layer configurations are possible. For example, you could define policy layers by company, by department, by network, or even by user. In the case of an intrusion policy, you could also include advanced settings in one layer and rule settings in another.

You can allow a user-configurable layer to be shared with other policies of the same type (intrusion or network analysis). When you modify a configuration within a sharable layer and then commit your changes, the system updates all policies that share the layer and provides you with a list of all affected policies. You can only change feature configurations in the policy where you created the layer.

You cannot disable sharing for a layer that you have added to another policy; you must first delete the layer from the other policy or delete the other policy.

You cannot add a shared layer to a policy when your base policy is a custom policy where the layer you want to share was created. To do so would give the policy a circular dependency.

## Managing Layers

### Procedure

- 
- Step 1** While editing your Snort 2 policy, click **Policy Layers** in the navigation panel.
- Step 2** You can take any of the following management actions on the Policy Layers page:
- Add a shared layer from another policy — Click **Add Shared Layer Add** (+) next to User Layers, choose the layer from the **Add Shared Layer** drop-down list, then click **OK**.
  - Add an unshared layer — Click add layer **Add** (+) next to User Layers, enter a **Name**, and click **OK**.
  - Add or change the layer description — Click **Edit** (✎) next to the layer, then add or change the **Description**.
  - Allow a layer to be shared with another policy — Click **Edit** (✎) next to the layer, then clear the **Sharing** check box.
  - Change the layer name — Click **Edit** (✎) next to the layer, then change the **Name**.
  - Copy a layer — Click **Copy** (📄) for the layer.
  - Delete a layer — Click **Delete** (🗑) for the layer, then click **OK**.
  - Merge two layers — Click **Merge** (📄) for the upper of the two layers, then click **OK**.
  - Move a layer — Click any open area in the layer summary and drag until the **Position Arrow** points to a line above or below a layer where you want to move the layer.
- Step 3** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
-

**What to do next**

- Deploy configuration changes.

**Related Topics**

[Conflicts and Changes: Network Analysis and Intrusion Policies](#), on page 2059

## Navigating Layers

**Procedure**

- 
- Step 1** While editing your Snort 2 policy, click **Policy Layers** in the navigation panel. To access your Snort 2 policy, choose **Policies > Intrusion > Intrusion Policies** tab and then click **Snort 2** against the policy you want to edit.
- Step 2** You can take any of the following actions to navigate through your layers:
- Access a preprocessor or advanced settings page — If you want to access a layer-level preprocessor or advanced setting configuration page, click the feature name in the row for the layer. Configuration pages are read-only in the base policy and in shared layers.
  - Access a rule page — If you want to access a layer-level rule configuration page filtered by rule state type, click **Drop and Generate Events**, **Generate Events**, or **Disabled** in the summary for the layer. No rules are displayed if the layer contains no rules set to the selected rule state.
  - Display the Policy Information page — If you want to display the Policy Information page, click **Policy Summary** in the navigation panel.
  - Display a layer summary page — If you want to display the summary page for a layer, click the layer name in the row for the layer or, alternately, click **Edit** (✎) next to a user layer. You can also click **View** (👁) to access the read-only summary page for a shared layer.
- Step 3** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

**What to do next**

- Deploy configuration changes.

**Related Topics**

[Conflicts and Changes: Network Analysis and Intrusion Policies](#), on page 2059

## Intrusion Rules in Layers

You can view individual layer settings on the Rules page for the layer, or view the net effect of all settings on the policy view of the Rules page. When you modify rule settings on the policy view of the Rules page,

you are modifying the highest user-configurable layer in the policy. You can switch to another layer using the layer drop-down list on any Rules page.

The following table describes the effects of configuring the same type of setting in multiple layers.

**Table 199: Layer Rule Settings**

You can set...	Of this setting type...	To...
one	rule state	override a rule state set for the rule in a lower layer, and ignore all thresholds, suppressions, rate-based rule states, and alerts for that rule configured in lower layers.  If you want a rule to inherit its state from the base policy or a lower layer, set the rule state to Inherit. Note that when you are working on the intrusion policy Rules page, you cannot set a rule state to Inherit because the intrusion policy Rules page is a composite view of the net effect of all rule settings.
one	threshold SNMP alert	override a setting of the same type for the rule in a lower layer. Note that setting a threshold overwrites any existing threshold for the rule in the layer.
one or more	suppression rate-based rule state	cumulatively combine settings of the same type for each selected rule down to the first layer where a rule state is set for the rule. Settings below the layer where a rule state is set are ignored.
one or more	comment	add a comment to a rule. Comments are rule-specific, not policy- or layer-specific. You can add one or more comments to a rule in any layer.

For example, if you set a rule state to Drop and Generate Events in one layer and to Disabled in a higher layer, the intrusion policy Rules page shows that the rule is disabled.

In another example, if you set a source-based suppression for a rule to 192.168.1.1 in one layer, and you also set a destination-based suppression for the rule to 192.168.1.2 in another layer, the Rules page shows that the cumulative effect is to suppress events for the source address 192.168.1.1 and the destination address 192.168.1.2. Note that suppression and rate-based rule state settings cumulatively combine settings of the same type for each selected rule down to the first layer where a rule state is set for the rule. Settings below the layer where a rule state is set are ignored.

Color-coding on each Rules page for a specific layer indicates whether the effective state is in a higher, lower, or the current layer, as follows:

- red—the effective state is in a higher layer
- yellow—the effective state is in a lower layer
- unshaded—the effective state is in the current layer

Because the intrusion policy Rules page is a composite view of the net effect of all rule settings, rule states are not color-coded on this page.

## Configuring Intrusion Rules in Layers

In an intrusion policy, you can set the rule state, event filtering, dynamic state, alerting, and rule comments for a rule in any user-configurable layer. After accessing the layer where you want to make your changes, you add settings on the Rules page for the layer the same as you would on the intrusion policy Rules page.

## Procedure

- 
- Step 1** While editing your Snort 2 intrusion policy, expand **Policy Layers** in the navigation panel.
- Step 2** Expand the policy layer you want to modify.
- Step 3** Click **Rules** immediately beneath the policy layer you want to modify.
- Step 4** Modify any of the settings described in [Tuning Intrusion Policies Using Rules](#), on page 2071.
- Tip** To delete an individual setting from an editable layer, double-click the rule message on the Rules page for the layer to display rule details. Click **Delete** next to the setting you want to delete, then click **OK** twice.
- Step 5** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
- 

### What to do next

- Deploy configuration changes.

### Related Topics

[Conflicts and Changes: Network Analysis and Intrusion Policies](#), on page 2059

## Removing Rule Settings from Multiple Layers

You can simultaneously remove a specific type of event filter, dynamic state, or alerting from multiple layers in your intrusion policy. The system removes the selected setting and copies the remaining settings for the rule to the highest editable layer in the policy.

The system removes the setting type downward through each layer where it is set until it removes all the settings or encounters a layer where a rule state is set for the rule. In the latter case, it removes the setting from that layer and stops removing the setting type.

When the system encounters the setting type in a shared layer or in the base policy, and if the highest layer in the policy is editable, the system copies the remaining settings and rule state for the rule to that editable layer. Otherwise, if the highest layer in the policy is a shared layer, the system creates a new editable layer above the shared layer and copies the remaining settings and rule state for the rule to that editable layer.

---

**Note** Removing rule settings derived from a shared layer or the base policy causes any changes to this rule from lower layers or the base policy to be ignored. To stop ignoring changes from lower layers or the base policy, set the rule state to **Inherit** on the summary page for the topmost layer.

---

## Procedure

**Step 1** While editing your Snort 2 intrusion policy, click **Rules** immediately beneath **Policy Information** in the navigation panel. To access your Snort 2 policy, choose **Policies > Intrusion > Intrusion Policies tab** and then click **Snort 2** against the policy you want to edit.

**Tip** You can also choose **Policy** from the layer drop-down list on the Rules page for any layer, or click **Manage Rules** on the Policy Information page.

**Step 2** Choose the rule or rules from which you want to remove multiple settings:

- Choose specific — If you want to choose specific rules, check the check box next to each rule.
- Choose all — If you want to choose all the rules in the current list, check the check box at the top of the column.

**Step 3** Choose one of the following options:

- **Event Filtering > Remove Thresholds**
- **Event Filtering > Remove Suppressions**
- **Dynamic State > Remove Rate-Based Rule States**
- **Alerting > Remove SNMP Alerts**

**Note** Removing rule settings derived from a shared layer or the base policy causes any changes to this rule from lower layers or the base policy to be ignored. To stop ignoring changes from lower layers or the base policy, set the rule state to **Inherit** on the summary page for the topmost layer.

**Step 4** Click **OK**.

**Step 5** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

### What to do next

- Deploy configuration changes.

### Related Topics

[Conflicts and Changes: Network Analysis and Intrusion Policies](#), on page 2059

## Accepting Rule Changes from a Custom Base Policy

When a custom network analysis or intrusion policy where you have not added layers uses another custom policy as its base policy, you must set a rule to inherit its rule state if:

- you delete an event filter, dynamic state, or SNMP alert that is set for the rule in the base policy, *and*

- you want the rule to accept subsequent changes that you make to it in the other custom policy that you use as your base policy

## Procedure

- 
- Step 1** While editing your Snort 2 intrusion policy, expand **Policy Layers** in the navigation panel.
- Step 2** Expand **My Changes**.
- Step 3** Click the **Rules** link immediately beneath **My Changes**.
- Step 4** Choose the rule or rules whose settings you want to accept. You have the following choices:
- Choose specific rules — If you want to choose specific rules, check the check box next to each rule.
  - Choose all rules — If you want to choose all the rules in the current list, check the check box at the top of the column.
- Step 5** Choose **Inherit** from the **Rule State** drop-down list.
- Step 6** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- Deploy configuration changes.

### Related Topics

[Conflicts and Changes: Network Analysis and Intrusion Policies](#), on page 2059

## Preprocessors and Advanced Settings in Layers

You use similar mechanisms to configure preprocessors in a network analysis policy and advanced settings in an intrusion policy. You can enable and disable preprocessors on the network analysis Settings page and intrusion policy advanced settings on the intrusion policy Advanced Settings page. These pages also provide summaries of the effective states for all relevant features. For example, if the network analysis SSL preprocessor is disabled in one layer and enabled in a higher layer, the Settings page shows it as enabled. Changes made on these pages appear in the top layer of the policy. Note that the Back Orifice preprocessor has no user-configurable options.

You can also enable or disable preprocessors or advanced settings and access their configuration pages on the summary page for a user-configurable layer. On this page you can modify the layer name and description and configure whether to share the layer with other policies of the same type. You can switch to the summary page for another layer by selecting the layer name beneath **Policy Layers** in the navigation panel.

When you enable a preprocessor or advanced setting, a sublink to the configuration page for that feature appears beneath the layer name in the navigation panel, and an **Edit** (✎) appears next to the feature on the summary page for the layer; these disappear when you disable the feature in the layer or set it to Inherit.

Setting the state (enabled or disabled) for a preprocessor or advanced setting overrides the state and configuration settings for that feature in lower layers. If you want a preprocessor or advanced setting to inherit its state and configuration from the base policy or a lower layer, set it to **Inherit**. Note that the Inherit selection is not available when you are working in the Settings or Advanced Settings page. Note also that if you inherit a feature that is currently enabled, the feature sublink in the navigation panel and the edit icon on the configuration page no longer appear.

The system uses the configuration in the highest layer where the feature is enabled. Unless you explicitly modify the configuration, the system uses the default configuration. For example, if you enable and modify the network analysis DCE/RPC preprocessor in one layer, and you also enable but do not modify it in a higher layer, the system uses the default configuration in the higher layer.

Color-coding on each layer summary page indicates whether the effective configuration is in a higher, lower, or the current layer, as follows:

- red—the effective configuration is in a higher layer
- yellow—the effective configuration is in a lower layer
- unshaded—the effective configuration is in the current layer

Because the Settings and Advanced Settings pages are composite views of all relevant settings, these page do not use color coding to indicate the positions of effective configurations.

## Configuring Preprocessors and Advanced Settings in Layers

### Procedure

- 
- Step 1** While editing your Snort 2 policy, expand **Policy Layers** in the navigation panel, then click the name of the layer you want to modify.
- Step 2** You have the following choices:
- Change the layer **Name**.
  - Add or change the **Description**.
  - Check or clear the **Sharing** check box to specify whether a layer can be shared with another policy.
  - To access the configuration page for an enabled preprocessor/advanced setting, click **Edit** (✎) or the feature sublink.
  - To disable a preprocessor/advanced setting in the current layer, click **Disabled** next to the feature.
  - To enable a preprocessor/advanced setting in the current layer, click **Enabled** next to the feature.
  - To inherit the preprocessor/advanced setting state and configuration from the settings in the highest layer below the current layer, click **Inherit**.
- Step 3** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

**What to do next**

- Deploy configuration changes.

## CHAPTER 79

# Tailoring Intrusion Protection to Your Network Assets

---

The following topics describe how to use Cisco recommended rules:

- [About Cisco Recommended Rules, on page 2225](#)
- [Default Settings for Cisco Recommendations, on page 2226](#)
- [Advanced Settings for Cisco Recommendations, on page 2227](#)
- [Generating and Applying Cisco Recommendations, on page 2228](#)
- [Script Detection, on page 2229](#)

## About Cisco Recommended Rules

You can use intrusion rule recommendations to associate the operating systems, servers, and client application protocols detected on your network with rules specifically written to protect those assets. This allows you to tailor your intrusion policy to the specific needs of your monitored network.

The system makes an individual set of recommendations for each intrusion policy. It typically recommends rule state changes for standard text rules and shared object rules. However, it can also recommend changes for preprocessor and decoder rules.

When you generate rule state recommendations, you can use the default settings or configure advanced settings. Advanced settings allow you to:

- Redefine which hosts on your network the system monitors for vulnerabilities
- Influence which rules the system recommends based on rule overhead
- Specify whether to generate recommendations to disable rules

You can also choose either to use the recommendations immediately or to review the recommendations (and affected rules) before accepting them.

Choosing to use recommended rule states adds a read-only Cisco Recommendations layer to your intrusion policy, and subsequently choosing not to use recommended rule states removes the layer.

The system does not change rule states that you set manually:

- Manually setting the states of specified rules *before* you generate recommendations prevents the system from modifying the states of those rules in the future.

- Manually setting the states of specified rules *after* you generate recommendations overrides the recommended states of those rules.

**Tip** The intrusion policy report can include a list of rules with rule states that differ from the recommended state.

While displaying the recommendation-filtered Rules page, or after accessing the Rules page directly from the navigation panel or the Policy Information page, you can manually set rule states, sort rules, and take any of the other actions available on the Rules page, such as suppressing rules, setting rule thresholds, and so on.

**Note** The Talos Intelligence Group determines the appropriate state of each rule in the system-provided policies. If you use a system-provided policy as your base policy, and you allow the system to set your rules to the Cisco recommended rule state, the rules in your intrusion policy match the settings recommended by Cisco for your network assets.

## Default Settings for Cisco Recommendations

When you generate Cisco recommendations, the system searches your base policy for rules that protect against vulnerabilities associated with your network assets, and identifies the current state of rules in your base policy. The system then recommends rule states and, if you choose to, sets the rules to the recommended states.

The system performs the following basic analysis to generate recommendations:

**Table 200: Rule State Recommendations Based on Vulnerabilities**

Rule Protects Discovered Assets?	Base Policy Rule State	Recommend Rule State
Yes	Disabled	Generate Events
	Generate Events	Generate Events
	Drop and Generate Events	Drop and Generate Events
No	Any	Disabled

Note the following in the table:

- If a rule is disabled in the base policy, or set to Generate Events, the recommended state is always Generate Events.

For example, if the base policy is No Rules Active, in which all rules are disabled, there will be no recommendations to Drop and Generate Events.

- Recommendations to Drop and Generate Events are made only for rules already set to Drop and Generate Events in the base policy.

If you want a rule to be set to Drop and Generate events and the rule was disabled or set to Generate Events in the base policy, you must manually reset the rule state.

When you generate recommendations without changing the advanced settings for Cisco recommended rules, the system recommends rule state changes for all hosts in your entire discovered network.

By default, the system generates recommendations only for rules with low or medium overhead, and generates recommendations to disable rules.

The system does not recommend a rule state for an intrusion rule that is based on a vulnerability that you disable using the Impact Qualification feature.

The system always recommends that you enable a local rule associated with a third-party vulnerability mapped to a host.

The system does not make state recommendations for unmapped local rules.

### Related Topics

[Third-Party Product Mappings](#), on page 2652

## Advanced Settings for Cisco Recommendations

### Include all differences between recommendations and rule states in policy reports

By default, an intrusion policy report lists the policy's enabled rules, that is, rules set to either Generate Events or Drop and Generate Events. Enabling the **Include all differences** option also lists the rules whose recommended states differ from their saved states. For information on policy reports, see [About Configuration Deployment](#), on page 227.

### Networks to Examine

Specifies the monitored networks or individual hosts to examine for recommendations. You can specify a single IP address or address block, or a comma-separated list comprised of either or both.

Lists of addresses within the hosts that you specify are linked with an OR operation except for negations, which are linked with an AND operation after all OR operations are calculated.

If you want to dynamically adapt active rule processing for specific packets based on host information, you can also enable adaptive profile updates.

### Recommendation Threshold (By Rule Overhead)

Prevents the system from recommending or automatically enabling intrusion rules with a higher overhead than the threshold you choose.

Overhead is based on the rule's potential impact on system performance and the likelihood that the rule may generate false positives. Permitting rules with higher overhead usually results in more recommendations, but can affect system performance. You can view the overhead rating for a rule in the rule detail view on the intrusion Rules page.

Note that the system does not factor rule overhead into recommendations to disable rules. Also, local rules are considered to have no overhead, unless they are mapped to a third-party vulnerability.

Generating recommendations for rules with the overhead rating at a particular setting does not preclude you from generating recommendations with different overhead, then generating recommendations again for the original overhead setting. You get the same rule state recommendations for each overhead setting each time you generate recommendations for the same rule set, regardless of the number of times you generate recommendations or how many different overhead settings you generate with. For example, you can generate recommendations with overhead set to medium, then to high, then finally to medium

again; if the hosts and applications on your network have not changed, both sets of recommendations with overhead set to medium are then the same for that rule set.

### Accept Recommendations to Disable Rules

Specifies whether the system disables intrusion rules based on Cisco recommendations.

Accepting recommendations to disable rules restricts your rule coverage. Omitting recommendations to disable rules augments your rule coverage.

### Related Topics

[Adaptive Profile Updates and Cisco Recommended Rules](#), on page 2939

## Generating and Applying Cisco Recommendations

Starting or stopping use of Cisco recommendations may take several minutes, depending on the size of your network and intrusion rule set.

### Before you begin

- Cisco recommendations have the following requirements:
  - Threat Defense License—IPS
  - Classic License—Protection
  - User Roles—Admin or Intrusion Admin
- Configure a network discovery policy before you begin with the steps. Configure the network discovery policy to define internal hosts so that the Cisco recommendations are suitable. See, [Network Discovery Customization, on page 2680](#).

### Procedure

- 
- Step 1** In the Snort 2 intrusion policy editor's navigation pane, click **Cisco Recommendations**.
- Step 2** (Optional) Configure advanced settings; see [Advanced Settings for Cisco Recommendations, on page 2227](#).
- Step 3** Generate and apply recommendations.
- **Generate and Use Recommendations**—Generates recommendations and changes rule states to match. Only available if you have never generated recommendations.
  - **Generate Recommendations**—Regardless of whether you are using recommendations, generates new recommendations but does not change rule states to match.
  - **Update Recommendations**—If you are using recommendations, generates recommendations and changes rule states to match. Otherwise, generates new recommendations without changing rule states.
  - **Use Recommendations**—Changes rule states to match any unimplemented recommendations.
  - **Do Not Use Recommendations**—Stops use of recommendations. If you manually changed a rule's state before you applied recommendations, the rule state returns to the value you gave it. Otherwise, the rule state returns to its default value.

When you generate recommendations, the system displays a summary of the recommended changes. To view a list of rules where the system recommends a state change, click **View** next to the newly proposed rule state.

- Step 4** Evaluate and adjust the recommendations you implemented.
- Even if you accept most Cisco recommendations, you can override individual recommendations by setting rule states manually; see [Setting Intrusion Rule States, on page 2086](#).
- Step 5** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
- 

#### What to do next

- Deploy configuration changes.

## Script Detection

The script detection prevents the Snort blocks-too-late intrusion failures with a partial inspection. When HTML files are transferred between a client and a server, these files can contain malicious scripts, such as JavaScript, to initiate an attack. When such malicious scripts are found, the partial inspection allows any IPS rule to match on the malicious script, and the inspector flushes that data segment through inspection and detection. The malicious file never reaches its destination. This feature supports both HTTP/1 and HTTP/2 traffic.

This feature is always enabled by default. To turn it off, set `http_inspect.script_detection=true` to false.

## CHAPTER 80

# Sensitive Data Detection

---

The following topics explain sensitive data detection and how to configure it:

- [Sensitive Data Detection Basics](#), on page 2231
- [Global Sensitive Data Detection Options](#), on page 2232
- [Individual Sensitive Data Type Options](#), on page 2233
- [System-Provided Sensitive Data Types](#), on page 2234
- [License Requirements for Sensitive Data Detection](#), on page 2234
- [Requirements and Prerequisites for Sensitive Data Detection](#), on page 2235
- [Configuring Sensitive Data Detection](#), on page 2235
- [Monitored Application Protocols and Sensitive Data](#), on page 2236
- [Special Case: Sensitive Data Detection in FTP Traffic](#), on page 2237
- [Custom Sensitive Data Types](#), on page 2237

## Sensitive Data Detection Basics

Sensitive data such as Social Security numbers, credit card numbers, driver's license numbers, and so on may be leaked onto the Internet, intentionally or accidentally. The system provides a sensitive data preprocessor that can detect and generate events on sensitive data in ASCII text, which can be particularly useful in detecting accidental data leaks.

Global sensitive data preprocessor options control how the preprocessor functions. You can modify global options that specify the following:

- whether the preprocessor replaces all but the last four credit card or Social Security numbers in triggering packets
- which destination hosts on your network to monitor for sensitive data
- how many total occurrences of all data types in a single session result in an event

Individual data types identify the sensitive data you can detect and generate events on in your specified destination network traffic. You can modify default settings for data type options that specify the following:

- a threshold that must be met for a detected data type to generate a single per-session event
- the destination ports to monitor for each data type
- the application protocols to monitor for each data type

You can create and modify custom data types to detect data patterns that you specify. For example, a hospital might create a data type to protect patient numbers, or a university might create a data type to detect student numbers that have a unique numbering pattern.

The system detects sensitive data per TCP session by matching individual data types against traffic. You can modify the default settings for each data type and for global options that apply to all data types in your intrusion policy. The system provides predefined, commonly used data types. You can also create custom data types.

A sensitive data preprocessor rule is associated with each data type. You enable sensitive data detection and event generation for each data type by enabling the corresponding preprocessor rule for the data type. A link on the configuration page takes you to a filtered view of sensitive data rules on the Rules page, where you can enable and disable rules and configure other rule attributes.

When you save changes to your intrusion policy, you are given the option to automatically enable the sensitive data preprocessor if the rule associated with a data type is enabled and sensitive data detection is disabled.

---

**Tip** The sensitive data preprocessor can detect sensitive data in unencrypted Microsoft Word files that are uploaded and downloaded using FTP or HTTP; this is possible because of the way Word files group ASCII text and formatting commands separately.

---

The system does not detect encrypted or obfuscated sensitive data, or sensitive data in a compressed or encoded format such as a Base64-encoded email attachment. For example, the system would detect the phone number (555)123-4567, but not an obfuscated version where each number is separated by spaces, as in (5 5 5) 1 2 3 - 4 5 6 7, or by intervening HTML code, such as `<b>(555)</b>-<i>123-4567</i>`. However, the system would detect, for example, the HTML coded number `<b>(555)-123-4567</b>` where no intervening codes interrupt the numbering pattern.

## Global Sensitive Data Detection Options

Global sensitive data options are policy-specific and apply to all data types.

### Mask

Replaces with Xs all but the last four digits of credit card numbers and Social Security numbers in the triggering packet. The masked numbers appear in the intrusion event packet view in the web interface and in downloaded packets.

### Networks

Specifies the destination host or hosts to monitor for sensitive data. You can specify a single IP address, address block, or a comma-separated list of either or both. The system interprets a blank field as `any`, meaning any destination IP address.

### Global Threshold

Specifies the total number of all occurrences of all data types during a single session that the preprocessor must detect in any combination before generating a global threshold event. You can specify 1 through 65535.

Cisco recommends that you set the value for this option higher than the highest threshold value for any individual data type that you enable in your policy.

Note the following points regarding global thresholds:

- You must enable preprocessor rule 139:1 to detect and generate events and, in an inline deployment, drop offending packets on combined data type occurrences.
- The preprocessor generates up to one global threshold event per session.
- Global threshold events are independent of individual data type events; that is, the preprocessor generates an event when the global threshold is reached, regardless of whether the event threshold for any individual data type has been reached, and vice versa.

## Individual Sensitive Data Type Options

At a minimum, each custom data type must specify an event threshold and at least one port or application protocol to monitor.

Each system-provided data type uses an otherwise inaccessible `sd_pattern` keyword to define a built-in data pattern to detect in traffic. You can also create custom data types for which you use simple regular expressions to specify your own data patterns.

Sensitive data types display in all intrusion policies where Sensitive Data Detection is enabled. System-provided data types display as read-only. For custom data types, the name and pattern fields display as read-only, but you can set the other options to policy-specific values.

**Table 201: Individual Data Type Options**

Option	Description
Data Type	Specifies the unique name for the data type.
Threshold	Specifies the number of occurrences of the data type when the system generates an event. You can specify 1 through 255.  Note that the preprocessor generates one event for a detected data type per session. Note also that global threshold events are independent of individual data type events; that is, the preprocessor generates an event when the data type event threshold is reached, regardless of whether the global event threshold has been reached, and vice versa.
Destination Ports	Specifies destination ports to monitor for the data type. You can specify a single port, a comma-separated list of ports, or <code>any</code> , meaning any destination port.
Application Protocols	Specifies up to eight application protocols to monitor for the data type. You must activate application detectors to identify application protocols to monitor.  Note that, for Classic devices, this feature requires a Control license.
Pattern	Specifies the pattern to detect. This field is only present for custom data types.

### Related Topics

[Activating and Deactivating Detectors](#), on page 2677

## System-Provided Sensitive Data Types

Each intrusion policy includes system-provided data types for detecting commonly used data patterns such as credit card numbers, email addresses, U.S. phone numbers, and U.S. Social Security numbers with and without dashes.

Each system-provided data type is associated with a single sensitive data preprocessor rule that has a generator ID (GID) of 138. You must enable the associated sensitive data rule in the intrusion policy to generate events and, in an inline deployment, drop offending packets for each data type that you want to use in your policy.

The following table describes each data type and lists the corresponding preprocessor rule.

**Table 202: System-Provided Sensitive Data Types**

Data Type	Description	Preprocessor GID:SID
Credit Card Numbers	Matches Visa®, MasterCard®, Discover® and American Express® fifteen- and sixteen-digit credit card numbers, with or without their normal separating dashes or spaces; also uses the Luhn algorithm to verify credit card check digits.	138:2
Email Addresses	Matches email addresses.	138:5
U.S. Phone Numbers	Matches U.S. phone numbers adhering to the pattern $(\d{3}) ?\d{3}-\d{4}$ .	138:6
U.S. Social Security Numbers Without Dashes	Matches 9-digit U.S. Social Security numbers that have valid 3-digit area numbers, valid 2-digit group numbers, and do not have dashes.	138:4
U.S. Social Security Numbers With Dashes	Matches 9-digit U.S. Social Security numbers that have valid 3-digit area numbers, valid 2-digit group numbers, and dashes.	138:3

To reduce false positives from 9-digit numbers other than Social Security numbers, the preprocessor uses an algorithm to validate the 3-digit area number and 2-digit group number that precede the 4-digit serial number in each Social Security number. The preprocessor validates Social Security group numbers through November 2009.

## Configuring Sensitive Data Detection

Because sensitive data detection can have a high impact on the performance of your system, Cisco recommends that you adhere to the following guidelines:

- Choose the No Rules Active default policy as your base intrusion policy.
- Ensure that the following settings are enabled in the corresponding network analysis policy:
  - **FTP and Telnet Configuration** under **Application Layer Preprocessors**
  - **IP Defragmentation** and **TCP Stream Configuration** under **Transport/Network Layer Preprocessors**.

### Before you begin

For classic devices, this procedure requires the Protection or Control license.

### Procedure

- 
- Step 1** Choose **Policies > Access Control > Intrusion**
  - Step 2** Click **Snort 2 Version** next to the policy you want to edit.  
If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
  - Step 3** Click **Advanced Settings** in the navigation panel.
  - Step 4** If **Sensitive Data Detection** under **Specific Threat Detection** is disabled, click **Enabled**.
  - Step 5** Click **Edit** (✎) next to **Sensitive Data Detection**.
  - Step 6** You have the following choices:

- Modify the global settings as described in [Global Sensitive Data Detection Options, on page 2232](#).
- Choose a data type in the **Targets** section, and modify the data type configuration as described in [Individual Sensitive Data Type Options, on page 2233](#).
- If you want to inspect custom sensitive data, create a custom data type; see [Custom Sensitive Data Types, on page 2237](#).

**Step 7** Add or remove application protocols to monitor for a data type; see [Monitored Application Protocols and Sensitive Data, on page 2236](#).

**Note** To detect sensitive data in FTP traffic:

- Ensure that the file policy is enabled for the access control policy.
- You must add the `Ftp_data` application protocol.

**Step 8** Optionally, to display sensitive data preprocessor rules, click **Configure Rules for Sensitive Data Detection**.

You can enable or disable any of the listed rules. You can also configure sensitive data rules for any of the other actions available on the Rules page, such as rule suppression, rate-based attack prevention, and so on; see [Intrusion Rule Types, on page 2071](#) for more information.

**Step 9** To save changes you made in this policy since the last policy commit, click **Policy Information** in the navigation panel, then click **Commit Changes**.

If you enable sensitive data preprocessor rules in your policy without enabling sensitive data detection, you are prompted to enable sensitive data detection when you save changes to your policy.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- If you want to generate intrusion events, enable Sensitive Data Detection rules 138:2, 138:3, 138:4, 138:5, 138:6, 138:>999999, or 139:1. For more information, see [Intrusion Rule States, on page 2085](#), [Global Sensitive Data Detection Options, on page 2232](#), [System-Provided Sensitive Data Types, on page 2234](#), and [Custom Sensitive Data Types, on page 2237](#).
- Deploy configuration changes.

### Related Topics

[Special Case: Sensitive Data Detection in FTP Traffic, on page 2237](#)

## Monitored Application Protocols and Sensitive Data

You can specify up to eight application protocols to monitor for each data type. At least one detector must be enabled for each application protocol you select. By default, all system-provided detectors are activated. If no detector is enabled for an application protocol, the system automatically enables all system-provided detectors for the application; if none exist, the system enables the most recently modified user-defined detector for the application.

You must specify at least one application protocol or port to monitor for each data type. However, except in the case where you want to detect sensitive data in FTP traffic, Cisco recommends for the most complete coverage that you specify corresponding ports when you specify application protocols. For example, if you specify HTTP, you might also configure the well-known HTTP port 80. If a new host on your network implements HTTP, the system monitors port 80 during the interval when it is discovering the new HTTP application protocol.

In the case where you want to detect sensitive data in FTP traffic, you must specify the `FTP data` application protocol; there is no advantage in specifying a port number.

#### Related Topics

[Activating and Deactivating Detectors](#), on page 2677

[Special Case: Sensitive Data Detection in FTP Traffic](#), on page 2237

## Special Case: Sensitive Data Detection in FTP Traffic

You usually determine which traffic to monitor for sensitive data by specifying the ports to monitor or specifying application protocols in deployments.

However, specifying ports or application protocols is not sufficient for detecting sensitive data in FTP traffic. Sensitive data in FTP traffic is found in traffic for the FTP application protocol, which occurs intermittently and uses a transient port number, making it difficult to detect. To detect sensitive data in FTP traffic, you **must** include the following in your configuration:

- Specify the `FTP data` application protocol to enable detection of sensitive data in FTP traffic.

In the special case of detecting sensitive data in FTP traffic, specifying the `FTP data` application protocol does not invoke detection; instead, it invokes the rapid processing of the FTP/Telnet processor to detect sensitive data in FTP traffic.

- Ensure that the FTP Data detector, which is enabled by default, is enabled.
- Ensure that your configuration includes at least one port to monitor for sensitive data.
- Ensure that the file policy is enabled for the Access Control Policy.

Note that it is not necessary to specify an FTP port except in the unlikely case where you only want to detect sensitive data in FTP traffic. Most sensitive data configurations will include other ports such as HTTP or email ports. In the case where you do want to specify only one FTP port and no other ports to monitor, Cisco recommends that you specify the FTP command port 23.

#### Related Topics

[The FTP/Telnet Decoder](#), on page 2816

[Activating and Deactivating Detectors](#), on page 2677

[Configuring Sensitive Data Detection](#), on page 2235

## Custom Sensitive Data Types

Each custom data type you create also creates a single sensitive data preprocessor rule that has a Generator ID (GID) of 138 and a Snort ID (SID) of 1000000 or greater, that is, a SID for a local rule.

You must enable the associated sensitive data rule to enable detection, generate events and, in an inline deployment, drop offending packets for each custom data type that you want to use in your policy.

To help you enable sensitive data rules, a link on the configuration page takes you to a filtered view of the intrusion policy Rules page that displays all system-provided and custom sensitive data rules. You can also display custom sensitive data rules along with any custom local rules by choosing the local filtering category on the intrusion policy Rules page. Note that custom sensitive data rules are not listed on the intrusion rules editor page (**Objects > Intrusion Rules**).

Once you create a custom data type, you can enable it in any intrusion policy in the system. To enable a custom data type, you must enable the associated sensitive data rule in any policy that you want to use to detect that custom data type.

## Data Patterns in Custom Sensitive Data Types

You define the data pattern for a custom data type using a simple set of regular expressions comprised of the following:

- three metacharacters
- escaped characters that allow you to use the metacharacters as literal characters
- six character classes

Metacharacters are literal characters that have special meaning within regular expressions.

**Table 203: Sensitive Data Pattern Metacharacters**

Metacharacter	Description	Example
?	Matches zero or one occurrence of the preceding character or escape sequence; that is, the preceding character or escape sequence is optional.	<code>colou?r</code> matches <code>color</code> or <code>colour</code>
{n}	Matches the preceding character or escape sequence n times.	For example, <code>\d{2}</code> matches <code>55</code> , <code>12</code> , and so on; <code>\l{3}</code> matches <code>AbC</code> , <code>www</code> , and so on; <code>\w{3}</code> matches <code>a1B</code> , <code>25C</code> , and so on; <code>x{5}</code> matches <code>xxxxx</code>
\	Allows you to use metacharacters as actual characters and is also used to specify a predefined character class.	<code>\?</code> matches a question mark, <code>\\</code> matches a backslash, <code>\d</code> matches numeric characters, and so on

You must use a backslash to escape certain characters for the sensitive data preprocessor to interpret them correctly as literal characters.

**Table 204: Escaped Sensitive Data Pattern Characters**

Use this escaped character...	To represent this literal character...
<code>\?</code>	<code>?</code>
<code>\{</code>	<code>{</code>

Use this escaped character...	To represent this literal character...
\}	}
\\	\

When defining a custom sensitive data pattern, you can use character classes.

**Table 205: Sensitive Data Pattern Character Classes**

Character Class	Description	Character Class Definition
\d	Matches any numeric ASCII character 0-9	0-9
\D	Matches any byte that is not a numeric ASCII character	not 0-9
\l (lowercase “ell”)	Matches any ASCII letter	a-zA-Z
\L	Matches any byte that is not an ASCII letter	not a-zA-Z
\w	Matches any ASCII alphanumeric character Note that, unlike PCRE regular expressions, this does not include an underscore (_).	a-zA-Z0-9
\W	Matches any byte that is not an ASCII alphanumeric character	not a-zA-Z0-9

The preprocessor treats characters entered directly, instead of as part of a regular expression, as literal characters. For example, the data pattern 1234 matches 1234.

The following data pattern example, which is used in system-provided sensitive data rule 138:4, uses the escaped digits character class, the multiplier and option-specifier metacharacters, and the literal dash (-) and left and right parentheses () characters to detect U.S. phone numbers:

```
(\d{3}) ?\d{3}-\d{4}
```

Exercise caution when creating custom data patterns. Consider the following alternative data pattern for detecting phone numbers which, although using valid syntax, could cause many false positives:

```
(?\d{3})? ?\d{3}-?\d{4}
```

Because the second example combines optional parentheses, optional spaces, and optional dashes, it would detect, among others, phone numbers in the following desirable patterns:

- (555) 123-4567
- 555123-4567
- 5551234567

However, the second example pattern would also detect, among others, the following potentially invalid patterns, resulting in false positives:

- (555 1234567

- 555) 123-4567
- 555) 123-4567

Consider finally, for illustration purposes only, an extreme example in which you create a data pattern that detects the lowercase letter `a` using a low event threshold in all destination traffic on a small company network. Such a data pattern could overwhelm your system with literally millions of events in only a few minutes.

## Configuring Custom Sensitive Data Types

You cannot delete a data type if the sensitive data rule for that data type is enabled in any intrusion policy.

### Procedure

- 
- Step 1** Choose **Policies > Access Control > Intrusion**
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 3** Click **Advanced Settings** in the navigation panel.
- Step 4** If **Sensitive Data Detection** under **Specific Threat Detection** is disabled, click **Enabled**.
- Step 5** Click **Edit** (✎) next to **Sensitive Data Detection**.
- Step 6** Click **Add** (+) next to **Data Types**.
- Step 7** Enter a name for the data type.
- Step 8** Enter the pattern you want to detect with this data type; see [Data Patterns in Custom Sensitive Data Types, on page 2238](#).
- Step 9** Click **OK**.
- Step 10** Optionally, click the data type name, and modify the options described in [Individual Sensitive Data Type Options, on page 2233](#).
- Step 11** Optionally, delete a custom data type by clicking **Delete** (🗑), then **OK** to confirm.
- Note** If the sensitive data rule for that data type is enabled in any intrusion policy, the system warns that you cannot delete the data type. You must disable the sensitive data rule in affected policies before attempting the deletion again; see [Setting Intrusion Rule States, on page 2086](#).
- Step 12** To save changes you made in this policy since the last policy commit, click **Policy Information** in the navigation panel, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
-

**What to do next**

- Enable the associated custom sensitive data preprocessing rule in each policy where you want to use that data type; see [Setting Intrusion Rule States, on page 2086](#).
- Deploy configuration changes.

**Related Topics**

[Editing Custom Sensitive Data Types, on page 2241](#)

## Editing Custom Sensitive Data Types

You can edit all fields in custom sensitive data types. Note, however, that when you modify the name or pattern field, these settings change in all intrusion policies on the system. You can set the other options to policy-specific values.

**Procedure**

- 
- Step 1** Choose **Policies > Access Control > Intrusion**
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 3** Click **Advanced Settings** in the navigation panel.
- Step 4** If **Sensitive Data Detection** under **Specific Threat Detection** is disabled, click **Enabled**.
- Step 5** Click **Edit** next to **Sensitive Data Detection**.
- Step 6** In the **Targets** section, click the name of the custom data type.
- Step 7** Click **Edit Data Type Name and Pattern**.
- Step 8** Modify the data type name and pattern; see [Data Patterns in Custom Sensitive Data Types, on page 2238](#).
- Step 9** Click **OK**.
- Step 10** Set the remaining options to policy-specific values; see [Individual Sensitive Data Type Options, on page 2233](#).
- Step 11** To save changes you made in this policy since the last policy commit, click **Policy Information** in the navigation panel, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
- 

**What to do next**

- Deploy configuration changes.

## CHAPTER 81

# Global Limit for Intrusion Event Logging

The following topics describe how to globally limit intrusion event logging:

- [Global Rule Thresholding Basics, on page 2243](#)
- [Global Rule Thresholding Options, on page 2244](#)
- [License Requirements for Global Thresholds, on page 2245](#)
- [Requirements and Prerequisites for Global Thresholds, on page 2246](#)
- [Configuring Global Thresholds, on page 2246](#)
- [Disabling the Global Threshold, on page 2247](#)

## Global Rule Thresholding Basics

The global rule threshold sets limits for event logging by an intrusion policy. You can set a global rule threshold across all traffic to limit how often the policy logs events from a specific source or destination and displays those events per specified time period. You can also set thresholds per shared object rule, standard text rule, or preprocessor rule in the policy. When you set a global threshold, that threshold applies for each rule in the policy that does not have an overriding specific threshold. Thresholds can prevent you from being overwhelmed with a large number of events.

Every intrusion policy contains a default global rule threshold that applies by default to all intrusion rules and preprocessor rules. This default threshold limits the number of events on traffic going to a destination to one event per 60 seconds.

You can:

- Change the global threshold.
- Disable the global threshold.
- Override the global threshold by setting individual thresholds for specific rules.

For example, you might set a global limit threshold of five events every 60 seconds, but then set a specific threshold of ten events for every 60 seconds for SID 1315. All other rules generate no more than five events in each 60-second period, but the system generates up to ten events for each 60-second period for SID 1315.

---

**Tip** A global or individual threshold on a managed device with multiple CPUs may result in a higher number of events than expected.

---

The following diagram demonstrates how the global rule thresholding works. In this example, an attack is in progress for a specific rule. The global limit threshold is set to limit event generation for each rule to two events every 20 seconds. Note that the period starts at one second and ends at 21 seconds. After the period ends, the cycle starts again and the next two rule matches generate events, then the system does not generate any more events during that period.

## Global Rule Thresholding Options

The default threshold limits event generation for each rule to one event every 60 seconds on traffic going to the same destination. The default values for the global rule thresholding options are:

- **Type** — Limit
- **Track By** — Destination
- **Count** — 1
- **Seconds** — 60

You can modify these default values as follows:

Table 206: Thresholding Types

Option	Description
Limit	<p>Logs and displays events for the specified number of packets (specified by the count argument) that trigger the rule during the specified time period.</p> <p>For example, if you set the type to <b>Limit</b>, the <b>Count</b> to 10, and the <b>Seconds</b> to 60, and 14 packets trigger the rule, the system stops logging events for the rule after displaying the first 10 that occur within the same minute.</p>
Threshold	<p>Logs and displays a single event when the specified number of packets (specified by the count argument) trigger the rule during the specified time period. Note that the counter for the time restarts after you hit the threshold count of events and the system logs that event.</p> <p>For example, you set the type to <b>Threshold</b>, <b>Count</b> to 10, and <b>Seconds</b> to 60, and the rule triggers 10 times by second 33. The system generates one event, then resets the Seconds and Count counters to 0. The rule then triggers another 10 times in the next 25 seconds. Because the counters reset to 0 at second 33, the system logs another event.</p>

Option	Description
Both	<p>Logs and displays an event once per specified time period, after the specified number (count) of packets trigger the rule.</p> <p>For example, if you set the type to <b>Both</b>, <b>Count</b> to 2, and <b>Seconds</b> to 10, the following event counts result:</p> <ul style="list-style-type: none"> <li>• If the rule is triggered once in 10 seconds, the system does not generate any events (the threshold is not met)</li> <li>• If the rule is triggered twice in 10 seconds, the system generates one event (the threshold is met when the rule triggers the second time)</li> <li>• If the rule is triggered four times in 10 seconds, the system generates one event (the threshold is met when the rule triggered the second time and following events are ignored)</li> </ul>

The **Track By** option determines whether the event instance count is calculated per source or destination IP address.

You can also specify the number of instances and time period that define the threshold, as follows:

**Table 207: Thresholding Instance/Time Options**

Option	Description
Count	<p>For a <b>Limit</b> threshold, the number of event instances per specified time period per tracking IP address or address range required to meet the threshold.</p> <p>For a <b>Threshold</b> threshold, the number of rule matches you want to use as your threshold.</p>
Seconds	<p>For a <b>Limit</b> threshold, the number of seconds that make up the time period when attacks are tracked.</p> <p>For a <b>Threshold</b> threshold, the number of seconds that elapse before the count resets. If you set the threshold type to <b>Limit</b>, the tracking to <b>Source</b>, <b>Count</b> to 10, and <b>Seconds</b> to 10, the system logs and displays the first 10 events that occur in 10 seconds from a given source port. If only seven events occur in the first 10 seconds, the system logs and displays those, if 40 events occur in the first 10 seconds, the system logs and displays 10, then begins counting again when the 10-second time period elapses.</p>

- [Packet and Intrusion Rule Latency Threshold Configuration, on page 2254](#)
- [Intrusion Performance Statistic Logging Configuration, on page 2260](#)
- [Configuring Intrusion Performance Statistic Logging, on page 2260](#)

## About Intrusion Prevention Performance Tuning

Cisco provides several features for improving the performance of your system as it analyzes traffic for attempted intrusions. You can:

- specify the number of packets to allow in the event queue. You can also, before and after stream reassembly, enable or disable inspection of packets that will be rebuilt into larger streams.
- override default match and recursion limits on PCRE that are used in intrusion rules to examine packet payload content.
- elect to have the rules engine log more than one event per packet or packet stream when multiple events are generated, allowing you to collect information beyond the reported event.
- balance security with the need to maintain device latency at an acceptable level with packet and rule latency thresholding.
- configure the basic parameters of how devices monitor and report their own performance. This allows you to specify the intervals at which the system updates performance statistics on your devices.

You configure these performance settings on a per-access-control-policy basis, and they apply to all intrusion policies invoked by that parent access control policy.

# Limiting Pattern Matching for Intrusions

## Procedure

---

**Step 1** In the access control policy editor, click **Advanced** (**Policies > Access Control > Edit > More > Advanced Settings**).

In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.

**Step 2** Click **Edit** (✎) next to **Performance Settings**.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

- Step 3** Click **Pattern Matching Limits** in the **Performance Settings** pop-up window.
- Step 4** Enter a value for the maximum number of events to queue in the **Maximum Pattern States to Analyze Per Packet** field.
- Step 5** To disable the inspection of packets that will be rebuilt into larger streams of data before and after stream reassembly in Snort 2, check the **Disable Content Checks on Traffic Subject to Future Reassembly** check box. Inspection before and after reassembly requires more processing overhead and may decrease performance.
- Important** In Snort 3, the **Disable Content Checks on Traffic Subject to Future Reassembly** check box settings are:
- **Checked**—Indicates detecting TCP payload before reassembly. It includes inspection of packets before and after stream reassembly. This process requires more processing overhead and may decrease performance.
  - **Unchecked**—Indicates detecting TCP payload after reassembly.
- Step 6** Click **OK**.
- Step 7** Click **Save** to save the policy.

---

#### What to do next

- Deploy configuration changes.

## Regular Expression Limits Overrides for Intrusion Rules

The default regular expression limits ensure a minimum level of performance. Overriding these limits could increase security, but could also significantly impact performance by permitting packet evaluation against inefficient regular expressions.

**Caution** Do not override default PCRE limits unless you are an experienced intrusion rule writer with knowledge of the impact of degenerative patterns.

**Table 208: Regular Expression Constraint Options**

Option	Description
Match Limit State	Specifies whether to override <b>Match Limit</b> . You have the following options: <ul style="list-style-type: none"> <li>• select <b>Default</b> to use the value configured for <b>Match Limit</b></li> <li>• select <b>Unlimited</b> to permit an unlimited number of attempts</li> <li>• select <b>Custom</b> to specify either a limit of 1 or greater for <b>Match Limit</b>, or to specify 0 to completely disable PCRE match evaluations</li> </ul>
Match Limit	Specifies the number of times to attempt to match a pattern defined in a PCRE regular expression.

Option	Description
Match Recursion Limit State	<p>Specifies whether to override <b>Match Recursion Limit</b>. You have the following options:</p> <ul style="list-style-type: none"> <li>• select <b>Default</b> to use the value configured for <b>Match Recursion Limit</b></li> <li>• select <b>Unlimited</b> to permit an unlimited number of recursions</li> <li>• select <b>Custom</b> to specify either a limit of 1 or greater for <b>Match Recursion Limit</b>, or to specify 0 to completely disable PCRE recursions</li> </ul> <p>Note that for <b>Match Recursion Limit</b> to be meaningful, it must be smaller than <b>Match Limit</b>.</p>
Match Recursion Limit	Specifies the number of recursions when evaluating a PCRE regular expression against the packet payload.

# Overriding Regular Expression Limits for Intrusion Rules

## Procedure

- 
- Step 1** In the access control policy editor, click **Advanced**.  
In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.
- Step 2** Click **Edit** (✎) next to **Performance Settings**.  
If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 3** Click **Regular Expression Limits** in the **Performance Settings** pop-up window.
- Step 4** You can modify any of the options as described in [Regular Expression Limits Overrides for Intrusion Rules, on page 2251](#).
- Step 5** Click **OK**.
- Step 6** Click **Save** to save the policy.
- 

**What to do next**

- Deploy configuration changes.

## Per Packet Intrusion Event Generation Limits

When the intrusion rules engine evaluates traffic against rules, it places the events generated for a given packet or packet stream in an event queue, then reports the top events in the queue to the user interface. When configuring the intrusion event logging limits, you can specify how many events can be placed in the queue and how many are logged, and select the criteria for determining event order within the queue.

*Table 209: Intrusion Event Logging Limits Options*

Option	Description
Maximum Events Stored Per Packet	The maximum number of events that can be stored for a given packet or packet stream.
Maximum Events Logged Per Packet	The number of events logged for a given packet or packet stream. This cannot exceed the <b>Maximum Events Stored Per Packet</b> value.
Prioritize Event Logging By	The value used to determine event ordering within the event queue. The highest ordered event is reported through the user interface. You can select from: <ul style="list-style-type: none"> <li>• <code>priority</code>, which orders events in the queue by the event priority.</li> <li>• <code>content_length</code>, which orders events by the longest identified content match. When events are ordered by content length, rule events always take precedence over decoder and preprocessor events.</li> </ul>

## Limiting Intrusion Events Generated Per Packet

### Procedure

- 
- Step 1** In the access control policy editor, click **Advanced**.  
In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.
- Step 2** Click **Edit** (✎) next to **Performance Settings**.  
If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 3** Click **Intrusion Event Logging Limits** in the **Performance Settings** pop-up window.
- Step 4** You can modify any of the options in [Per Packet Intrusion Event Generation Limits, on page 2253](#).
- Step 5** Click **OK**.
- Step 6** Click **Save** to save the policy.
-

### What to do next

- Deploy configuration changes.

## Packet and Intrusion Rule Latency Threshold Configuration

Each access control policy has latency-based settings that use thresholding to manage packet and rule processing performance.

Packet latency thresholding measures the total elapsed time taken to process a packet by applicable decoders, preprocessors, and rules, and ceases inspection of the packet if the processing time exceeds a configurable threshold.

Rule latency thresholding measures the elapsed time each rule takes to process an individual packet, suspends the violating rule along with a group of related rules for a specified time if the processing time exceeds the rule latency threshold a configurable consecutive number of times, and restores the rules when the suspension expires.

## Latency-Based Performance Settings

By default, the system takes latency-based performance settings from the latest intrusion rule update deployed on your system.

The latency settings that are actually applied depend on the security level of the network analysis policy (NAP) associated with the access control policy. Generally, this is the default NAP policy. However, if custom network analysis rules are configured, and if any of these specify a NAP policy that is more secure than the default NAP policy, then latency settings are based on the most secure NAP policy among the custom rules. If the default NAP policy or any custom rules invoke a custom NAP policy, then the security level used in the evaluation is the system-provided base policy on which each custom NAP policy is based.

The above is true regardless of whether the effective threshold and/or network analysis configurations are inherited or configured directly in the policy.

## Packet Latency Thresholding

Packet latency thresholding measures elapsed time, not just processing time, in order to more accurately reflect the actual time required for the rule to process a packet. However, latency thresholding is a software-based latency implementation that does not enforce strict timing.

The trade-off for the performance and latency benefits derived from latency thresholding is that uninspected packets could contain attacks. A timer starts for each packet when decoder processing begins. Timing continues either until all processing ends for the packet or until the processing time exceeds the threshold at a timing test point.

As illustrated in the above figure, packet latency timing is tested at the following test points:

- after the completion of all decoder and preprocessor processing and before rule processing begins
- after processing by each rule

If the processing time exceeds the threshold at any test point, packet inspection ceases.

**Tip** Total packet processing time does not include routine TCP stream or IP fragment reassembly times.

Packet latency thresholding has no effect on events triggered by a decoder, preprocessor, or rule processing the packet. Any applicable decoder, preprocessor, or rule triggers normally until a packet is fully processed, or until packet processing ends because the latency threshold is exceeded, whichever comes first. If a drop rule detects an intrusion in an inline deployment, the drop rule triggers an event and the packet is dropped.

**Note** No packets are evaluated against rules after processing for that packet ceases because of a packet latency threshold violation. A rule that would have triggered an event cannot trigger that event, and for drop rules, cannot drop the packet.

Packet latency thresholding can improve system performance in both passive and inline deployments, and can reduce latency in inline deployments, by stopping inspection of packets that require excessive processing time. These performance benefits might occur when, for example:

- for both passive and inline deployments, sequential inspection of a packet by multiple rules requires an excessive amount of time
- for inline deployments, a period of poor network performance, such as when someone downloads an extremely large file, slows packet processing

In a passive deployment, stopping the processing of packets might not contribute to restoring network performance because processing simply moves to the next packet.

## Packet Latency Thresholding Notes

By default, the latency-based performance settings for packet handling is disabled. You may choose to enable it. However, Cisco recommends that you do not change the default value for the threshold setting.

The information in this below applies only if you choose to specify custom values.

**Table 210: Packet Latency Thresholding Option**

Option	Description
Threshold (microseconds)	Specifies the time, in microseconds, when inspection of a packet ceases.

## Enabling Packet Latency Thresholding

### Procedure

- 
- Step 1** In the access control policy editor, click **Advanced**.  
In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.
- Step 2** Click **Edit** (✎) next to **Latency-Based Performance Settings**.  
If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings.
- Step 3** Click **Packet Handling** in the **Latency-Based Performance Settings** pop-up window.
- Step 4** Check the **Enabled** check box.
- Step 5** Click **OK**.
- Step 6** Click **Save** to save the policy.
- 

### What to do next

- Deploy configuration changes.

## Configuring Packet Latency Thresholding

By default, the latency-based performance settings for packet handling is disabled. You may choose to enable it. However, Cisco recommends that you do not change the default value for the threshold setting.

### Procedure

- 
- Step 1** In the access control policy editor, click **Advanced**.  
In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.
- Step 2** Click **Edit** (✎) next to **Latency-Based Performance Settings**.  
**System** (⚙) > **Monitoring** > **Statistics**
- Step 3** If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 4** Click **Packet Handling** in the **Latency-Based Performance Settings** pop-up window.

By default, **Installed Rule Update** is selected. We recommend using this default.

The values displayed do not reflect the automated settings.

- Step 5** If you choose to specify custom values:
- Check the **Enabled** check box, and see [Packet Latency Thresholding Notes, on page 2255](#) for recommended minimum **Threshold** settings.
  - You must specify custom values in both the packet handling tab and the rule handling tab.
- Step 6** Click **OK**.
- Step 7** Click **Save** to save the policy.

#### What to do next

- Deploy configuration changes.

## Rule Latency Thresholding

Rule latency thresholding measures elapsed time, not just processing time, in order to more accurately reflect the actual time required for the rule to process a packet. However, latency thresholding is a software-based latency implementation that does not enforce strict timing.

The trade-off for the performance and latency benefits derived from latency thresholding is that uninspected packets could contain attacks. A timer measures the processing time each time a packet is processed against a group of rules. Any time the rule processing time exceeds a specified rule latency threshold, the system increments a counter. If the number of consecutive threshold violations reaches a specified number, the system takes the following actions:

- suspends the rules for the specified period
- triggers an event indicating the rules have been suspended
- re-enables the rules when the suspension expires
- triggers an event indicating the rules have been re-enabled

The system zeroes the counter when the group of rules has been suspended, or when rule violations are not consecutive. Permitting some consecutive violations before suspending rules lets you ignore occasional rule violations that might have negligible impact on performance and focus instead on the more significant impact of rules that repeatedly exceed the rule latency threshold.

The following example shows five consecutive rule processing times that do not result in rule suspension.

1	2	3	4	5	Packet
1100	1100	1100	500	1100	Processing time (microseconds) (Threshold = 1000)
1	2	3	0	1	Violations (Consecutive violations before suspending = 5)

= No violation       = Threshold violation

372158

In the above example, the time required to process each of the first three packets violates the rule latency threshold of 1000 microseconds, and the violations counter increments with each violation. Processing of the fourth packet does not violate the threshold, and the violations counter resets to zero. The fifth packet violates the threshold and the violations counter restarts at one.

The following example shows five consecutive rule processing times that do result in rule suspension.

In the second example, the time required to process each of the five packets violates the rule latency threshold of 1000 microseconds. The group of rules is suspended because the rule processing time of 1100 microseconds for each packet violates the threshold of 1000 microseconds for the specified five consecutive violations. Any subsequent packets, represented in the figure as packets 6 through n, are not examined against suspended rules until the suspension expires. If more packets occur after the rules are re-enabled, the violations counter begins again at zero.

Rule latency thresholding has no effect on intrusion events triggered by the rules processing the packet. A rule triggers an event for any intrusion detected in the packet, regardless of whether the rule processing time exceeds the threshold. If the rule detecting the intrusion is a drop rule in an inline deployment, the packet is dropped. When a drop rule detects an intrusion in a packet that results in the rule being suspended, the drop rule triggers an intrusion event, the packet is dropped, and that rule and all related rules are suspended.

**Note** Packets are not evaluated against suspended rules. A suspended rule that would have triggered an event cannot trigger that event and, for drop rules, cannot drop the packet.

Rule latency thresholding can improve system performance in both passive and inline deployments, and can reduce latency in inline deployments, by suspending rules that take the most time to process packets. Packets are not evaluated again against suspended rules until a configurable time expires, giving the overloaded device time to recover. These performance benefits might occur when, for example:

- hastily written, largely untested rules require an excessive amount of processing time
- a period of poor network performance, such as when someone downloads an extremely large file, causes slow packet inspection

## Rule Latency Thresholding Notes

By default, latency-based performance settings for both packet and rule handling are automatically populated by the latest deployed intrusion rule update, and we recommend that you do not change the default.

The information in this topic applies only if you choose to specify custom values.

Rule latency thresholding suspends rules for the time specified by **Suspension Time** when the time rules take to process a packet exceeds **Threshold** for the consecutive number of times specified by **Consecutive Threshold Violations Before Suspending Rule**.

You can enable rule 134:1 to generate an event when rules are suspended, and rule 134:2 to generate an event when suspended rules are enabled. See [Intrusion Rule State Options, on page 2085](#).

**Table 211: Rule Latency Thresholding Options**

Option	Description
Threshold	Specifies the time in microseconds that rules should not exceed when examining a packet.
Consecutive Threshold Violations Before Suspending Rule	Specifies the consecutive number of times rules can take longer than the time set for <b>Threshold</b> to inspect packets before rules are suspended.
Suspension Time	Specifies the number of seconds to suspend a group of rules.

## Configuring Rule Latency Thresholding

By default, latency-based performance settings for both packet and rule handling are automatically populated by the latest deployed intrusion rule update, and we recommend that you do not change the default.

### Procedure

- 
- Step 1** In the access control policy editor, click **Advanced**.
- In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.
- Step 2** Click **Edit** (✎) next to **Latency-Based Performance Settings**.
- If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 3** Click **Rule Handling** in the **Latency-Based Performance Settings** pop-up window.
- By default, **Installed Rule Update** is selected. We recommend using this default.
- The values displayed do not reflect the automated settings.
- Step 4** If you choose to specify custom values:
- You can configure any of the options in [Rule Latency Thresholding Notes, on page 2258](#).
  - You must specify custom values in both the packet handling tab and the rule handling tab.
- Step 5** Click **OK**.
- Step 6** Click **Save** to save the policy.
- 

### What to do next

- If you want to generate events, enable latency rules 134:1 and 134:2. For more information, see [Intrusion Rule State Options, on page 2085](#).

- Deploy configuration changes.

## Intrusion Performance Statistic Logging Configuration

### Sample time (seconds) and Minimum number of packets

When the number of seconds specified elapses between performance statistics updates, the system verifies it has analyzed the specified number of packets. If it has, the system updates performance statistics. Otherwise, the system waits until it analyzes the specified number of packets.

---

**Caution** Configuring a very low value (for example 1 second) for the sample time can cause a huge impact on the device; the performance statistics logged on the device can cause disk space issues and affect the operation of the device. Hence we recommend you do not configure a very low value.

---

### Troubleshooting Options: Log Session/Protocol Distribution

Support might ask you during a troubleshooting call to log protocol distribution, packet length, and port statistics.

---

**Caution** Do not enable **Log Session/Protocol Distribution** unless instructed to by Support.

---

### Troubleshooting Options: Summary

Support might ask you during a troubleshooting call to configure the system to calculate the performance statistics only when the Snort process is shut down or restarted. To enable this option, you must also enable the **Log Session/Protocol Distribution** troubleshooting option.

---

**Caution** Do not enable **Summary** unless instructed to do so by Support.

---

## Configuring Intrusion Performance Statistic Logging

### Procedure

- 
- Step 1** In the access control policy editor, click **Advanced**, then click **Edit** (✎) next to **Performance Settings**.  
In the new UI, select **Advanced Settings** from the drop-down arrow at the end of the packet flow line.  
If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 2** Click **Performance Statistics** in the pop-up window that appears.

- Step 3** Modify the **Sample time** or **Minimum number of packets** as described in [Intrusion Performance Statistic Logging Configuration, on page 2260](#).
- Caution** Configuring a very low value (for example 1 second) for the **Sample time** can cause a huge impact on the device; the performance statistics logged on the device can cause disk space issues and affect the operation of the device. Hence we recommend you do not configure a very low value.
- Step 4** Optionally, expand the **Troubleshoot Options** section and modify those options only if asked to do so by Support.
- Step 5** Click **OK**.
- 

#### What to do next

- Deploy configuration changes.

- [\(Optional\) Malware Protection with AMP for Endpoints](#), on page 2295
- [History for Network Malware Protection and File Policies](#), on page 2299

## About Network Malware Protection and File Policies

To detect and block malware, use file policies. You can also use file policies to detect and control traffic by file type.

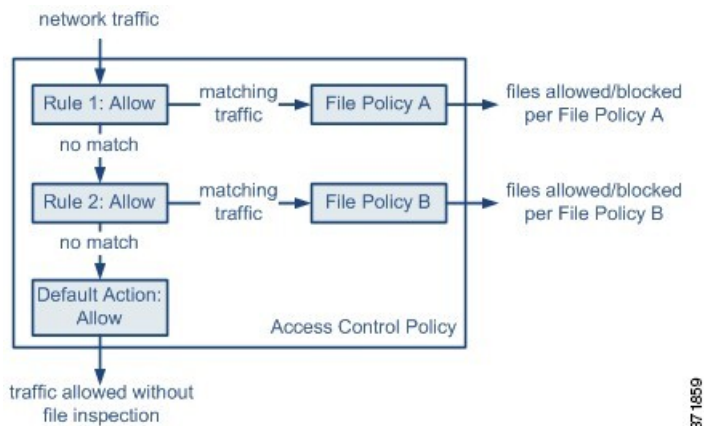

Advanced Malware Protection (AMP) for Firepower can detect, capture, track, analyze, log, and optionally block the transmission of malware in network traffic. In the Secure Firewall Management Center web interface, this feature is called *malware defense*, formerly called *AMP for Firepower*. Advanced Malware Protection identifies malware using managed devices deployed inline and threat data from the Cisco cloud.

You associate file policies with access control rules that handle network traffic as part of your overall access control configuration.

When the system detects malware on your network, it generates file and malware events. To analyze file and malware event data, see the *File/Malware Events and Network File Trajectory* chapter in the [Cisco Secure Firewall Management Center Administration Guide](#).

## File Policies

A file policy is a set of configurations that the system uses to perform malware protection and file control, as part of your overall access control configuration. This association ensures that before the system passes a file in traffic that matches an access control rule's conditions, it first inspects the file. Consider the following diagram of a simple access control policy in an inline deployment.

The policy has two access control rules, both of which use the Allow action and are associated with file policies. The policy's default action is also to allow traffic, but without file policy inspection. In this scenario, traffic is handled as follows:

- Traffic that matches `Rule 1` is inspected by `File Policy A`.
- Traffic that does not match `Rule 1` is evaluated against `Rule 2`. Traffic that matches `Rule 2` is inspected by `File Policy B`.
- Traffic that does not match either rule is allowed; you cannot associate a file policy with the default action.

By associating different file policies with different access control rules, you have granular control over how you identify and block files transmitted on your network.

## Requirements and Prerequisites for File Policies

### Model Support

Any

### Supported Domains

Any

### User Roles

- Admin
- Access Admin

## License Requirements for File and Malware Policies

To Do This	License Required	File Rule Action
Block or allow all files of a particular type (for example, block all .exe files)	IPS (for threat defense devices) Protection (for Classic devices)	Allow, Block, Block with Reset
Selectively allow or block files based on a judgment that it contains or is likely to contain malware	IPS (for threat defense devices) Protection (for Classic devices) Malware Defense	Malware Cloud Lookup, Block Malware
Store files	IPS (for threat defense devices) Protection (for Classic devices) Malware Defense	Any file rule action with <b>Store Files</b> selected

For details about Malware Defense licenses, see:

- *Malware Defense Licenses* in the [Cisco Secure Firewall Management Center Administration Guide](#)

## Best Practices for File Policies and Malware Detection

In addition to the items described below, follow the steps in [How to Configure Malware Protection, on page 2270](#) and referenced topics.

### File Rule Best Practices

Note the following guidelines and limitations when configuring file rules:

- A rule configured to block files in a passive deployment does not block matching files. Because the connection continues to transmit the file, if you configure the rule to log the beginning of the connection, you may see multiple events logged for this connection.
- A policy can include multiple rules. When you create the rules, ensure that no rule is "shadowed" by a previous rule.
- The file types supported for dynamic analysis are a subset of the file types supported for other types of analysis. To view the file types supported for each type of analysis, navigate to the file rule configuration page, select the **Block Malware** action, and select the checkboxes of interest.

To ensure that the system examines all file types, create separate rules (within the same policy) for dynamic analysis and for other types of analysis.

- If a file rule is configured with a **Malware Cloud Lookup** or **Block Malware** action and the management center cannot establish connectivity with the AMP cloud, the system cannot perform any configured rule action options until connectivity is restored.
- Cisco recommends that you enable **Reset Connection** for the **Block Files** and **Block Malware** actions to prevent blocked application sessions from remaining open until the TCP connection resets. If you do not reset connections, the client session will remain open until the TCP connection resets itself.
- If you are monitoring high volumes of traffic, do **not** store all captured files, or submit all captured files for dynamic analysis. Doing so can negatively impact system performance.
- You cannot perform malware analysis on all file types detected by the system. After you select values from the **Application Protocol**, **Direction of Transfer**, and **Action** drop-down lists, the system constrains the list of file types.

## File Detection Best Practices

Consider the following notes and limitations for file detection:

- If adaptive profiling is not enabled, access control rules cannot perform file control, including AMP.
- If a file matches a rule with an application protocol condition, file event generation occurs after the system successfully identifies a file's application protocol. Unidentified files do not generate file events.
- FTP transfers commands and data over different channels. In a passive or inline tap mode deployment, the traffic from an FTP data session and its control session may not be load-balanced to the same internal resource.
- If the total number of bytes for all file names for files in a POP3, POP, SMTP, or IMAP session exceeds 1024, file events from the session may not reflect the correct file names for files that were detected after the file name buffer filled.
- When transmitting text-based files over SMTP, some mail clients convert newlines to the CRLF newline character standard. Since Mac-based hosts use the carriage return (CR) character and Unix/Linux-based hosts use the line feed (LF) character, newline conversion by the mail client can modify the size of the file. Note that some mail clients default to newline conversion when processing an unrecognizable file type.
- To detect ISO files, set the "Limit the number of bytes inspected when doing file type detection" option to a value greater than 36870, as described in [File and Malware Inspection Performance and Storage Options, on page 2292](#).
- .Exe files inside some .rar archives cannot be detected, including possibly rar5.
- If the file disposition is Neutral, it is an unknown disposition.

## File Blocking Best Practices

Consider the following notes and limitations for file blocking:

- If an end-of-file marker is not detected for a file, regardless of transfer protocol, the file will not be blocked by a **Block Malware** rule or the custom detection list. The system waits to block the file until the entire file has been received, as indicated by the end-of-file marker, and blocks the file after the marker is detected.

- If the end-of-file marker for an FTP file transfer is transmitted separately from the final data segment, the marker will be blocked and the FTP client will indicate that the file transfer failed, but the file will actually completely transfer to disk.
- File rules with **Block Files** and **Block Malware** actions block automatic resumption of file download via HTTP by blocking new sessions with the same file, URL, server, and client application detected for 24 hours after the initial file transfer attempt occurs.
- In rare cases, if traffic from an HTTP upload session is out of order, the system cannot reassemble the traffic correctly and therefore will not block it or generate a file event.
- If you transfer a file over NetBIOS-ssn (such as an SMB file transfer) that is blocked with a **Block Files** rule, you may see a file on the destination host. However, the file is unusable because it is blocked after the download starts, resulting in an incomplete file transfer.
- If you create file rules to detect or block files transferred over NetBIOS-ssn (such as an SMB file transfer), the system does not inspect the ongoing file transfers. However, the system inspects the new files that are transferred after you deploy an access control policy invoking the file policy.
- SMB has a functionality called multi-channel which creates multiple parallel sessions with the same IP address and different ports. For a given transaction over multi-channel, the file download is multiplexed across these sessions which is not inspected by the system as a single file.
- Files transferred concurrently in a single TCP or SMB session are not inspected.
- In a cluster environment, if an existing SMB session is moved to a new device due to a cluster role change or a device failure, then the files in any ongoing file transfers may not be inspected.
- Some SMB file transfers between Microsoft Windows systems use very high TCP window size for quick file transfers. To detect or block such file transfers, it is recommended that you increase the value of **Maximum Queued Bytes** and **Maximum Queued Segments** under **Network Analysis Policy > TCP Stream Configuration > Troubleshooting Options**.
- If you configure threat defense high availability, and failover occurs while the original active device is identifying the file, the file type is not synced. Even if your file policy blocks that file type, the new active device downloads the file.

## File Policy Best Practices

Note the following general guidelines and limitations when configuring file policies.

- You can associate a single file policy with an access control rule whose action is **Allow**, **Interactive Block**, or **Interactive Block with reset**.
- You **cannot** use a file policy to inspect traffic handled by the access control default action.
- For a new policy, the web interface indicates that the policy is not in use. If you are editing an in-use file policy, the web interface tells you how many access control policies use the file policy. In either case, you can click the text to jump to the Access Control Policies page.
- For file blocking to work, the NAP policy you apply to the access control policy must be operating in Protection mode, also known as Inline mode.
- Based on your configuration, you can either inspect a file the first time the system detects it, and wait for a cloud lookup result, or pass the file on this first detection without waiting for the cloud lookup result.

- By default, file inspection of encrypted payloads is disabled. This helps reduce false positives and improve performance when an encrypted connection matches an access control rule that has file inspection configured.

---

**Attention** The File Inpsct preprocessor with the following generator IDs (GIDs) are enabled by default for file/malware policy: GID: 146 and GID: 147.

---

- If you enable an access control policy with a file policy that uses either a Malware action or a Store Files option, the computing power and system performance of the device is reduced.

## How to Configure Malware Protection

This topic summarizes the steps you must take to set up your system to protect your network from malicious software.

### Procedure

- 
- Step 1** [Plan and Prepare for Malware Protection, on page 2270](#)
  - Step 2** [Configure File Policies, on page 2271](#)
  - Step 3** [Add File Policies to Your Access Control Configuration, on page 2272](#)
  - Step 4** Configure network discovery policies to associate file and malware events with hosts on your network.  
(Do not simply turn on network discovery; you must configure it to discover hosts on your network to build a network map of your organization.)  
See [Network Discovery Policies, on page 2679](#) and subtopics.
  - Step 5** Deploy policies to managed devices.  
See [Deploy Configuration Changes, on page 240](#).
  - Step 6** Test your system to be sure it is processing malicious files as you expect it to.
  - Step 7** [Set Up Maintenance and Monitoring of Malware Protection, on page 2274](#)
- 

### What to do next

- (Optional) To further enhance detection of malware in your network, deploy and integrate Cisco's AMP for Endpoints product. See [\(Optional\) Malware Protection with AMP for Endpoints, on page 2295](#) and subtopics.

## Plan and Prepare for Malware Protection

This procedure is the first set of steps in the complete process for configuring your system to provide malware protection.

## Procedure

- 
- Step 1** Purchase and install licenses.  
See [License Requirements for File and Malware Policies, on page 2267](#) and *Licenses* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- Step 2** Understand how file policies and malware protection fit into your access control plan.  
See the chapter [Access Control Overview, on page 1809](#).
- Step 3** Understand the file analysis and malware protection tools.  
See [File Rule Actions, on page 2284](#) and subtopics.  
Consider also [Advanced and Archive File Inspection Options, on page 2279](#).
- Step 4** Determine whether you will use public clouds or private (on-premises) clouds for malware protection (file analysis and dynamic analysis.)  
See [Cloud Connections for Malware Protection, on page 2274](#) and subtopics.
- Step 5** If you will use private (on-premises) clouds for malware protection: Purchase, deploy, and test those products.  
For information, contact your Cisco sales representative or authorized reseller.
- Step 6** Configure your firewall to allow communications with your chosen clouds.  
See *Security, Internet Access, and Communication Ports* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- Step 7** Configure connections between Firepower and the malware protection clouds (public or private, as applicable).
- 

### What to do next

Continue with the next step in the malware protection workflow:

See [How to Configure Malware Protection, on page 2270](#).

## Configure File Policies

### Before you begin

Complete the tasks up to this point in the malware protection workflow:

See [How to Configure Malware Protection, on page 2270](#).

## Procedure

- 
- Step 1** Review file policy and file rule restrictions.  
See [Best Practices for File Policies and Malware Detection , on page 2267](#) and subtopics.

- Step 2** Create a file policy.  
See [Create or Edit a File Policy, on page 2278](#).
- Step 3** Create rules within your file policy.  
See [File Rules, on page 2282](#) and subtopics.
- Step 4** Configure advanced options.  
See [Advanced and Archive File Inspection Options, on page 2279](#).
- 

#### What to do next

Continue with the next step in the malware protection workflow:  
See [How to Configure Malware Protection, on page 2270](#).

## Add File Policies to Your Access Control Configuration

An access control policy can have multiple access control rules associated with file policies. You can configure file inspection for any Allow or Interactive Block access control rule, which permits you to match different file and malware inspection profiles against different types of traffic on your network before it reaches its final destination.

#### Before you begin

Complete the tasks up to this point in the malware protection workflow:  
See [How to Configure Malware Protection, on page 2270](#).

#### Procedure

---

- Step 1** Review guidelines for file policies in access control policies. (These are different from the file rule and file policy guidelines that you looked at previously.)  
Review [File and Intrusion Inspection Order, on page 1816](#).
- Step 2** Associate the file policy with an access control policy.  
See [Configuring an Access Control Rule to Perform Malware Protection, on page 2273](#)
- Step 3** Assign the access control policy to managed devices.  
See [Setting Target Devices for an Access Control Policy, on page 1838](#).
- 

#### What to do next

Continue with the next step in the malware protection workflow:  
See [How to Configure Malware Protection, on page 2270](#).

## Configuring an Access Control Rule to Perform Malware Protection

**Caution** Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis** or **MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware**, **Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior](#), on page 234 for more information.

**Note** Inline normalization is enabled automatically when a file policy is included in an access control rule. For more information, see [The Inline Normalization Preprocessor](#), on page 2887.

### Before you begin

- Adaptive profiling **must** be enabled (its default state) as described in [Configuring Adaptive Profiles](#), on page 2940 for access control rules to perform file control, including AMP.
- You must be an Admin, Access Admin, or Network Admin user to perform this task.

### Procedure

- 
- Step 1** In the access control rule editor (from **Policies > Access Control**), choose an **Action** of **Allow**, **Interactive Block**, or **Interactive Block with reset**.
- Step 2** Choose a **File Policy** to inspect traffic that matches the access control rule, or choose **None** to disable file inspection for matching traffic.
- Step 3** (Optional) Disable logging of file or malware events for matching connections by clicking **Logging** and unchecking **Log Files**.
- Note** Cisco recommends that you leave file and malware event logging enabled.
- Step 4** Save the rule.
- Step 5** Click **Save** to save the policy.
- 

### What to do next

- Deploy configuration changes.

### Related Topics

- [Create or Edit a File Policy](#), on page 2278
- [Snort Restart Scenarios](#), on page 232

## Set Up Maintenance and Monitoring of Malware Protection

Ongoing maintenance is essential for protecting your network.

### Before you begin

Configure your system to protect your network from malware.

See [How to Configure Malware Protection, on page 2270](#) and referenced procedures.

### Procedure

- 
- Step 1** Ensure that your system always has the most current and effective protection.  
See [Maintain Your System: Update File Types Eligible for Dynamic Analysis, on page 2277](#).
- Step 2** Configure alerts for malware-related events and health monitoring.  
See the [Cisco Secure Firewall Management Center Administration Guide](#) for information on *Configuring malware defense Alerting* and for information about the following modules:
- Local Malware Analysis
  - Security Intelligence
  - Threat Data Updates on Devices
  - Intrusion and File Event Rate
  - AMP for Firepower Status
  - AMP for Endpoints Status
- 

### What to do next

Review "What to do next items" in the malware protection workflow:

See [How to Configure Malware Protection, on page 2270](#).

## Cloud Connections for Malware Protection

Connections to public or private clouds are required in order to protect your network from malware.

### AMP Clouds

The Advanced Malware Protection (AMP) cloud is a Cisco-hosted server that uses big data analytics and continuous analysis to provide intelligence that the system uses to detect and block malware on your network.

The AMP cloud provides dispositions for possible malware detected in network traffic by managed devices, as well as data updates for local malware analysis and file pre-classification.

If your organization has deployed AMP for Endpoints and configured Firepower to import its data, the system imports this data from the AMP cloud, including scan records, malware detections, quarantines, and indications of compromise (IOC).

Cisco offers the following options for obtaining data from the Cisco cloud about known malware threats:

- **AMP public cloud**

Your Secure Firewall Management Center communicates directly with the public Cisco cloud. There are three public AMP clouds, in the United States, Europe, and Asia.

### **Dynamic Analysis Cloud**

- **Secure Malware Analytics Cloud**

Public cloud that processes eligible files that you send for dynamic analysis, and provides threat scores and dynamic analysis reports. Firepower supports 200 samples/day for Secure Malware Analytics analysis.

## **AMP Cloud Connection Configurations**

### **Requirements and Best Practices for AMP Cloud Connections**

#### **Requirements for AMP Cloud Connections**

You must be an Admin user to set up the AMP cloud.

To ensure your management center can communicate with the AMP cloud, see the topics under *Security, Internet Access, and Communication Ports* in the [Cisco Secure Firewall Management Center Administration Guide](#).

To use the legacy port for AMP communications, see *Communication Port Requirements* in the [Cisco Secure Firewall Management Center Administration Guide](#).

#### **AMP and High Availability**

Although they share file policies and related configurations, management centers in a high availability pair share neither cloud connections nor captured files, file events, and malware events. To ensure continuity of operations, and to ensure that detected files' malware dispositions are the same on both management centers, both Active and Standby management centers must have access to the cloud.

In high availability deployments, configure AMP cloud connections on both management centers. These configurations are not synchronized.

## **Change AMP Options**

### **Procedure**

- 
- Step 1** Choose **Integration > Other Integrations**.
  - Step 2** Click **Cloud Services**.
  - Step 3** Select options:

Table 212: AMP for Networks Options

Option	Description
<b>Enable Automatic Local Malware Detection Updates</b>	The local malware detection engine statically analyzes and preclassifies files using signatures provided by Cisco. If you enable this option, the Secure Firewall Management Center checks for signature updates once every 30 minutes.
<b>Share URI from Malware Events with Cisco</b>	The system can send information about the files detected in network traffic to the AMP cloud. This information includes URI information associated with detected files and their SHA-256 hash values. Although sharing is opt-in, transmitting this information to Cisco helps future efforts to identify and track malware.

**Step 4** Click **Save**.

## Dynamic Analysis Connections

### Requirements for Dynamic Analysis

You must be an Admin, Access Admin, or Network Admin user, and be in the global domain, to use dynamic analysis.

With the appropriate license, the system automatically has access to the Secure Malware Analytics Cloud.

Dynamic analysis requires that managed devices have direct or proxied access to the Secure Malware Analytics Cloud or an on-premises Secure Malware Analytics Appliance on port 443.

See also [Which Files Are Eligible for Dynamic Analysis?](#), on page 2288.

### Viewing the Default Dynamic Analysis Connection

By default, the Secure Firewall Management Center can connect to the public Secure Malware Analytics Cloud for file submission and report retrieval. You can neither configure nor delete this connection.

#### Procedure

**Step 1** Choose **Integration > AMP > Dynamic Analysis Connections**.

**Step 2** You can view the cloud in use on the default dynamic analysis connection. To associate the device, click **Associate** (). For more information, see [Enabling Access to Dynamic Analysis Results in the Public Cloud](#), on page 2276.

### Enabling Access to Dynamic Analysis Results in the Public Cloud

Secure Malware Analytics offers more detailed reporting on analyzed files than is available in the management center. If your organization has a Secure Malware Analytics Cloud account, you can access the Secure Malware

Analytics portal directly to view additional details about files sent for analysis from your managed devices. However, for privacy reasons, file analysis details are available only to the organization that submitted the files. Therefore, before you can view this information, you must associate your management center with the files submitted by its managed devices.

### Before you begin

You must have a Secure Malware Analytics Cloud account, and have your account credentials ready.

## Procedure

- 
- Step 1** Select **Integration > AMP > Dynamic Analysis Connections**.
- Step 2** Click **Associate** (  ) in the table row corresponding to the Secure Malware Analytics Cloud. A Secure Malware Analytics portal window opens.
- Step 3** Sign in to the Secure Malware Analytics Cloud.
- Step 4** Click **Submit Query**.

**Note** Do not change the default value in the **Devices** field.

If you have difficulties with this process, contact your Secure Malware Analytics representative at Cisco TAC. It may take up to 24 hours for this change to take effect.

---

### What to do next

After the association is activated, see *Viewing Dynamic Analysis Results in the Cisco Cloud* in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Maintain Your System: Update File Types Eligible for Dynamic Analysis

The list of file types eligible for Dynamic Analysis is determined by the vulnerability database (VDB), which is updated periodically (but no more than once per day.) If you are an Admin user, you can update file types eligible for dynamic analysis.

To ensure that your system has the current list:

## Procedure

- 
- Step 1** Do one of the following:
- (Recommended) See *Vulnerability Database Update Automation* as discussed in the [Cisco Secure Firewall Management Center Administration Guide](#)
  - Regularly check for new VDB updates, and *Manually Update the VDB* as discussed in the [Cisco Secure Firewall Management Center Administration Guide](#) when needed.

If you choose this option, we recommend that you schedule regular reminders to do this.

- Step 2** If your file policies specify individual file types instead of the **Dynamic Analysis Capable** file type category, update your file policies to use the newly supported file types.
- Step 3** If the list of eligible file types changes, deploy to managed devices.
- 

## File Policies and File Rules

### Create or Edit a File Policy

#### Before you begin

If you are configuring policies for malware protection, see all required procedures in [Configure File Policies, on page 2271](#).

#### Procedure

---

**Step 1** Select **Policies > Access Control > Malware & File**.

**Step 2** Create a new policy, or edit an existing policy.

If you are editing an existing policy: If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Tip** To make a copy of an existing file policy, click **Copy** (📄), then type a unique name for the new policy in the dialog box that appears. You can then modify the copy.

**Step 3** Add one or more rules to the file policy as described in [Creating File Rules, on page 2291](#).

**Step 4** Optionally, select **Advanced** and configure advanced options as described in [Advanced and Archive File Inspection Options, on page 2279](#).

**Step 5** Save the file policy.

---

#### What to do next

- If you are configuring policies for malware protection, see other required procedures in [Configure File Policies, on page 2271](#).
- Otherwise:
  - Add the file policy to an access control rule as described in [Add File Policies to Your Access Control Configuration, on page 2272](#).
  - Deploy configuration changes.

## Advanced and Archive File Inspection Options

The Advanced Settings in the file policy editor has the following general options:

- **First Time File Analysis**—Select this option to analyze first-seen files while AMP cloud disposition is pending. The file must match a rule configured to perform a malware cloud lookup and Spero, local malware, or dynamic analysis. If you deselect this option, files detected for the first time are marked with an Unknown disposition
- **Enable Custom Detection List**—Block files on the custom detection list.
- **Enable Clean List**—If enabled, this policy will allow files that are on the clean list.
- **If AMP Cloud disposition is Unknown, override disposition based upon threat score**—Select an option:
  - If you select **Disabled**, the system will not override the disposition provided by the AMP Cloud.
  - If you set a threshold threat score, files with an AMP cloud verdict of Unknown are considered malware if their Dynamic Analysis score is equal to or worse than the threshold.
  - If you select a lower threshold value, you increase the number of files treated as malware. Depending on the action selected in your file policy, this can result in an increase of blocked files.

The Advanced Settings in the file policy editor has the following archive file inspection options:

- **Inspect Archives**—Enables inspection of the contents of archive files, for archive files as large as the **Maximum file size to store** advanced access control setting.
- **Block Encrypted Archives**—Blocks password-protected archives.
- **Block Uninspectable Archives**—Blocks archive files with contents that the system is unable to inspect for reasons other than encryption. This usually applies to corrupted files, or those that exceed your specified maximum archive depth.
- **Max Archive Depth**—Blocks nested archive files that exceed the specified depth. The top-level archive file is not considered in this count; depth begins at 1 with the first nested file .

### Archive Files

Archive files are files that contain other files, such as `.zip` or `.rar` files.

If any individual file in an archive matches a file rule with a block action, the system blocks the entire archive, not just the individual file.

For details about options for archive file inspection, see [Advanced and Archive File Inspection Options, on page 2279](#).

#### Archive Files That Can Be Inspected

- **File types**

A complete list of inspectable archive file types appears in the management center web interface on the file rule configuration page. To view that page, see [Creating File Rules, on page 2291](#).

Contained files that can be inspected appears in the same page.

- **File size**

You can inspect archive files as large as the **Maximum file size to store** file policy advanced access control setting.

- **Nested archives**

Archive files can contain other archive files, which can in turn contain archive files. The level at which a file is nested is its *archive file depth*. Note that the top-level archive file is not included in the depth count; depth begins at 1 with the first nested file.

The system can inspect up to three levels of nested files beneath the outermost archive file (level 0). You can configure your file policy to block archive files that exceed that depth (or a lower maximum depth that you specify).

If you choose not to block files that exceed the maximum archive file depth of 3, when archive files that contain some extractable contents and some contents nested at a depth of 3 or greater appear in monitored traffic, the system examines and reports data only for the files it was able to inspect.

All features applicable to uncompressed files (such as dynamic analysis and file storage) are available for nested files inside archive files.

- **Encrypted files**

You can configure the system to block archives whose contents are encrypted or otherwise cannot be inspected.

- **Archives that are not inspected**

If traffic that contains an archive file is on a Security Intelligence Block list or Do Not Block list, or if the top-level archive file's SHA-256 value is on the custom detection list, the system does not inspect the contents of the archive file.

If a nested file is blocked, the entire archive is blocked; however, if a nested file is allowed, the archive is not automatically passed (depending on any other nested files and characteristics).

.Exe files inside some .rar archives cannot be detected, including possibly rar5.

### Archive File Dispositions

Archive file dispositions are based on the dispositions assigned to the files inside the archive. **All** archives that contain identified malware files receive a disposition of `Malware`. Archives without identified malware files receive a disposition of `Unknown` if they contain any unknown files, and a disposition of `Clean` if they contain only clean files.

**Table 213: Archive File Disposition by Contents**

Archive File Disposition	Number of Unknown Files	Number of Clean Files	Number of Malware Files
Unknown	1 or more	Any	0
Clean	0	1 or more	0
Malware	Any	Any	1 or more

Archive files, like other files, may have dispositions of `Custom Detection` or `Unavailable` if the conditions for those dispositions apply.

### Viewing Archive Contents and Details

If your file policy is configured to inspect archive file contents, you can use the context menu in a table on pages under the Analysis > Files menu, and the network file trajectory viewer to view information about the files inside an archive when the archive file appears in a file event, malware event, or as a captured file.

All file contents of the archive are listed in table form, with a short summary of their relevant information: name, SHA-256 hash value, type, category, and archive depth. A network file trajectory icon appears by each file, which you can click to view further information about that specific file.

### Override File Disposition Using Custom Lists

If a file has a disposition in the AMP cloud that you know to be incorrect, you can add the file's SHA-256 value to a file list that overrides the disposition from the cloud:

- To treat a file as if the AMP cloud assigned a clean disposition, add the file to the *clean list*.
- To treat a file as if the AMP cloud assigned a malware disposition, add the file to the *custom detection list*.

On subsequent detection, the device either allows or blocks the file without reevaluating the file's disposition. You can use the clean list or custom detection list per file policy.

---

**Note** To calculate a file's SHA-256 value, you must configure a rule in the file policy to either perform a malware cloud lookup or block malware on matching files.

---

For complete information about using file lists in Firepower, see [File List](#), on page 1488.

Alternatively, if applicable, use [Centralized File Lists from AMP for Endpoints](#), on page 2281.

#### Centralized File Lists from AMP for Endpoints

If your organization has deployed AMP for Endpoints, Firepower can use Block and Allow lists created in AMP for Endpoints when it queries the AMP cloud for file dispositions.

Requirements:

- Your organization must be using the AMP public cloud.
- Your organization has deployed AMP for Endpoints.
- You have registered your system to AMP for Endpoints using the procedure in [Integrate Firepower and Secure Endpoint](#), on page 2297.

To create and deploy these lists, see the documentation or online help for AMP for Endpoints.

---

**Note** File lists created in Firepower override file lists created in AMP for Endpoints.

---

## Managing File Policies

The File Policies page displays a list of existing file policies along with their last-modified dates. You can use this page to manage your file policies.

---

**Note** The system checks for updates to the list of file types eligible for dynamic analysis (no more than once a day). If the list of eligible file types changes, this constitutes a change in the file policy; any access control policy using the file policy is marked out-of-date if deployed to any devices. You must deploy policies before the updated file policy can take effect on the device. See [Maintain Your System: Update File Types Eligible for Dynamic Analysis, on page 2277](#).

---

## Procedure

---

**Step 1** Select **Policies > Access Control > Malware & File** .

**Step 2** Manage your file policies:

- Compare—Click **Compare Policies**; see [Compare Policies](#).
  - Create — To create a file policy, click **New File Policy** and proceed as described in [Create or Edit a File Policy, on page 2278](#).
  - Copy — To copy a file policy, click **Copy** ().  
If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
  - Delete — If you want to delete a file policy, click **Delete** () , then click **Yes** and **OK** as prompted.  
If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
  - Deploy—Choose **Deploy > Deployment**; see [Deploy Configuration Changes, on page 240](#).
  - Edit — If you want to modify an existing file policy, click **Edit** ().
  - Report—Click **Report** (); see [Generate Current Policy Reports, on page 253](#).
- 

## File Rules

A file policy, like its parent access control policy, contains rules that determine how the system handles files that match the conditions of each rule. You can configure separate file rules to take different actions for different file types, application protocols, or directions of transfer.

For example, when a file matches a rule, the rule can:

- allow or block files based on simple file type matching
- block files based on disposition (whether or not evaluation indicates that it is malicious)
- store files to the device (For information, see [Captured Files and File Storage, on page 2289](#))
- submit stored (captured) files for local malware, Spero, or dynamic analysis

In addition, the file policy can:

- automatically treat a file as if it is clean or malware based on entries in the clean list or custom detection list
- treat a file as if it is malware if the file's threat score exceeds a configurable threshold
- inspect the contents of archive files (such as .zip or .rar)
- block archive files whose contents are encrypted, nested beyond a specified maximum archive depth, or otherwise uninspectable

## File Rule Components

Table 214: File Rule Components

File Rule Component	Description
application protocol	The system can detect and inspect files transmitted via FTP, HTTP, SMTP, IMAP, POP3, and NetBIOS-ssn (SMB). <b>Any</b> , the default, detects files in HTTP, SMTP, IMAP, POP3, FTP, and NetBIOS-ssn (SMB) traffic. To improve performance, you can restrict file detection to only one of those application protocols on a per-file rule basis.
direction of transfer	You can inspect incoming FTP, HTTP, IMAP, POP3, and NetBIOS-ssn (SMB) traffic for downloaded files; you can inspect outgoing FTP, HTTP, SMTP, and NetBIOS-ssn (SMB) traffic for uploaded files.  <b>Tip</b> Use <b>Any</b> to detect files over multiple application protocols, regardless of whether users are sending or receiving.
file categories and types	The system can detect various types of files. These file types are grouped into basic categories, including multimedia (swf, mp3), executables (exe, torrent), and PDFs. You can configure file rules that detect individual file types, or on entire categories of file types.  For example, you could block all multimedia files, or just ShockWave Flash (swf) files. Or, you could configure the system to alert you when a user downloads a BitTorrent (torrent) file.  Note that executables include file types that can run macros and scripts, since these can contain malware.  For a list of file types the system can inspect, select <b>Policies &gt; Access Control &gt; Malware &amp; File</b> , create a temporary new file policy, then click <b>Add Rule</b> . Select a file type category and the file types that the system can inspect appear in the <b>File Types</b> list.  <b>Note</b> Frequently triggered file rules can affect system performance. For example, detecting multimedia files in HTTP traffic (YouTube, for example, transmits significant Flash content) could generate an overwhelming number of events.

File Rule Component	Description
file rule action	<p>A file rule's action determines how the system handles traffic that matches the conditions of the rule.</p> <p>Depending on the selected action, you can configure whether the system stores the file or performs Spero, local malware, or dynamic analysis on a file. If you select a Block action, you can also configure whether the system also resets the blocked connection.</p> <p>For descriptions of these actions and options, see <a href="#">File Rule Actions, on page 2284</a>.</p> <p>File rules are evaluated in rule-action, not numerical, order. For details, see <a href="#">File Rule Actions: Evaluation Order, on page 2290</a>.</p>

## File Rule Actions

File rules give you granular control over which file types you want to log, block, or scan for malware. Each file rule has an associated action that determines how the system handles traffic that matches the conditions of the rule. To be effective, a file policy must contain one or more rules. You can use separate rules within a file policy to take different actions for different file types, application protocols, or directions of transfer.

### File Rule Actions

- *Detect Files* rules allow you to log the detection of specific file types to the database, while still allowing their transmission.
- *Block Files* rules allow you to block specific file types. You can configure options to reset the connection when a file transfer is blocked, and store captured files to the managed device.
- *Malware Cloud Lookup* rules allow you to obtain and log the disposition of files traversing your network, while still allowing their transmission.
- *Block Malware* rules allow you to calculate the SHA-256 hash value of specific file types, query the AMP cloud to determine if files traversing your network contain malware, then block files that represent threats.

### File Rule Action Options

Depending on the action you select, you have different options:

File Rule Action Option	Block Files capable?	Block Malware capable?	Detect Files capable?	Malware Cloud Lookup capable?
Spero Analysis* for MSEXE	no	yes, you can submit executable files	no	yes, you can submit executable files
Dynamic Analysis*	no	yes, you can submit executable files with Unknown file dispositions	no	yes, you can submit executable files with Unknown file dispositions
Capacity Handling	no	yes	no	yes

File Rule Action Option	Block Files capable?	Block Malware capable?	Detect Files capable?	Malware Cloud Lookup capable?
Local Malware Analysis*	no	yes	no	yes
Reset Connection	yes (recommended)	yes (recommended)	no	no
Store files	yes, you can store all matching file types	yes, you can store file types matching the file dispositions you select	yes, you can store all matching file types	yes, you can store file types matching the file dispositions you select

\* For complete information about these options, see [Malware Protection Options \(in File Rule Actions\)](#), on [page 2285](#) and its subtopics.

**Caution** Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis** or **MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware**, **Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior](#), on [page 234](#) for more information.

### Malware Protection Options (in File Rule Actions)

The system applies several methods of file inspection and analysis to determine whether a file contains malware.

Depending on the options you enable in a file rule, the system inspects files using the following tools, in order:

1. [Spero Analysis](#), on [page 2287](#) and [AMP Cloud Lookup](#), on [page 2287](#)
2. [Local Malware Analysis](#), on [page 2287](#)
3. [Dynamic Analysis](#), on [page 2288](#)

For a comparison of these tools, see [Comparison of Malware Protection Options](#), on [page 2285](#).

(You can also, if you choose, block all files based on their file type. For more information, see [Block All Files by Type](#), on [page 2290](#).)

See also information about Cisco's AMP for Endpoints product at [\(Optional\) Malware Protection with AMP for Endpoints](#), on [page 2295](#) and subtopics.

### Comparison of Malware Protection Options

The following table details the benefits and drawbacks of each type of file analysis, as well as the way each malware protection method determines a file's disposition.

Analysis Type	Benefit	Limitations	Malware Identification
Spero analysis	Structural analysis of executable files, submits Spero signature to the AMP Cloud for analysis	Less thorough than local malware analysis or dynamic analysis, only for executable files	Disposition changes from Unknown to Malware only on positive identification of malware.
Local malware analysis	Consumes fewer resources than dynamic analysis, and returns results more quickly, especially if the detected malware is common	Less thorough results than dynamic analysis	Disposition changes from Unknown to Malware only on positive identification of malware.
Dynamic analysis	Thorough analysis of unknown files using Secure Malware Analytics	Eligible files are uploaded to the public cloud or an on-premises appliance. It takes some time to complete analysis	Threat score determines maliciousness of a file. Disposition can be based on the threat score threshold configured in the file policy.
Spero analysis and local malware analysis	Consumes fewer resources than configuring local malware analysis and dynamic analysis, while still using AMP cloud resources to identify malware	Less thorough than dynamic analysis, Spero analysis only for executable files	Disposition changes from Unknown to Malware only on positive identification of malware.
Spero analysis and dynamic analysis	Uses full capabilities of AMP cloud in submitting files and Spero signatures	Results obtained less quickly than if using local malware analysis	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes based on configured threat score threshold in the file policy, and from Unknown to Malware if the Spero analysis identifies malware.
Local malware analysis and dynamic analysis	Thorough results in using both types of file analysis	Consumes more resources than either alone	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if local malware analysis identifies malware, or based on configured threat score threshold in the file policy.

Analysis Type	Benefit	Limitations	Malware Identification
Spero analysis, local malware analysis and dynamic analysis	Most thorough results	Consumes most resources in running all three types of file analysis	Threat score changes based on dynamic analysis results for files preclassified as possible malware. Disposition changes from Unknown to Malware if Spero analysis or local malware analysis identifies malware, or based on configured threat score threshold in the file policy.
(Block transmission of all files of a specified file type)	Does not require a Malware Defense license  (This option is not technically a malware protection option.)	Legitimate files will also be blocked	(No analysis is performed.)

**Note** Preclassification does not itself determine a file's disposition; it is merely one of the factors that determine whether a file is eligible for Dynamic Analysis.

### Spero Analysis

Spero analysis examines structural characteristics such as metadata and header information in executable files. After generating a Spero signature based on this information, if the file is an eligible executable file, the device submits it to the Spero heuristic engine in the AMP cloud. Based on the Spero signature, the Spero engine determines whether the file is malware. You can also configure rules to submit files for Spero analysis without also submitting them to the AMP cloud.

Note that you cannot manually submit files for Spero analysis.

### AMP Cloud Lookup

For files that are eligible for assessment using Advanced Malware Protection, the management center performs a *malware cloud lookup*, querying the AMP cloud for the file's disposition based on its SHA-256 hash value.

To improve performance, the system caches dispositions returned by the cloud and uses the cached disposition for known files rather than querying the AMP cloud. For more information about this cache, see [Cached Disposition Longevity](#), on page 2288.

### Local Malware Analysis

Local malware analysis allows a managed device to locally inspect executables, PDFs, office documents, and other types of files for the most common types of malware, using a detection rule set provided by the Talos Intelligence Group. Because local analysis does not query the AMP cloud, and does not run the file, local malware analysis saves time and system resources.

If the system identifies malware through local malware analysis, it updates the existing file disposition from Unknown to Malware. The system then generates a new malware event. If the system does not identify malware, it does not update the file disposition from Unknown to Clean. After the system runs local malware

analysis, it caches file information such as SHA-256 hash value, timestamp, and disposition, so that if detected again within a certain period of time, the system can identify malware without additional analysis. For more information about the cache, see [Cached Disposition Longevity, on page 2288](#).

Local malware analysis does not require establishing communications with the Secure Malware Analytics Cloud. However, you must configure communications with the cloud to submit files for dynamic analysis, and to download updates to the local malware analysis ruleset.

### Cached Disposition Longevity

Dispositions returned from an AMP cloud query, associated threat scores, and dispositions assigned by local malware analysis, have a time-to-live (TTL) value. After a disposition has been held for the duration specified in the TTL value without update, the system purges the cached information. Dispositions and associated threat scores have the following TTL values:

- Clean — 4 hours
- Unknown — 1 hour
- Malware — 1 hour

If a query against the cache identifies a cached disposition that timed out, the system re-queries the local malware analysis database and the AMP cloud for a new disposition.

### Dynamic Analysis

You can configure your file policy to automatically submit files for dynamic analysis using Secure Malware Analytics (formerly Threat Grid), Cisco's file analysis and threat intelligence platform.

Devices submit eligible files to Secure Malware Analytics (either the public cloud or to an on-premises appliance, whichever you have specified) regardless of whether the device stores the file.

Secure Malware Analytics runs the file in a sandbox environment, analyzes the file's behavior to determine whether the file is malicious, and returns a threat score that indicates the likelihood that a file contains malware. From the threat score, you can view a dynamic analysis summary report with the reasons for the assigned threat score. You can also look in Secure Malware Analytics to view detailed reports for files that your organization submitted, as well as scrubbed reports with limited data for files that your organization did not submit.

For more information about Cisco Secure Malware Analytics, see <https://www.cisco.com/c/en/us/products/security/threat-grid/index.html>

To configure your system to perform dynamic analysis, see the topics under [Dynamic Analysis Connections, on page 2276](#).

### Which Files Are Eligible for Dynamic Analysis?

A file's eligibility for dynamic analysis depends on:

- the file type
- the file size
- the file rule's action

Additionally:

- The system submits only files that match the file rules you configure.

- The file must have a malware cloud lookup disposition of Unknown or Unavailable at the time the file is sent for analysis.
- The system must preclassify the file as potential malware.

### Dynamic Analysis and Capacity Handling

Capacity handling allows you to temporarily store files that are otherwise eligible for dynamic analysis if the system is temporarily unable to submit files to the cloud, either because the device cannot communicate with the cloud or because the maximum number of submissions has been reached. The system submits the stored files when the hindering condition has passed.

Some devices can store files on the device hard drive or in a malware storage pack. See also [Malware Storage Pack, on page 2290](#).

### Captured Files and File Storage

The file storage feature allows you to capture selected files detected in traffic, and automatically store a copy of the file temporarily to a device's hard drive, or, if installed, to the malware storage pack.

After your device captures the files, you can:

- Store captured files on the device's hard drive for later analysis.
- Download the stored file to a local computer for further manual analysis or archival purposes.
- Manually submit eligible captured files for AMP cloud lookup or dynamic analysis.

Note that once a device stores a file, it will not re-capture it if the file is detected in the future and the device still has that file stored.

---

**Note** When a file is detected for the first time on your network, you can generate a file event that represents the file's detection. However, if your file rule performs a malware cloud lookup, the system requires additional time to query the AMP cloud and return a disposition. Due to this delay, the system cannot store this file until the second time it is seen on your network, and the system can immediately determine the file's disposition.

---

Whether the system captures or stores a file, you can:

- Review information about the captured file from Analysis > Files > Captured Files, including whether the file was stored or submitted for dynamic analysis, file disposition, and threat score, allowing you to quickly review possible malware threats detected on your network.
- View the file's trajectory to determine how it traversed your network and which hosts have a copy.
- Add the file to the clean list or custom detection list to always treat the file as if it had a clean or malware disposition on future detection.

You configure file rules in a file policy to capture and store files of a specific type, or with a particular file disposition, if available. After you associate the file policy with an access control policy and deploy it to your devices, matching files in traffic are captured and stored. You can also limit the minimum and maximum file sizes to store.

Stored files are not included in system backups.

You can view captured file information under Analysis > Files > Captured Files, and download a copy for offline analysis.

## Malware Storage Pack

Based on your file policy configuration, your device may store a substantial amount of file data to the hard drive. You can install a malware storage pack in the device; the system stores files to the malware storage pack, allowing more room on the primary hard drive to store events and configuration files. The system periodically deletes older files. If the device's primary hard drive does not have enough available space, and does not have an installed malware storage pack, you cannot store files.

---

**Caution** Do not attempt to install a hard drive that was not supplied by Cisco in your device. Installing an unsupported hard drive may damage the device. Malware storage pack kits are available for purchase **only** from Cisco. Contact Support if you require assistance with the malware storage pack.

---

Without a malware storage pack installed, when you configure a device to store files, it allocates a set portion of the primary hard drive's space to captured file storage. If you configure capacity handling to temporarily store files for dynamic analysis, the system uses the same hard drive allocation to store these files until it can resubmit them to the cloud.

When you install a malware storage pack in a device and configure file storage or capacity handling, the device allocates the entire malware storage pack for storing these files. The device cannot store any other information on the malware storage pack.

When the allocated space for captured file storage fills to capacity, the system deletes the oldest stored files until the allocated space reaches a system-defined threshold. Based on the number of files stored, you may see a substantial drop in disk usage after the system deletes files.

If a device has already stored files when you install a malware storage pack, the next time you restart the device, any captured files or capacity handling files stored on the primary hard drive are moved to the malware storage pack. Any future files the device stores are stored to the malware storage pack.

For more information on using MSP on the Firepower devices, see the [Firepower Hardware Installation Guide](#) for your device.

## *Block All Files by Type*

If your organization wants to block not only the transmission of malware files, but all files of a specific type, regardless of whether the files contain malware, you can do so.

File control is supported for all file types where the system can detect malware, plus many additional file types. These file types are grouped into basic categories, such as multimedia (swf, mp3), executables (exe, torrent), and PDFs.

Blocking all files based on their type is not technically a malware protection feature; it does not require a Malware Defense license and does not query the AMP cloud.

## **File Rule Actions: Evaluation Order**

A file policy will likely contain multiple rules with different actions for different situations. If more than one rule can apply to a particular situation, the evaluation order described in this topic applies. In general, simple blocking takes precedence over malware inspection and blocking, which takes precedence over simple detection and logging.

The order of precedence of file-rule actions is:

- *Block Files*
- *Block Malware*
- *Malware Cloud Lookup*
- *Detect Files*

## Creating File Rules

**Caution** Enabling or disabling **Store files** in a **Detect Files** or **Block Files** rule, or adding the first or removing the last file rule that combines the **Malware Cloud Lookup** or **Block Malware** file rule action with an analysis option (**Spero Analysis** or **MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware**, **Unknown**, **Clean**, or **Custom**), restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior](#), on page 234 for more information.

### Before you begin

If you are configuring rules for malware protection, see [Configure File Policies](#), on page 2271.

### Procedure

- Step 1** Select **Policies > Access Control > Malware & File**.
- Step 2** Click the edit icon to modify an existing file policy.
- Step 3** In the file policy editor, click **Add Rule**.
- Step 4** Select an **Application Protocol** and **Direction of Transfer** as described in [File Rule Components](#), on page 2283.
- Step 5** Select one or more **File Types**.  
The file types you see depend on the selected application protocol, direction of transfer, and action.  
You can filter the list of file types in the following ways:
  - Select one or more **File Type Categories**, then click **All types in selected Categories**.
  - Search for a file type by its name or description. For example, type **Windows** in the **Search name and description** field to display a list of Microsoft Windows-specific files.
- Tip** Hover your pointer over a file type to view its description.
- Step 6** Select a file rule **Action** as described in [File Rule Actions](#), on page 2284, with consideration for [File Rule Actions: Evaluation Order](#), on page 2290.  
The actions available to you depend on the licenses you have installed. See [License Requirements for File and Malware Policies](#), on page 2267.
- Step 7** Depending on the action you selected, configure options:

- reset the connection after blocking the file
- store files that match the rule
- enable Spero analysis\*
- enable local malware analysis\*
- enable dynamic analysis\* and capacity handling

\* For information about these options, see [File Rule Actions, on page 2284](#) and [Malware Protection Options \(in File Rule Actions\), on page 2285](#) and its subtopics.

**Step 8** Click **Add**.

**Step 9** Click **Save** to save the policy.

---

#### What to do next

- If you are configuring policies for malware protection, return to [Configure File Policies, on page 2271](#).
- Deploy configuration changes.

## Access Control Rule Logging for Malware Protection

When the system detects a prohibited file (including malware) according to the settings in the file policy, it automatically logs an event to the Secure Firewall Management Center database. If you do not want to log file or malware events, you can disable this logging on a per-access-control-rule basis.

The system also logs the end of the associated connection to the Secure Firewall Management Center database, regardless of the logging configuration of the invoking access control rule.

## Retrospective Disposition Changes

File dispositions can change. For example, as new information is discovered, the AMP cloud can determine that a file that was previously thought to be clean is now identified as malware, or the reverse—that a malware-identified file is actually clean. When the disposition changes for a file you queried in the past week, the AMP cloud notifies the system so it can automatically take action the next time it detects that file being transmitted. A changed disposition is called a *retrospective* disposition.

## File and Malware Inspection Performance and Storage Options

Increasing the file sizes can affect the performance of the system.

Table 215: Advanced Access Control File and malware defense Options

Field	Description	Guidelines and Restrictions
<b>Limit the number of bytes inspected when doing file type detection</b>	Specifies the number of bytes inspected when performing file type detection.	0 - 4294967295 (4GB) 0 removes the restriction. The default value is the maximum segment size of a TCP packet (1460 bytes). In most cases, the system can identify common file types using the first packet. To detect ISO files, enter a value greater than 36870.
<b>Allow file if cloud lookup for Block Malware takes longer than (seconds)</b>	Specifies how long the system will hold the last byte of a file that matches a <b>Block Malware</b> rule and that does not have a cached disposition, while malware cloud lookup occurs. If the time elapses without the system obtaining a disposition, the file passes. Dispositions of Unavailable are not cached.	0 - 30 seconds Do <i>not</i> set this option to 0 without contacting Support. Cisco recommends that you use the default value to avoid blocking traffic because of connection failures.
<b>Do not calculate SHA-256 hash values for files larger than (in bytes)</b>	Prevents the system from storing files larger than a certain size, performing a malware cloud lookup on the files, or blocking the files if added to the custom detection list.	0 - 4294967295 (4GB) 0 removes the restriction. This value must be greater than or equal to <b>Maximum file size to store (bytes)</b> and <b>Maximum file size for dynamic analysis testing (bytes)</b> .
<b>Minimum file size for advanced file inspection and storage (bytes)</b>	These settings specify: <ul style="list-style-type: none"> <li>The file size that the system can inspect using the following detectors: <ul style="list-style-type: none"> <li>Spero analysis</li> <li>Sandboxing and preclassification</li> </ul> </li> <li>Local malware analysis/ClamAV</li> <li>Archive inspection</li> </ul>	0 - 10485760 (10MB) 0 disables file storage. Must be less than or equal to <b>Maximum file size to store (bytes)</b> and <b>Do not calculate SHA-256 hash values for files larger than (in bytes)</b> .
<b>Maximum file size for advanced file inspection and storage (bytes)</b>	<ul style="list-style-type: none"> <li>The file size that the system can store using a file rule.</li> </ul>	0 - 10485760 (10MB) 0 disables file storage. Must be greater than or equal to <b>Minimum file size to store (bytes)</b> , and less than or equal to <b>Do not calculate SHA-256 hash values for files larger than (in bytes)</b> .

Field	Description	Guidelines and Restrictions
<b>Minimum file size for dynamic analysis testing (bytes)</b>	Specifies the minimum file size the system can submit to the AMP cloud for dynamic analysis.	<p>0 -10485760 (10MB)</p> <p>Must be less than or equal to <b>Maximum file size for dynamic analysis testing (bytes)</b> and <b>Do not calculate SHA-256 hash values for files larger than (in bytes)</b>.</p> <p>The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis.</p> <p>The system checks the AMP cloud for updates to the minimum file size you can submit (no more than once a day). If the new minimum size is larger than your current value, your current value is updated to the new minimum, and your policy is marked out-of-date.</p>
<b>Maximum file size for dynamic analysis testing (bytes)</b>	Specifies the maximum file size the system can submit to the AMP cloud for dynamic analysis.	<p>0 -10485760 (10MB)</p> <p>Must be greater than or equal to <b>Minimum file size for dynamic analysis testing (bytes)</b>, and less than or equal to <b>Do not calculate SHA-256 hash values for files larger than (in bytes)</b>.</p> <p>The file size for dynamic analysis must be within the limits defined by the minimum and maximum settings for file analysis.</p> <p>The system checks the AMP cloud for updates to the maximum file size you can submit (no more than once a day). If the new maximum size is smaller than your current value, your current value is updated to the new maximum, and your policy is marked out-of-date.</p>

## Tuning File and Malware Inspection Performance and Storage

You must be an Admin, Access Admin, or Network Admin user to perform this task.

### Procedure

- 
- Step 1** In the access control policy editor, click **Advanced Settings**.
- Step 2** Click **Edit** (✎) next to **Files and Malware Settings**.
- If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 3** Set any of the options described in [File and Malware Inspection Performance and Storage Options, on page 2292](#).
- Step 4** Click **OK**.

**Step 5** Click **Save** to save the policy.

#### What to do next

- Deploy configuration changes.

## (Optional) Malware Protection with AMP for Endpoints

Cisco's AMP for Endpoints is a separate malware-protection product that can supplement malware protection provided by the system and be integrated with your Firepower deployment.

AMP for Endpoints is Cisco's enterprise-class Advanced Malware Protection solution that runs as a lightweight connector on individual users' *endpoints* (computers and mobile devices) to discover, understand, and block advanced malware outbreaks, advanced persistent threats, and targeted attacks.

Benefits of AMP for Endpoints include:

- configure custom malware detection policies and profiles for your entire organization, as well as perform flash and full scans on all your users' files
- perform malware analysis, including view heat maps, detailed file information, network file trajectory, and threat root causes
- configure multiple aspects of outbreak control, including automatic quarantines, application blocking to stop non-quarantined executables from running, and exclusion lists
- create custom protections, block execution of certain applications based on group policy, and create custom Allowed Applications lists
- use the AMP for Endpoints management console to help you mitigate the effect of malware. The management console provides a robust, flexible web interface where you control all aspects of your AMP for Endpoints deployment and manage all phases of an outbreak.

For detailed information about AMP for Endpoints, see:

- <https://www.cisco.com/c/en/us/products/security/amp-for-endpoints/index.html>.
- Online help in the AMP for Endpoints management console.
- AMP for Endpoints documentation available from: <http://docs.amp.cisco.com>.

## Comparison of Malware Protection: Firepower vs. AMP for Endpoints

*Table 216: Advanced Malware Protection Differences by Detecting Product*

Feature	Firepower Malware Protection (malware defense)	AMP for Endpoints
File type detection and blocking method (file control)	In network traffic, using access control and file policies	Not supported

Feature	Firepower Malware Protection (malware defense)	AMP for Endpoints
Malware detection and blocking method	In network traffic, using access control and file policies	On individual endpoints (end-user computers and mobile devices), using a connector that communicates with the AMP cloud
Network traffic inspected	Traffic passing through a managed device	None; connectors installed on endpoints directly inspect files
Malware intelligence data source	AMP cloud (public or private)	AMP cloud (public or private)
Malware detection robustness	Limited file types	All file types
Malware analysis choices	management center-based, plus analysis in the AMP cloud	management center-based, plus additional options on the AMP for Endpoints management console
Malware mitigation	Malware blocking in network traffic, management center-initiated remediations	AMP for Endpoints-based quarantine and outbreak control options, management center-initiated remediations
Events generated	File events, captured files, malware events, and retrospective malware events	Malware events
Information in malware events	Basic malware event information, plus connection data (IP address, port, and application protocol)	In-depth malware event information; no connection data
Network file trajectory	management center-based	management center and the AMP for Endpoints management console each have a network file trajectory. Both are useful.
Required licenses or subscriptions	Licenses required to perform file control and malware defense	AMP for Endpoints subscription. No license is required to bring AMP for Endpoints data into management center.

## About Integrating Firepower with AMP for Endpoints

If your organization has deployed AMP for Endpoints, you can optionally integrate that product with your Firepower deployment.

Integration with AMP for Endpoints does not require a dedicated Firepower license.

### Benefits of Integrating Firepower and AMP for Endpoints

Integrating your AMP for Endpoints deployment with your system offers the following benefits:

- Centralized Blocked Applications and Allowed Applications lists configured in AMP for Endpoints can determine verdicts for file SHAs sent from Firepower to the AMP cloud for disposition.

See [Centralized File Lists from AMP for Endpoints, on page 2281](#).

- The system can import malware events detected by AMP for Endpoints into Secure Firewall Management Center so you can manage these events along with malware events generated by the system. Imported data for these events includes scans, malware detections, quarantines, blocked executions, and cloud

recalls, as well as indications of compromise (IOCs) that management center displays for hosts that it monitors.

- You can view file trajectory and other details in the AMP for Endpoints console.

---

**Important** If you use a Cisco AMP Private Cloud, see limitations at [AMP for Endpoints and AMP Private Cloud, on page 2297](#).

---

## AMP for Endpoints and AMP Private Cloud

If you configure a Cisco AMP private cloud to collect AMP endpoint data on your network, all AMP for Endpoints connectors send data to the private cloud, which forwards that data to the Secure Firewall Management Center. The private cloud does not share any of your endpoint data over an external connection.

If your organization has deployed an AMP private cloud, all connections to the AMP cloud funnel through the private cloud, which acts as an anonymized proxy to ensure the security and privacy of your monitored network. This includes importing AMP for Endpoints data. The private cloud does not share any of your endpoint data over an external connection.

The following integration features are not available if you use an AMP private cloud:

- Use of Blocked Applications and Allowed Applications lists configured in AMP for Endpoints. (These lists are used to block or allow files.)
- Visibility in AMP for Endpoints of malware events generated from Firepower.

You can configure multiple private clouds to support the capacity you require.

## Integrate Firepower and Secure Endpoint

If your organization has deployed Cisco's Secure Endpoint product, you can integrate that application with Firepower to achieve the benefits described in [Benefits of Integrating Firepower and AMP for Endpoints, on page 2296](#).

When you integrate with Secure Endpoint, you must configure the Secure Endpoint connection even if you already have malware defense (AMP for Firepower) connections configured. You can configure multiple Secure Endpoint cloud connections.

---

**Note** The Secure Endpoint connections that have not registered successfully does not affect malware defense.

---

### Before you begin

- You must be an Admin user to perform this task.
- If your deployment uses Cisco AMP Private Cloud, see limitations at [AMP for Endpoints and AMP Private Cloud, on page 2297](#).
- Secure Endpoint must be set up and working properly on your network.
- The management center must have direct access to the Internet.

- Make sure your management center and Secure Endpoint can communicate with each other. See the topics under *Security, Internet Access, and Communication Ports* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- If you are connecting to the AMP cloud after either restoring your Secure Firewall Management Center to factory defaults or reverting to a previous version, use the AMP for Endpoints management console to remove the previous connection.
- You will need your Secure Endpoint credentials to log in to the Secure Endpoint console during this procedure.

## Procedure

- 
- Step 1** Choose **Integration > AMP > AMP Management**.
- Step 2** Click **Add AMP Cloud Connection**.
- Step 3** From the **Cloud Name** drop-down list, choose the cloud you want to use:
- The AMP cloud closest to the geographical location of your Secure Firewall Management Center.  
**APJC** is Asia/Pacific/Japan/China.
- Step 4** If you want to use this cloud for both malware defense and Secure Endpoint, select the **Use for AMP for Firepower** check box.
- If you configured a different cloud to handle malware defense (AMP for Firepower) communications, you can clear this check box; if this is your only AMP cloud connection, you cannot.
- Step 5** Click **Register**.
- A spinning state icon indicates that a connection is pending, for example, after you configure a connection on the Secure Firewall Management Center, but before you authorize it using the Secure Endpoint management console. A **Denied** (🚫) indicates that the cloud denied the connection or the connection failed for another reason.
- Step 6** Confirm that you want to continue to the Secure Endpoint management console, then log into the management console.
- Step 7** Using the management console, authorize the AMP cloud to send Secure Endpoint data to management center.
- Step 8** If you want to restrict the data that the management center receives, select specific groups within your organization for which you want to receive information.
- By default, the AMP cloud sends data for all groups. To manage groups, choose **Management > Groups** on the Secure Endpoint management console. For detailed information, see the management console online help.
- Step 9** Click **Allow** to enable the connection and start the transfer of data.
- Clicking **Deny** returns you to the Secure Firewall Management Center, where the connection is marked as denied. If you navigate away from the Applications page on the Secure Endpoint management console, and neither deny nor allow the connection, the connection is marked as pending on the Secure Firewall Management Center's web interface. The health monitor does **not** alert you of a failed connection in either of these situations. If you want to connect to the AMP cloud later, delete the failed or pending connection, then recreate it.
- Incomplete registration of the Secure Endpoint connection does not disable the malware defense connection.

**Step 10**

To verify that the connection is correctly configured:

- a) On the **Integration > AMP > AMP Management** page, click the Cloud Name that includes **AMP for Endpoints** in the **Cisco AMP Solution Type** column.
- b) In the AMP for Endpoints console window that displays, choose **Accounts > Applications**.
- c) Verify that your management center is on the list.
- d) In the AMP for Endpoints console window, choose **Manage > Computers**.
- e) Verify that your management center is on the list.

**What to do next**

- In the AMP for Endpoints console window, configure settings as needed. For example, define group membership for your management center and assign policies. For information, see the AMP for Endpoints online help or other documentation.
- In high availability deployments, configure AMP cloud connections on both management centers. These configurations are not synchronized.
- The default health policy warns you if the management center cannot connect to the AMP for Endpoints portal after an initial successful connection, or if the connection is deregistered using the AMP portal.

Verify that the **AMP for Endpoints Status** monitor is enabled under **System > Health > Policy**.

## History for Network Malware Protection and File Policies

Feature	Minimum Management Center	Minimum Threat Defense	Details
Communication with AMP cloud	7.0	Any	Legacy port 32137 is no longer supported for communicating with the AMP public or private cloud.  New/Modified screens: On the <b>System &gt; Integration &gt; Cloud Services</b> page, the <b>Use Legacy Port 32137 for AMP for Networks</b> option is no longer available.

- [Troubleshooting Policy Analyzer and Optimizer, on page 2314](#)
- [Frequently Asked Questions About Policy Analyzer and Optimizer, on page 2315](#)

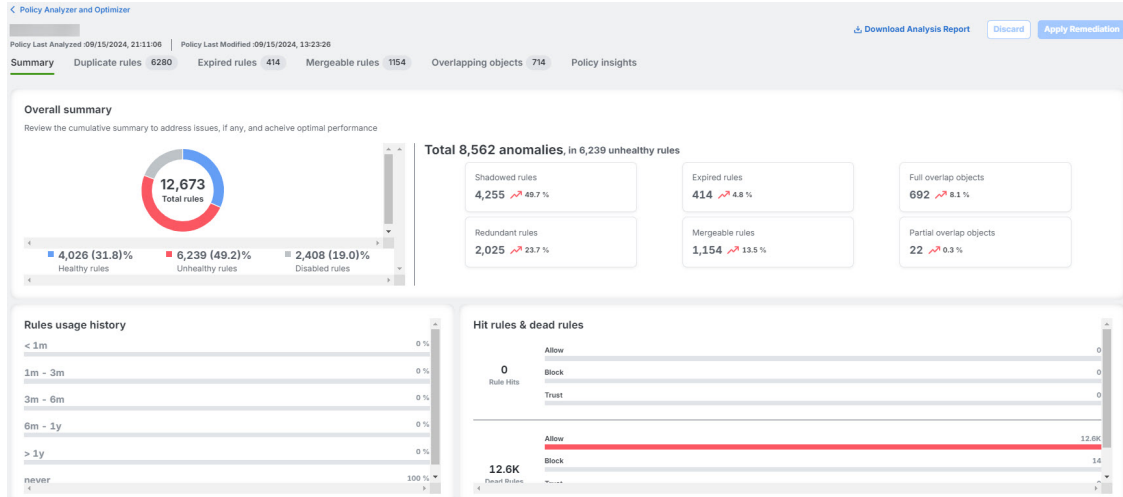

## About Policy Analyzer and Optimizer

Secure Firewall Threat Defense devices with extensive access control policies, especially those generated through the firewall migration process, may have numerous duplicate or shadowed rules. Such bloated policies with unoptimized rulesets can lead to excessive consumption of device memory, delayed loading of rules, long search times, resulting in inefficient security policy enforcement, reduced network speeds, and extended deployment durations.

To deal with such situations, Security Cloud Control provides Policy Analyzer and Optimizer. It is an intelligent cloud service that can analyze security policies, detect anomalies, and provide recommendations on remediations that can be performed to optimize the policies, thereby improving the firewall performance. The Policy Analyzer and Optimizer can analyze policies both in the cloud-delivered Firewall Management Center and On-Premises Firewall Management Centers that are onboarded to Security Cloud Control. In addition, this feature can:

- provide comprehensive visualization of policy health information, including an analysis overview and policy insights based on aggregate hit counts.
- analyze policies regularly on scheduled intervals or whenever preferred.
- detect rule anomalies, such as duplicate rules, object overlap in rules, and expired rules.

Figure 379: Analysis Summary

Note that the Policy Analyzer and Optimizer can get launched from Security Cloud Control's **Services** page, **Insights > Policy Analyzer and Optimizer** on the left pane, and on-premises management center's **Access Control** policies page for the administrator's convenience.

## Analysis, Remediation, and Reporting

The Policy Analyzer and Optimizer performs these services: analysis, remediation, and reporting.

### Analysis

The Policy Analyzer and Optimizer polls cloud-delivered Firewall Management Center and on-premises management center for policies and displays them on the Policy Analyzer and Optimizer page. To open the **Policy Analyzer and Optimizer** page, in the left pane, click **Administration > Firewall Management Center**, select **Cloud-delivered FMC** or any on-premises management center, and choose **Policy Analyzer and Optimizer** from the right pane. Alternatively, on the Security Cloud Control left pane, choose **Insights & Reports > Policy Analyzer and Optimizer**. Choose **Cloud-delivered FMC** or any on-premises management center from the **Data Source** tab on the top-left corner.

When you have created a new access control policy or imported a policy, it will take a while for the Policy Analyzer and Optimizer to identify it, after which you can manually trigger the policy analysis. You can also wait for the auto-analysis that occurs every 24 hours. When the analysis is done, Policy Analyzer and Optimizer provides insights on the number of rules in the policy, the percentage of the policy that can be optimized, and a detailed summary that contains information such as Rule Health Summary, Rule Last Usage, Rule Hits & Dead Rules, and so on.

<input type="checkbox"/>	Access Control Policy Name	Devices	Total Rules	Observations	Analysis Status	Last Modified	Last Analyzed	Remediation Status	Remediation Time
<input type="checkbox"/>	Japan_Tokyo_Corp	1	161	50 <b>18% Optimizable</b>	Completed	06/26/2024, 13:30:25	06/26/2024, 14:45:24 <i>Analysis up-to-date</i>		
<input type="checkbox"/>	Geo_Location_Base_Pc		3	0 <b>0% Optimizable</b>	Completed	05/16/2024, 15:28:38	05/16/2024, 20:05:09 <i>Analysis up-to-date</i>		

**Note** The **Optimizable** percentage under **Observations** column is an approximation of how many rules in the policies can be optimized if the suggested remediations are applied.

### Remediation

The policy analysis summary describes the health of your security policy and lets you choose which remediations suggested by the Policy Analyzer and Optimizer you want to apply to your policies. Using the suggested remediations, you could either disable or delete Duplicate Rules, Overlapping Objects, Expired Rules and merge rules that have similar allow and block settings, which can be merged into a single rule. The hit count data is listed under the **Policy Insights** tab. You can **Apply Remediation** to make the chosen remediations get applied to your policies.

### Reporting

A detailed report is available for an analyzed policy. After remediation is applied on a policy, a remediation report becomes available. This report contains a consolidated list of the policy anomalies that existed and the remediations that were applied and can be downloaded as a PDF.

## Prerequisites to Use Policy Analyzer and Optimizer

- The On-Premises Firewall Management Center must be Version 7.2 or later and must be onboarded to Security Cloud Control. Ensure that the policy that you want to analyze is associated with at least one device.
- An On-Premises Firewall Management Center Version 7.6 or later must be integrated with the Cisco Security Cloud; the On-Premises Firewall Management Center gets onboarded to the selected Security Cloud Control tenant as part of the Security Cloud integration.

## Policy Analyzer and Optimizer Licensing Requirements

The Policy Analyzer and Optimizer does not require any additional licensing. It comes as part of the Security Cloud Control base subscription.

## Enable Policy Analyzer and Optimizer for Cloud-delivered Firewall Management Center

The Policy Analyzer and Optimizer is enabled for the cloud-delivered Firewall Management Center by default. To use it to analyze access policies on your cloud-delivered Firewall Management Center, follow the steps below:

### Procedure

- 
- Step 1** In the left pane, click **Administration > Firewall Management Center**.
  - Step 2** The **Services** page opens with the cloud-delivered Firewall Management Center selected by default.
  - Step 3** Click **Policy Analyzer and Optimizer** under **System** on the right pane.

You should now see the access control policies on your cloud-delivered Firewall Management Center listed. You can choose one to analyze or view details for an already analyzed policy.

---

## Enable Policy Analyzer and Optimizer for Security Cloud Control-managed On-Premises Firewall Management Center

If you have an On-Premises Firewall Management Center Version 7.2 or later, integrate it with SecureX, onboard your on-premises management center to Security Cloud Control, navigate to **Administration > Firewall Management Center**, select the on-premises management center, and choose **Policy Analyzer and Optimizer** under **System** in the right pane. See [Onboard an On-Premises Firewall Management Center](#) for more information.

If you have an on-premises management center Version 7.6 and want to use Policy Analyzer and Optimizer, follow the steps below:

### Procedure

---

- Step 1** In your on-premises management center, navigate **Integration > Cisco Security Cloud**.
  - Step 2** If you have not integrated your on-premises management center with Cisco Security Cloud, click **Enable Cisco Security Cloud** and follow the steps. To authorize the cloud integration, you must choose an existing Security Cloud Control tenant or provision a new one, to which your on-premises management center will get onboarded, after the cloud integration is successful.
  - Step 3** After integrating your on-premises management center with Cisco Security Cloud, check the **Enable Policy Analyzer and Optimizer** checkbox and click **Save**.
  - Step 4** Go to **Policies > Access Control**.
  - Step 5** Select a policy and click **Analyze Policy**. Note that the **Anomaly** column displays **In Progress** and once the analysis is complete, it displays the number of anomalies and the percentage of the policy optimizable.
  - Step 6** Click on the percentage to be cross-launched to the **Policy Analyzer and Optimizer** page in the Security Cloud Control tenant to which your on-premises management center is registered.
- 

## Policy Analysis

After provisioning a cloud-delivered Firewall Management Center or onboarding an On-Premises Firewall Management Center to your Security Cloud Control tenant, and creating policies, you can start to analyze them using the Policy Analyzer and Optimizer. See [Onboard an On-Premises Firewall Management Center](#) and [Enable Cloud-delivered Firewall Management Center on Your Security Cloud Control](#) tenant, for more information.

This section covers the various ways in which you can get your policies analyzed.

# Analyze Cloud-delivered Firewall Management Center Policies

If you have the cloud-delivered Firewall Management Center already provisioned on your Security Cloud Control tenant, you can readily start analyzing the policies. To provision the cloud-delivered Firewall Management Center on Security Cloud Control, see [Enable Cloud-delivered Firewall Management Center on Your Security Cloud Control](#).

**Note** When you create a new policy, it might take a while for the Policy Analyzer and Optimizer to fetch the policy details and show up on the **Policy Analyzer and Optimizer**. Click the refresh () button on the top-right corner to manually refresh the page to see new policies.

## Procedure

**Step 1** From the Security Cloud Control left navigation pane, navigate to **Administration > Firewall Management Center**—the **Services** page comes up, with **Cloud-Delivered FMC** selected by default.

**Step 2** Click **Policy Analyzer and Optimizer** under **System** on the right pane.

Alternatively, on the left pane, choose **Insights & Reports > Policy Analyzer and Optimizer**. The **Showing policy for** option at the top-left corner shows which device's policies are displayed; click to switch among cloud-delivered Firewall Management Center and other On-Premises Firewall Management Centers.

**Step 3** For analyzed policies, the Policy Analyzer and Optimizer provides an overview of the analysis that includes **Total Rules**, **Observations**, **Analysis Status**, and **Last Modified** and **Last Analyzed** timestamps. You can also see more details on the right pane when you select a policy.

Access Control Policy Name	Devices	Total Rules	Observations	Analysis Status	Last Modified	Last Analyzed	Remediation Status	Remediation Time
	0	3	1 <span>33% Optimizable</span>	Completed	10/09/2024, 08:46:17	09/25/2024, 11:50:00		
	0	124	117 <span>93% Optimizable</span>	Completed	09/15/2024, 13:23:26	09/15/2024, 22:54:28		
	0	1000	15 <span>1% Optimizable</span>	Completed	09/15/2024, 12:55:46	09/15/2024, 22:53:06		
	0	236	273 <span>85% Optimizable</span>	Completed	10/09/2024, 08:46:17	Analysis out-of-date		
	0	12673	8562 <span>68% Optimizable</span>	Completed	09/15/2024, 13:23:26	09/15/2024, 20:32:33		
	0	9	5 <span>55% Optimizable</span>	Completed	09/11/2024, 12:46:13	Analysis up-to-date	Completed	09/11/2024, 12:46:14
	0	0	0 <span>0% Optimizable</span>	Completed	10/09/2024, 08:46:17	08/28/2024, 12:40:23		
	1			Failed	10/09/2024, 08:46:17	Analysis out-of-date		
	1			Failed	09/15/2024, 13:23:26	08/07/2024, 10:34:48		
	0				09/15/2024, 12:55:46	Analysis out-of-date		

**Policy Analyzer and Optimizer**

Devices: 0

Total Rules: 12673

Observations: 8562 68% Optimizable

Analysis Status: Completed

Last Analyzed: 09/15/2024, 20:32:33

Remediation Status: Not Running

HS Count Aggregation Status: Completed

**Analysis Actions**

- View Analysis Details & Optimize
- Download Analysis Report

**Remediation Actions**

- Remediation History (0 Version Available)

**Policy Observation**

We found a total of 8562 anomalies.

**Duplicate Rules (6290)**

- Fully Shadowed Rules: 4255
- Fully Redundant Rules: 2025

**Overlapping Objects (714)**

- Fully Overlapped Objects: 692
- Partially Overlapped Objects: 22

**Mergeable Rules (1154)**

Expired Rules (414)

**Step 4** Select the policy for which you want to view the analysis details or re-analyze.

The Policy Analyzer and Optimizer automatically analyzes all the policies every 24 hours, and there are high chances that all your policies already got analyzed and details are ready for you to review.

**Step 5** Click **Re-analyze Policy** to manually trigger another analysis.

---

## Analyze On-Premises Firewall Management Center Policies

To use Policy Analyzer and Optimizer to analyze policies on an On-Premises Firewall Management Center Version 7.2 or later, you need to have onboarded it to Security Cloud Control, either using **Auto discover from Cisco Security Cloud** or **Use Credentials** way of onboarding. For an On-Premises Firewall Management Center Version 7.6, you need to have integrated it to the Cisco Security Cloud, which in turn onboards your On-Premises Firewall Management Center to your Security Cloud Control tenant. Make sure that you do the following before you begin:

- After onboarding your On-Premises Firewall Management Center, ensure that its in **Active** status in **Administration > Firewall Management Center**.
- Check the **Enable Policy Analysis & Optimization** checkbox after you integrate with the Cisco Security cloud, by navigating to **Integration > Cisco Security Cloud**.
- If you have just onboarded an On-Premises Firewall Management Center or created or imported a new policy in an already onboarded On-Premises Firewall Management Center, wait until the Policy Analyzer and Optimizer fetches the policies.
- You can trigger analysis of the policies manually or they get automatically analyzed as part of the scheduled automated analysis.

### Procedure

---

**Step 1** From the Security Cloud Control left navigation pane, navigate to **Administration > Firewall Management Center**—the **Services** page comes up, with **Cloud-Delivered FMC** selected by default.

**Step 2** Select the On-Premises Firewall Management Center whose policies you want to analyze.

**Step 3** Click **Policy Analyzer and Optimizer** under **System** on the right pane.

Alternatively, on the left pane, choose **Insights & Reports > Policy Analyzer and Optimizer**. The **Showing policy for** option at the top-left corner shows which device's policies are displayed; click to switch among cloud-delivered Firewall Management Center and other On-Premises Firewall Management Centers.

**Step 4** For analyzed policies, the Policy Analyzer and Optimizer provides an overview of the analysis that includes **Total Rules**, **Observations**, **Analysis Status**, and **Last Modified** and **Last Analyzed** timestamps. You can also see more details on the right pane when you select a policy.

---

## Policy Reporting

When your policies are analyzed and ready, on the **Policy Analyzer and Optimizer** page, the **Analysis Status** is **Completed** and the **Observations** column displays if your policy is healthy or can be optimized.

The screenshot shows the 'Policy Analyzer and Optimizer' interface. At the top, there's a search bar and navigation options. Below, a table lists policies with columns for 'Access Control Policy Name', 'Devices', 'Total Rules', 'Observations', 'Analysis Status', 'Last Modified', 'Last Analyzed', 'Remediation Status', and 'Remediation Time'. One policy is selected, showing 101 total rules and 268 observations (32% Optimizable). The right sidebar provides a detailed summary: Total Rules: 101, Observations: 268, Analysis Status: Completed, Last Modified: 06/05/2024, 13:30:43, Last Analyzed: 06/05/2024, 14:05:09. It also lists remediation actions like 'View Analysis Details', 'Download Analysis Report', and 'Remediation History'. A 'Policy Observation' section notes 268 anomalies, including 153 duplicate rules (17 fully shadowed, 36 fully redundant), 210 overlapping objects (157 fully overlapped, 53 partially overlapped), 4 mergeable rules, and 1 expired rule.

Select the policy to see details about the analysis on the right pane. You can **View Analysis Details**, **Download Analysis Report**, and view the **Remediation History**.

## Policy Analysis Summary

The **Summary** tab includes the following rule information, presented in pie charts and bar graphs:

**Rule Health Summary**—provides insights on how many rules are healthy, disabled, expired, and contain anomalies, using a pie chart. You can also hover over the part of the pie to view the percentage of rules.

### Overall summary

Review the cumulative summary to address issues, if any, and achieve optimal performance

**Rule Last Usage**—provides insights on the recentness on the rule usage, with time periods.

**Rules with Anomalies**—provides insights on how many rules have anomalies, using a bar graph. Hover over the bars to see the number of rules having anomalies.

Total 8,562 anomalies, in 6,239 unhealthy rules

**Rule Hits & Dead Rules**—provides insights on hitcount of expired rules, for rule types including allow, block, monitor, and trust.

## Duplicate Rules

The **Duplicate Rules** tab lists shadowed and redundant rules with anomalies:

- A **Fully Shadowed Rule** is one that will never evaluate network traffic because another rule that precedes it over shadows this rule.
- A **Fully Redundant Rule** is one that is just a part of another larger rule, such that removing this redundant rule does not have an impact on the network traffic, because the traffic evaluation that this rule must perform is already performed by another rule.

You can choose to either disable or delete all the fully shadowed or fully redundant rules.

**Note** Expand each observation to see the list of rules that are redundant because of the larger rule. Each rule in the list is displayed with a set of attributes; click the settings button on the top right to select which rule attributes you would like to see along with the rule.

Fully Shadowed Rules (17)

A shadowed rule is a rule that will never evaluate network traffic because the traffic matches the criteria of a preceding rule in the policy, and the preceding rule takes action before the shadowed rule can be matched. [Learn More](#)

[Disable All Fully Shadowed Rules](#) [Delete All Fully Shadowed Rules](#)

Observation - 1	1 rule is fully shadowed by rule [redacted]
Observation - 2	2 rules are fully shadowed by rule [redacted]
Observation - 3	1 rule is fully shadowed by rule [redacted]
Observation - 4	1 rule is fully shadowed by rule [redacted]
Observation - 5	1 rule is fully shadowed by rule [redacted]

After you disable the shadowed rules, you still get to **Undo** it before applying the changes. It is recommended that you disable the rules first to measure the impact and delete them, because when you delete them later, they get permanently deleted.

You can enable the disabled rules any time by navigating to the cloud-delivered Firewall Management Center or the On-Premises Firewall Management Center on which the rules are present.

## Overlapping Objects

The **Overlapping Objects** tab lists objects that are either fully overlapping (the IP addresses are either the same or a complete subset) or partially overlapping (some subset of IP addresses are repeated, but not all).

For example, if a rule contains an object for 192.168.1.1 and another for 192.168.1.0/24, the 192.168.1.1 object is fully overlapped by the other object and is not needed in the rule. You can click the **Remove All Fully Overlapped Objects from Rules** button.

Fully Overlapped Objects (157)

Fully overlapped objects refers to objects which are subset of other objects in same rule, and can be removed to optimise the rule. [Learn More](#)

[Remove All Fully Overlapped Objects from Rules](#)

**i** The 40 rules below have fully overlapped objects. We recommend that you remove all fully overlapped objects to increase efficiency.

Rule Name	Overlapped Objects
3. [redacted]	Destination Network Fully Overlapped by [redacted]
4. [redacted]	Source Network Fully Overlapped by [redacted]

For partial overlaps, you need to evaluate each occurrence, determine if any changes can be made, and implement those changes directly by editing the objects.

Partially Overlapped Objects (53)

**i** The 28 rules below have partially overlapped objects. We recommend that you remove all partially overlapped objects to increase efficiency.

Rule Name	Overlapped Objects
[redacted]	Destination Network Partially Overlapped by [redacted]
[redacted]	Public-DNS_1 PUBLIC-DNS +1 more...
[redacted]	Source Network Partially Overlapped by [redacted]
[redacted]	Japan_Tokyo_Data JAPAN_TOKYO
[redacted]	JAPAN_TOKYO JAPAN_SERVER_SEGMENT

## Expired Rules

The **Expired Rules** tab lists rules that were configured with a time range and the time range has expired. You can also see rule information such as the date on which the rule expired, hit count, last hit time, and the time range.

You can choose to either **Disable All Expired Rules** or **Delete All Expired Rules**.

## Expired Rules

An expired rule is one that was configured with a time range and that time range has expired. [Learn More](#)

[Disable All Expired Rules](#)
[Delete All Expired Rules](#)

Rule Name	Expired on	Hit Count	Last Hit Time	Time Range
	09/24/2022, 05:29:00	0	never hit	1513938_1513942

## Mergeable Rules

The **Mergeable Rules** tab lists the rules that have similar allow and block settings and can be merged into a single rule. You can read the observations and click **Merge All Rules** at once to merge the objects in those rules, to reduce the number of rules you manage.

## Mergeable Rules

Mergeable rules are two or more rules that have similar criteria for allowing or blocking traffic, and can be combined into a single rule. [Learn More](#)

[Merge All Rules](#)

Observation - 1 These 2 rules can be merged by combining the values into one rule. We recommend you merge these 2 rules to increase efficiency

Rule Name	Action	Hit Count	Last Hit Time	Time Range	Source Zone	Destination Zone	Source Network	Destination Network	Source Port	Destination Port	VLAN
	Allow	0	never hit		test-zone-1	test-zone-2		Any	Any	Any	Any

The 2 rules listed below can be merged with 'AMP-Access' by combining the 'APPLICATION' values into one rule.

Rule Name	Action	Hit Count	Last Hit Time	Time Range	Source Zone	Destination Zone	Source Network	Destination Network	Source Port	Destination Port	VLAN
	Allow	0	never hit		test-zone-1	test-zone-2		Any	Any	Any	Any
	Allow	0	never hit		test-zone-1	test-zone-2		Any	Any	Any	Any

**Note** When you merge two rules, the logging settings from the first rule are applied to the rule that the first rule is getting merged with. Therefore, the logging behavior for the merged rule will follow the settings configured on the first rule, and any unique logging configurations from other rules will be overwritten.

## Policy Insights

The **Policy Insights** tab has a **Hit Count** section that initially lists any rules that have never been triggered (**Never Hit Rules**). The hit count information is from all devices that are assigned to the policy. You can change criteria and see other hit count information, for example, **Not Hit Rules** for the past 6 months, or **Hit Rules** over a selected time period. You can filter the rules using the actions set in the rules, hit information, and time period:

- **Never Hit Rules**—Rules that have never been hit from the time they were created.
- **Hit Rules**—Rules that have been hit in the selected time period.
- **Not Hit Rules**—Rules that have not been hit in the selected time period.

Select the rules you want to disable or delete and click **Disable Rules** or **Delete Rules**. It is recommended that you disable the rules first to measure the impact of disabling them and then delete them.

**Hit Count Insights**  
Hit count data shows you how often a rule's criteria matches network traffic. Use the filters to identify ineffective rules so that you can reconfigure them or delete them.

Displaying 50 of 161 results

Select Action | Select Rules Type | Select Time Period

4 rules selected out of 161

Rule Name	Action	Hit Count	First Hit Time	Last Hit Time
119. SERVER_DECOM_ACTIVITY (1)	Block	0	never hit	never hit
121. CSPSC	Allow	0	never hit	never hit
122. CSPSC (1)	Allow	0	never hit	never hit
123. CSPSC (2)	Allow	0	never hit	never hit

Disable Rules | Delete Rules

## Policy Remediation

When you choose to delete or disable rules with anomalies from the analysis summary, the Policy Analyzer and Optimizer does not immediately apply those changes. The changes that you wanted to do are staged and are applied only when you click **Apply Remediation**.

Note that after clicking **Apply Remediation** once, you cannot apply remediations again based on the same report. You must run a policy analysis again on the new policy settings and remediate the anomalies using the new report.

## Apply Policy Remediation

### Before you begin

- Ensure you take a backup of all the policies before applying remediations.
- Ensure you have a few policy remediations that are staged to be applied. If there are no staged changes, the **Apply Remediation** button is disabled.
- Ensure you have verified the **Policy Last Modified**, **Policy Last Analysed** dates and timestamps, and the number of rules that you have marked for remediation, at the top-right corner, so that you are sure which version of the policies you are applying the remediations to.

### Procedure

**Step 1** In the **Policy Analyzer and Optimizer** page, click **Apply Remediation**.

**Step 2** Read through the confirmation pop-up, which contains a gist of all the remediations that will be applied, and ensure you are not applying remediations to policies that you do not want remediated.

**Step 3** Click **Apply**.

**Note** When you click **Apply**, you will see pop-up messages such as **Remediations are being applied** and **The policy is locked for remediation**.

**Step 4** After the remediations are completed successfully, click **Download Optimization Report**.

Because the policy just got modified when the remediations were applied, you must reanalyze the newly modified set of policies to get a different analysis summary, using which you can further remediate any left-over policy anomalies.

The remediation report contains consolidated data of all the remediations applied and the rules they were applied to. When you select a policy from the **Policy Analyzer and Optimizer** page, you can view the **Remediation History** from the right pane, which includes data about the date and time of the remediation, the user who initiated the remediation, and the remediation status. You can also download the remediation report from the same pop-up.

All the remediations are recorded and are available under **Remediation History**, with information such as date and time of the remediation, the user who performed the remediation, and so on.

**Note** For an On-Premises Firewall Management Center in which the Change Management Workflow is enabled, when policy remediations are applied, an internal workflow ticket is created and the changes are staged. The changes take effect only when the ticket is submitted or approved. See [Change Management](#) in *Cisco Secure Firewall Management Center Administration Guide* for more information.

---

## What Does the Policy Remediation Report Contain?

The policy remediation report consolidates all the pieces of a completed remediation and can be downloaded as a PDF. This report contains the following sections, based on what remediations you have performed on your policies. Each section carries information about the rule name, the remediation action taken, and any related comments. For example, if you have not remediated any duplicate rules, the report does not contain the section pertaining to the duplicate rules remediation:

- Remediation Summary
- Hit Count Remediation
- Expired Rules Remediation
- Duplicate Rules Remediation
- Mergeable Rules Remediation

---

**Note** To know if a policy is remediated by the Policy Analyzer and Optimizer, navigate to **Policies > Access Policies** and edit a policy to view the rules in the **Policy Editor**. When a policy is remediated by Policy Analyzer and Optimizer, a comment gets added to the rules that are optimized. You can also filter all the rules optimized by the Policy Analyzer and Optimizer using "updated by Policy Analyzer and Optimizer" to view all the rules remediated by the Policy Analyzer and Optimizer.

---

## Troubleshooting Policy Analyzer and Optimizer

Read the following sections to troubleshoot any issues with the Policy Analyzer and Optimizer:

## Policy Analyzer and Optimizer Does Not Analyze Policies

If you notice that Policy Analyzer and Optimizer is not analyzing policies despite clicking **Analyze Policy**, try the following:

### Procedure

---

- Step 1** Navigate **Administration > Firewall Management Center**.
  - Step 2** Select the On-Premises Management Center or **Cloud-Delivered FMC** for which the policy analysis is not happening and choose **Workflows** under **Actions** on the right pane.
  - Step 3** If you see that the latest workflow's **Current State** shows up as **Error**, expand the workflow and scroll to the last action whose **END STATE** is **ERROR**.
  - Step 4** Click **Error Message** under the **RESULT** column to see a detailed error message or click **Stack Trace** to see the series of exceptions that occurred, which caused the error.
  - Step 5** Resolve the error or contact Cisco TAC for assistance.
- 

## Policy Analyzer and Optimizer Does Not Fetch Policies

If policies on your On-Premises Management Center are not displayed on the Policy Analyzer and Optimizer page on Security Cloud Control, do the following:

### Procedure

---

- Step 1** On the On-Premises Management Center, navigate **Integration > Cisco Security Cloud**.
  - Step 2** Ensure that the **Enable Policy Analyzer and Optimizer** checkbox is checked.
  - Step 3** (Optional) In the left navigation pane of your Security Cloud Control tenant, navigate **Tools Services > Firewall Management Center**, and ensure that the On-Premises Management Center is active and reachable.
- 

## Frequently Asked Questions About Policy Analyzer and Optimizer

### Can Cisco AI Assistant analyze and remediate policies instead of manually doing it using Policy Analyzer and Optimizer?

The Cisco AI Assistant collaborates with Policy Analyzer and Optimizer to scrutinize policies with anomalies and notify users. However, the AI Assistant cannot automatically analyze and remediate policies.

**Can Policy Analyzer and Optimizer detect new changes to an already-analyzed policy and run analysis again on the same policy?**

No, the Policy Analyzer and Optimizer can analyze policies only when manually triggered or at a 24-hour scheduled policy analysis run.

**For a shared policy, does the Policy Analyzer and Optimizer provide individual device-based reports?**

No. The Policy Analyzer and Optimizer provides reports only based on the access policy analysis data.

**I am an On-Premises Firewall Management Center user. Should I purchase the Security Cloud Control base license to use the Policy Analyzer and Optimizer?**

No. The Policy Analyzer and Optimizer comes as part of an existing or a newly created Security Cloud Control tenant during the Cisco Security Cloud integration.

**I provisioned a Security Cloud Control tenant when I integrated my On-Premises Firewall Management Center with the Cisco Security Cloud. What other features, except Policy Analyzer and Optimizer, can I leverage in Security Cloud Control?**

You can only leverage Policy Analyzer and Optimizer capabilities of this Security Cloud Control tenant. To use other features of Security Cloud Control, you need to purchase the Security Cloud Control base license and other device-specific licenses.

**For an On-Premises Firewall Management Center on which the change management workflow is enabled and there are policies with pending changes to be approved, can the Policy Analyzer and Optimizer still apply remediations those policies?**

No. The remediation will be hindered with an error saying the policies are locked for use.

**Is there a maximum number of rules that Policy Analyzer and Optimizer can analyze in a policy?**

There are no such limits. The Policy Analyzer and Optimizer can analyze any number of policies and rules. However, when the policies have more number of rules, the analysis takes a long time too.

**What is the difference between disable rules and delete rules? Which is the better option?**

Deleting a rule removes the rule completely from the device memory. However, disabling a rule keeps it in the device memory as a backup and does not get deployed to the device.

**If a policy remediation fails when it is partially done, are the changes automatically revoked by Policy Analyzer and Optimizer?**

No. In such a case, you get a failure notification and a remediation report. You can read the report to know which rules were impacted by the half-done remediation, manually revoke the changes, and start the remediation all over again.

## CHAPTER 85

# Traffic Decryption Overview

The following topics provide an overview of Transport Layer Security/Secure Sockets Layer (TLS/SSL) inspection, discuss the prerequisites for TLS/SSL inspection configuration, and detail deployment scenarios.

**Note** Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, see a resource such as [SSL vs. TLS - What's the Difference?](#)

- [Traffic Decryption Explained, on page 2319](#)
- [TLS/SSL Handshake Processing, on page 2320](#)
- [Decryption Rule and Policy Basics, on page 2326](#)
- [How to Configure Decryption Policies and Rules, on page 2333](#)
- [How to Configure Decryption Policies and Rules, on page 2334](#)
- [History for Decryption Policy, on page 2335](#)

## Traffic Decryption Explained

Most traffic on the internet is encrypted and in most cases, you don't want to decrypt it; even if you don't, you can still glean some information about it and block it from your network if necessary.

Your choices are:

- Decrypt the traffic and subject it to the full array of deep inspection:
  - Advanced Malware Protection
  - Security intelligence
  - Threat Intelligence Director
  - Application detectors
  - URL and category filtering

- Leave the traffic encrypted and set up your access control and decryption policy to look for and potentially block:
  - Old protocol versions (such as Secure Sockets Layer)
  - Unsecure cipher suites
  - Applications with high risk and low business relevance
  - Untrusted issuer Distinguished Names

### Access control policy

An access control policy is the main configuration that invokes subpolicies and other configurations, including a decryption policy. If you associate a decryption policy with access control, the system uses that decryption policy to handle encrypted sessions before it evaluates the sessions with access control rules. If you do not configure TLS/SSL inspection, or your devices do not support it, access control rules handle all encrypted traffic.

Access control rules also handle encrypted traffic when your TLS/SSL inspection configuration allows the traffic to pass. However, some access control rule conditions require unencrypted traffic, so encrypted traffic might match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads. This helps reduce false positives and improves performance when an encrypted connection matches an access control rule that has intrusion and file inspection configured.

### Notes

Decryption rules require processing overhead that can impact performance. Before you decide to decrypt traffic, see [When to Decrypt Traffic, When Not to Decrypt, on page 2327](#).

As long as your managed devices have Snort 3 enabled, the system supports decrypting TLS 1.3 traffic. You can enable TLS 1.3 decryption in an decryption policy's advanced options; for more information, see [Decryption Policy Advanced Options, on page 2355](#).

The Firepower System does not support mutual authentication; that is, you cannot upload a [client certificate](#) to the Security Cloud Control and use it for either **Decrypt - Resign** or **Decrypt - Known Key** decryption rule actions. For more information, see [Decrypt and Resign \(Outgoing Traffic\), on page 2328](#). and [Known Key Decryption \(Incoming Traffic\), on page 2329](#).

If you set the value of TCP maximum segment size (MSS) using FlexConfig, the observed MSS could be less than your setting. For more information, see [About the TCP MSS, on page 1008](#).

### Related Topics

[TLS/SSL Handshake Processing, on page 2320](#)

[Decryption Rule and Policy Basics, on page 2326](#)

## TLS/SSL Handshake Processing

In this documentation, the term *TLS/SSL handshake* represents the two-way handshake that initiates encrypted sessions in both the SSL protocol and its successor protocol, TLS.

In an inline deployment, the system processes the TLS/SSL handshake, potentially modifying the ClientHello message and acting as a TCP proxy server for the session.

The following figure shows an inline deployment.

After the client establishes a TCP connection with the server (after it successfully completes the TCP [three-way handshake](#)), the managed device monitors the TCP session for any attempt to initiate an encrypted session. The TLS/SSL handshake establishes an encrypted session using the exchange of specialized packets between client and server. In the SSL and TLS protocols, these specialized packets are called *handshake messages*. The handshake messages communicate which encryption attributes both the client and server support:

- ClientHello—The client specifies multiple supported values for each encryption attribute.
- ServerHello—The server specifies a single supported value for each encryption attribute, and the ServerHello response determines which encryption method the system uses during the secure session.

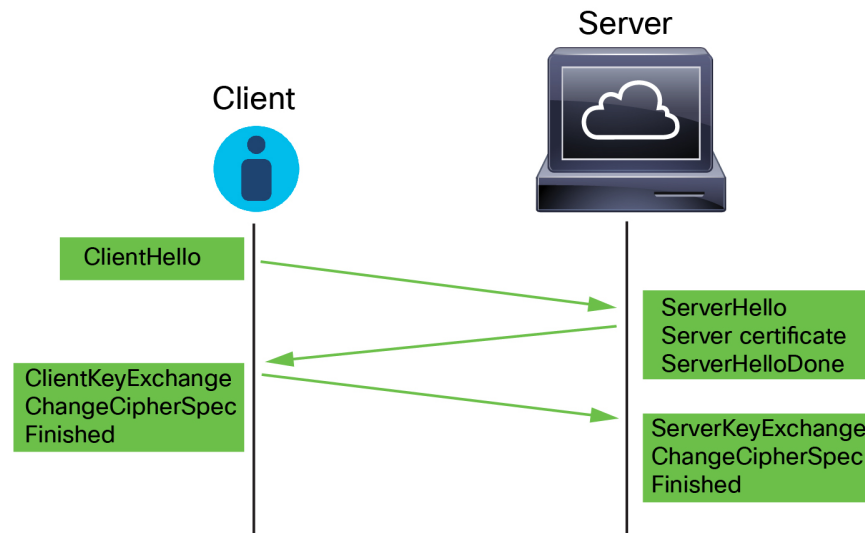

After a TLS/SSL handshake completes, the managed device caches encrypted session data, which allows session resumption without requiring the full handshake. The managed device also caches server certificate data, which allows faster handshake processing in subsequent sessions that use the same certificate.

## ClientHello Message Handling

The client sends the ClientHello message to the server that acts as the packet destination if a secure connection can be established. The client sends the message to initiate the TLS/SSL handshake or in response to a ServerHello message from the destination server.

### Overview

The following figure shows an example. Also see [RFC 8446, sec. 4](#). You can also consult a resource such as [What Happens in a TLS Handshake?](#) at [cloudflare.com](#).

The process can be summarized as follows:

1. ClientHello initiates the process.

The ClientHello message contains the [Server Name Indication \(SNI\)](#), which has the server's fully qualified domain name.

2. After a managed device processes a ClientHello message and transmits it to the destination server, the server determines whether it supports the decryption attributes the client specified in the message. If it does not support those attributes, the server sends a handshake failure alert to the client. If it supports those attributes, the server sends the ServerHello message. If the agreed-upon key exchange method uses certificates for authentication, the server certificate message immediately follows the ServerHello message.

The server certificate contains the [Subject Alternative Name \(SAN\)](#), which can have fully qualified domain names and IP addresses. For more information about the SAN, see [Distinguished Name](#), on page 1479.

3. When the managed device receives these messages, it attempts to match them with decryption rules configured on the system. These messages contain information that was absent from either the ClientHello message or the session data cache. Specifically, the system can potentially match these messages on decryption rules' Distinguished Names, Certificate Status, Cipher Suites, and Versions conditions.

The entire process is encrypted.

### Data exchange

If you configure TLS/SSL decryption, when a managed device receives a ClientHello message, the system attempts to match the message to decryption rules that have the **Decrypt - Resign** or **Decrypt - Known Key** action. The match relies on data from the ClientHello message and from cached server certificate data. Possible data includes:

**Table 217: Data Availability for Decryption Rule Conditions**

Decryption Rule Condition	Data Present In
Zones	ClientHello
Networks	ClientHello
VLAN Tags	ClientHello
Ports	ClientHello
Users	ClientHello
Applications	ClientHello (Server Name Indicator extension)
Categories	ClientHello (Server Name Indicator extension)
Certificate	Server certificate (potentially cached)
Distinguished Names	Server certificate (potentially cached)
Certificate Status	Server certificate (potentially cached)
Cipher Suites	ServerHello
Versions	ServerHello

**Important** Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with either **Decrypt - Resign** or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

### ClientHello modifications

If the ClientHello message matches a **Decrypt - Resign** or **Decrypt - Known Key** rule, the system modifies the ClientHello message as follows:

- (TLS 1.2 only; TLS 1.3 does not support compression.) Compression methods—Strips the `compression_methods` element, which specifies the compression methods the client supports. The system cannot decrypt compressed sessions.
  - Cipher suites—Strips cipher suites from the `cipher_suites` element if the system does not support them. If the system does not support any of the specified cipher suites, the system transmits the original, unmodified element. This modification reduces the Unknown Cipher Suite and Unsupported Cipher Suite types of undecryptable traffic.
  - Session identifiers—Strips any value from the `Session Identifier` element and the [SessionTicket extension](#) (RFC 5077, sec 3.2) that does not match cached session data. If a ClientHello value matches cached data, an interrupted session can resume without the client and server performing the full TLS/SSL handshake. This modification increases the chances of session resumption and reduces the Session Not Cached type of undecryptable traffic.
  - Elliptic curves—Strips elliptic curves from the Supported Elliptic Curves extension if the system does not support them. If the system does not support any of the specified elliptic curves, the managed device removes the extension and strips any related cipher suites from the `cipher_suites` element.
  - ALPN extensions—Strips any value from the Application-Layer Protocol Negotiation (ALPN) extension that is unsupported in the system (for example, the HTTP/2 protocol).
  - Other Extensions—Strips the Next Protocol Negotiation (NPN) and TLS Channel IDs extensions.
- decryption rules with a **Decrypt - Resign** or **Decrypt - Known Key** action now natively support the Extended Master Secret (EMS) extension during ClientHello negotiation, enabling more secure communications. The EMS extension is defined by [RFC 7627](#).

After the system modifies the ClientHello message, it determines whether the message passes access control evaluation (which can include deep inspection). If the message passes, the system transmits it to the destination server.

If the ClientHello message does *not* match a **Decrypt - Resign** or **Decrypt - Known Key** rule, the system does not modify the message. It then determines whether the message passes access control evaluation (which can include deep inspection). If the message passes inspection, the system transmits it to the destination server.

ClientHello is *not* modified if traffic matches a **Monitor** rule condition.

### Man-in-the-middle

Direct communication between the client and server is no longer possible during the TLS/SSL handshake, because after message modification the Message Authentication Codes (MACs) computed by the client and server no longer match. For all subsequent handshake messages (and for the encrypted session once established),

the managed device acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. As a result, each session contains different cryptographic session details.

**Note** The cipher suites that the system can decrypt are frequently updated and do not correspond directly to the cipher suites you can use in decryption rule conditions. For the current list of decryptable cipher suites, contact Cisco TAC.

[ServerHello and Server Certificate Message Handling](#), on page 2324

## ServerHello and Server Certificate Message Handling

### Overview

The following figure shows an example. Also see [RFC 8446, sec. 4](#). You can also consult a resource such as [What Happens in a TLS Handshake?](#) at [cloudflare.com](#).

The process can be summarized as follows:

1. ClientHello initiates the process.

The ClientHello message contains the [Server Name Indication \(SNI\)](#), which has the server's fully qualified domain name.

2. After a managed device processes a ClientHello message and transmits it to the destination server, the server determines whether it supports the decryption attributes the client specified in the message. If it does not support those attributes, the server sends a handshake failure alert to the client. If it supports those attributes, the server sends the ServerHello message. If the agreed-upon key exchange method uses certificates for authentication, the server certificate message immediately follows the ServerHello message.

The server certificate contains the [Subject Alternative Name \(SAN\)](#), which can have fully qualified domain names and IP addresses. For more information about the SAN, see [Distinguished Name, on page 1479](#).

3. When the managed device receives these messages, it attempts to match them with decryption rules configured on the system. These messages contain information that was absent from either the ClientHello message or the session data cache. Specifically, the system can potentially match these messages on decryption rules' Distinguished Names, Certificate Status, Cipher Suites, and Versions conditions.

The entire process is encrypted.

### Decryption Rule actions

If the messages do not match any decryption rules, the managed device performs the [Decryption Policy Default Actions, on page 2352](#).

If the messages match a rule that belongs to an decryption policy associated with an access control policy, the managed device continues as appropriate:

#### Action: Monitor

The TLS/SSL handshake continues to completion. The managed device tracks and logs traffic but does not decrypt encrypted it.

#### Action: Block or Block with Reset

The managed device blocks the TLS/SSL session and, if configured, resets the TCP connection.

#### Action: Do Not Decrypt

The TLS/SSL handshake continues to completion. The managed device does not decrypt the application data exchanged during the TLS/SSL session.

#### Action: Decrypt - Known Key

The managed device attempts to match the server certificate data to an Internal Certificate object previously imported into the Security Cloud Control. Because you cannot generate an Internal Certificate object, and you must possess its private key, we assume you own the server on which you're using known key decryption.

If the certificate matches a known certificate, the TLS/SSL handshake continues to completion. The managed device uses the uploaded private key to decrypt and re encrypt the application data exchanged during the TLS/SSL session.

If the server changes its certificate between the initial connection with the client and subsequent connections, you must import the new server certificate in the Security Cloud Control for future connections to be decrypted.

#### Action: Decrypt - Resign

The managed device processes the server certificate message and re-signs the server certificate with the previously imported or generated certificate authority (CA). The TLS/SSL handshake continues to completion. The managed device then uses the uploaded private key to decrypt and re encrypt the application data exchanged during the TLS/SSL session.

---

**Note** The Firepower System does not support mutual authentication; that is, you cannot upload a [client certificate](#) to the Security Cloud Control and use it for either **Decrypt - Resign** or **Decrypt - Known Key** decryption rule actions. For more information, see [Decrypt and Resign \(Outgoing Traffic\), on page 2328](#). and [Known Key Decryption \(Incoming Traffic\), on page 2329](#).

[Other Decryption Rule Actions](#), on page 2329

[Decryption Rule Components](#), on page 2329

[Decryption Rule Order Evaluation](#), on page 2330

[TLS 1.3 Decryption Best Practices](#), on page 2357

## The Case for Decryption

Traffic that is encrypted when it passes through the system can be allowed or blocked only but it *cannot* be subjected to deep inspection or the full range of policy enforcement (such as intrusion prevention).

All encrypted connections:

- Are sent through the decryption policy to determine if they should be decrypted or blocked.

You can also configure decryption rules to block encrypted traffic of types you know you do not want on your network, such as traffic that uses the nonsecure SSL protocol or traffic with an expired or invalid certificate.

- If unblocked, whether or not decrypted, traffic goes through the access control policy for a final allow or block decision.

Only *decrypted* traffic takes advantage of the system's threat defense and policy enforcement features, such as:

- Advanced Malware Protection
- Security intelligence
- Threat Intelligence Director
- Application detectors
- URL and category filtering

Keep in mind that decrypting and then re-encrypting traffic adds a processing load on the device, which can reduce overall system performance.

In summary:

- Encrypted traffic can be allowed or blocked by policy; encrypted traffic *cannot* be inspected
- Decrypted traffic is subject to threat defense and policy enforcement; decrypted traffic can be allowed or blocked by policy

### Related Topics

[Deep Inspection Using File and Intrusion Policies](#), on page 1814

## When to Decrypt Traffic, When Not to Decrypt

This section provides guidelines on when you should decrypt traffic and when you should allow it to pass through the firewall encrypted.

### When not to decrypt traffic

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

(Snort 2.) If you elect to bypass decryption for certain types of traffic, no processing is done on the traffic. The encrypted traffic is first evaluated by decryption policy and then proceeds to the access control policy, where a final allow or block decision is made.

(Snort 3.) Decryption policy is *not* bypassed for any connections that match access control rules with actions of Trust, Block, or Block with Reset, unless the traffic is prefiltered. The encrypted traffic is first evaluated by decryption policy and then proceeds to the access control policy, where a final allow or block decision is made.

Encrypted traffic can be allowed or blocked on any decryption rule condition, including, but not limited to:

- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- Exact URL or URL category
- Port
- User group

Decryption rules provide a **Do Not Decrypt** action for this traffic; for more information, see [Decryption Rule Do Not Decrypt Action, on page 2391](#).

**Note** The related information links at the end of this topic explain how some aspects of rule evaluation work. Conditions such as URL and application filtering have limitations with respect to encrypted traffic. Make sure you understand those limitations.

For more information about using URL filtering in **Do Not Decrypt** rules, see [Decryption Rule Do Not Decrypt Action, on page 2391](#).

### When to decrypt traffic

All encrypted traffic must be decrypted to take advantage of the system's threat protection and policy enforcement features. To the extent your managed device allows traffic to be decrypted (subject to its memory and processing power), you should decrypt traffic that is not prohibited by law or regulation. If you must decide what traffic to decrypt, base your decision on the risk of allowing the traffic on your network. The system provides a flexible framework for classifying traffic using rule conditions, which include URL reputation, cipher suite, protocol, and many other factors.

## Decrypt and Resign (Outgoing Traffic)

The **Decrypt - Resign** decryption rule action enables the system to act as a man in the middle, intercepting, decrypting, and (if the traffic is allowed to pass) inspecting and re-encrypting it. The **Decrypt - Resign** rule action is used with outgoing traffic; that is, the destination server is outside your protected network.

The threat defense device negotiates with the client using an internal Certificate Authority (CA) object specified in the rule and builds a TLS/SSL tunnel between the client and the threat defense device. At the same time, the device connects to the destination web site and creates an SSL tunnel between the server and the threat defense device.

Thus, the client sees the CA certificate configured for the decryption rule instead of the certificate from the destination server. The client must trust the firewall's certificate to complete the connection. The threat defense device then performs decryption/re-encryption in both directions for traffic between the client and the destination server.

### Prerequisite

To use the **Decrypt - Resign** rule action, you must create an internal CA object using a CA file and paired private key file. You can generate a CA and private key in the system if you don't already have them.

We simplify the process of configuring the **Decrypt - Resign** rule by automatically adding **Do Not Decrypt** rules to the decryption policy based on your choices for types of traffic to exempt from encryption, such as undecryptable applications. (Typically, these applications use certificate pinning so that decrypting the connection breaks the connection.) For more information, see [Create a Decryption Policy with Outbound Connection Protection, on page 2341](#).

---

**Note** The Firepower System does not support mutual authentication; that is, you cannot upload a [client certificate](#) to the Security Cloud Control and use it for either **Decrypt - Resign** or **Decrypt - Known Key** decryption rule actions. For more information, see [Decrypt and Resign \(Outgoing Traffic\), on page 2328](#). and [Known Key Decryption \(Incoming Traffic\), on page 2329](#).

---

#### Related Topics

[Decryption Rule Decrypt Actions](#), on page 2392

[External Certificate Objects](#), on page 1507

## Known Key Decryption (Incoming Traffic)

The **Decrypt - Known Key** decryption rule action uses a server's private key to decrypt traffic. The **Decrypt - Known Key** rule action is used with incoming traffic; that is, the destination server is inside your protected network.

The main purpose of decrypting with a known key is to protect your servers from external attacks.

#### Prerequisite

To use the **Decrypt - Known Key** rule action, you must create an internal certificate object using the server's certificate file and paired private key file.

---

**Note** The Firepower System does not support mutual authentication; that is, you cannot upload a [client certificate](#) to the Security Cloud Control and use it for either **Decrypt - Resign** or **Decrypt - Known Key** decryption rule actions. For more information, see [Decrypt and Resign \(Outgoing Traffic\), on page 2328](#). and [Known Key Decryption \(Incoming Traffic\), on page 2329](#).

[Internal Certificate Objects](#), on page 1508

## Other Decryption Rule Actions

The following sections discuss other decryption rule actions.

#### Related Topics

[Decryption Rule Blocking Actions](#), on page 2392

[Decryption Rule Monitor Action](#), on page 2390

## Decryption Rule Components

Each decryption rule has the following components.

### State

By default, rules are enabled. If you disable a rule, the system does not use it to evaluate network traffic, and stops generating warnings and errors for that rule.

### Position

Rules in a decryption policy are numbered, starting at 1. The system matches traffic to rules in top-down order by ascending rule number. With the exception of Monitor rules, the first rule that traffic matches is the rule that handles that traffic.

### Conditions

Conditions specify the specific traffic the rule handles. Conditions can match traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate subject or issuer, certificate status, cipher suite, or encryption protocol version. The use of conditions can depend on target device licenses.

### Action

A rule's action determines how the system handles matching traffic. You can monitor, allow, block, or decrypt encrypted matching traffic. Decrypted and allowed encrypted traffic is subject to further inspection. Note that the system does **not** perform inspection on blocked encrypted traffic.

### Logging

A rule's logging settings govern the records the system keeps of the traffic it handles. You can keep a record of traffic that matches a rule. You can log a connection when the system blocks an encrypted session or allows it to pass without decryption, according to the settings in a decryption policy. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. You can log connections to the Secure Firewall Management Center database, as well as to the system log (syslog) or to an SNMP trap server.

---

**Tip** Properly creating and ordering decryption rule is a complex task. If you do not plan your policy carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. To help ensure that the system handles traffic as you expect, the decryption policy interface has a robust warning and error feedback system for rules.

---

### Categories

For information about using decryption rule categories (such as Applications, Category, and Cert Status), see [Decryption Rule Conditions, on page 2372](#).

## Decryption Rule Order Evaluation

When you create the decryption rule in a decryption policy, you specify its position using the **Insert** list in the rule editor. decryption rules in an a decryption policy are numbered, starting at 1. The system matches traffic to decryption rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic

flow), the system does *not* continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use *specific* conditions (such as network and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules. For more information about the OSI model, see this [Wikipedia article](#).

---

**Tip** Proper decryption rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

---

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

## Multi-Rule Example

The following scenario summarizes the ways that decryption rules handle traffic in an inline deployment.

In this scenario, traffic is evaluated as follows:

- **Undecryptable Traffic Action** evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.
- **Decryption Rule 1: Monitor** evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.
- **Decryption Rule 2: Do Not Decrypt** evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- **Decryption Rule 3: Block** evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.
- **Decryption Rule 4: Decrypt - Known Key** evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule continues to the next rule.
- **Decryption Rule 5: Decrypt - Resign** is the final rule. If traffic matches this rule, the system re-signs the server certificate with an uploaded CA certificate, then acts as a man-in-the-middle to decrypt traffic. The decrypted traffic is then evaluated against access control rules. Access control rules treat decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the SSL rule continues to the next rule.
- **Decryption policy Default Action** handles all traffic that does not match any of the decryption rules. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

## How to Configure Decryption Policies and Rules

This topic provides a high-level overview of tasks you must complete to configure decryption policies and decryption rules in those policies to block, monitor, or allow TLS/SSL traffic on your network.

You must be an Admin, Access Admin, or Network Admin to perform this task.

### Procedure

- 
- Step 1** (Optional.) For **Decrypt - Known Key** decryption rules (to decrypt inbound traffic to an internal server), create an internal certificate object.
- The internal certificate object uses your server's certificate and private key. See [Internal Certificate Objects, on page 1508](#).
- Step 2** (Optional.) For **Decrypt - Resign** decryption rules (to decrypt outbound traffic to a server outside of your network), create an internal certificate authority (CA) object.
- The internal CA object uses a CA and private key. See [Internal Certificate Authority Objects, on page 1501](#).
- Step 3** For outbound protection policies (**Decrypt - Resign**) or inbound protection policies (**Decrypt - Known Key**), run the decryption policy wizard.
- [Create a Decryption Policy with Outbound Connection Protection, on page 2341](#)
  - [Create a Decryption Policy with Inbound Connection Protection, on page 2343](#)
- Step 4** For any other rule action (**Do Not Decrypt**, **Block**, **Block with Reset**, or **Monitor**), create a decryption policy and rules manually.
- See [Create a Decryption Policy with Other Rule Actions, on page 2351](#).
-

**What to do next**

See one of the following:

- [Create a Decryption Policy with Outbound Connection Protection, on page 2341](#)
- [Create a Decryption Policy with Inbound Connection Protection, on page 2343](#)
- [Create a Decryption Policy with Other Rule Actions, on page 2351](#)

## How to Configure Decryption Policies and Rules

This topic provides a high-level overview of tasks you must complete to configure decryption policies and decryption rules in those policies to block, monitor, or allow TLS/SSL traffic on your network.

You must be an Admin, Access Admin, or Network Admin to perform this task.

**Procedure**

	<b>Command or Action</b>	<b>Purpose</b>
<b>Step 1</b>	For <b>Decrypt - Known Key</b> decryption rules (to decrypt inbound traffic to an internal server), create an internal certificate object.	The internal certificate object uses your server's certificate and private key. See <a href="#">Internal Certificate Objects, on page 1508</a> .
<b>Step 2</b>	For <b>Decrypt - Resign</b> decryption rules (to decrypt outbound traffic to a server outside of your network), create an internal certificate authority (CA) object.	The internal CA object uses a CA and private key. See <a href="#">Internal Certificate Authority Objects, on page 1501</a> .
<b>Step 3</b>	Create a decryption policy and, optionally, rules.	You can create a decryption policy with multiple rules at the same time. You can also create a decryption policy without rules; for example, to add the rules later or to create a policy with <b>Do Not Decrypt</b> rule actions. For more information, see <a href="#">Create a Decryption Policy, on page 2341</a> .
<b>Step 4</b>	Set a default action for your decryption policy.	The default action is taken when traffic matches no rules defined by the decryption policy. See <a href="#">Decryption Policy Default Actions, on page 2352</a> .
<b>Step 5</b>	Specify how undecryptable traffic should be handled.	Traffic can be undecryptable for a number of reasons, including unsecure protocols, uses and unknown cipher suite, or in the event of errors with the handshake or decryption. See <a href="#">Default Handling Options for Undecryptable Traffic, on page 2353</a> .
<b>Step 6</b>	Configure advanced settings for your decryption policy.	Advanced settings include disabling HTTP/3 advertisements, enabling TLS 1.3 decryption, and enabling the TLS server identity probe.

	Command or Action	Purpose
		For more information, see <a href="#">Decryption Policy Advanced Options</a> , on page 2355.
<b>Step 7</b>	Associate the decryption policy with an access control policy.	Unless you associate your decryption policy with an access control policy, it has no effect. After you do this, you can choose to allow or block traffic that matches the access control rule and take other actions. See <a href="#">Associating Other Policies with Access Control</a> , on page 1844.
<b>Step 8</b>	Configure your access control rules to allow or block decrypted traffic.	See <a href="#">Access Control Policy Components</a> , on page 1829.
<b>Step 9</b>	Choose whether or not to enable TLS server identity discovery in the access control policy.	For more information, see <a href="#">Access Control Policy Advanced Settings</a> , on page 1840.
<b>Step 10</b>	Deploy the access control policy to managed devices.	Before your policy can take effect, it must be deployed to managed devices. See <a href="#">Deploy Configuration Changes</a> , on page 240.

## History for Decryption Policy

Feature	Minimum Management Center	Minimum Threat Defense	Details
Easily bypass decryption for sensitive and undecryptable traffic.	20240808	7.6.0	<p>It is now easier to bypass decryption for sensitive and undecryptable traffic, which protects users and improves performance.</p> <p>New decryption policies now include predefined rules that, if enabled, can automatically bypass decryption for sensitive URL categories (such as finance or medical), undecryptable distinguished names, and undecryptable applications. Distinguished names and applications are undecryptable typically because they use TLS/SSL certificate pinning, which is itself not decryptable.</p> <p>For outbound decryption, you enable/disable these rules as part of creating the policy. For inbound decryption, the rules are disabled by default. After the policy is created, you can edit, reorder, or delete the rules entirely.</p> <p>New/modified screens: <b>Policies &gt; Access Control &gt; Decryption &gt; Create Decryption Policy</b></p> <p>See: <a href="#">Create a Decryption Policy</a></p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Decryption policy.	20221213	7.3.0	<p>Feature renamed to <i>decryption policy</i> to better reflect what it does. We now enable you to configure a decryption policy with one or more <b>Decrypt - Resign</b> or <b>Decrypt - Known Key</b> rules at the same time.</p> <p>New/modified screens:</p> <ul style="list-style-type: none"> <li>• <b>Policies &gt; Access Control &gt; Decryption</b>(create new decryption policy)</li> <li>• The Create Decryption Policy dialog box now has two tab pages: <b>Outbound Connections</b> and <b>Inbound Connections</b>.</li> </ul> <p>Use the <b>Outbound Connections</b> tab page to configure one or more decryption rules with a <b>Decrypt - Resign</b> rule action. (You can either upload or generate certificate authorities at the same time). Each combination of a CA with networks and ports results in one decryption rule.</p> <p>Use the <b>Inbound Connections</b> tab page to configure one or more decryption rules with a <b>Decrypt - Known Key</b> rule action. (You can upload your server's certificate at the same time.) Each combination of a server certificate with networks and ports results in one decryption rule.</p> <ul style="list-style-type: none"> <li>• <b>Policies &gt; Access Control &gt; Decryption</b> (edit a decryption rule) &gt; <b>Advanced Settings</b> has new options discussed in <a href="#">TLS 1.3 Decryption Best Practices, on page 2357</a>.</li> <li>• <b>Policies &gt; Access Control</b> &gt; (edit an access control policy), click the word <b>Decryption</b> to associate a decryption policy with an access control policy.</li> </ul>
TLS 1.3 decryption.	20220609	7.2.0	<p>You can now enable TLS 1.3 decryption in an SSL policy's advanced actions. TLS 1.3 decryption requires the managed device run Snort 3.</p> <p>Other options are available as well; for more information, see <a href="#">TLS 1.3 Decryption Best Practices, on page 2357</a>.</p> <p>New/modified screens: <b>SSL Policy &gt; Advanced Settings</b></p>
SSL policy advanced settings.	20220609	7.2.0	<p>SSL policy advanced settings</p> <p>New/modified screens: <b>SSL Policy &gt; Advanced Settings</b></p>
Ability to specify handling of URLs having unknown reputation.	20220609	7.0.3	<p>For details, see <a href="#">About URL Filtering with Category and Reputation, on page 1919</a>.</p>
ClientHello modification for <b>Decrypt - Known</b> key rules.	20220609	7.0.3	<p>For details, see <a href="#">ClientHello Message Handling, on page 2321</a>.</p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Ability to extract the certificate in TLS 1.3 traffic to enable traffic to match URL and application criteria in access control rules.	20220609		New/modified screens: <b>Policies &gt; Access Control &gt; (edit an access control policy) &gt; Advanced</b> link. For details, see <a href="#">Decryption Policy Advanced Options, on page 2355</a> .
Changes to category and reputation-based URL Filtering.	20220609	7.0.3	For details, see <a href="#">About URL Filtering with Category and Reputation, on page 1919</a> .
TLS crypto acceleration cannot be disabled.	20220609	7.0.3	TLS crypto acceleration is enabled on all supported devices. On a managed device with native interfaces, TLS crypto acceleration cannot be disabled. Support for TLS crypto acceleration on threat defense container instances is limited as discussed in the next row of this table. Removed commands: <ul style="list-style-type: none"> <li>• <b>system support ssl-hw-accel enable</b></li> <li>• <b>system support ssl-hw-accel disable</b></li> <li>• <b>system support ssl-hw-status</b></li> </ul>
Support for TLS crypto acceleration on one threat defense container instance on a Firepower 4100/9300 module/security engine.	20220609	7.0.3	You can now enable TLS crypto acceleration for one threat defense container instance on a module/security engine. TLS crypto acceleration is disabled for other container instances, but enabled for native instances. New/modified commands: <ul style="list-style-type: none"> <li>• <b>config hwCrypto enable</b></li> <li>• <b>show crypto accelerator status</b> replaces <b>system support ssl-hw-status</b>)</li> </ul>
TLS/SSL hardware acceleration is now referred to as <i>TLS crypto acceleration</i> .	20220609	7.0.3	The name change reflects that TLS/SSL encryption and decryption acceleration is supported on more devices. Depending on the device, acceleration might be performed in software or in hardware. New/modified screens: <b>Devices &gt; Device Management &gt; Edit &gt; Device &gt; General &gt; TLS Crypto Acceleration</b>
TLS/SSL hardware acceleration enabled by default.	20220609	7.0.3	TLS/SSL hardware acceleration is enabled by default on all supported devices but can be disabled if desired.
Extended Master Secret extension supported (see <a href="#">RFC 7627</a> ).	20220609	7.0.3	The TLS Extended Master Secret extension is supported for SSL policies; specifically, policies with a rule action of <b>Decrypt - Resign</b> or <b>Decrypt - Known Key</b> .

Feature	Minimum Management Center	Minimum Threat Defense	Details
Aggressive TLS 1.3 downgrade.	20220609	7.0.3	Using the <b>system support ssl-client-hello-enabled aggressive_tls13_downgrade {true/false}</b> CLI command, you can determine the behavior for downgrading TLS 1.3 traffic to TLS 1.2. For details, see the <a href="#">Cisco Secure Firewall Threat Defense Command Reference</a> .
TLS/SSL hardware acceleration introduced.	20220609	7.0.3	Certain managed device models perform TLS/SSL encryption and decryption in hardware, improving performance. By default, the feature is enabled.  Affected screen: To view the status of TLS/SSL hardware acceleration, <b>Devices &gt; Device Management &gt; Device</b> , General page.
Category and reputation conditions supported.	20220609	7.0.3	Access control rules or SSL rules with category/reputation conditions.
SafeSearch supported.	20220609	7.0.3	The system displays an HTTP response page for connections decrypted by the SSL policy, then blocked (or interactively blocked) either by access control rules or by the access control policy default action. In these cases, the system encrypts the response page and sends it at the end of the reencrypted SSL stream.  SafeSearch filters objectionable content and stops people from searching adult sites.
TLS/SSL policy.	20220609	7.0.3	Feature introduced.

## CHAPTER 86

# Decryption Policies

---

The following topics provide an overview of decryption policy creation, configuration, management, and logging.

- [About Decryption Policies, on page 2339](#)
- [Requirements and Prerequisites for Decryption Policies, on page 2340](#)
- [Create a Decryption Policy, on page 2341](#)
- [Decryption Policy Default Actions, on page 2352](#)
- [Default Handling Options for Undecryptable Traffic, on page 2353](#)
- [Decryption Policy Advanced Options, on page 2355](#)

## About Decryption Policies

A decryption policy determines how the system handles encrypted traffic on your network. You can configure one or more decryption policies, associate a decryption policy with an access control policy, then deploy the access control policy to a managed device. When the device detects a TCP handshake, the access control policy first handles and inspects the traffic. If it subsequently identifies a TLS/SSL-encrypted session over the TCP connection, the decryption policy takes over, handling and decrypting the encrypted traffic.

You can create multiple rules at the same time, including rules for decrypting incoming traffic (**Decrypt - Known Key** rule action) and outgoing traffic (**Decrypt - Resign** rule action). To create a rule with a **Do Not Decrypt** or other rule action (such as **Block** or **Monitor**), create an empty decryption policy and add the rule afterward.

### Create a decryption policy using the wizard

You can use a wizard to create the following types of decryption policies:

- Outbound protection (**Decrypt - Resign** rule action). If traffic matches this rule, the system re-signs the server certificate with the CA certificate, then acts as a man-in-the-middle.

For more information, see [Create a Decryption Policy with Outbound Connection Protection, on page 2341](#).

- Inbound protection (**Decrypt - Known Key** rule action). You can associate one or more server certificates and paired private keys with the action. If traffic matches the rule, and the certificate used to encrypt the traffic matches the certificate associated with the action, the system uses the appropriate private key to obtain the session encryption and decryption keys.

For more information, see [Create a Decryption Policy with Inbound Connection Protection, on page 2343](#).

- Any other decryption rule action (such as blocking or monitoring).

For more information, see [Create a Decryption Policy with Other Rule Actions, on page 2351](#).

The wizard automatically creates a separate rule for each certificate you specify. For example, an inbound protection rule might specify one certificate for traffic coming to the Finance department internal network and a different certificate for traffic coming to the Engineering network.

The wizard creates additional rules for outbound and inbound protection policies as follows:

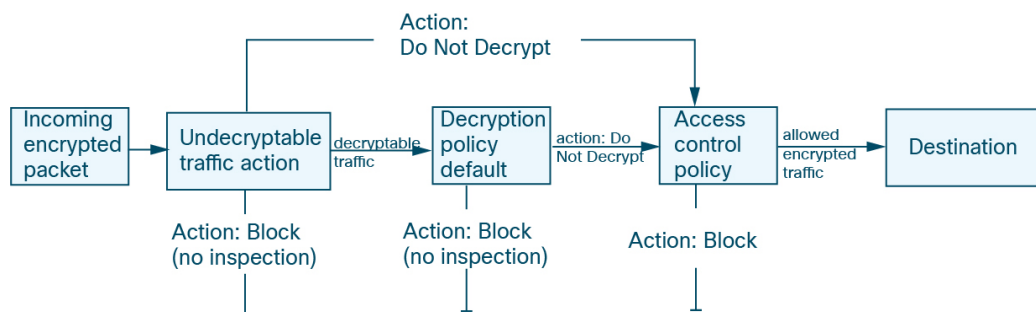

- Outbound protection (**Decrypt - Resign** rule action): The wizard creates Do Not Decrypt rules for traffic that matches exceptions you specify in the wizard. For example, you can choose to not decrypt traffic from undecryptable applications, typically those using certificate pinning.

The Do Not Decrypt rules are placed first in the decryption policy so that traffic is passed through the firewall with minimal processing.

- Inbound protection (**Decrypt - Known Key** rule action): The wizard does not allow you to choose any exceptions but it adds the Do Not Decrypt rules to the policy and disables them; that way, you can enable those exceptions later if you need to.

### Do Not Decrypt policy example

Following is an example decryption policy with a **Do Not Decrypt** rule action:

The simplest decryption policy, as shown in the following diagram, directs the device where it is deployed to handle encrypted traffic with a single default action. You can set the default action to block decryptable traffic without further inspection, or to inspect undecrypted decryptable traffic with access control. The system can then either allow or block the encrypted traffic. If the device detects undecryptable traffic, it either blocks the traffic without further inspection or does not decrypt it, inspecting it with access control.

To get started, see [Create a Decryption Policy, on page 2341](#)

## Requirements and Prerequisites for Decryption Policies

### Supported Domains

Any

### User Roles

- Admin

- Access Admin
- Network Admin

## Create a Decryption Policy

You can create any of the following types of decryption policies:

- *Outbound protection* policy with rules that protect outbound connections; that is, the destination server is outside your protected network. This type of rule has a **Decrypt - Resign** rule action. We also create additional rules with a **Do Not Decrypt** action that excludes traffic you specify (such as traffic that uses certificate pinning.)

See [Create a Decryption Policy with Outbound Connection Protection, on page 2341](#)

- *Inbound protection* policy with a rule that protects inbound connections; that is, the destination server is inside your protected network. This type of rule has a **Decrypt - Known Key** rule action. We also create additional rules with a **Do Not Decrypt** action that excludes traffic you specify (such as traffic that uses certificate pinning.) These rules are disabled initially but you can modify and enable them later if you wish.

See [Create a Decryption Policy with Inbound Connection Protection, on page 2343](#)

- Other actions (including **Do Not Decrypt**, **Block**, and **Block with Reset**).

See [Create a Decryption Policy with Other Rule Actions, on page 2351](#)

## Create a Decryption Policy with Outbound Connection Protection

This task discusses how to create a decryption policy with a rule that protects outbound connections; that is, the destination server is outside your protected network. This type of rule has a **Decrypt - Resign** rule action.

When you create a decryption policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules and multiple **Decrypt - Resign** rules.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see [Creating Change Management Tickets, on page 214](#) and [Policies and Objects that Support Change Management, on page 209](#).

### Before you begin

You can optionally must upload an internal CA certificate for your managed device before you can create a decryption policy that protects outbound connections. You can do this in any of the following ways:

- Create an internal CA certificate object by going to **Objects > Object Management > PKI > Internal CAs** and referring to [PKI, on page 1500](#).
- At the time you create this decryption policy.

## Procedure

- Step 1** Log in to Security Cloud Control if you haven't already done so.
- Step 2** Click **Administration > Firewall Management Center** and choose **Policies > Access Control > Decryption**.
- Step 3** Click **Create Decryption Policy**.
- Step 4** Give the policy a unique **Name** and, optionally, a **Description**.
- Step 5** Click the **Outbound Connections** tab.

## Create Decryption Policy ?

**1** Policy Details  
Enter name, description, choose policy type and certificates.

**2** Decryption Exclusions  
(Optional) Configure exclusions for outbound connections.

**i** A decryption policy is not required to only perform application or URL discovery; instead, you can use TLS 1.3 Server Identity Discovery on the access control policy.

**Name \***

**Description**

**Outbound Connections** (User Protection)
Inbound Connections (Server Protection)
IntCA Associated: 1 Network, 1 Port
Cancel Next

- Step 6** From the **Internal Certificates** list, upload or choose certificates for the rules.
- For more information about internal certificates, see [Generate an Internal CA for Outbound Protection, on page 2348](#) and [Upload an Internal CA for Outbound Protection, on page 2349](#).
- Step 7** (Optional.) Choose networks and ports.
- For more information:

- [Network Rule Conditions](#), on page 1065
- [Port Rule Conditions](#), on page 1067

- Step 8** Click **Next**.
- Step 9** Continue with [Decryption Policy Exclusions](#), on page 2345.
- Step 10** Click **Save**.

---

### What to do next

- Add rule conditions: [Decryption Rule Conditions](#), on page 2372
- Add a default policy action: [Decryption Policy Default Actions](#), on page 2352
- Configure logging options for the default action .
- Set advanced policy properties: [Decryption Policy Advanced Options](#), on page 2355.
- Associate the decryption policy with an access control policy as described in [Associating Other Policies with Access Control](#), on page 1844.
- Deploy configuration changes.

## Create a Decryption Policy with Inbound Connection Protection

This task discusses how to create a decryption policy with a rule that protects inbound connections; that is, the destination server is inside your protected network. This type of rule has a **Decrypt - Known Key** rule action.

When you create a decryption policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules and multiple **Decrypt - Resign** rules.

### Before you begin

You can optionally must upload an internal certificate for your internal server before you can create a decryption policy that protects inbound connections. You can do this in any of the following ways:

- Create an internal certificate object by going to **Objects > Object Management > PKI > Internal Certs** and referring to [PKI](#), on page 1500.
- At the time you create this decryption policy.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see [Creating Change Management Tickets](#), on page 214 and [Policies and Objects that Support Change Management](#), on page 209.

### Procedure

- 
- Step 1** Log in to Security Cloud Control if you haven't already done so.

**Step 2** Click **Tools & Services > Firewall Management Center > Policies > Access Control > Decryption**.

**Step 3** Click **Create Decryption Policy**.

**Step 4** Give the policy a unique **Name** and, optionally, a **Description**.

**Step 5** From the **Internal CA** list, upload or choose certificates for the rules.

For more information about internal CA certificates, see [Internal Certificate Authority Objects, on page 1501](#).

**Step 6** (Optional.) Choose networks and ports.

For more information:

- [Network Rule Conditions, on page 1065](#)
- [Port Rule Conditions, on page 1067](#)

**Step 7** Click the **Inbound Connections** tab.

**Create Decryption Policy**

1 Policy Details  
Enter name, description, choose policy type and certificates.

2 Decryption Exclusions  
(Optional) Configure exclusions for outbound connections.

1 A decryption policy is not required to only perform application or URL discovery; instead, you can use TLS 1.3 Server Identity Discovery on the access control policy.

**Name \***  
Inbound example

**Description**

Outbound Connections (User Protection) **Inbound Connections (Server Protection)**

**How Inbound Protection Works**  
Protect internal services from external attackers.

INTERNAL SERVICE ← Encrypted Traffic → DECRYPT KNOWN-KEY → Encrypted Traffic → SOURCE

A rule will be auto-created for each certificate.

+  
1. InboundCertFacebook Associated: 1 Network, 1 Port  
2. InternalCert Associated: 1 Network, 1 Port

Cancel **Next**

**Step 8** Click **Next**.

**Step 9** Continue with [Decryption Policy Exclusions, on page 2345](#).

### What to do next

- Add rule conditions: [Decryption Rule Conditions, on page 2372](#)
- Add a default policy action: [Decryption Policy Default Actions, on page 2352](#)
- Configure logging options for the default action .

- Set advanced policy properties: [Decryption Policy Advanced Options, on page 2355](#).
- Associate the decryption policy with an access control policy as described in [Associating Other Policies with Access Control, on page 1844](#).
- Deploy configuration changes.

## Decryption Policy Exclusions

This task discusses how to exclude certain types of traffic from decryption. We create **Do Not Decrypt** rules in your decryption policy for these although the rules are initially enabled only for an outbound decryption policy (that is, one that uses the **Decrypt - Resign** policy action).

### Before you begin

You must upload an internal CA certificate for your managed device before you can create a decryption policy that protects outbound connections. You can do this in any of the following ways:

- Create an internal CA certificate object by going to **Objects > Object Management > PKI > Internal CAs** and referring to [PKI, on page 1500](#).
- At the time you create this decryption policy.

### Procedure

- Step 1** Complete the tasks discussed in:
- [Create a Decryption Policy with Outbound Connection Protection, on page 2341](#)
  - For more information, see [Create a Decryption Policy with Inbound Connection Protection, on page 2343](#)
- Step 2** The exclusions page provides the following options. All options are *enabled* for an outbound protection policy (**Decrypt - Resign** rule action) and *disabled* for all other decryption policy actions.

Item	Description
<b>Bypass decryption for sensitive URL categories</b>	<p>Check the box to not decrypt traffic from the indicated categories. Depending on the laws in your area, decryption certain traffic, such as finance or health-related, might be prohibited. Consult an authority in your area for more information.</p> <p>Click <b>Add</b> to add more categories.</p> <p>Click <b>Delete</b> (✕) to remove categories.</p>
<b>Bypass decryption for undecryptable distinguished names</b>	<p>Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with <i>certificate pinning</i>, which is discussed in <a href="#">TLS/SSL Certificate Pinning Guidelines, on page 2366</a>.</p> <p>The list of undecryptable distinguished names is maintained by Cisco.</p>

Item	Description
<b>Bypass decryption for undecryptable applications</b>	<p>Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with <i>certificate pinning</i>, which is discussed in <a href="#">TLS/SSL Certificate Pinning Guidelines</a>, on page 2366.</p> <p>Undecryptable applications are updated automatically in the Vulnerability Database (VDB). You can find a list of all applications on the <a href="#">Secure Firewall Application Detectors</a> page; the <b>undecryptable</b> tag identifies applications Cisco determines are undecryptable.</p> <p>The list of undecryptable applications is maintained by Cisco.</p>

The following figure shows default options.

### Create Decryption Policy ?

**1 Policy Details**  
Enter name, description, choose policy type and certificates.

**2 Decryption Exclusions**  
(Optional) Configure exclusions for outbound connections.

**Bypass decryption for sensitive URL categories**

In many environments, certain categories of websites are not inspected for regulatory, compliance or privacy reasons. Customize the list below to bypass inspection for designated categories.  
Note: **URL License is Required**

URL Categories: Finance Online Trading Health and Medicine + Add

**Bypass decryption for undecryptable distinguished names**

Bypass decryption based on Cisco's list of known undecryptable distinguished names.  
Note: **This option is selected by default to allow traffic which cannot be decrypted to remain encrypted. Disabling this option might cause decryption to fail for unsupported distinguished names.**

[56 Distinguished names included](#) ▼

**Bypass decryption for undecryptable applications**

Certain enterprise applications are not supported for decryption due to a variety of reasons (Certificate Pinning, Client Certificate Authentication, etc.). Bypass decryption based on Cisco's list of known undecryptable applications.  
Note: **This option is selected by default to allow traffic which cannot be decrypted to remain encrypted. Disabling this option might cause decryption to fail for unsupported applications.**

4	<input checked="" type="checkbox"/> Auto-Rule-IntCA	any	any	IPv4-Link-Local	any	any	any	any	any	Bittorrent	any	any	<input checked="" type="radio"/> Decrypt - Resign
<b>Root Rules</b>													
This category is empty													
<b>Default Action</b>												Do not decrypt	

In the preceding example, the **Do Not Decrypt** rules corresponding to your choices for rule exclusions are automatically added before the **Decrypt - Resign** rule. The rule for sensitive URL categories is disabled because, by default, that exclusion is disabled. Had you selected the **Bypass decryption for sensitive URL categories** check box, the rule would have been enabled.

#### Step 4 Click **Create Policy**.

#### What to do next

- Add rule conditions: [Decryption Rule Conditions, on page 2372](#)
- Add a default policy action: [Decryption Policy Default Actions, on page 2352](#)
- Configure logging options for the default action .
- Set advanced policy properties: [Decryption Policy Advanced Options, on page 2355](#).
- Associate the decryption policy with an access control policy as described in [Associating Other Policies with Access Control, on page 1844](#).
- Deploy configuration changes.

## Generate an Internal CA for Outbound Protection

This task discusses how you can optionally generate an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects > Object Management** as discussed in [Uploading a Signed Certificate Issued in Response to a CSR, on page 1504](#).

#### Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in [Internal Certificate Authority Objects, on page 1501](#).

## Procedure

- 
- Step 1** Log in to Security Cloud Control if you haven't already done so.
- Step 2** Click **Administration > Firewall Management Center** and choose **Policies > Access Control > Decryption**.
- Step 3** Click **Create Decryption Policy**.
- Step 4** Enter a name for the policy in the **Name** field and an optional description in the **Description** field.
- Step 5** Click the **Outbound Connections** tab.
- Step 6** From the **Internal CA** list, click **Create New > Generate CA**.
- Step 7** Give the internal CA a **Name** and provide a two-letter **Country Name**.
- Step 8** Click **Self-Signed** or **CSR**.
- For more information about these options, see [Internal Certificate Authority Objects, on page 1501](#).
- Step 9** Enter the requested information in the provided fields.
- Step 10** Click **Save**.
- Step 11** If you chose **CSR**, after the signing request has been completed, click **Install Certificate** as follows:
- Repeat the preceding steps in this procedure.
  - Edit the CA from the **Internal CA** list as follows.

- Click **Install Certificate**.
  - Follow the prompts on your screen to complete the task.
- Step 12** Continue creating the policy as discussed in [Create a Decryption Policy with Inbound Connection Protection, on page 2343](#).
- 

## Upload an Internal CA for Outbound Protection

This task discusses how you can optionally upload an internal certificate authority when you create a decryption rule that protects outbound connections. You can also perform these tasks using **Objects > Object Management** as discussed in [Uploading a Signed Certificate Issued in Response to a CSR, on page 1504](#).

### Before you begin

Make sure you understand the requirements for generating an internal certificate authority object as discussed in [Internal Certificate Authority Objects, on page 1501](#).

## Procedure

- 
- Step 1** Log in to Security Cloud Control if you haven't already done so.
  - Step 2** Click **Administration > Firewall Management Center** and choose **Policies > Access Control > Decryption**.
  - Step 3** Click **Create Decryption Policy**.
  - Step 4** Enter a name for the policy in the **Name** field and an optional description in the **Description** field.
  - Step 5** Click the **Outbound Connections** tab.
  - Step 6** From the **Internal CA** list, click **Create New > Upload CA**.
  - Step 7** Give the internal CA a **Name**.
  - Step 8** Paste or browse to locate the certificate and its private key in the provided fields.
  - Step 9** If the CA has a password, select the **Encrypted** check box and enter the password in the adjacent field.
  - Step 10** Continue creating the policy as discussed in [Create a Decryption Policy with Outbound Connection Protection, on page 2341](#).
- 

## Upload an Internal Certificate for Inbound Protection

This task discusses how to upload an internal certificate authority when you create a decryption rule that protects outbound connections. You can also upload the internal CA using **Objects > Object Management** as discussed in [Importing a CA Certificate and Private Key, on page 1502](#).

### Before you begin

Make sure you have an internal certificate authority in one of the formats discussed in [Internal Certificate Authority Objects, on page 1501](#).

## Procedure

- 
- Step 1** Log in to Security Cloud Control if you haven't already done so.
  - Step 2** Click **Administration > Firewall Management Center** and choose **Policies > Access Control > Decryption**.
  - Step 3** Click **Create Decryption Policy**.
  - Step 4** Enter a name for the policy in the **Name** field and an optional description in the **Description** field.
  - Step 5** Click the **Inbound Connections** tab.
  - Step 6** From the **Internal Certificates** list, click **Add (+)**.
  - Step 7** Click **Upload**.
  - Step 8** Give the internal CA a **Name**.
  - Step 9** Paste or browse to locate the certificate and its private key in the provided fields.
  - Step 10** If the certificate has a password, select the **Encrypted** check box and enter the password in the adjacent field.

- Step 11** Continue creating the decryption policy as discussed in [Create a Decryption Policy with Inbound Connection Protection, on page 2343](#).
- 

## Create a Decryption Policy with Other Rule Actions

To create a decryption rule with a **Do Not Decrypt**, **Block**, **Block With Reset**, or **Monitor** rule action, create a decryption policy and edit the policy to add the rule.

When you create a decryption policy, you can create multiple rules at the same time, including multiple **Decrypt - Known Key** rules and multiple **Decrypt - Resign** rules.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see [Creating Change Management Tickets, on page 214](#) and [Policies and Objects that Support Change Management, on page 209](#).

### Procedure

---

- Step 1** Log in to Security Cloud Control if you haven't already done so.
- Step 2** Click **Administration > Firewall Management Center** and choose **Policies > Access Control > Decryption**.
- Step 3** Give the policy a unique **Name** and, optionally, a **Description**.
- Step 4** Click **Next**.
- Step 5** The bypass page is provided for your information only; you cannot bypass traffic for other types of decryption (such as **Block**).
- Step 6** Click **Create Policy**.
- Step 7** Wait for the policy to be created.
- Step 8** Click **Edit** (✎) next to the decryption policy name.
- Step 9** Click **Add Rule**.
- Step 10** Give the rule a **Name**.
- Step 11** From the **Action** list, click a rule action and see one of the following sections for more information:
- [Decryption Rule Do Not Decrypt Action, on page 2391](#)
  - [Decryption Rule Blocking Actions, on page 2392](#)
  - [Decryption Rule Monitor Action, on page 2390](#)
- Step 12** Click **Save**.
- 

### What to do next

- Add rule conditions: [Decryption Rule Conditions, on page 2372](#)
- Add a default policy action: [Decryption Policy Default Actions, on page 2352](#)

- Configure logging options for the default action as described in *Logging Connections with a Policy Default Action* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- Set advanced policy properties: [Decryption Policy Advanced Options, on page 2355](#).
- Associate the decryption policy with an access control policy as described in [Associating Other Policies with Access Control, on page 1844](#).
- Deploy configuration changes.

## Decryption Policy Default Actions

The default action for a decryption policy determines how the system handles decryptable encrypted traffic that does not match any non-monitor rule in the policy. When you deploy a decryption policy that does not contain any decryption rules, the default action determines how all decryptable traffic on your network is handled. Note that the system does not perform any kind of inspection on encrypted traffic blocked by the default action.

To set the decryption policy default action:

1. Log in to the Security Cloud Control if you haven't already done so.
2. Click **Administration** > **Firewall Management Center** and choose **Policies** > **Access Control** > **Decryption**.
3. Click **Edit** (✎) next to the name of the decryption policy.
4. In the Default Action row, click one of the following actions from the list.

**Table 218: Decryption Policy Default Actions**

Default Action	Effect on Encrypted Traffic
Block	Block the TLS/SSL session without further inspection.
Block with reset	Block the TLS/SSL session without further inspection and reset the TCP connection. Choose this option if traffic uses a connectionless protocol like UDP. In that case, the connectionless protocol tries to reestablish the connection until it is reset.  This action also displays a connection reset error in the browser so the user is informed that the connection is blocked.
Do not decrypt	Inspect the encrypted traffic with access control.

## Default Handling Options for Undecryptable Traffic

Table 219: Undecryptable Traffic Types

Type	Description	Default Action	Available Action
Compressed Session	The TLS/SSL session applies a data compression method.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
SSLv2 Session	The session is encrypted with SSL version 2. Note that traffic is decryptable if the ClientHello message is SSL 2.0, and the remainder of the transmitted traffic is SSL 3.0.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Unknown Cipher Suite	The system does not recognize the cipher suite.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Unsupported Cipher Suite	The system does not support decryption based on the detected cipher suite.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Session not cached	The TLS/SSL session has session reuse enabled, the client and server reestablished the session with the session identifier, and the system did not cache that session identifier.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Handshake Errors	An error occurred during TLS/SSL handshake negotiation.	Inherit default action	Do not decrypt Block Block with reset Inherit default action
Decryption Errors	An error occurred during traffic decryption.	Block	Block Block with Reset

When you first create a decryption policy, logging connections that are handled by the default action is disabled by default. Because the logging settings for the default action also apply to undecryptable traffic handling, logging connections handled by the undecryptable traffic actions is disabled by default.

Note that if your browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. For more information, see [Decryption Rule Guidelines and Limitations, on page 2360](#).

#### Related Topics

[Set Default Handling for Undecryptable Traffic](#), on page 2354

## Set Default Handling for Undecryptable Traffic

You can set undecryptable traffic actions at the decryption policy level to handle certain types of encrypted traffic the system cannot decrypt or inspect. When you deploy a decryption policy that contains no decryption rules, the undecryptable traffic actions determine how all undecryptable encrypted traffic on your network is handled.

Depending on the type of undecryptable traffic, you can choose to:

- Block the connection.
- Block the connection, then reset it. This option is preferable for connectionless protocols like UDP, which keep trying to connect until the connection is blocked.
- Inspect the encrypted traffic with access control.
- Inherit the default action from the decryption policy.

### Procedure

- 
- Step 1** Log in to Security Cloud Control if you haven't already done so.
  - Step 2** Click **Administration** > **Firewall Management Center** and choose **Policies** > **Access Control** > **Decryption**.
  - Step 3** Click **Edit** (✎) next to the name of the decryption policy.
  - Step 4** In the decryption policy editor, click **Undecryptable Actions**.
  - Step 5** For each field, choose either the decryption policy's default action or another action you want to take on the type of undecryptable traffic. See [Default Handling Options for Undecryptable Traffic, on page 2353](#) and [Decryption Policy Default Actions, on page 2352](#) for more information.
  - Step 6** Click **Save** to save the policy.
- 

#### What to do next

- Configure default logging for connections handled by the undecryptable traffic actions; see *Logging Connections with a Policy Default Action* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- Deploy configuration changes.

# Decryption Policy Advanced Options

A decryption policy's **Advanced Settings** page has global settings that are applied to all managed devices that are configured for Snort 3 to which the policy is applied.

A decryption policy advanced settings are all ignored on any managed device that runs:

- A version earlier than 7.1
- Snort 2

## Block flows requesting ESNI

Encrypted Server Name Indication (ESNI ([link to draft proposal](#))) is a way for a client to tell a TLS 1.3 server what the client is requesting. Because the SNI is encrypted, you can optionally block these connections because the system cannot determine what the server is.

## Disable HTTP/3 advertisement

This option strips HTTP/3 ([RFC 9114](#)) from the ClientHello in TCP connections. HTTP/3 is part of the QUIC transport protocol, not the TCP transport protocol. Blocking clients from advertising HTTP/3 provides protection against attacks and evasion attempts potentially burried within QUIC connections.

## Propagate untrusted server certificates to clients

This applies only to traffic matching a **Decrypt - Resign** rule action.

Enable this option to substitute the certificate authority (CA) on the managed device for the server's certificate in cases where the server certificate is untrusted. An *untrusted* server certificate is one that is not listed as a trusted CA in the Cisco Security Cloud Control (**Objects > FTD Network Objects, Objects > Object Management > PKI > Trusted CAs**).

## Enable TLS 1.3 Decryption

Whether to apply decryption rules to TLS 1.3 connections. If you do not enable this option, the decryption rules apply to TLS 1.2 or lower traffic only. See [TLS 1.3 Decryption Best Practices, on page 2357](#).

## Enable adaptive TLS server identity probe

Automatically enabled when TLS 1.3 decryption is enabled. A *probe* is a partial TLS connection with the server, the purpose of which is to obtain the server certificate and cache it. (If the certificate is already cached, the probe is never established.)

If TLS 1.3 Server Identity Discovery is disabled on the access control policy with which the decryption policy is associated, we attempt to use the Server Name Indication (SNI), which is not as reliable.

The adaptive TLS server identity probe occurs on any of the following conditions as opposed to on every connection as in earlier releases:

- Certificate Issuer—Matched when the value of **Issuer DNs** in a decryption rule's DN rule condition is matched.  
For more information, see [Distinguished Name \(DN\) Rule Conditions, on page 2378](#).
- Certificate Status—Matched when any of the **Cert Status** conditions are matched in a decryption rule.

For more information, see [Certificate Status Decryption Rule Conditions, on page 2384](#).

- Internal/External Certificate—Internal certificates can be matched by the certificate used in **Decrypt - Known Key** rule actions; external certificates can be matched in **Certificates** rule conditions.

For more information, see [Known Key Decryption \(Incoming Traffic\), on page 2329](#) and [Certificate Decryption Rule Conditions, on page 2377](#).

- Application ID—Can be matched by **Applications** rule conditions in either an access control policy or a decryption policy.

For more information, see [Application Rule Conditions, on page 1065](#).

- URL Category—Can be matched by **URLs** rule conditions in an access control policy.

For more information, see [URL Rule Conditions, on page 1068](#).

---

**Note** **Enable adaptive TLS server discovery mode** is not supported on any Secure Firewall Threat Defense Virtual deployed to AWS. If you have any such managed devices managed by the Cisco Security Cloud Control, the connection event **PROBE\_FLOW\_DROP\_BYPASS\_PROXY** increments every time the device attempts to extract the server certificate.

---

### QUIC Decryption

Whether to apply decryption rules to connections that use the HTTP/3 over the QUIC protocol. When you decrypt QUIC connections, the system can inspect the contents of the sessions for intrusions, malware, or other issues. You can also apply granular control and filtering of decrypted QUIC connections based on specific criteria in the access control policy. QUIC support is in line with RFC 9000, 9001, 9002, 9114, 9204.

Consider the following when implementing QUIC decryption:

- QUIC decryption is not supported on high availability or clustered devices. Multi-instance is supported.
- Rules that apply to QUIC traffic would include the UDP protocol with destination port 443.
- Access control rules that apply to QUIC traffic would include the HTTP/3 or QUIC protocols, either explicitly or by implication.

The following limitations apply to QUIC decryption:

- QUIC decryption applies to Threat Defense 7.6+ only. Devices running a lower release cannot decrypt QUIC connections.
- Connections from browsers using the Chromium stack (Google Chrome, Opera, Edge) cannot be decrypted for outbound traffic. But inbound traffic from the same browsers can be decrypted.
- Connection Migration as described in RFC 9000 is not supported. The concept of Connection ID in QUIC allows endpoints to retain the same connection in the event of address change.
- Key update, session resumption, and QUIC version 2 are not supported.
- Interactive Block and Interactive Block with Reset (in access control rules) is not supported. These actions will work as Block and Block with Reset.

- The active connection-ID per connection is limited to 5. The maximum stream support per connection is limited to 25. If necessary, you can modify these limits using the **system support quic-tuning** and **system support quic-tuning-reset** commands in the device CLI.

## TLS 1.3 Decryption Best Practices

### Recommendation: When to enable advanced options

Both the decryption policy and the access control policy have advanced options that affect how traffic is handled, whether the traffic is being decrypted or not.

The advanced options are:

- Decryption policy:
  - TLS 1.3 decryption
  - TLS adaptive server identity probe
- Access control policy: TLS 1.3 Server Identity Discovery

The access control policy setting takes precedence over the decryption policy setting.

Use the following table to decide which option to enable:

TLS adaptive server identity probe setting (decryption policy)	TLS 1.3 Server Identity Discovery setting (access control policy)	Result	Recommended when
Enabled	Disabled	Adaptive probe sent if decryption policy contains <i>any</i> rule conditions specified in <a href="#">Decryption Policy Advanced Options, on page 2355</a> and if the server certificate is not cached.	<ul style="list-style-type: none"> <li>• You're not using application or URL conditions in access control rules</li> <li>• You're decrypting traffic</li> </ul>
Enabled	Enabled	Probe is always sent if the server certificate is not cached.	Use only if your access control rules have URL or application conditions
Disabled	Enabled	Probe is always sent if the server certificate is not cached.	Not recommended.
Disabled	Disabled	Probe is never sent.	Very limited usefulness; use only if not decrypting traffic and not using application or URL conditions in the access control rule

---

**Note** A cached TLS server's certificate is available to all Snort instances on a particular threat defense. The cache can be cleared with a CLI command and is automatically cleared when the device is rebooted.

---

## CHAPTER 87

# Decryption Rules

The following topics provide an overview of creating, configuring, managing, and troubleshooting decryption rules:

**Note** Because TLS and SSL are often used interchangeably, we use the expression *TLS/SSL* to indicate that either protocol is being discussed. The SSL protocol has been deprecated by the IETF in favor of the more secure TLS protocol, so you can usually interpret *TLS/SSL* as referring to TLS only.

For more information about SSL and TLS protocols, see a resource such as [SSL vs. TLS - What's the Difference?](#)

- [Decryption Rules Overview](#), on page 2359
- [Requirements and Prerequisites for Decryption Rules](#), on page 2359
- [Decryption Rule Guidelines and Limitations](#), on page 2360
- [Decryption Rule Traffic Handling](#), on page 2368
- [Decryption Rule Conditions](#), on page 2372
- [Decryption Rule Actions](#), on page 2390
- [Troubleshoot Decryption Rules](#), on page 2393

## Decryption Rules Overview

*Decryption rules* provide a granular method of handling encrypted traffic across multiple managed devices, whether blocking the traffic without further inspection, not decrypting the traffic and inspecting it with access control, or decrypting the traffic for access control analysis.

## Requirements and Prerequisites for Decryption Rules

### Supported Domains

Any

### User Roles

- Admin

- Access Admin
- Network Admin

## Decryption Rule Guidelines and Limitations

Keep the following points in mind when setting up your decryption rules. Properly configuring decryption rules is a complex task, but one that is essential to building an effective deployment that handles encrypted traffic. Many factors influence how you configure rules, including certain application behavior that you cannot control.

In addition, rules can preempt each other, require additional licenses, or contain invalid configurations. Thoughtfully configured rules can also reduce the resources required to process network traffic. Creating overly complex rules and ordering rules the wrong way can adversely affect performance.

For detailed information, see [Best Practices for Access Control Rules, on page 1823](#).

[SSL Rule Order](#)

## Guidelines for Using TLS/SSL Decryption

### General guideline

Decryption rules require processing overhead that can impact performance. Determine which traffic must be decrypted and subjected to deep inspection before you set up any policies or rules.

You cannot decrypt traffic on a device that has passive or inline tap mode interfaces.

### Guidelines for undecryptable traffic

We can determine that certain traffic is not decryptable either because the website itself is not decryptable or because the website uses TLS/SSL pinning, which effectively prevents users from accessing a decrypted site without errors in their browser.

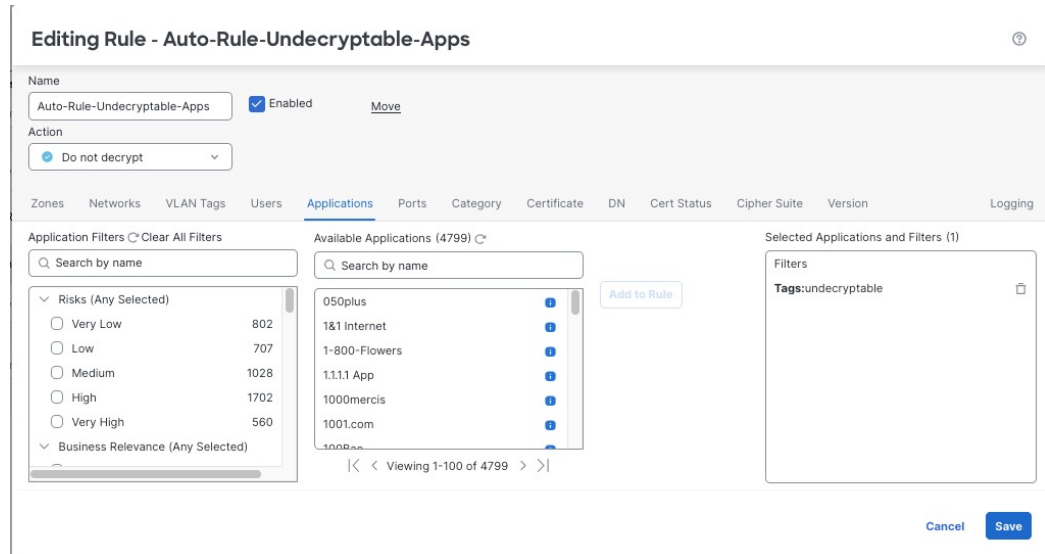

For more information about certificate pinning, see [About TLS/SSL Pinning, on page 2396](#).

We maintain the list of these sites as follows:

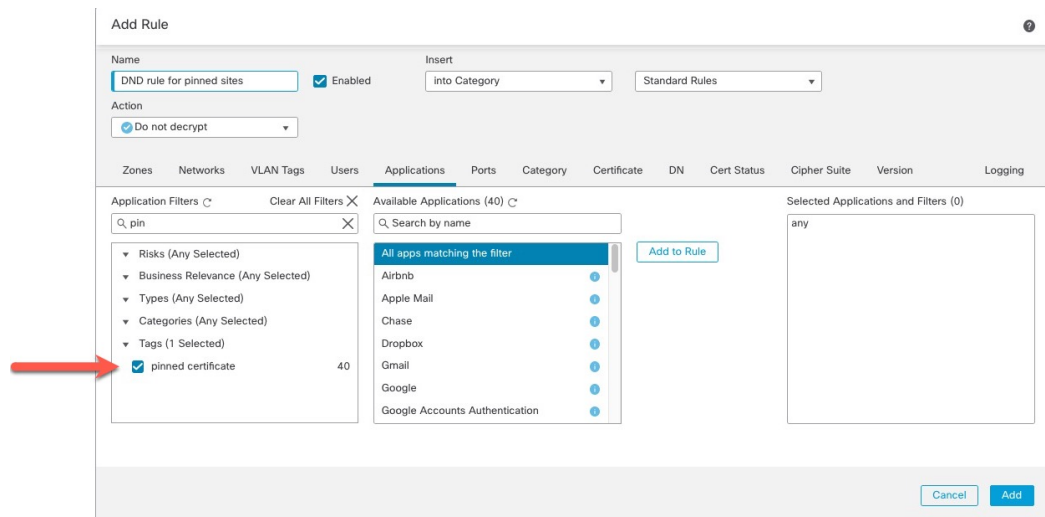

- A Distinguished Name (DN) group named **Cisco-Undecryptable-Sites**
- The **pinned certificate** or **undecryptable** application filter

If you are decrypting traffic and you do not want users to see errors in their browsers when going to these sites, we recommend you set up a **Do Not Decrypt** rule toward the bottom of your decryption rules.

If you use the decryption policy wizard to create a policy for outbound traffic protection, a **Do Not Decrypt** rule for pinned certificates is created for you as the following example shows.

An example of setting up a **pinned certificate** application filter follows.

## Decryption Rule Unsupported Features

### RC4 cipher suite is unsupported

The Rivest Cipher 4 (also referred to as *RC4* or *ARC4*) cipher suite is known to have vulnerabilities and is considered insecure. Decryption policies identify the RC4 cipher suite as unsupported; you should configure the **Unsupported Cipher Suite** action in policy's **Undecryptable Actions** page to match your organization's requirements. For more information, see [Default Handling Options for Undecryptable Traffic, on page 2353](#).

### Passive, inline tap mode, and SPAN interfaces not supported

TLS/SSL traffic cannot be decrypted on passive, inline tap mode, or SPAN interfaces.

## TLS/SSL Do Not Decrypt Guidelines

You should not decrypt traffic if doing so is forbidden by:

- Law; for example, some jurisdictions forbid decrypting financial information
- Company policy; for example, your company might forbid decrypting privileged communications
- Privacy regulations
- Traffic that uses certificate pinning (also referred to as *TLS/SSL pinning*) must remain encrypted to prevent breaking the connection

Encrypted traffic can be allowed or blocked on any decryption rule condition, including, but not limited to:

- Certificate status (for example, expired or invalid certificate)
- Protocol (for example, the nonsecure SSL protocol)
- Network (security zone, IP address, VLAN tag, and so on)
- Exact URL or URL category
- Port
- User group

### Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the [WebMD](#) website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for [WebMD](#) and everything else. General information about decryption rules can be found in [Guidelines for Using TLS/SSL Decryption, on page 2360](#).

**Decrypt** Save Cancel

Default Action												Block	

**Note** Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see [Best Practices for Configuring Application Control, on page 1820](#).

## TLS/SSL Decrypt - Resign Guidelines

You can associate one internal Certificate Authority (CA) certificate and private key with the **Decrypt - Resign** action. If traffic matches this rule, the system re-signs the server certificate with the CA certificate, then acts as a man-in-the-middle. It creates two TLS/SSL sessions, one between client and managed device, one between managed device and server. Each session contains different cryptographic session details, and allows the system to decrypt and reencrypt traffic.

### Best practices

We recommend the following:

- Use the **Decrypt - Resign** rule action for decrypting *outgoing* traffic, as opposed to incoming traffic for which we recommend the **Decrypt - Known Key** rule action.

For more information about **Decrypt - Known Key**, see [TLS/SSL Decrypt - Known Key Guidelines, on page 2365](#).

- Always check the **Replace Key Only** check box when you set up a **Decrypt - Resign** rule action.

When a user browses to a web site that uses a *self-signed* certificate, the user sees a security warning in the web browser and is aware that they are communicating with an insecure site.

When a user browses to a web site that uses a trusted certificate, the user does not see a security warning.

### Details

If you configure a rule with the **Decrypt - Resign** action, the rule matches traffic based on the referenced internal CA certificate's signature algorithm type, in addition to any configured rule conditions. Because you associate one CA certificate with a **Decrypt - Resign** action, you cannot create a decryption rule that decrypts multiple types of outgoing traffic encrypted with different signature algorithms. In addition, any external

certificate objects and cipher suites you add to the rule must match the associated CA certificate encryption algorithm type.

For example, outgoing traffic encrypted with an elliptic curve (EC) algorithm matches a **Decrypt - Resign** rule only if the action references an EC-based CA certificate; you must add EC-based external certificates and cipher suites to the rule to create certificate and cipher suite rule conditions.

Similarly, a **Decrypt - Resign** rule that references an RSA-based CA certificate matches only outgoing traffic encrypted with an RSA algorithm; outgoing traffic encrypted with an EC algorithm does not match the rule, even if all other configured rule conditions match.

### Guidelines and limitations

Also note the following:

#### Anonymous cipher suite unsupported

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see [RFC 5246, appendix F.1.1.1](#). (Replaced for TLS 1.3 by [RFC 8446 appendix C.5](#).)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

#### Do not use Version or Cipher Suite rule conditions

---

**Important** *Never* use either **Cipher Suite** or **Version** rule conditions in a rule with a **Decrypt - Resign** or **Decrypt - Known Key** rule action. The use of these conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

---

#### Decrypt - Resign rule action and a Certificate Signing Request

To use a **Decrypt - Resign** rule action, you should create a Certificate Signing Request (CSR) and have it signed by a trusted certificate authority. (You can use the FMC to create a CSR: **Objects > Object Management > PKI > Internal CAs**.)

To be used in a **Decrypt - Resign** rule, your certificate authority (CA) must have at least one of the following extensions:

- **CA: TRUE**

For more information, see the discussion of Basic Constraints in [RFC3280, section 4.2.1.10](#).

- **KeyUsage=CertSign**

For more information see [RFC 5280, section 4.2.1.3](#).

To verify your CSR or CA has at least one of the preceding extensions, you can use the **openssl** command as discussed in a reference such as the [openssl documentation](#).

This is necessary because for **Decrypt - Resign** inspection to work, the certificate that used in the decryption policy generates certificates on-the-fly and signs them so as to act as man-in-the middle and proxy all TLS/SSL connections.

### Certificate pinning

If the customer's browser uses certificate pinning to verify a server certificate, you cannot decrypt this traffic by re-signing the server certificate. To allow this traffic, configure a decryption rule with the **Do Not Decrypt** action to match the server certificate common name or distinguished name.

### Non-matching cipher suite

The following error is displayed if you attempt to save a decryption rule with a cipher suite that does not match the certificate.

```
Traffic cannot match this rule; none of your selected cipher suites contain a signature algorithm that the resigning CA's signature algorithm
```

### Untrusted Certificate Authority

If the client does not trust the Certificate Authority (CA) used to re-sign the server certificate, it warns the user that the certificate should not be trusted. To prevent this, import the CA certificate into the client trusted CA store. Alternatively, if your organization has a private PKI, you can issue an intermediate CA certificate signed by the root CA which is automatically trusted by all clients in the organization, then upload that CA certificate to the device.

### HTTP proxy limitation

The system cannot decrypt traffic if an HTTP proxy is positioned between a client and your managed device, and the client and server establish a tunneled TLS/SSL connection using the CONNECT HTTP method. The **Handshake Errors** undecryptable action determines how the system handles this traffic.

### Upload signed CA

If you create an internal CA object and choose to generate a certificate signing request (CSR), you cannot use this CA for a **Decrypt - Resign** action until you upload the signed certificate to the object.

### Mismatched signature algorithm

If you configure a rule with the **Decrypt - Resign** action, and mismatch signature algorithm type for one or more external certificate objects or cipher suites, the policy editor displays an **Information** (i) next to the rule. If you mismatch signature algorithm type for all external certificate objects, or all cipher suites, the policy displays a warning icon **Warning** (⚠) next to the rule, and you cannot deploy the access control policy associated with the decryption policy.

## TLS/SSL Decrypt - Known Key Guidelines

When you configure the **Decrypt - Known Key** action, you can associate one or more server certificates and paired private keys with the action. If traffic matches the rule, and the certificate used to encrypt the traffic matches the certificate associated with the action, the system uses the appropriate private key to obtain the session encryption and decryption keys. Because you must have access to the private key, this action is best suited to decrypt traffic incoming to servers your organization controls.

Also note the following:

### Anonymous cipher suite unsupported

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see [RFC 5246, appendix F.1.1.1](#). (Replaced for TLS 1.3 by [RFC 8446 appendix C.5](#).)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

#### Cannot match on Distinguished Name or Certificate

You cannot match on **Distinguished Name** or **Certificate** rule conditions when creating a decryption rule with a **Decrypt - Known Key** action. The assumption is that if this rule matches traffic, the certificate, subject DN, and issuer DN already match the certificate associated with the rule.

#### Do not use Version or Cipher Suite rule conditions

---

**Important** *Never* use either **Cipher Suite** or **Version** rule conditions in a rule with a **Decrypt - Resign** or **Decrypt - Known Key** rule action. The use of these conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

---

#### Elliptic Curve Digital Signature Algorithm (ECDSA) certificate results in blocked traffic

(TLS 1.3 decryption enabled only.) If you use an ECDSA certificate with a **Decrypt - Known Key** rule action, matching traffic will be blocked. To avoid this, use a certificate with another type of certificate.

## TLS/SSL Block Guidelines

If your decryption rule is associated with an access control policy that has a rule with an action of either **Interactive Block** or **Interactive Block with reset**, the system displays a customizable response page.

Provided you enabled logging in your rule, two connection events are displayed (in **Analysis > Events > Connections**): One event for the interactive block and another event to indicate whether or not the user chose to continue to the site or not.

#### Related Topics

[Configure HTTP Response Pages](#), on page 1935

## TLS/SSL Certificate Pinning Guidelines

Some applications use a technique referred to as *TLS/SSL pinning* or *certificate pinning*, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a decryption rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

Because TLS/SSL pinning is used to avoid man-in-the-middle attacks, there is no way to prevent or work around it. We recommend adding a Do Not Decrypt rule before the **Decrypt - Resign** rule so pinning traffic is excluded from being decrypted.

- Create a **Do Not Decrypt** for those applications rule ordered before **Decrypt - Resign** rules.
- Instruct users to access the applications using a web browser.

For more information about rule ordering, see [SSL Rule Order](#).

To determine whether applications are using TLS/SSL pinning, see [Troubleshoot TLS/SSL Pinning, on page 2397](#).

## TLS/SSL Heartbeat Guidelines

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by [RFC6520](#). TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

You can configure a **Max Heartbeat Length** in a Network Analysis Policy (NAP) to determine how to handle TLS heartbeats. For more information, see [The SSL Preprocessor, on page 2863](#).

For more information, see [About TLS Heartbeat, on page 2395](#).

## TLS/SSL Anonymous Cipher Suite Limitation

By nature, anonymous cipher suites are not used for authentication and do not use key exchanges. There are limited uses for anonymous cipher suites; for more information, see [RFC 5246, appendix F.1.1.1](#). (Replaced for TLS 1.3 by [RFC 8446 appendix C.5](#).)

You cannot use the **Decrypt - Resign** or **Decrypt - Known Key** action in the rule because anonymous cipher suites are not used for authentication.

You can add an anonymous cipher suite to the **Cipher Suite** condition in a decryption rule, but the system automatically strips anonymous cipher suites during ClientHello processing. For the system to use the rule, you must also configure your decryption rules in an order that prevents ClientHello processing. For more information, see [SSL Rule Order](#).

## TLS/SSL Normalizer Guidelines

If you enable the **Normalize Excess Payload** option in the inline normalization preprocessor, when the preprocessor normalizes decrypted traffic, it might drop a packet and replace it with a trimmed packet. This does not end the TLS/SSL session. If the traffic is allowed, the trimmed packet is encrypted as part of the TLS/SSL session.

## Other Decryption Rule Guidelines

### Users and groups

If you add a group or user to a rule, then change your realm settings to exclude that group or user, the rule has no effect. (The same applies to disabling the realm.) For more information about realms, see [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).

### Categories in decryption rules

If your decryption policy has a **Decrypt - Resign** action but web sites are not being decrypted, check **Category** page on rules associated with that policy.

In some cases, a web site redirects to another site for authentication or other purposes and the redirected site might have a different URL categorization than the site you're trying to decrypt. For example, `gmail.com` (**Web based email** category) redirects to `accounts.gmail.com` (**Internet Portals** category) for authentication. Be sure to include all relevant categories in the SSL rule.

---

**Note** In order to fully process traffic based on URL category, you must also configure URL filtering. See the [URL Filtering, on page 1919](#) chapter.

---

#### Query for URLs not in the local database

If you create a **Decrypt - Resign** rule and users browse to a web site whose category and reputation are not in the local database, data might not be decrypted. Some web sites are not categorized in the local database and, if not, data from those web sites is not decrypted by default.

You can control this behavior with the setting **System > Integration > Cloud Services**, and check **Query Cisco cloud for unknown URLs**.

For more information about this option, see *Cisco Clouds* in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Decryption Rule Traffic Handling

The system matches traffic to decryption rules in the order you specify. In most cases, the system handles encrypted traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does inspect encrypted and undecryptable traffic with access control. However, some access control rule conditions require unencrypted traffic, so encrypted traffic may match fewer rules. Also, by default, the system disables intrusion and file inspection of encrypted payloads.

The following scenario summarizes the ways that decryption rules handle traffic in an inline deployment.

In this scenario, traffic is evaluated as follows:

- **Undecryptable Traffic Action** evaluates encrypted traffic first. For traffic the system cannot decrypt, the system either blocks it without further inspection or passes it for access control inspection. Encrypted traffic that does not match continues to the next rule.
- **Decryption Rule 1: Monitor** evaluates encrypted traffic next. Monitor rules track and log encrypted traffic but do not affect traffic flow. The system continues to match traffic against additional rules to determine whether to permit or deny it.
- **Decryption Rule 2: Do Not Decrypt** evaluates encrypted traffic third. Matching traffic is not decrypted; the system inspects this traffic with access control, but not file or intrusion inspection. Traffic that does not match continues to the next rule.

- **Decryption Rule 3: Block** evaluates encrypted traffic fourth. Matching traffic is blocked without further inspection. Traffic that does not match continues to the next rule.
- **Decryption Rule 4: Decrypt - Known Key** evaluates encrypted traffic fifth. Matching traffic incoming to your network is decrypted using a private key you upload. The decrypted traffic is then evaluated against access control rules. Access control rules handle decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the decryption rule continues to the next rule.
- **Decryption Rule 5: Decrypt - Resign** is the final rule. If traffic matches this rule, the system re-signs the server certificate with an uploaded CA certificate, then acts as a man-in-the-middle to decrypt traffic. The decrypted traffic is then evaluated against access control rules. Access control rules treat decrypted and unencrypted traffic identically. The system can block traffic as a result of this additional inspection. All remaining traffic is reencrypted before being allowed to the destination. Traffic that does not match the SSL rule continues to the next rule.
- **Decryption policy Default Action** handles all traffic that does not match any of the decryption rules. The default action either blocks encrypted traffic without further inspection or does not decrypt it, passing it for access control inspection.

## Encrypted Traffic Inspection Configuration

You must create reusable public key infrastructure (PKI) objects to control encrypted traffic based on encrypted session characteristics and decrypt encrypted traffic. You can add this information on the fly when uploading trusted certificate authority (CA) certificates to the a decryption policy and creating decryption rule, creating the associated object in the process. However, configuring these objects ahead of time reduces the chance of improper object creation.

### Decrypting Encrypted Traffic with Certificates and Paired Keys

The system can decrypt incoming encrypted traffic if you configure an internal certificate object by uploading the server certificate and private key used to encrypt the session. If you reference that object in a decryption policy rule with an action of **Decrypt - Known Key** and traffic matches that rule, the system uses the uploaded private key to decrypt the session.

The system can also decrypt outgoing traffic if you configure an internal CA object by uploading a CA certificate and private key. If you reference that object in a decryption rule with an action of **Decrypt - Resign** and traffic matches that rule, the system re-signs the server certificate passed to the client browser, then acts as a man-in-the-middle to decrypt the session. You can optionally replace the self-signed certificate key only and not the entire certificate, in which case users see a self-signed certificate key notice in the browser.

### Controlling Traffic Based on Encrypted Session Characteristics

The system can control encrypted traffic based on the cipher suite or server certificate used to negotiate the session. You can configure one of several different reusable objects and reference the object in a decryption rule condition to match traffic. The following table describes the different types of reusable objects you can configure:

If you configure...	You can control encrypted traffic based on whether...
A cipher suite list containing one or more cipher suites	The cipher suite used to negotiate the encrypted session matches a cipher suite in the cipher suite list

If you configure...	You can control encrypted traffic based on whether...
A trusted CA object by uploading a CA certificate your organization trusts	The trusted CA trusts the server certificate used to encrypt the session, whether: <ul style="list-style-type: none"> <li>• The CA issued the certificate directly</li> <li>• The CA issued a certificate to an intermediate CA that issued the server certificate</li> </ul>
An external certificate object by uploading a server certificate	The server certificate used to encrypt the session matches the uploaded server certificate
A distinguished name object containing a certificate subject or issuer distinguished name	The subject or issuer common name, country, organization, or organizational unit on the certificate used to encrypt the session matches the configured distinguished name

[PKI](#), on page 1500

## Decryption Rule Order Evaluation

When you create the decryption rule in a decryption policy, you specify its position using the **Insert** list in the rule editor. Decryption rules in a decryption policy are numbered, starting at 1. The system matches traffic to decryption rules in top-down order by ascending rule number.

In most cases, the system handles network traffic according to the *first* decryption rule where *all* the rule's conditions match the traffic. Except in the case of Monitor rules (which log traffic but do not affect traffic flow), the system does *not* continue to evaluate traffic against additional, lower-priority rules after that traffic matches a rule. Conditions can be simple or complex; you can control traffic by security zone, network or geographical location, VLAN, port, application, requested URL, user, certificate, certificate distinguished name, certificate status, cipher suite, or encryption protocol version.

Each rule also has an *action*, which determines whether you monitor, block, or inspect matching encrypted or decrypted traffic with access control. Note that the system does *not* further inspect encrypted traffic it blocks. It does subject encrypted and undecryptable traffic to access control. However, access control rule conditions require unencrypted traffic, so encrypted traffic matches fewer rules.

Rules that use *specific* conditions (such as network and IP addresses) should be ordered *before* rules that use general conditions (such as applications). If you're familiar with the Open Systems Interconnect (OSI) model, use similar numbering in concept. Rules with conditions for layers 1, 2, and 3 (physical, data link, and network) should be ordered first in your rules. Conditions for layers 5, 6, and 7 (session, presentation, and application) should be ordered later in your rules. For more information about the OSI model, see this [Wikipedia article](#).

---

**Tip** Proper decryption rule order reduces the resources required to process network traffic, and prevents rule preemption. Although the rules you create are unique to every organization and deployment, there are a few general guidelines to follow when ordering rules that can optimize performance while still addressing your needs.

---

In addition to ordering rules by number, you can group rules by category. By default the system provides three categories: Administrator, Standard, and Root. You can add custom categories, but you cannot delete the system-provided categories or change their order.

[SSL Rule Order](#)

## Decryption Rule Conditions

A decryption rule's conditions identify the type of encrypted traffic the rule handles. Conditions can be simple or complex, and you can specify more than one condition type per rule. Only if traffic meets all the conditions in a rule does the rule apply to the traffic.

If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion. For example, a rule with a certificate condition but no version condition evaluates traffic based on the server certificate used to negotiate the session, regardless of the session SSL or TLS version.

Every decryption rule has an associated action that determines the following for matching encrypted traffic:

- **Handling:** Most importantly, the rule action governs whether the system will monitor, trust, block, or decrypt encrypted traffic that matches the rule's conditions
- **Logging:** The rule action determines when and how you can log details about matching encrypted traffic.

Your TLS/SSL inspection configuration handles, inspects, and logs decrypted traffic:

- The decryption policy's undecryptable actions handle traffic that the system cannot decrypt.
- The policy's default action handles traffic that does not meet the condition of any non-Monitor decryption rule.

You can log a connection event when the system blocks or trusts an encrypted session. You can also force the system to log connections that it decrypts for further evaluation by access control rules, regardless of how the system later handles or inspects the traffic. Connection logs for encrypted sessions contain details about the encryption, such as the certificate used to encrypt that session. You can log only end-of-connection events, however:

- For blocked connections (Block, Block with reset), the system immediately ends the sessions and generates an event
- For Do Not Decrypt connections, the system generates an event when the session ends

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

**Caution**

Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

[Server Certificate-Based Decryption Rule Conditions](#), on page 2377

## Security Zone Rule Conditions

Security zones segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices.

Zone rule conditions control traffic by its source and destination security zones. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

Just as all interfaces in a zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

**Tip**

Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

## Network Rule Conditions

Network rule conditions control traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

---

**Note** You *cannot* use FDQN network objects in identity rules.

---

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

## VLAN Tags Rule Conditions

---

**Note** VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

---

VLAN rule conditions control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic. The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note the following Q-in-Q support:

- Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

## User Rule Conditions

User rule conditions match traffic based the user who initiates the connection, or the group to which the user belongs. For example, you could configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in [Associating Other Policies with Access Control, on page 1844](#).

In addition to configuring users and groups for configured realms, you can set policies for the following Special Identities users:

- Failed Authentication: User that failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.

- Unknown: Users that cannot be identified; for example, users that are not downloaded by a configured realm.

## Application Rule Conditions

When the system analyzes IP traffic, it can identify and classify the commonly used applications on your network. This discovery-based *application awareness* is the basis for *application control*—the ability to control application traffic.

System-provided *application filters* help you perform application control by organizing applications according to basic characteristics: type, risk, business relevance, category, and tags. You can create reusable user-defined filters based on combinations of the system-provided filters, or on custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled for an application, the system automatically enables all system-provided detectors for the application; if none exist, the system enables the most recently modified user-defined detector for the application. For more information about application detectors, see [Application Detector Fundamentals, on page 2660](#).

You can use both application filters and individually specified applications to ensure complete coverage. However, understand the following note before you order your access control rules.

### Benefits of Application Filters

Application filters help you quickly configure application control. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

### Application Characteristics

The system characterizes each application that it detects using the criteria described in the following table. Use these characteristics as application filters.

**Table 220: Application Characteristics**

Characteristic	Description	Example
Type	Application protocols represent communications between hosts. Clients represent software running on a host. Web applications represent the content or requested URL for HTTP traffic.	HTTP and SSH are application protocols. Web browsers and email clients are clients. MPEG video and Facebook are web applications.
Risk	The likelihood that the application is being used for purposes that might be against your organization's security policy.	Peer-to-peer applications tend to have a very high risk.
Business Relevance	The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.	Gaming applications tend to have a very low business relevance.

Characteristic	Description	Example
Category	A general classification for the application that describes its most essential function. Each application belongs to at least one category.	Facebook is in the social networking category.
Tag	Additional information about the application. Applications can have any number of tags, including none.	Video streaming web applications often are tagged <code>high bandwidth</code> and <code>displays ads</code> .

### Related Topics

[Best Practices for Configuring Application Control](#), on page 1820

## Port Rule Conditions

Port conditions allow you to control traffic by its source and destination ports.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

### Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic.

Application filtering is also recommended for applications, like threat defense, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

### Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

## Category Rule Conditions

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security.

For more information, see [URL Filtering Overview, on page 1919](#).

If you are using category rule conditions in decryption policies in a rule with the **Do Not Decrypt** rule action, see [Decryption Rule Do Not Decrypt Action, on page 2391](#).

## Server Certificate-Based Decryption Rule Conditions

decryption rules can handle and decrypt encrypted traffic based on server certificate characteristics. You can configure decryption rules based on the following server certificate attributes:

- Distinguished name conditions allow you to handle and inspect encrypted traffic based on the CA that issued a server certificate, or the certificate holder. Based on the issuer distinguished name, you can handle traffic based on the CA that issued a site's server certificate.
- Certificate conditions in decryption rules allow you to handle and inspect encrypted traffic based on the server certificate used to encrypt that traffic. You can configure a condition with one or more certificates; traffic matches the rule if the certificate matches any of the condition's certificates.
- Certificate status conditions in decryption rules allow you to handle and inspect encrypted traffic based on the status of the server certificate used to encrypt the traffic, including whether a certificate is valid, revoked, expired, not yet valid, self-signed, signed by a trusted CA, whether the Certificate Revocation List (CRL) is valid; whether the Server Name Indication (SNI) in the certificate matches the server in the request.
- Cipher suite conditions in decryption rules allow you to handle and inspect encrypted traffic based on the cipher suite used to negotiate the encrypted session.
- Session conditions in decryption rules allow you to inspect encrypted traffic based on the SSL or TLS version used to encrypt the traffic.

To detect multiple cipher suites in a rule, the certificate issuer, or the certificate holder, you can create reusable cipher suite list and distinguished name objects and add them to your rule. To detect the server certificate and certain certificate statuses, you must create external certificate and external CA objects for the rule.

## Certificate Decryption Rule Conditions

When you build a certificate-based decryption rule condition, you can upload a server certificate; you save the certificate as an external certificate *object*, which is reusable and associates a name with a server certificate. Alternately, you can configure certificate conditions with existing external certificate objects and object groups.

You can search the **Available Certificates** field in the rule condition based for external certificate objects and object groups based on the following certificate distinguished name characteristics:

- Subject or issuer common name (CN), or if the URL is contained in the certificate's [Subject Alternative Name \(SAN\)](#)
  - The URL the user enters in the browser matches the Common Name (CN)
- Subject or issuer organization (O)
- Subject or issuer organizational unit (OU)

You can choose to match against multiple certificates in a single certificate rule condition; if the certificate used to encrypt the traffic matches any of the uploaded certificates, the encrypted traffic matches the rule.

You can add a maximum of 50 external certificate objects and external certificate object groups to the **Selected Certificates** in a single certificate condition.

Note the following:

- You cannot configure a certificate condition if you also select the **Decrypt - Known Key** action. Because that action requires you to select a server certificate to decrypt traffic, the implication is that the certificate already matches the traffic.
- If you configure a certificate condition with an external certificate object, any cipher suites you add to a cipher suite condition, or internal CA objects you associate with the **Decrypt - Resign** action, must match the external certificate's signature algorithm type. For example, if your rule's certificate condition references an EC-based server certificate, any cipher suites you add, or CA certificates you associate with the **Decrypt - Resign** action, must also be EC-based. If you mismatch signature algorithm types in this case, the policy editor displays a warning next to the rule.
- The first time the system detects an encrypted session to a new server, certificate data is not available for ClientHello processing, which can result in an undecrypted first session. After the initial session, the managed device caches data from the server Certificate message. For subsequent connections from the same client, the system can match the ClientHello message conclusively to rules with certificate conditions and process the message to maximize decryption potential.

## Distinguished Name (DN) Rule Conditions

This topic discusses how to use distinguished name conditions in a decryption rule. If you're not sure, you can find a certificate's [Subject Alternative Name \(SAN\)](#) and Common Name using a web browser, then you can add those values to a decryption rule as distinguished name conditions.

For detailed information about SANs, see [RFC 528, section 4.2.1.6](#).

The following sections discuss:

- [DN rule matching example](#)
- [How the system uses the SNI and SANs](#)
- [How to find a certificate's Common Name and subject alternative names](#)
- [How to add a DN rule condition](#)

### DN rule matching example

Following is an example of DN rule conditions in a Do Not Decrypt rule. Suppose you want to make sure to *not* decrypt traffic going to `amp.cisco.com` or to YouTube. You could set up your DN conditions as follows:

**Add Rule**

Name:   Enabled

Action:

Zones Networks VLAN Tags Users Applications Ports Category Certificate **DN** Cert Status Cipher Suite Version Logging

Available DNs

- Cisco-Undecryptable-Sites
- CN\_api.smarthings.com
- CN\_apps.apple.com
- CN\_ciscospark.com
- CN\_citrixonline.com
- CN\_core.windows.net
- CN\_data.microsoft.com
- CN\_data.toolbar.yahoo.com

Subject DNs (4)

- CN=\*.amp.cisco.com
- CN=\*.amp.cisco.com
- CN=\*.youtube.com
- CN=\*.yt.be

Issuer DNs (0)

- any

Enter DN or CN   Enter DN or CN

The preceding DN rule conditions would match the following URLs and therefore, the traffic would be undecrypted an earlier rule prevented it:

- www.amp.cisco.com
- auth.amp.cisco.com
- auth.us.amp.cisco.com
- www.youtube.com
- kids.youtube.com
- www.yt.be

The preceding DN rule conditions would *not* match any of the following URLs and therefore, the traffic would not match the Do Not Decrypt rule but might match any other decryption rules in the same decryption policy.

- amp.cisco.com
- youtube.com
- yt.be

To match any of the preceding host names, add more CNs to the rule (for example, adding `CN=yt.be` would match that URL.)

### How the system uses the SNI and SANs

The host name portion of the URL in the client request is the [Server Name Indication \(SNI\)](#). The client specifies which hostname they want to connect to (for example, `auth.amp.cisco.com`) using the SNI extension in the TLS handshake. The server then selects the corresponding private key and certificate chain that are required to establish the connection while hosting all certificates on a single IP address.

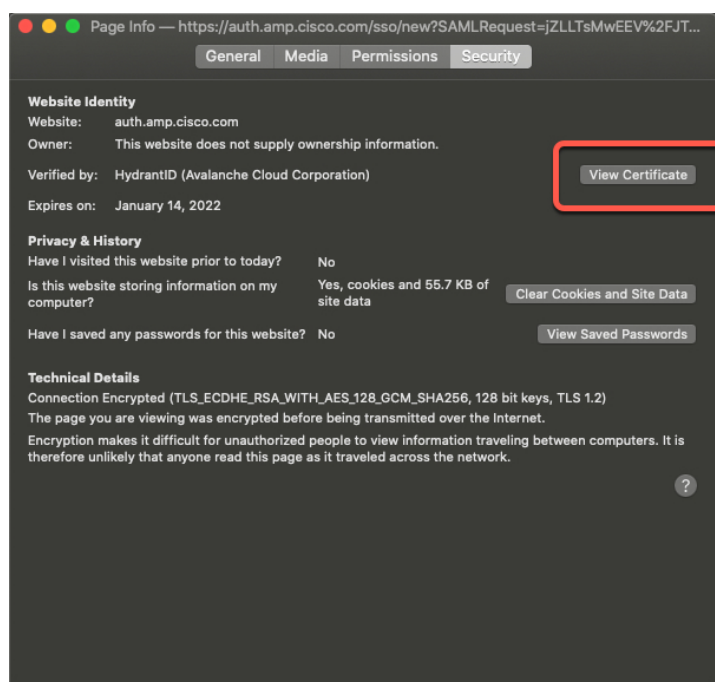

If there's a match between the SNI and the CN or a SAN in the certificate, we use the SNI when comparing against the DNs listed in the rule. If there is no SNI or if it doesn't match the certificate, we use the certificate's CN when comparing against the DNs listed in the rule.

## How to find a certificate's Common Name and subject alternative names

To find any certificate's Common Name, use the following steps. You can even use these steps to find the common name and SANs for a self-signed certificate.

These steps are for Firefox but other browsers are similar. The following procedure uses `amp.cisco.com` as an example.

1. Browse to `amp.cisco.com` in Firefox.
2. In the browser's location bar, to the left of the URL, click .
3. Click **Connection secure** > **More Information**.  
(For a non-secure or self-signed certificate, click **Connection not secure** > **More Information**.)
4. On the Page Info dialog box, click **View Certificate**.

5. The next page shows certificate details.

Certificate	
amp.cisco.com      HydrantID SSL CA G3      QuoVadis Root CA 2	
<b>Subject Name</b>	
Country	US
State/Province	California
Locality	San Jose
Organization	Cisco Systems, Inc.
Common Name	amp.cisco.com
<b>Issuer Name</b>	
Country	US
Organization	HydrantID (Avalanche Cloud Corporation)
Common Name	HydrantID SSL CA G3
<b>Validity</b>	
Not Before	Thu, 14 Jan 2021 21:24:29 GMT
Not After	Fri, 14 Jan 2022 21:34:00 GMT
<b>Subject Alt Names</b>	
DNS Name	amp.cisco.com
DNS Name	android.amp.cisco.com
DNS Name	apde.amp.cisco.com
DNS Name	api-docs.amp.cisco.com
DNS Name	api-visibility.amp.cisco.com
DNS Name	api.amp.cisco.com
DNS Name	auth.amp.cisco.com

Note the following:

- `CN=auth.amp.cisco.com`, if used as a DN rule condition, would match *only* that host name (that is, SNI). The SNI `amp.cisco.com` would *not* match.
- To match as many domain name fields as possible, use wildcards.  
For example, to match `auth.amp.cisco.com`, use `CN=*.amp.cisco.com`. To match `auth.us.amp.cisco.com`, use `CN=*.*.amp.cisco.com`.  
A DN like `CN=*.example.com` matches `www.example.com` but *not* `example.com`. To match both SNIs, use two DNs in the rule condition.
- Don't go overboard with wildcards though. For example, a DN object like `CN=*.google.com` matches a very large number of SANs. Instead of `CN=*.google.com`, use a DN object like `CN=*.youtube.com` as the DN object so it matches names like `www.youtube.com`.  
You can also use variations of the SNI that match SANs like `CN=*.youtube.com`, `CN=youtu.be`, `CN=*.yt.be`, and so on.
- A self-signed certificate should work the same way. You can confirm it's a self-signed certificate by the fact the issuer DN is the same as the subject DN.

### How to add a DN rule condition

After you know the CN you want to match, edit the decryption rule in one of the following ways:

- Use an existing DN.

Click the name of a DN and then click either **Add to Subject** or **Add to Issuer**. (**Add to Subject** is much more common.) To view the value of a DN object, hover the mouse pointer over it.)

Add Rule ?

Name   Enabled Insert into Category Standard Rules

## Related Topics

[Distinguished Name](#), on page 1479

## Trusting External Certificate Authorities

You can trust CAs by adding root and intermediate CA certificates to your decryption policy, then use these trusted CAs to verify server certificates used to encrypt traffic.

If a trusted CA certificate contains an uploaded certificate revocation list (CRL), you can also verify whether a trusted CA revoked the encryption certificate.

**Tip** Upload all certificates in a root CA's chain of trust to the list of trusted CA certificates, including the root CA certificate and all intermediate CA certificates. Otherwise, it is more difficult to detect trusted certificates issued by intermediate CAs. Also, if you configure certificate status conditions to trust traffic based on the root issuer CA, all traffic within a trusted CA's chain of trust can be allowed without decryption, rather than unnecessarily decrypting it.

For more information, see [Trusted CA Object, on page 1506](#).

**Note** When you create a decryption policy, the policy's **Trusted CA Certificate** tab page is populated with several trusted CA certificates, including the **Cisco-Trusted-Authorities** group, which is added to the **Select Trusted CAs** list.

### Procedure

- 
- Step 1** Click **Policies > Access Control > Decryption**.
- Step 2** Click **Edit** (✎) next to the decryption policy to edit.
- Step 3** Click **Add Rule** to add a new decryption rule or click **Edit** (✎) to edit an existing rule.
- Step 4** Click the **Certificates** tab.
- Step 5** Find the trusted CAs you want to add from the **Available Certificates**, as follows:
- To add a trusted CA object on the fly, which you can then add to the condition, click **Add** (+) above the **Available Certificates** list.
  - To search for trusted CA objects and groups to add, click the **Search by name or value** prompt above the **Available Certificates** list, then enter either the name of the object, or a value in the object. The list updates as you type to display matching objects.
- Step 6** To select an object, click it. To select all objects, right-click and then **Select All**.
- Step 7** Click **Add to Rule**.
- Tip** You can also drag and drop selected objects.
- Step 8** Add or continue editing the rule.
-

**What to do next**

- Add a certificate status decryption rule condition to your SSL rule. See [Matching Traffic on Certificate Status](#) for more information.
- Deploy configuration changes.

**Certificate Status Decryption Rule Conditions**

For each certificate status decryption rule you configure, you can match traffic against the presence or absence of a given status. You can select several statuses in one rule condition; if the certificate matches any of the selected statuses, the rule matches the traffic.

You can choose to match against the presence or absence of multiple certificate statuses in a single certificate status rule condition; the certificate needs to match only one of the criteria to match the rule.

You should consider, when setting this parameter, whether you're configuring a decrypt rule or a block rule. Typically, you should click **Yes** for a block rule and **No** for a decrypt rule. Examples:

- If you're configuring a **Decrypt - Resign** rule, the default behavior is to decrypt traffic with an expired certificate. To change that behavior, click **No** for **Expired** so traffic with an expired certificate is not decrypted and resigned.
- If you're configuring a **Block** rule, the default behavior is to allow traffic with an expired certificate. To change that behavior click **Yes** for **Expired** so traffic with an expired certificate is blocked.

The following table describes how the system evaluates encrypted traffic based on the encrypting server certificate's status.

**Table 221: Certificate Status Rule Condition Criteria**

Status Check	Status Set to Yes	Status Set to No
Revoked	The policy trusts the CA that issued the server certificate, and the CA certificate uploaded to the policy contains a CRL that revokes the server certificate.	The policy trusts the CA that issued the server certificate, and the CA certificate uploaded to the policy does not contain a CRL that revokes the server certificate.
Self-signed	The detected server certificate contains the same subject and issuer distinguished name.	The detected server certificate contains different subject and issuer distinguished names.

Status Check	Status Set to Yes	Status Set to No
Valid	All of the following are true: <ul style="list-style-type: none"> <li>• The policy trusts the CA that issued the certificate.</li> <li>• The signature is valid.</li> <li>• The issuer is valid.</li> <li>• None of the policy's trusted CAs revoked the certificate.</li> <li>• The current date is between the certificate Valid From and Valid To date.</li> </ul>	At least one of the following is true: <ul style="list-style-type: none"> <li>• The policy does not trust the CA that issued the certificate.</li> <li>• The signature is invalid.</li> <li>• The issuer is invalid.</li> <li>• A trusted CA in the policy revoked the certificate.</li> <li>• The current date is before the certificate Valid From date.</li> <li>• The current date is after the certificate Valid To date.</li> </ul>
Invalid signature	The certificate's signature cannot be properly validated against the certificate's content.	The certificate's signature is properly validated against the certificate's content.
Invalid issuer	The issuer CA certificate is not stored in the policy's list of trusted CA certificates.	The issuer CA certificate is stored in the policy's list of trusted CA certificates.
Expired	The current date is after the certificate Valid To date.	The current date is before or on the certificate Valid To date.
Not yet valid	The current date is before the certificate Valid From date.	The current date is after or on the certificate Valid From date.

Status Check	Status Set to Yes	Status Set to No
Invalid certificate	<p>The certificate is not valid. At least one of the following is true:</p> <ul style="list-style-type: none"> <li>• Invalid or inconsistent certificate extension; that is, a certificate extension had an invalid value (for example, an incorrect encoding) or some value inconsistent with other extensions.</li> <li>• The certificate cannot be used for the specified purpose.</li> <li>• The Basic Constraints path length parameter has been exceeded.</li> </ul> <p>For more information, see <a href="#">RFC 5280, section 4.2.1.9</a>.</p> <ul style="list-style-type: none"> <li>• The certificate's value for Not Before or Not After is invalid. These dates can be encoded as UTCTime or GeneralizedTime</li> </ul> <p>For more information, see <a href="#">RFC 5280 section 4.1.2.5</a>.</p> <ul style="list-style-type: none"> <li>• The format of the name constraint is not recognized; for example, an email address format of a form not mentioned in <a href="#">RFC 5280, section 4.2.1.10</a>. This could be caused by an improper extension or some new feature not currently supported.</li> </ul> <p>An unsupported name constraint type was encountered. OpenSSL currently supports only directory name, DNS name, email, and URI types.</p> <ul style="list-style-type: none"> <li>• The root certificate authority is not trusted for the specified purpose.</li> <li>• The root certificate authority rejects the specified purpose.</li> </ul>	<p>The certificate is valid. All of the following:</p> <ul style="list-style-type: none"> <li>• Valid certificate extension.</li> <li>• The certificate can be used for the specified purpose.</li> <li>• Valid Basic Constraints path length.</li> <li>• Valid values for Not Before and Not After.</li> <li>• Valid name constraint.</li> <li>• The root certificate is trusted for the specified purpose.</li> <li>• The root certificate accepts the specified purpose.</li> </ul>

Status Check	Status Set to Yes	Status Set to No
Invalid CRL	The <a href="#">Certificate Revocation List (CRL)</a> digital signature is not valid. At least one of the following is true: <ul style="list-style-type: none"> <li>The value of the CRL's Next Update or Last Update field is invalid.</li> <li>The CRL is not yet valid.</li> <li>The CRL has expired.</li> <li>An error occurred when attempting to verify the CRL path. This error occurs only if extended CRL checking is enabled.</li> <li>CRL could not be found.</li> <li>The only CRLs that could be found did not match the scope of the certificate.</li> </ul>	The CRL is valid. All of the following: <ul style="list-style-type: none"> <li>Next Update and Last Update fields</li> <li>The CRL's date is valid.</li> <li>The path is valid.</li> <li>The CRL was found.</li> <li>The CRL matches the certificate's</li> </ul>
Server mismatch	The server name does not match the server's <a href="#">Server Name Indication (SNI)</a> name, which could indicate an attempt to spoof the server name.	The server name matches the SNI name to which the client is requesting access

Note that even though a certificate might match more than one status, the rule causes an action to be taken on the traffic only once.

Checking whether a CA issued or revoked a certificate requires uploading root and intermediate CA certificates and associated CRLs as objects. You then add these trusted CA objects to an decryption policy's list of trusted CA certificates.

## Cipher Suite Decryption Rule Conditions

The system provides predefined cipher suites you can add to a cipher suite rule condition for Block or Block with Reset rule actions. You can also add cipher suite list objects containing multiple cipher suites.

**Important** Cipher suite rule conditions should be used only to *block* traffic, they should not be used to *decrypt* traffic.

**Note** You cannot add new cipher suites. You can neither modify nor delete predefined cipher suites.

You can add a maximum of 50 cipher suites and cipher suite lists to the **Selected Cipher Suites** in a single cipher suite condition. The system supports adding the following cipher suites to a cipher suite condition:

- SSL\_RSA\_FIPS\_WITH\_3DES\_EDE\_CBC\_SHA
- SSL\_RSA\_FIPS\_WITH\_DES\_CBC\_SHA
- TLS\_DHE\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA

- TLS\_DHE\_RSA\_WITH\_AES\_128\_CBC\_SHA
- TLS\_DHE\_RSA\_WITH\_AES\_128\_CBC\_SHA256
- TLS\_DHE\_RSA\_WITH\_AES\_128\_GCM\_SHA256
- TLS\_DHE\_RSA\_WITH\_AES\_256\_CBC\_SHA
- TLS\_DHE\_RSA\_WITH\_AES\_256\_CBC\_SHA256
- TLS\_DHE\_RSA\_WITH\_AES\_256\_GCM\_SHA384
- TLS\_DHE\_RSA\_WITH\_CAMELLIA\_128\_CBC\_SHA
- TLS\_DHE\_RSA\_WITH\_CAMELLIA\_128\_CBC\_SHA256
- TLS\_DHE\_RSA\_WITH\_CAMELLIA\_256\_CBC\_SHA
- TLS\_DHE\_RSA\_WITH\_CAMELLIA\_256\_CBC\_SHA256
- TLS\_DHE\_RSA\_WITH\_DES\_CBC\_SHA
- TLS\_DH\_Annon\_WITH\_AES\_128\_GCM\_SHA256
- TLS\_DH\_Annon\_WITH\_AES\_256\_GCM\_SHA384
- TLS\_DH\_Annon\_WITH\_CAMELLIA\_128\_CBC\_SHA
- TLS\_DH\_anon\_WITH\_CAMELLIA\_128\_CBC\_SHA256
- TLS\_DH\_Annon\_WITH\_CAMELLIA\_256\_CBC\_SHA
- TLS\_DH\_anon\_WITH\_CAMELLIA\_256\_CBC\_SHA256
- TLS\_ECDHE\_ECDSA\_WITH\_3DES\_EDE\_CBC\_SHA
- TLS\_ECDHE\_ECDSA\_WITH\_AES\_128\_CBC\_SHA
- TLS\_ECDHE\_ECDSA\_WITH\_AES\_128\_CBC\_SHA256
- TLS\_ECDHE\_ECDSA\_WITH\_AES\_128\_GCM\_SHA256
- TLS\_ECDHE\_ECDSA\_WITH\_AES\_256\_CBC\_SHA
- TLS\_ECDHE\_ECDSA\_WITH\_AES\_256\_CBC\_SHA384
- TLS\_ECDHE\_ECDSA\_WITH\_AES\_256\_GCM\_SHA384
- TLS\_ECDHE\_ECDSA\_WITH\_NULL\_SHA
- TLS\_ECDHE\_ECDSA\_WITH\_RC4\_128\_SHA
- TLS\_ECDHE\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA
- TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA
- TLS\_ECDHE\_RSA\_WITH\_AES\_128\_CBC\_SHA256
- TLS\_ECDHE\_RSA\_WITH\_AES\_128\_GCM\_SHA256
- TLS\_ECDHE\_RSA\_WITH\_AES\_256\_CBC\_SHA
- TLS\_ECDHE\_RSA\_WITH\_AES\_256\_CBC\_SHA384

- TLS\_ECDHE\_RSA\_WITH\_AES\_256\_GCM\_SHA384
- TLS\_ECDHE\_RSA\_WITH\_NULL\_SHA
- TLS\_ECDHE\_RSA\_WITH\_RC4\_128\_SHA
- TLS\_RSA\_WITH\_3DES\_EDE\_CBC\_SHA
- TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA
- TLS\_RSA\_WITH\_AES\_128\_CBC\_SHA256
- TLS\_RSA\_WITH\_AES\_128\_GCM\_SHA256
- TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA
- TLS\_RSA\_WITH\_AES\_256\_CBC\_SHA256
- TLS\_RSA\_WITH\_AES\_256\_GCM\_SHA384
- TLS\_RSA\_WITH\_CAMELLIA\_128\_CBC\_SHA
- TLS\_RSA\_WITH\_CAMELLIA\_128\_CBC\_SHA256
- TLS\_RSA\_WITH\_CAMELLIA\_256\_CBC\_SHA
- TLS\_RSA\_WITH\_CAMELLIA\_256\_CBC\_SHA256
- TLS\_RSA\_WITH\_DES\_CBC\_SHA
- TLS\_RSA\_WITH\_NULL\_MD5
- TLS\_RSA\_WITH\_NULL\_SHA
- TLS\_RSA\_WITH\_RC4\_128\_MD5
- TLS\_RSA\_WITH\_RC4\_128\_SHA

Note the following:

- If you add cipher suites not supported for your deployment, you cannot deploy your configuration. For example, passive deployments do not support decrypting traffic with any of the ephemeral Diffie-Hellman (DHE) or ephemeral elliptic curve Diffie-Hellman (ECDHE) cipher suites. Creating a rule with these cipher suites prevents you from deploying your access control policy.
- You can add an anonymous cipher suite to the **Cipher Suite** condition in decryption policy to use the rule, you must also configure your in an order that prevents ClientHello processing. For more information, see [SSL Rule Order](#).
- When specifying a cipher suite as a rule condition, consider that the rule matches on the negotiated cipher suite in the ServerHello message, rather than on the full list of cipher suites specified in the ClientHello message. During ClientHello processing, the managed device strips unsupported cipher suites from the ClientHello message. However, if this results in all specified cipher suites being stripped, the system retains the original list. If the system retains unsupported cipher suites, subsequent evaluation results in an undecrypted session.

## Encryption Protocol Version Decryption Rule Conditions

You can choose to match against traffic encrypted with SSL version 3.0, or TLS version 1.0, 1.1, or 1.2. By default, all protocol versions are selected when you create a rule; if you select multiple versions, encrypted traffic that matches any of the selected versions matches the rule. You must select at least one protocol version when saving the rule condition.

You can use SSL 3.0 in a Do Not Decrypt, Block, or Block with Reset rule action.

You *cannot* select SSL v2.0 in a version rule condition; the system does not support decrypting traffic encrypted with SSL version 2.0. You can configure an undecryptable action to allow or block this traffic without further inspection. For more information, see [Set Default Handling for Undecryptable Traffic, on page 2354](#).

**Important** Protocol version rule conditions should be used *only* to *block* traffic, they should not be used to *decrypt* traffic.

For example, to block all SSL v3.0, TLS v1.0, TLS v1.1, and TLS v1.2 traffic, set the options as follows:

**Add Rule**

Name: Block old versions  Enabled Insert: below rule 3

Action: Block

Zones Networks VLAN Tags Users Applications Ports Category Certificate DN Cert Status Cipher Suite **Version** Logging

- SSL v3.0
- TLS v1.0
- TLS v1.1
- TLS v1.2
- TLS v1.3

[Revert to Defaults](#) Cancel **Add**

## Decryption Rule Actions

The following sections discuss the actions available with Decryption rules.

### Decryption Rule Monitor Action

The **Monitor** action is not designed to permit or deny traffic. Rather, its primary purpose is to force connection logging, regardless of how matching traffic is eventually handled. The ClientHello message is not modified if traffic matches a **Monitor** rule condition.

Traffic is then matched against additional rules, if present, to determine whether to trust, block, or decrypt it. The first non-Monitor rule matched determines traffic flow and any further inspection. If there are no additional matching rules, the system uses the default action.

Because the primary purpose of Monitor rules is to track network traffic, the system automatically logs end-of-connection events for monitored traffic to the Cisco Security Cloud Control database, regardless of the logging configuration of the rule or default action that later handles the connection.

## Decryption Rule Do Not Decrypt Action

The **Do Not Decrypt** action passes encrypted traffic for evaluation by the access control policy's rules and default action. Because some access control rule conditions require unencrypted traffic, this traffic might match fewer rules. The system cannot perform deep inspection on encrypted traffic, such as intrusion or file inspection.

Typical reasons for a **Do Not Decrypt** rule action include:

- When decrypting TLS/SSL traffic is prohibited by law.
- Sites you know you can trust.
- Sites you can disrupt by inspecting traffic (such as Windows Update).
- To view the values of TLS/SSL fields using connection events. (You do not need to decrypt traffic to view connection event fields.)

For more information, see [Default Handling Options for Undecryptable Traffic, on page 2353](#)

### Limitations of categories in Do Not Decrypt rules

You can optionally choose to include categories in your decryption policies. These categories, also referred to as *URL filtering*, are updated by the Cisco Talos intelligence group. Updates are based on machine learning and human analysis according to content that is retrievable from the website destination and sometimes from its hosting and registration information. Categorization is *not* based on the declared company vertical, intent, or security. While we strive to continuously update and improve URL filtering categories, it is not an exact science. Some websites are not categorized at all and it's possible some websites might be improperly categorized.

Avoid overusing categories in do not decrypt rules to avoid decrypting traffic without a reason; for example, the Health and Medicine category includes the [WebMD](#) website, which does not threaten patient privacy.

Following is a sample decryption policy that can prevent decryption for websites in the Health and Medicine categories but allows decryption for [WebMD](#) and everything else. General information about decryption rules can be found in [Guidelines for Using TLS/SSL Decryption, on page 2360](#).

**Note** Don't confuse URL filtering with application detection, which relies on reading some of the packet from a website to determine more specifically what it is (for example, Facebook Message or Salesforce). For more information, see [Best Practices for Configuring Application Control, on page 1820](#).

## Decryption Rule Blocking Actions

The system provides the following decryption rule actions for traffic you do not want to pass through the system:

- **Block** to terminate the connection, resulting in an error in the client browser.

The error message does not indicate the site was blocked due to policy. Instead, errors might indicate that there are no common encryption algorithms. It is not obvious from this message that you blocked the connection on purpose.

- **Block with reset** to terminate and reset the connection, resulting in an error in the client browser.

The error indicates the connection was reset but does not indicate why.

**Tip** You cannot use the **Block** or **Block with reset** action in a passive or inline (tap mode) deployment because the device does not directly inspect the traffic. If you create a rule with the **Block** or **Block with reset** action that contains passive or inline (tap mode) interfaces within a security zone condition, the policy editor displays a warning (⚠) next to the rule.

## Decryption Rule Decrypt Actions

The **Decrypt - Known Key** and **Decrypt - Resign** actions decrypt encrypted traffic. The system inspects decrypted traffic with access control. Access control rules handle decrypted and unencrypted traffic identically — you can inspect it for discovery data as well as detect and block intrusions, prohibited files, and malware. The system reencrypts allowed traffic before passing it to its destination.

We recommend you use a certificate from a trusted Certificate Authority (CA) to decrypt traffic. This prevents **Invalid Issuer** from being displayed in the SSL Certificate Status column in connection events.

For more information about adding trusted objects, see [Trusted Certificate Authority Objects, on page 1505](#).

**Related topic:** [TLS 1.3 Decryption Best Practices, on page 2357](#).

#### Related Topics

[TLS 1.3 Decryption Best Practices, on page 2357](#)

## Troubleshoot Decryption Rules

The following topics discuss how to troubleshoot decryption rules.

### About TLS/SSL Oversubscription

*TLS/SSL oversubscription* is a state where a managed device is overloaded with TLS/SSL traffic. Any managed device can experience TLS/SSL oversubscription but only managed devices that support TLS crypto acceleration provide a configurable way to handle it.

When a managed device with TLS crypto acceleration enabled is oversubscribed, any packet received by the managed device is acted on according to the setting for **Handshake Errors** in the decryption policy's

#### Undecryptable Actions:

- Inherit default action
- Do not decrypt
- Block
- Block with reset

If the setting for **Handshake Errors** in the decryption policy's **Undecryptable Actions** is **Do Not decrypt** and the associated access control policy is configured to inspect the traffic, inspection occurs; decryption does *not* occur.

### Troubleshoot TLS/SSL Oversubscription

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are experiencing SSL oversubscription. You must add at least the **SSL Flow Flags** event to the table view of connection events.

#### Before you begin

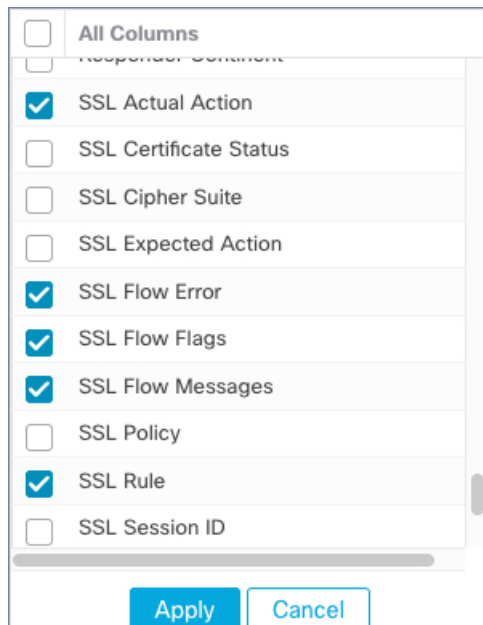

- Configure a decryption policy with a setting for **Handshake Errors** on **Undecryptable Actions** page.  
For more information, see [Set Default Handling for Undecryptable Traffic, on page 2354](#).
- Enable logging for your SSL rules as discussed in the section on logging decryptable connections in decryption rules in the [Secure Firewall Management Center and Threat Defense Management Network Administration](#) guide.

## Procedure

- Step 1** Click **Analysis > Connections > Events**.
- Step 2** Click **Table View of Connection Events**.
- Step 3** Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events. (Look in the Disabled Columns section of the dialog box.)

- Step 4** Click **Apply**.  
 TLS/SSL oversubscription is indicated by the values of `ERROR_EVENT_TRIGGERED` and `OVER_SUBSCRIBED` in the **SSL Flow Flags** column.
- Step 5** If TLS/SSL oversubscription is occurring, log in to the managed device and enter any of the following commands:

Command	Result
<code>show counters</code>	If the value of <code>TCP_PRX_BYPASS_NOT_ENOUGH_MEM</code> is large, consider upgrading your device to one with a larger capacity for SSL traffic or use <b>Do Not Decrypt</b> rules for lower priority encrypted traffic.

Command	Result
<code>show snort tls-offload</code>	If the value of <b>BYPASS_NOT_ENOUGH_MEM</b> is large, consider upgrading your device to one with a larger capacity for SSL traffic or use <b>Do Not Decrypt</b> rules for lower priority encrypted traffic.

## About TLS Heartbeat

Some applications use the *TLS heartbeat* extension to the Transport Layer Security (TLS) and Datagram Transport Layer Security (DTLS) protocols defined by [RFC6520](#). TLS heartbeat provides a way to confirm the connection is still alive—either the client or server sends a specified number of bytes of data and requests the other party echo the response. If this is successful, encrypted data is sent.

When a managed device with TLS crypto acceleration enabled encounters a packet that uses the TLS heartbeat extension, the managed device takes the action specified by the setting for **Decryption Errors** in the decryption policy's **Undecryptable Actions**:

- Block
- Block with reset

### Related Topics

[Troubleshoot TLS Heartbeat](#), on page 2395

## Troubleshoot TLS Heartbeat

If your managed device has TLS crypto acceleration enabled, you can view connection events to determine whether or not the devices are seeing traffic with the TLS heartbeat extension. You must add at least the **SSL Flow Messages** event to the table view of connection events.

### Before you begin

SSL heartbeat is indicated by the value of `HEARTBEAT` in the **SSL Flow Messages** column in the table view of connection events. To determine if applications in your network use SSL heartbeat, first perform the following tasks:

- Configure an decryption policy with a setting for **Decryption Errors** on **Undecryptable Actions** page. For more information, see [Set Default Handling for Undecryptable Traffic, on page 2354](#).
- Enable logging for your SSL rules as discussed in [Secure Firewall Management Center and Threat Defense Management Network Administration](#).

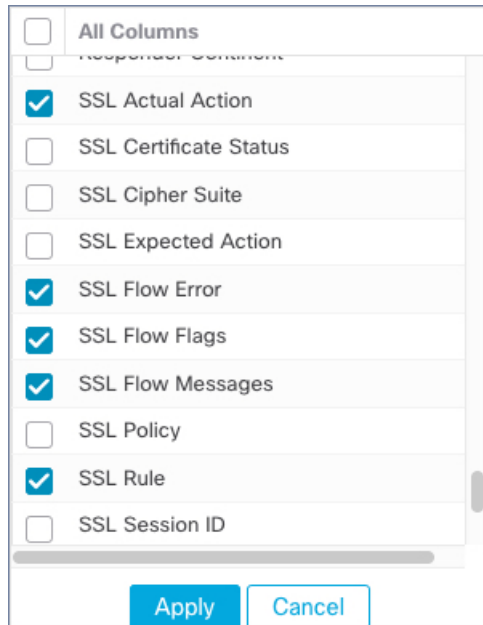

### Procedure

- 
- Step 1** Click **Analysis > Connection > Events**.
- Step 2** Click **Table View of Connection Events**.

- Step 3** Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.

- Step 4** Click **Apply**.  
 TLS heartbeat is indicated by the value of HEARTBEAT in the **SSL Flow Messages** column.
- Step 5** If applications in your network use SSL heartbeat, see [Decryption Rule Guidelines and Limitations](#), on page 2360.

## About TLS/SSL Pinning

Some applications use a technique referred to as *TLS/SSL pinning* or *certificate pinning*, which embeds the fingerprint of the original server certificate in the application itself. As a result, if you configured a decryption rule with a **Decrypt - Resign** action, when the application receives a resigned certificate from a managed device, validation fails and the connection is aborted.

To confirm that TLS/SSL pinning is occurring, attempt to log in to a mobile application like Facebook. If a network connection error is displayed, log in using a web browser. (For example, you *cannot* log in to a Facebook mobile application but *can* log in to Facebook using Safari or Chrome.) You can use Firepower Management Center connection events as further proof of TLS/SSL pinning

---

**Note** TLS/SSL pinning is not limited to mobile applications.

---

If applications in your network use SSL pinning, see [TLS/SSL Certificate Pinning Guidelines](#), on page 2366.

#### Related Topics

[Troubleshoot TLS/SSL Pinning](#), on page 2397

## Troubleshoot TLS/SSL Pinning

You can view connection events to determine whether or not the devices are experiencing SSL pinning. You must add at least the **SSL Flow Flags** and **SSL Flow Messages** columns to the table view of connection events.

#### Before you begin

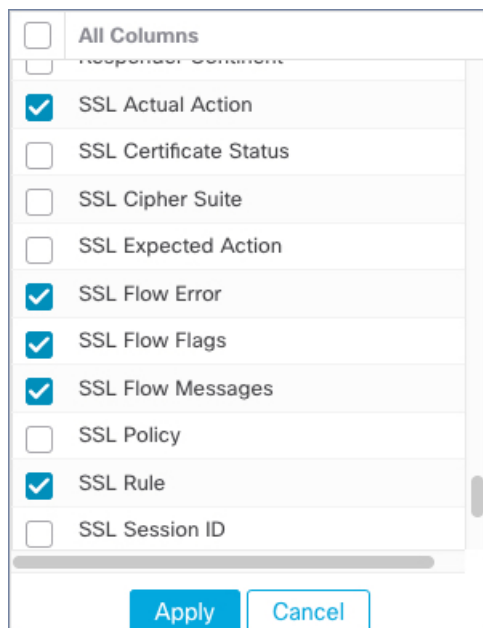

- Enable logging for your decryption rules as discussed in the section on logging decryptable connections in decryption rules in the [Secure Firewall Management Center and Threat Defense Management Network Administration](#) guide.
- Log in to a mobile application like Facebook; if a network connection error displays, log in to Facebook using Chrome or Safari. If you *can* log in using a web browser but not the native application, SSL pinning is likely occurring.

#### Procedure

- 
- Step 1** Click **Analysis > Connections > Events**.
- Step 2** Click **Table View of Connection Events**.
- Step 3** Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.

The columns are added in the order discussed in the section on connection and security intelligence event fields in the [Secure Firewall Management Center and Threat Defense Management Network Administration](#) guide.

**Step 4** Click **Apply**.

**Step 5** The following paragraphs discuss how you can identify SSL pinning behavior.

**Step 6** If you determine that applications in your network use SSL pinning, see [Decryption Rule Guidelines and Limitations, on page 2360](#).

---

### What to do next

You can use TLS/SSL connection events to confirm TLS/SSL pinning is occurring by looking for any of the following:

- Applications that send an SSL ALERT Message as soon as the client receives the SERVER\_HELLO, SERVER\_CERTIFICATE, SERVER\_HELLO\_DONE message from the server, followed by a TCP Reset, exhibit the following symptoms. (The alert, Unknown CA (48), can be viewed using a packet capture.)
  - The SSL Flow Flags column displays ALERT\_SEEN but *not* APP\_DATA\_C2S or APP\_DATA\_S2C.
  - If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: CLIENT\_ALERT, CLIENT\_HELLO, SERVER\_HELLO, SERVER\_CERTIFICATE, SERVER\_KEY\_EXCHANGE, SERVER\_HELLO\_DONE.
  - If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: CLIENT\_HELLO, SERVER\_HELLO, SERVER\_CERTIFICATE, SERVER\_KEY\_EXCHANGE, SERVER\_HELLO\_DONE.
  - Success is displayed in the SSL Flow Error column.

- Applications that send no alerts but instead send TCP Reset after the SSL handshake is finished exhibit the following symptoms:
  - The SSL Flow Flags column does *not* display ALERT\_SEEN, APP\_DATA\_C2S, or APP\_DATA\_S2C.
  - If your managed device has SSL hardware acceleration enabled, the SSL Flow Messages column typically displays: CLIENT\_HELLO, SERVER\_HELLO, SERVER\_CERTIFICATE, SERVER\_KEY\_EXCHANGE, SERVER\_HELLO\_DONE, CLIENT\_KEY\_EXCHANGE, CLIENT\_CHANGE\_CIPHER\_SPEC, CLIENT\_FINISHED, SERVER\_CHANGE\_CIPHER\_SPEC, SERVER\_FINISHED.
  - If your managed device doesn't support SSL hardware acceleration or if the feature is disabled, the SSL Flow Messages column typically displays: CLIENT\_HELLO, SERVER\_HELLO, SERVER\_CERTIFICATE, SERVER\_KEY\_EXCHANGE, SERVER\_HELLO\_DONE, CLIENT\_KEY\_EXCHANGE, CLIENT\_CHANGE\_CIPHER\_SPEC, CLIENT\_FINISHED, SERVER\_CHANGE\_CIPHER\_SPEC, SERVER\_FINISHED.
  - Success is displayed in the SSL Flow Error column.

### Related Topics

[Troubleshoot Unknown or Bad Certificates or Certificate Authorities](#), on page 2399

## Troubleshoot Unknown or Bad Certificates or Certificate Authorities

You can view connection events to determine whether or not the devices are experiencing unknown certificate authorities, bad certificates, or unknown certificates. This procedure can also be used if a TLS/SSL certificate has been pinned. You must add at least the **SSL Flow Flags** and **SSL Flow Messages** columns to the table view of connection events.

### Before you begin

- Set up a decryption rule.
- Enable logging for your decryption rules as discussed in the section on logging decryptable connections in decryption rules in the [Secure Firewall Management Center and Threat Defense Management Network Administration](#) guide.

### Procedure

- 
- Step 1** Click **Analysis > Connections > Events**.
  - Step 2** Click **Table View of Connection Events**.
  - Step 3** Click **x** on any column in the connection events table to add additional columns for at least **SSL Flow Flags** and **SSL Flow Messages**.

The following example shows adding the **SSL Actual Action**, **SSL Flow Error**, **SSL Flow Flags**, **SSL Flow Messages**, **SSL Policy**, and **SSL Rule** columns to the table of connection events.

Column Name	Selected
SSL Actual Action	Yes
SSL Certificate Status	No
SSL Cipher Suite	No
SSL Expected Action	No
SSL Flow Error	Yes
SSL Flow Flags	Yes
SSL Flow Messages	Yes
SSL Policy	No
SSL Rule	Yes
SSL Session ID	No

The columns are added in the order discussed in the section on connection and security intelligence event fields in the [Secure Firewall Management Center and Threat Defense Management Network Administration](#) guide.

**Step 4** Click **Apply**.

**Step 5** The following table discusses how you can determine if a certificate or certificate authority is bad or missing.

SSL flow flag	Meaning
CLIENT_ALERT_SEEN_UNKNOWN_CA	Indicates a valid certificate chain or partial chain was received by an SSL client application, but the certificate was not accepted because the CA certificate could not be located or could not be matched with a known, trusted CA. This message always indicates an unrecoverable error.
CLIENT_ALERT_SEEN_BAD_CERTIFICATE	A certificate was corrupt, contained signatures that did not verify correctly, or had other problems.
CLIENT_ALERT_SEEN_CERTIFICATE_UNKNOWN	Some other (unspecified) issue arose in processing the certificate, rendering it unacceptable.

# Verify TLS/SSL Cipher Suites

## Before you begin

This topic discusses actions you must take if you see the following error when saving a decryption rule that has cipher suite conditions:

```
Traffic cannot match this rule; none of your selected cipher suites contain a signature algorithm that the resigning CA's signature algorithm
```

The error indicates that one or more of the cipher suites you chose for the decryption rule condition are incompatible with the certificate used in the decryption rule. To resolve the issue, you must have access to the certificate you're using.

---

**Note** The tasks in this topic assume knowledge of how TLS/SSL encryption works.

---

## Procedure

---

**Step 1** When you attempt to save an SSL rule with either **Decrypt - Resign** or **Decrypt - Known Key** with specified cipher suites, the following error is displayed:

**Example:**

```
Traffic cannot match this rule; none of your selected cipher suites contain a signature algorithm that the resigning CA's signature algorithm
```

**Step 2** Locate the certificate you're using to decrypt traffic and, if necessary, copy the certificate to a system that can run openssl commands.

**Step 3** Run the following command to display the signature algorithm used by the certificate:

```
openssl x509 -in CertificateName -text -noout
```

The first few lines of output are displayed similar to the following:

```
Certificate:
  Data:
    Version: 3 (0x2)
    Serial Number: 4105 (0x1009)
    Signature Algorithm: ecdsa-with-SHA256
```

**Step 4** The **Signature algorithm** tells you the following:

- The cryptographic function used (in the preceding example, **ECDSA** means Elliptic Curve Digital Signature Algorithm).
- The hash function used to create a digest of the encrypted message (in the preceding example, **SHA256**).

**Step 5** Search a resource such as [OpenSSL at University of Utah](#) for cipher suites that match those values. The cipher suite must be in RFC format.

You can also search a variety of other sites, such as [Server Side TLS](#) at the Mozilla wiki or [Appendix C of RFC 5246. Cipher Suites in TLS/SSL \(Schannel SSP\)](#) in Microsoft documentation has a detailed explanation of cipher suites.

**Step 6** If necessary, translate the OpenSSL name to an RFC name that the Firepower Management System uses.

See the [RFC mapping list](#) on the on the <https://testssl.sh> site.

**Step 7**

The previous example, **ecdsa-with-SHA256**, can be found in the [Modern Compatibility List](#) on the Mozilla wiki.

a) Choose only cipher suites that have **ECDSA** and **SHA-256** in the name. These cipher suites follow:

```
ECDHE-ECDSA-AES128-GCM-SHA256  
ECDHE-ECDSA-AES128-SHA256
```

b) Find the corresponding RFC cipher suite on [RFC mapping list](#). These cipher suites follow:

```
TLS_ECDHE_ECDSA_WITH_AES_128_GCM_SHA256  
TLS_ECDHE_ECDSA_WITH_AES_128_CBC_SHA256
```

**Step 8**

Add the preceding cipher suites to your decryption rule.

---

## CHAPTER 88

# Decryption Rules and Policy Example

This chapter builds on concepts discussed in this guide to provide a specific example of an SSL policy with decryption rules that follow our best practices and recommendations. You should be able to apply this example to your situation, adapting it to the needs of your organization.

In short:

- For trusted traffic (such as transferring a large compressed server backup), bypass inspection entirely, using prefiltering and flow offload.
- Put *first* any decryption rules that can be evaluated quickly, such as those that apply to specific IP addresses.
- Put *last* any decryption rules that require processing, **Decrypt - Resign**, and rules that block insecure protocol versions and cipher suites.
- [Decryption Rule Examples, on page 2403](#)
- [Run the Decryption Policy Wizard, on page 2403](#)
- [First Manual Do Not Decrypt Rule: Specific Traffic, on page 2409](#)
- [Next Manual Rule: Decrypt Specific Test Traffic, on page 2411](#)
- [Last Manual Decryption Rules: Block or Monitor Certificates and Protocol Versions, on page 2412](#)
- [Associate the Decryption Policy with an Access Control Policy and Advanced Settings, on page 2418](#)
- [Traffic to Prefilter, on page 2420](#)
- [Decryption Rule Settings, on page 2420](#)

## Decryption Rule Examples

This section provides an example of decryption rule that illustrate our best practices.

See one of the following sections for more information.

## Run the Decryption Policy Wizard

This task discusses how to run the decryption policy wizard for outbound traffic protection. This policy has four rules:

1. **Do Not Decrypt** rule for distinguished names that are known to be undecryptable, most likely because they use TLS/SSL pinning.

2. **Do Not Decrypt** rule for URL categories that we classify as sensitive based on their content (for example, medical and financial).
3. **Do Not Decrypt** rule for applications that are known to be undecryptable, most likely because they use TLS/SSL pinning.
4. **Decrypt - Resign** rule that uses a certificate authority object named **IntCA** to decrypt the remainder of the traffic.

You can then edit the rules if you want and also manually add:

- **Decrypt - Resign** rules for traffic to monitor and determine whether the traffic should be blocked in the future.
- **Do Not Decrypt** rules for other types of traffic
- **Block** or **Block with Reset** rules for bad certificates and unsecure cipher suites.

If you enabled Change Management, you must create and assign a ticket before you can create a decryption policy. Before the decryption policy can be used, the ticket and all associated objects (like certificate authorities) must be approved. For more information, see [Creating Change Management Tickets, on page 214](#) and [Policies and Objects that Support Change Management, on page 209](#).

## Procedure

- 
- Step 1** Log in to the Secure Firewall Management Center if you haven't already done so.
  - Step 2** Click **Policies > Access Control > Decryption**.
  - Step 3** Click **Create Decryption Policy**.
  - Step 4** Give the decryption policy a **Name** and optionally a **Description**.
  - Step 5** Click the **Outbound Protection** tab.
  - Step 6** From the **Internal CA** list, click the name of an internal certificate authority object or click **Create New** to upload or generate one.

The following figure shows an example.

For more information about creating or uploading an internal certificate authority object, see:

- [Upload an Internal CA for Outbound Protection, on page 2349](#)
- [Generate an Internal CA for Outbound Protection, on page 2348](#)

- Step 7** (Optional.) To restrict traffic to source and destination networks, click **Click to assign networks and ports**.
- Step 8** Click **Next**.
- Step 9** Complete the wizard as discussed in [Decryption Policy Exclusions, on page 2345](#).

## Decryption Policy Exclusions

This task discusses how to exclude certain types of traffic from decryption. We create **Do Not Decrypt** rules in your decryption policy for these although the rules are initially enabled only for an outbound decryption policy (that is, one that uses the **Decrypt - Resign** policy action).

### Before you begin

You must upload an internal CA certificate for your managed device before you can create a decryption policy that protects outbound connections. You can do this in any of the following ways:

- Create an internal CA certificate object by going to **Objects > Object Management > PKI > Internal CAs** and referring to [PKI, on page 1500](#).
- At the time you create this decryption policy.

## Procedure

- Step 1** Complete the tasks discussed in:
- [Create a Decryption Policy with Outbound Connection Protection, on page 2341](#)
  - For more information, see [Create a Decryption Policy with Inbound Connection Protection, on page 2343](#)
- Step 2** The exclusions page provides the following options. All options are *enabled* for an outbound protection policy (**Decrypt - Resign** rule action) and *disabled* for all other decryption policy actions.

Item	Description
<b>Bypass decryption for sensitive URL categories</b>	<p>Check the box to not decrypt traffic from the indicated categories. Depending on the laws in your area, decryption certain traffic, such as finance or health-related, might be prohibited. Consult an authority in your area for more information.</p> <p>Click <b>Add</b> to add more categories.</p> <p>Click <b>Delete</b> (✕) to remove categories.</p>
<b>Bypass decryption for undecryptable distinguished names</b>	<p>Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with <i>certificate pinning</i>, which is discussed in <a href="#">TLS/SSL Certificate Pinning Guidelines, on page 2366</a>.</p> <p>The list of undecryptable distinguished names is maintained by Cisco.</p>
<b>Bypass decryption for undecryptable applications</b>	<p>Check the box to not decrypt traffic when re-signing the certificate is likely to cause the connection to fail. Typically, this behavior is associated with <i>certificate pinning</i>, which is discussed in <a href="#">TLS/SSL Certificate Pinning Guidelines, on page 2366</a>.</p> <p>Undecryptable applications are updated automatically in the Vulnerability Database (VDB). You can find a list of all applications on the <a href="#">Secure Firewall Application Detectors</a> page; the <b>undecryptable</b> tag identifies applications Cisco determines are undecryptable.</p> <p>The list of undecryptable applications is maintained by Cisco.</p>

The following figure shows default options.

## Create Decryption Policy ?

1 Policy Details 2 Decryption Exclusions

Enter name, description, choose policy type and certificates. (Optional) Configure exclusions for outbound connections.

**Bypass decryption for sensitive URL categories**  
In many environments, certain categories of websites are not inspected for regulatory, compliance or privacy reasons. Customize the list below to bypass inspection for designated categories.  
Note: **URL License is Required**

URL Categories: Finance Online Trading Health and Medicine + Add

**Bypass decryption for undecryptable distinguished names**  
Bypass decryption based on Cisco's list of known undecryptable distinguished names.  
Note: **This option is selected by default to allow traffic which cannot be decrypted to remain encrypted. Disabling this option might cause decryption to fail for unsupported distinguished names.**

[56 Distinguished names included](#)

**Bypass decryption for undecryptable applications**  
Certain enterprise applications are not supported for decryption due to a variety of reasons (Certificate Pinning, Client Certificate Authentication, etc.). Bypass decryption based on Cisco's list of known undecryptable applications.  
Note: **This option is selected by default to allow traffic which cannot be decrypted to remain encrypted. Disabling this option might cause decryption to fail for unsupported applications.**

2	<input type="checkbox"/> Auto-Rule-URL-Categories (Disabled)	any	any	any	any	any	any	any	any	any	Finance (Any res), Health and Med, Online Trading (	any	<input checked="" type="checkbox"/> Do not decrypt
3	<input type="checkbox"/> Auto-Rule-Undecryptable-Aj	any	any	any	any	any	any	Tags: undecrypt	any	any	any	any	<input checked="" type="checkbox"/> Do not decrypt
4	<input checked="" type="checkbox"/> Auto-Rule-IntCA	any	any	IPv4-Link-Local	any	any	any	any	any	Bittorrent	any	any	<input checked="" type="checkbox"/> Decrypt - Resign
<b>Root Rules</b>													
This category is empty													
<b>Default Action</b>												Do not decrypt	

In the preceding example, the **Do Not Decrypt** rules corresponding to your choices for rule exclusions are automatically added before the **Decrypt - Resign** rule. The rule for sensitive URL categories is disabled because, by default, that exclusion is disabled. Had you selected the **Bypass decryption for sensitive URL categories** check box, the rule would have been enabled.

#### Step 4 Click **Create Policy**.

#### What to do next

- Add rule conditions: [Decryption Rule Conditions, on page 2372](#)
- Add a default policy action: [Decryption Policy Default Actions, on page 2352](#)
- Configure logging options for the default action .
- Set advanced policy properties: [Decryption Policy Advanced Options, on page 2355](#).
- Associate the decryption policy with an access control policy as described in [Associating Other Policies with Access Control, on page 1844](#).
- Deploy configuration changes.

## First Manual Do Not Decrypt Rule: Specific Traffic

The first decryption rule in the example does not decrypt traffic that goes to an internal network (defined as **intranet**). **Do Not Decrypt** rule actions are matched during ClientHello so they are processed very fast.

## Decryption Policy Example

**Note** If you have traffic going from internal DNS servers to internal DNS resolvers (such as Cisco Umbrella Virtual Appliances), you can add **Do Not Decrypt** rules for them as well. You can even add those to prefiltering policies if the internal DNS servers do their own logging.

However, we strongly recommend you *do not* use **Do Not Decrypt** rules or prefiltering for DNS traffic that goes to the internet, such as internet root servers (for example, Microsoft internal DNS resolvers built into Active Directory). In those cases, you should fully inspect the traffic or even consider blocking it.

Rule detail:

**Add Rule**

Name: DND - internal source network  Enabled Insert: below rule 4

Action: Do not decrypt

Zones: Networks VLAN Tags Users Applications Ports Category Certificate DN Cert Status Cipher Suite Version Logging

Available Networks: Search by name or value

Source Networks (1): Internal

Destination Networks (0): any

Buttons: Add to Source, Add to Destination, Add, Cancel, Add

## Next Manual Rule: Decrypt Specific Test Traffic

The next rule is *optional* in the example; use it to decrypt and monitor limited types of traffic before determining whether or not to allow it on your network.

After you run the decryption policy wizard, edit the policy to add the following rule. Drag it to the second position in the list of rules.

Revert to Defaults Cancel Add

## Example: Decryption Rule to Monitor or Block Certificate Status

The last decryption rules, because they are the most specific and require the most processing, are rules that either monitor or block bad certificates and insecure protocol versions. The example in this section shows how to monitor or block traffic by certificate status.

### Important

Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with either **Decrypt - Resign** or **Decrypt - Known Key** rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

### Procedure

- Step 1** Log in to the Secure Firewall Management Center if you haven't already done so.
- Step 2** Click **Policies > Access Control > Decryption**.
- Step 3** Click **Edit** (✎) next to your decryption policy.
- Step 4** Click **Edit** (✎) next to a decryption rule.
- Step 5** Click **Add Rule**.
- Step 6** In the Add Rule dialog box, in the **Name** field, enter a name for the rule.
- Step 7** Click **Cert Status**.
- Step 8** For each certificate status, you have the following options:
  - Click **Yes** to match against the *presence* of that certificate status.
  - Click **No** to match against the *absence* of that certificate status.
  - Click **Any** to skip the condition when matching the rule. In other words, choosing **Any** means the rule matches whether the certificate status is present or absent.

- Step 9** From the **Action** list, click either **Monitor** to only monitor and log traffic that matches the rule or click **Block** or **Block with Reset** to block the traffic and optionally reset the connection.
- Step 10** To save changes to the rule, at the bottom of the page, click **Add**.
- Step 11** To save changes to the policy, at the top of the page, click **Save**.

### Example

The organization trusts the Verified Authority certificate authority. The organization does not trust the Spammer Authority certificate authority. The system administrator uploads the Verified Authority certificate and an intermediate CA certificate issued by Verified Authority to the system. Because Verified Authority revoked a certificate it previously issued, the system administrator uploads the CRL that Verified Authority provided.

The following figure shows a certificate status rule condition checking for valid certificates, those issued by a Verified Authority, are not on the CRL, and still within the Valid From and Valid To date. Because of the configuration, traffic encrypted with these certificates is not decrypted and inspected with access control.

<b>Revoked:</b>	Yes	No	<b>Any</b>	<b>Self Signed:</b>	Yes	No	<b>Any</b>
<b>Valid:</b>	<b>Yes</b>	No	Any	<b>Invalid Signature:</b>	Yes	No	<b>Any</b>
<b>Invalid Issuer:</b>	Yes	No	<b>Any</b>	<b>Expired:</b>	Yes	No	<b>Any</b>
<b>Not Yet Valid:</b>	Yes	No	<b>Any</b>	<b>Invalid Certificate:</b>	Yes	No	<b>Any</b>
<b>Invalid CRL:</b>	Yes	No	<b>Any</b>	<b>Server Mismatch:</b>	Yes	No	<b>Any</b>

The following figure shows a certificate status rule condition checking for the absence of a status. In this case, because of the configuration, it matches against traffic encrypted with a certificate that has not expired.

<b>Revoked:</b>	Yes	No	<b>Any</b>	<b>Self Signed:</b>	Yes	No	<b>Any</b>
<b>Valid:</b>	Yes	No	<b>Any</b>	<b>Invalid Signature:</b>	Yes	No	<b>Any</b>
<b>Invalid Issuer:</b>	Yes	No	<b>Any</b>	<b>Expired:</b>	Yes	<b>No</b>	Any
<b>Not Yet Valid:</b>	Yes	No	<b>Any</b>	<b>Invalid Certificate:</b>	Yes	No	<b>Any</b>
<b>Invalid CRL:</b>	Yes	No	<b>Any</b>	<b>Server Mismatch:</b>	Yes	No	<b>Any</b>

In the following example, traffic would match this rule condition if the incoming traffic is using a certificate that has an invalid issuer, is self-signed, expired, and it is an invalid certificate.

The following graphic illustrates a certificate status rule condition that matches if the SNI of the request matches the server name or if the CRL is not valid.

Revoked:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any	Self Signed:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any
Valid:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any	Invalid Signature:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any
Invalid Issuer:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any	Expired:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any
Not Yet Valid:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any	Invalid Certificate:	<input type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any
Invalid CRL:	<input checked="" type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any	Server Mismatch:	<input checked="" type="checkbox"/> Yes	<input type="checkbox"/> No	<input type="checkbox"/> Any

## Example: Decryption Rule to Monitor or Block Protocol Versions

This example shows how to block TLS and SSL protocols on your network that are no longer considered secure, such as TLS 1.0, TLS 1.1, and SSLv3. It's included to give you a little more detail about how protocol version rules work.

You should exclude nonsecure protocols from your network because they are all exploitable. In this example:

- You can block some protocols using **Version** page on the decryption rule.
- Because the system considers SSLv2 as undecryptable, you can block it using the **Undecryptable Actions** on the decryption policy.
- Similarly, because compressed TLS/SSL is not supported, you should block it as well.

### Important

Use the **Cipher Suite** and **Version** rule conditions *only* in rules with either the **Block** or **Block with reset** rule actions. Do not use **Cipher Suite** and **Version** with either Decrypt - Resign or Decrypt - Known Key rule actions. These conditions in rules with other rule actions can interfere with the system's ClientHello processing, resulting in unpredictable performance.

### Procedure

- Step 1** Click **Policies > Access Control > Decryption**.
- Step 2** Click **Edit** (✎) next to your decryption policy.
- Step 3** Click **Edit** (✎) next to a decryption rule.
- Step 4** Click **Add Rule**.
- Step 5** In the Add Rule dialog box, in the **Name** field, enter a name for the rule.
- Step 6** From the **Action** list, click **Block** or **Block with reset**.
- Step 7** Click **Version** page.
- Step 8** Check the check boxes for protocols that are no longer secure, such as **SSL v3.0**, **TLS 1.0**, and **TLS 1.1**. Clear the check boxes for any protocols that are still considered secure.

The following figure shows an example.

Editing Rule - Block SSLv3. TLS 1.0

Name: Block SSLv3. TLS 1.0  Enabled [Move](#)

Action: Block

Zones Networks VLAN Tags Users Applications Ports Category Certificate DN Cert Status Cipher Suite **Version** Logging

SSL v3.0  
 TLS v1.0  
 TLS v1.1  
 TLS v1.2

[Revert to Defaults](#)

[Cancel](#) [Save](#)

**Step 9** Choose other rule conditions as needed.

**Step 10** Click **Add**.

## Optional Example: Manual Decryption Rule to Monitor or Block Certificate Distinguished Name

This rule is included to give you an idea about how to monitor or block traffic based on the server certificate's distinguishedname. It's included to give you a little more detail.

The distinguished name can consist of country code, common name, organization, and organizational unit, but typically consists of a common name only. For example, the common name in the certificate for `https://www.cisco.com` is `cisco.com`. (However, it's not always this simple; [Distinguished Name \(DN\) Rule Conditions](#), on page 2378 shows how to find common names.)

The host name portion of the URL in the client request is the [Server Name Indication \(SNI\)](#). The client specifies which hostname they want to connect to (for example, `auth.amp.cisco.com`) using the SNI extension in the TLS handshake. The server then selects the corresponding private key and certificate chain that are required to establish the connection while hosting all certificates on a single IP address.

### Procedure

**Step 1** Click **Policies > Access Control > Decryption**.

**Step 2** Click **Edit** (✎) next to your decryption policy.

**Step 3** Click **Edit** (✎) next to a decryption rule.

**Step 4** Click **Add Rule**.

**Step 5** In the Add Rule dialog box, in the **Name** field, enter a name for the rule.

**Step 6** From the **Action** list, click **Block** or **Block with reset**.

**Step 7** Click **DN**.

**Step 8** Find the distinguished names you want to add from the **Available DNs**, as follows:

- To add a distinguished name object on the fly, which you can then add to the condition, click **Add (+)** above the **Available DNs** list.
- To search for distinguished name objects and groups to add, click the **Search by name or value** prompt above the **Available DNs** list, then type either the name of the object, or a value in the object. The list updates as you type to display matching objects.

**Step 9** To select an object, click it. To select all objects, right-click and then **Select All**.

**Step 10** Click **Add to Subject** or **Add to Issuer**.

**Tip** You can also drag and drop selected objects.

**Step 11** Add any literal common names or distinguished names that you want to specify manually. Click the **Enter DN or CN** prompt below the **Subject DNs** or **Issuer DNs** list; then type a common name or distinguished name and click **Add**.

Although you can add a CN or DN to either list, it's more common to add them to the **Subject DNs** list.

**Step 12** Add or continue editing the rule.

**Step 13** When you're done, to save changes to the rule, click **Add** at the bottom of the page.

**Step 14** To save changes to the policy, click **Save** at the top of the page.

### Example

The following figure shows a distinguished name rule condition searching for certificates issued to goodbakery.example.com or issued by goodca.example.com. Traffic encrypted with these certificates is allowed, subject to access control.

Subject DNs (1)	Issuer DNs (1)
<div style="border: 1px solid #ccc; padding: 5px; min-height: 150px;"> <p>GoodBakery <span style="float: right;">🗑️</span></p> </div>	<div style="border: 1px solid #ccc; padding: 5px; min-height: 150px;"> <p>CN=goodca.example.com <span style="float: right;">🗑️</span></p> </div>
<input type="text" value="Enter DN or CN"/> <input type="button" value="Add"/>	<input type="text" value="Enter DN or CN"/> <input type="button" value="Add"/>

# Associate the Decryption Policy with an Access Control Policy and Advanced Settings

This task discusses how to associate the decryption policy with an access control policy and setting recommended advanced settings for the access control policy.

For your decryption policy to be used by the system, you *must* associate it with an access control policy.

## Before you begin

Create the sample decryption policy as discussed in this guide.

For more information about decryption policy advanced options, see [Decryption Policy Advanced Options, on page 2355](#).

## Procedure

- Step 1** Log in to the Secure Firewall Management Center if you haven't already done so.
- Step 2** Click **Policies > Access Control**.
- Step 3** Either create a new access control policy or click **Edit** (✎) to edit an existing one.
- Step 4** Click the word Decryption as the following figure shows.

- Step 5** From the list, click the name of your decryption policy and also check **Early application detection and URL categorization** as the following figure shows.

- Step 6** Click **Apply**.
- Step 7** Click **More > Advanced Settings** as the following figure shows.

**Step 8** Click **Edit** (✎) next to **TLS Server Identity Discovery**.

**Step 9** Select the check box as the following figure shows.

**Step 10** Click **OK**.

**Step 11** At the top of the page, click **Save**.

**Step 12** At the top of the page, click **Return to Access Control Policy Management**, as the following figure shows

**Step 13** Click **Edit** (✎) to edit the access control rule.

**Step 14** At the bottom of the page, next to the default action, click  (Default Logging and Inspection).

**Step 15** Check **Log at beginning of connection** and any other options you choose.

For more information, see [Logging Settings for Access Control Policies, on page 1839](#) [Logging Settings for Access Control Policies](#) in the *Cisco Secure Firewall Management Center Device Configuration Guide*.

**Step 16** Click **Apply**.

**Step 17** At the top of the page, click **Save**.

### What to do next

- Add rule conditions: [Decryption Rule Conditions, on page 2372](#).
- Add a default policy action: [Decryption Policy Default Actions, on page 2352](#).
- Configure logging options for the default action .
- Set advanced policy properties: [Decryption Policy Advanced Options, on page 2355](#).

- Associate the decryption policy with an access control policy as described in [Associating Other Policies with Access Control](#), on page 1844.
- Deploy configuration changes.

## Traffic to Prefilter

*Prefiltering* is the first phase of access control, before the system performs more resource-intensive evaluation. Prefiltering is simple, fast, and early compared to subsequent evaluation, which uses inner headers and has more robust inspection capabilities.

Based on your security needs and traffic profile, you should consider prefiltering and therefore excluding from any policy and inspection the following:

- Common intraoffice applications such as Microsoft Outlook 365
- [Elephant flows](#), such as server backups

## Decryption Rule Settings

How to configure recommended best practice settings for your decryption rules.

Decryption rules: Enable logging for every rule except those with a **Do Not Decrypt** rule action. (It's up to you; if you want to see information about traffic that isn't decrypted, enable logging for those rules also.)

### Procedure

- 
- Step 1** Click **Policies > Access Control > Decryption**.
  - Step 2** Click **Edit** (✎) next to your decryption policy.
  - Step 3** Click **Edit** (✎) next to a decryption rule.
  - Step 4** Click the **Logging** tab.
  - Step 5** Click **Log at End of Connection**.
  - Step 6** Click **Save**.
  - Step 7** Click **Save** at the top of the page.
-

- [User Control with Remote Access VPN, on page 2601](#)
- [User Control with TS Agent, on page 2605](#)
- [User Identity Policies, on page 2609](#)

## CHAPTER 89

# User Identity Overview

---

The following topics discuss user identity:

- [About User Identity](#), on page 2423
- [Cloud-delivered Firewall Management Center Host and User Limits](#), on page 2437
- [User Limits for Microsoft Azure Active Directory Realms](#), on page 2438

## About User Identity

User identity information can help you to identify the source of policy breaches, attacks, or network vulnerabilities, and trace them to specific users. For example, you could determine:

- Who owns the host targeted by an intrusion event that has a Vulnerable (level 1: red) impact level.
- Who initiated an internal attack or portscan.
- Who is attempting unauthorized access to a specified host.
- Who is consuming an unreasonable amount of bandwidth.
- Who has not applied critical operating system updates.
- Who is using instant messaging software or peer-to-peer file-sharing applications in violation of company policy.
- Who is associated with each indication of compromise on your network.

Armed with this information, you can use other features of the system to mitigate risk, perform access control, and take action to protect others from disruption. These capabilities also significantly improve audit controls and enhance regulatory compliance.

After you configure user identity sources to gather user data, you can perform user awareness and user control.

For more information about identity sources, see [About User Identity Sources](#), on page 2424.

### Related Topics

- [Identity Terminology](#), on page 2424
- [About User Identity Sources](#), on page 2424
- [Identity Deployments](#), on page 2428
- [How to Set Up an Identity Policy](#), on page 2431

## Identity Terminology

This topic discusses common terminology for user identity and user control.

### User awareness

Identifying users on your network using *identity sources* (such as or TS Agent). User awareness enables you to identify users from both *authoritative* (such as Active Directory) and *non-authoritative* (application-based) sources. To use Active Directory as an identity source, you must configure a realm and directory. For more information, see [About User Identity Sources, on page 2424](#).

### User control

Configuring an *identity policy* that you associate with an *access control policy*. (The identity policy is then referred to as an access control *subpolicy*.) The identity policy specifies the identity source and, optionally, users and groups belonging to that source.

By associating the identity policy with an access control policy, you determine whether to monitor, trust, block, or allow users or user activity in traffic on your network. For more information, see [Access Control Policies, on page 1829](#).

### Authoritative identity sources

A trusted server validated the user login (for example, Active Directory). You can use the data obtained from authoritative logins to perform user awareness and user control. Authoritative user logins are obtained from passive and active authentications:

- *Passive authentications* occur when a user authenticates through an external repository. ISE/ISE-PIC, the TS Agent, Microsoft Active Directory, and Microsoft Azure Active Directory, and the Passive Identity Agent are passive authentication user repositories supported by the system.  
*Passive authentications* occur when a user authenticates with Cisco ISE.
- *Active authentications* occur when a user authenticates through preconfigured managed devices. Captive portal is another name for active authentication. Active authentication generally uses the same user repositories as passive authentication (the exceptions being ISE/ISE-PIC, and TS Agent, and the Passive Identity Agent, which are passive only).

### Non-authoritative identity sources

An unknown or untrusted server validated the user login. Traffic-based detection is the only non-authoritative identity source supported by the system. You can use the data obtained from non-authoritative logins to perform user awareness.

## About User Identity Sources

The following table provides a brief overview of the user identity sources supported by the system. Each identity source provides a store of users for user awareness. These users can then be controlled with identity and access control policies.

User Identity Source	Server Requirements	Login Type	Authentication Type	User Control	For more, see...
Captive portal	OpenLDAP Microsoft Active Directory Microsoft Azure Active Directory	Authoritative	Active	Yes	<a href="#">The Captive Portal Identity Source, on page 2563</a> <a href="#">Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal), on page 2470</a>
Passive authentication	OpenLDAP Microsoft Active Directory	Non-authoritative	Active	Yes	<a href="#">Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475</a>
Passive authentication	Microsoft Azure Active Directory	Passive	Passive	Yes	<a href="#">Configure Microsoft Azure Active Directory for Passive Authentication, on page 2453</a>
Passive authentication with the TS Agent	Microsoft Windows Terminal Server	Authoritative	Passive	Yes	<a href="#">The Terminal Services (TS) Agent Identity Source, on page 2605</a>
Passive authentication with pxGrid cloud identity source	Cisco ISE	Non-authoritative	Passive	Yes	<a href="#">About the pxGrid Cloud Identity Source, on page 2581</a>
Remote Access VPN	OpenLDAP or Microsoft Active Directory	Authoritative	Active	Yes	<a href="#">The Remote Access VPN Identity Source, on page 2601</a>
	RADIUS	Authoritative	Active	No, awareness only	
ISE/ISE-PIC	Microsoft Active Directory	Authoritative	Passive	Yes	<a href="#">The ISE/ISE-PIC Identity Source, on page 2533</a>
Traffic-based detection (Configured in the network discovery policy.)	—	Non-authoritative	—	No, awareness only	<a href="#">The Traffic-Based Detection Identity Source, on page 2687</a>

Consider the following when selecting identity sources to deploy:

- You must use traffic-based detection for non-LDAP user logins.
- You must use traffic-based detection or captive portal to record failed login or authentication activity. A failed login or authentication attempt does not add a new user to the list of users in the database.
- The captive portal identity source requires a managed device with a routed interface. You *cannot* use an inline (also referred to as tap mode) interface with captive portal.

Data from those identity sources is stored in the Security Cloud Control's users database and the user activity database. You can configure Security Cloud Control-server user downloads to automatically and regularly download new user data to your databases.

After you configure identity rules using the desired identity source, you must associate each rule with an access control policy and deploy the policy to managed devices for the policy to have any effect. For more information about access control policies and deployment, see [Associating Other Policies with Access Control, on page 1844](#).

For general information about user identity, see [About User Identity, on page 2423](#).

## Best Practices for User Identity

We recommend you review the following information before you set up identity policies.

- Know user limits
- Health monitor
- Use latest version of ISE/ISE-PIC, two types of remediation
- Captive portal requires routed interface, several individual tasks

### Microsoft Active Directory and LDAP

The system supports Active Directory, LDAP, and other user repositories for user awareness and control. The association between an Active Directory or LDAP repository and the Security Cloud Control is referred to as a *realm*. You should create one realm per LDAP server or Active Directory domain. For details about which versions are supported, see [Supported Servers for Realms, on page 2446](#).

The only user identity source supported by LDAP is captive portal. To use other identity sources (with the exception of ISE/ISE-PIC), you must use Active Directory.

For Active Directory only:

- Create one *directory* per domain controller.  
For details, see [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#)
- Users and groups in trust relationships between two domains are supported provided you add all Active Directory domains and domain controllers as realms and directories, respectively.  
For more information, see [Realms and Trusted Domains, on page 2443](#).

### Passive Identity Agent identity source

The passive identity agent software can monitor multiple Microsoft Active Directory servers and domain controllers and send user name and IP address information to the Security Cloud Control.

For more information, see [The Passive Identity Agent Identity Source, on page 2507](#).

### pxGrid Cloud Identity Source

The Cisco Identity Services Engine (Cisco ISE) pxGrid Cloud Identity Source enables you to use subscription and user data from Cisco ISE in cloud-delivered Firewall Management Center access control rules.

The pxGrid cloud identity source enables the use of constantly changing dynamic objects from ISE to be used for user control in access control policies in the cloud-delivered Firewall Management Center.

For more information, see [About the pxGrid Cloud Identity Source, on page 2581](#).

### Proxy sequence

A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)

Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over.

### Health monitor

The Security Cloud Control health monitor provides valuable information about the status of various Security Cloud Control functions, including:

- User/realm mismatches
- Short memory usage
- ISE connection status

For more information about health modules, see *Health Modules* in the [Cisco Secure Firewall Management Center Administration Guide](#).

To set up policies to monitor health modules, see *Creating Health Policies* in the [Cisco Secure Firewall Management Center Administration Guide](#).

### Use the latest version of ISE/ISE-PIC

If you expect to use the ISE/ISE-PIC identity source, we strongly recommend you always use the latest version to make sure you get the latest features and bug fixes.

pxGrid 2.0 (which is used by version 2.6 patch 6 or later; or 2.7 patch 2 or later) also changes the remediation used by ISE/ISE-PIC from Endpoint Protection Service (EPS) to Adaptive Network Control (ANC). If you upgrade ISE/ISE-PIC, you must migrate your mediation policies from EPS to ANC.

More information about using ISE/ISE-PIC can be found in [ISE/ISE-PIC Guidelines and Limitations, on page 2535](#).

To set up the ISE/ISE-PIC identity source, see [How to Configure ISE/ISE-PIC for User Control, on page 2538](#).

### Captive portal information

You can use captive portal active authentication with any of the following:

- LDAP

For more information, see [The Captive Portal Identity Source, on page 2563](#).

- Microsoft AD

For more information, see [The Captive Portal Identity Source, on page 2563](#).

- Microsoft Azure AD (SAML)

For more information, see [Create a Microsoft Azure AD \(SAML\) Realm, on page 2450](#).

### TS Agent information

The TS Agent user identity source is required to identify user sessions on a Windows Terminal Server. The TS Agent software must be installed on the Terminal Server machine as discussed in the *Cisco Terminal Services (TS) Agent Guide*. In addition, you must synchronize the time on your TS Agent server with the time on the Security Cloud Control.

TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control.

For more information, see [TS Agent Guidelines, on page 2606](#).

### Associate the identity policy with an access control policy

After you configure your realm, directory, and user identity source, you must set up identity rules in an identity policy. To make the policy effective, you must associate the identity policy with an access control policy.

For more information about creating an identity policy, see [Create an Identity Policy, on page 2611](#).

For more information about creating identity rules, see [Create an Identity Rule, on page 2618](#).

To associate an identity policy with an access control policy, see [Associating Other Policies with Access Control, on page 1844](#).

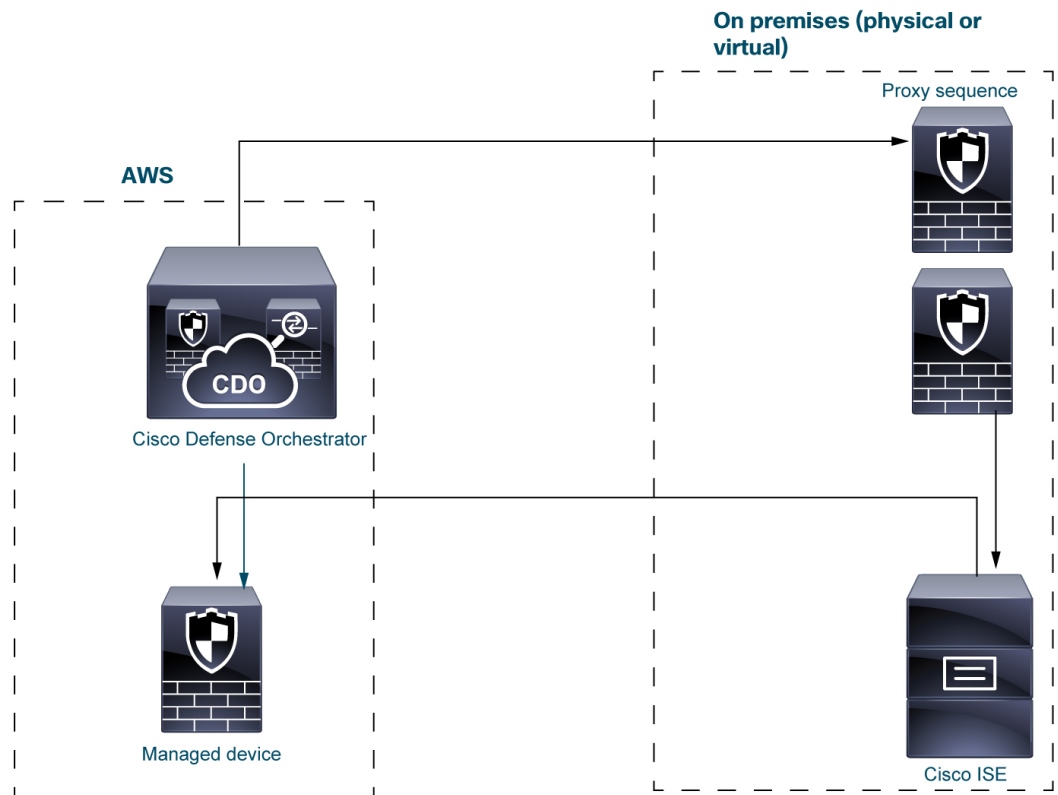

## Identity Deployments

When the system detects user data from a user login, from any identity source, the user from the login is checked against the list of users in the Security Cloud Control user database. If the login user matches an existing user, the data from the login is assigned to the user. Logins that do not match existing users cause a new user to be created, unless the login is in SMTP traffic. Non-matching logins in SMTP traffic are discarded.

The group to which the user belongs is associated with the user as soon as the user is seen by the Security Cloud Control.

### Sample identity deployments

The sample deployments discussed in this section are based on the system shown in the following figure.

In the preceding figure, Security Cloud Control and one managed device are deployed to AWS and the other devices are located on premises. These devices can be either physical or virtual; they just need to be able to communicate with each other.

The two on-premises managed devices are intended to be used as a proxy sequence. You must add those devices to Security Cloud Control as well.

A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)

LDAP or Active Directory are needed only for TS Agent and captive portal, as the following paragraphs explain.

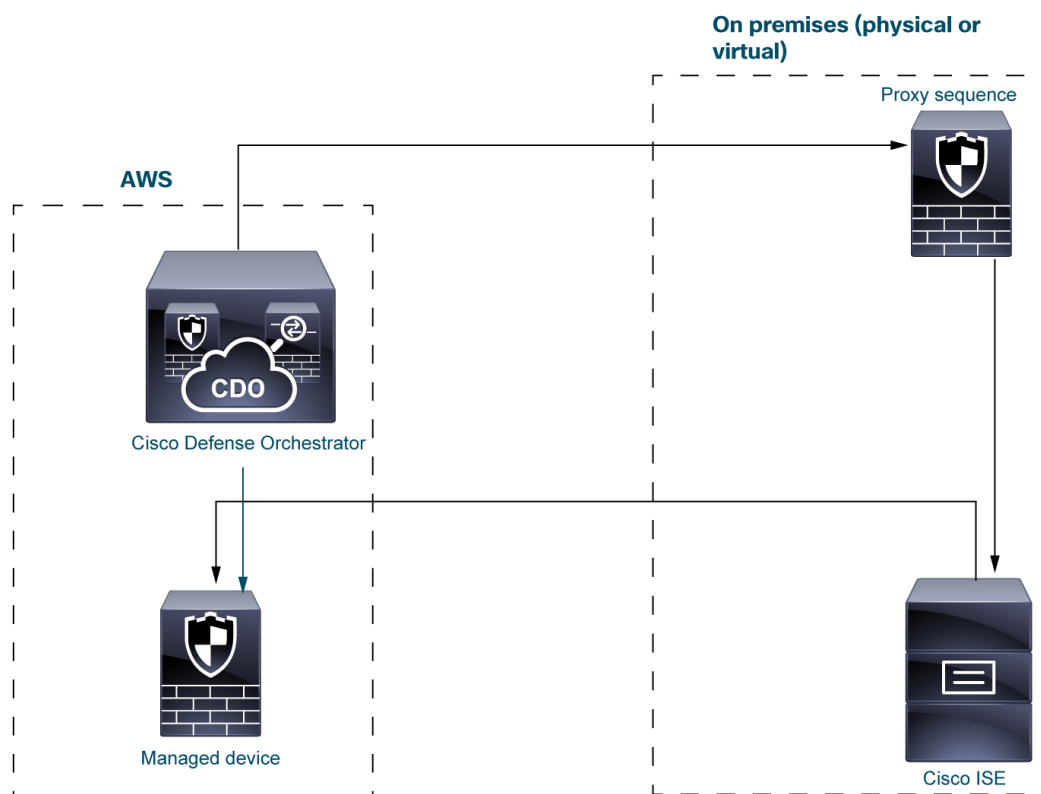

For more information about setting up a system like this, see [How to Set Up an Identity Policy, on page 2431](#).

### ISE/ISE-PIC identity source

When you deploy the ISE/ISE-PIC identity source, Security Cloud Control contacts the proxy sequence if Security Cloud Control cannot contact the ISE/ISE-PIC server directly. Users, groups, and subscriptions are sent from the ISE/ISE-PIC server to the managed device in AWS.

You can optionally have an LDAP server in an ISE/ISE-PIC deployment but because it's optional, it isn't shown in the following figure.

For more information about ISE/ISE-PIC, see [The ISE/ISE-PIC Identity Source, on page 2533](#).

### Passive identity agent identity source

Software that monitors one or several Microsoft AD domain controllers, sending user name and IP address information to the Security Cloud Control.

For more information, see [The Passive Identity Agent Identity Source, on page 2507](#).

### pxGrid Cloud Identity Source

The Cisco Identity Services Engine (Cisco ISE) pxGrid Cloud Identity Source enables you to use subscription and user data from Cisco ISE in cloud-delivered Firewall Management Center access control rules.

The pxGrid cloud identity source enables the use of constantly changing dynamic objects from ISE to be used for user control in access control policies in the cloud-delivered Firewall Management Center.

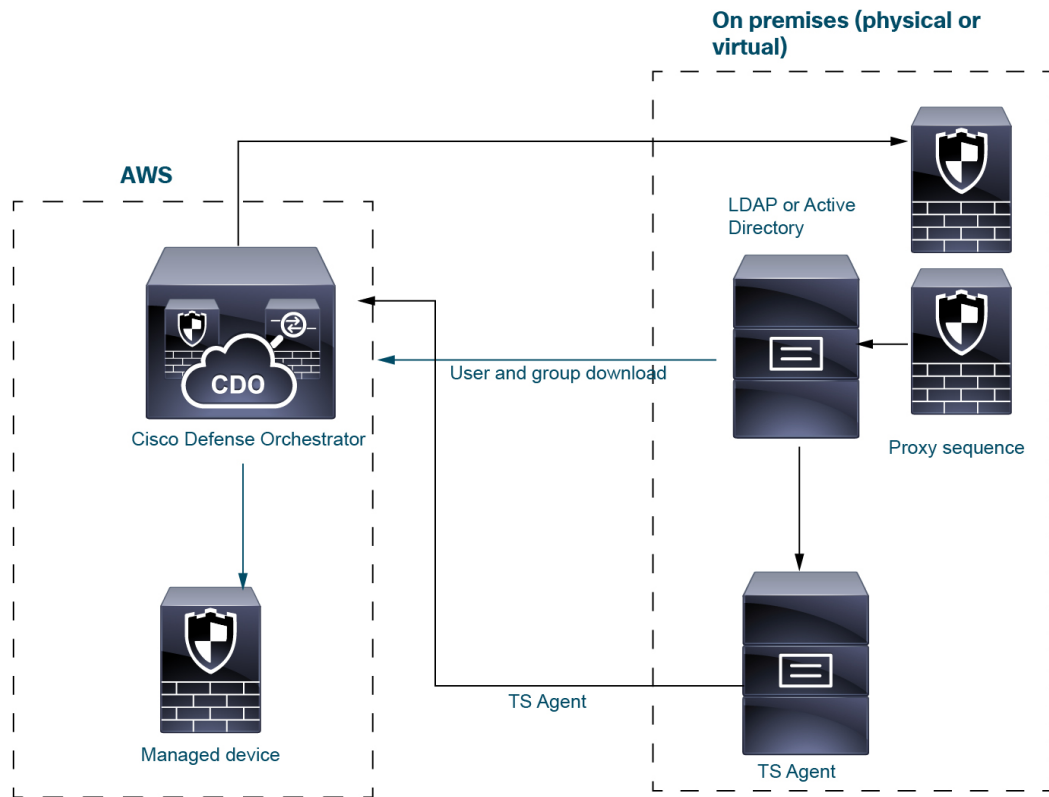

For more information, see [About the pxGrid Cloud Identity Source, on page 2581](#).

### TS Agent identity source

The Terminal Services (TS) Agent software runs on a Microsoft Server and sends Security Cloud Control user information based on the port range the users log in to the server with. TS Agent gets user identity information from LDAP or Active Directory and sends it to Security Cloud Control.

For more information about the TS Agent identity source, see [The Terminal Services \(TS\) Agent Identity Source, on page 2605](#).

### Captive portal

You can use captive portal active authentication with any of the following:

- LDAP  
For more information, see [The Captive Portal Identity Source, on page 2563](#).
- Microsoft AD  
For more information, see [The Captive Portal Identity Source, on page 2563](#).
- Microsoft Azure AD (SAML)  
For more information, see [Create a Microsoft Azure AD \(SAML\) Realm, on page 2450](#).

## How to Set Up an Identity Policy

This topic provides a high-level overview of setting up an identity policy using any available user identity source: TS Agent, ISE/ISE-PIC, Microsoft Azure AD (SAML), captive portal.

### Procedure

	Command or Action	Purpose
<b>Step 1</b>	Choose your identity source.	<ul style="list-style-type: none"> <li>• To use Microsoft Active Directory or LDAP, continue with the next step.</li> </ul>

	Command or Action	Purpose
		<ul style="list-style-type: none"> <li>• To use a Microsoft Azure AD (SAML) realm, see <a href="#">Create a Microsoft Azure AD (SAML) Realm</a>, on page 2450.</li> <li>• To use the Cisco ISE identity source, see <a href="#">Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source</a>, on page 2550.</li> <li>• To use the passive identity agent identity source, see <a href="#">The Passive Identity Agent Identity Source</a>, on page 2507.</li> <li>• To use the pxGrid cloud identity source, see <a href="#">About the pxGrid Cloud Identity Source</a>, on page 2581.</li> </ul>
<b>Step 2</b>	(Optional.) Create a proxy sequence.	<p>A <i>proxy sequence</i> is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)</p> <p>Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over.</p> <p>See <a href="#">Create a Proxy Sequence</a>, on page 2448.</p>
<b>Step 3</b>	(Optional.) Create a realm and directory, one realm for every domain in the forest that contain users you want to use in user control. Also create one directory for every domain controller. Only users and groups that have corresponding management center realms and directories can be used in identity policies..	<p>Creating a realm, realm directory, and proxy sequence is optional if any of the following are true:</p> <ul style="list-style-type: none"> <li>• You use SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions.</li> <li>• You are using an identity policy only to filter network traffic.</li> <li>• A proxy sequence is required only if you use Cisco Security Cloud Control (Security Cloud Control) and it cannot directly communicate with Active Directory or ISE/ISE-PIC.</li> </ul>

	Command or Action	Purpose
		<p>The <i>realm</i> is a trusted user and group store, typically a Microsoft Active Directory repository. The management center downloads users and groups at intervals you specify. You can include or exclude users and groups from being downloaded.</p> <p>See <a href="#">Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475</a>. For details about the options to create a realm, see <a href="#">Realm Fields, on page 2478</a>.</p> <p>A <i>directory</i> is an Active Directory domain controller that organizes information about a computer network's users and network shares. An Active Directory controller provides Directory Services for the realm. Active Directory distributes user and group objects across multiple domain controllers, which are peers that propagate local changes between each other by the use of Directory Services. For more information, see the <a href="#">Active Directory technical specification glossary</a> on MSDN.</p> <p>You can specify more than one directory for a realm, in which case each domain controller is queried in the order listed on the realm's <b>Directory</b> tab page to match user and group credentials for user control.</p> <p><b>Note</b> Configuring a realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions.</p>
<b>Step 4</b>	Synchronize users and groups from the realm.	<p>To be able to control users and groups, you must synchronize them with the management center. You can synchronize them with users and groups whenever you want or you can configure the system to synchronize them at a specified interval.</p> <p>When you synchronize users and groups, you can specify exceptions; for example, you can exclude the Engineering group from all user control for that realm, or you can exclude the user <b>joe.smith</b> from user controls that apply to the Engineering group.</p> <p>See <a href="#">Synchronize Users and Groups, on page 2487</a></p>

	Command or Action	Purpose
<b>Step 5</b>	(Optional.) Create a realm sequence.	A realm sequence is an ordered list of realms that, when used in an identity policy, causes the system to search the realms in the specified order to find users to match the rule. See <a href="#">Create a Realm Sequence, on page 2488</a> .
<b>Step 6</b>	Create a method to retrieve user and group data (the <i>identity source</i> ).	Set up an identity source with its unique configuration to be able to control users and groups using data stored in the realm. Identity sources include TS Agent, captive portal, or Remote VPN. See one of the following: <ul style="list-style-type: none"> <li>• <a href="#">How to Configure the Captive Portal for User Control, on page 2567</a></li> <li>• <a href="#">Configure ISE for User Control, on page 2547</a></li> <li>• <a href="#">Configure RA VPN for User Control, on page 2602</a></li> </ul>
<b>Step 7</b>	Create an identity policy.	An identity policy contains one or more identity rules, optionally organized in categories. See <a href="#">Create an Identity Policy, on page 2611</a> . <p><b>Note</b> Configuring a realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions; or if you use your identity policy only to filter network traffic.</p>
<b>Step 8</b>	Create one or more identity rules.	Identity rules enable you to specify a number of matching criteria, including the type of authentication, network zones, networks or geolocation, realms, realm sequences, and so on. See <a href="#">Create an Identity Rule, on page 2618</a> .
<b>Step 9</b>	Associate your identity policy with an access control policy.	An access control policy filters and optionally inspects traffic. An identity policy must be associated with an access control policy to have any effect. See <a href="#">Associating Other Policies with Access Control, on page 1844</a> .
<b>Step 10</b>	Deploy the access control policy to at least one managed device.	To use your policy to control user activity, the policy must be deployed to the managed devices to which clients connect. See <a href="#">Deploy Configuration Changes, on page 240</a> .

	Command or Action	Purpose
<b>Step 11</b>	Monitor user activity.	<p>View a list of active sessions collected by user identity sources or a list of user information collected by user identity sources. .</p> <p>An identity policy is not required if all of the following are true:</p> <ul style="list-style-type: none"> <li>• You use the ISE/ISE-PIC identity source.</li> <li>• You do not use users or groups in access control policies.</li> <li>• You use Security Group Tags (SGT) in access control policies. For more information, see <a href="#">ISE SGT vs Custom SGT Rule Conditions</a>.</li> </ul>

**Related Topics**

[Configuring Traffic-Based User Detection](#), on page 2689

## The User Activity Database

The user activity database on the Secure Firewall Management Center contains records of user activity on your network detected or reported by all of your configured identity sources. The system logs events in the following circumstances:

- When it detects individual logins or logoffs.
- When it detects a new user.
- When a system administrator manually delete a user.
- When the system detects a user that is not in the database, but cannot add the user because you have reached your user limit.
- When you resolve an indication of compromise associated with a user, or enable or disable indication of compromise rules for a user.

**Note** If the TS Agent monitors the same users as another passive authentication identity source (such as the ISE/ISE-PIC), the management center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the management center.

You can view user activity detected by the system using the Secure Firewall Management Center. (**Analysis > Users > User Activity**.)

## The Users Database

The users database on the Secure Firewall Management Center contains a record for each user detected or reported by all of your configured identity sources. You can use data obtained from an authoritative source for user control.

See [About User Identity Sources, on page 2424](#) for more information about the supported non-authoritative and authoritative identity sources.

The total number of users the Secure Firewall Management Center can store depends on the Secure Firewall Management Center model. After the user limit is reached, the system prioritizes previously-undetected user data based on its identity source, as follows:

- If the new user is from a non-authoritative identity source, the system does not add the user to the database. To allow new users to be added, you must delete users manually or with a database purge.
- If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period and adds the new user to the database.

If an identity source is configured to exclude specific user names, user activity data for those user names are not reported to the Secure Firewall Management Center. These excluded user names remain in the database, but are not associated with IP addresses.

If you have management center high availability configured and the primary fails, no logins reported by a captive portal, ISE/ISE-PIC, TS Agent, or Remote Access VPN device can be identified during failover downtime, even if the users were previously seen and downloaded to the management center. The unidentified users are logged as Unknown users on the management center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.

---

**Note** If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the management center prioritizes the TS Agent data. If the TS Agent and another passive source report identical activity from the same IP address, only the TS Agent data is logged to the management center.

---

When the system detects a new user session, the user session data remains in the users database until one of the following occurs:

- A user on the management center manually deletes the user session.
- An identity source reports the logoff of that user session.
- A realm ends the user session as specified by the realm's **User Session Timeout: Authenticated Users**, **User Session Timeout: Failed Authentication Users**, or **User Session Timeout: Guest Users** setting.

# Cloud-delivered Firewall Management Center Host and User Limits

## Cloud-delivered Firewall Management Center Host Limit

The Cloud-delivered Firewall Management Center adds a host to the network map when it detects activity associated with an IP address in your monitored network (as defined in your network discovery policy).

Cloud-delivered Firewall Management Center can store a maximum of 600,000 hosts in its host database but we recommend the following.

Number of devices managed by Security Cloud Control	Recommended number of hosts
1-50	100,000
51-300	300,000
301-1000	600,000

You cannot view contextual data for hosts not in the network map. However, you can perform access control. For example, you can perform application control on traffic to and from a host not in the network map, even though you cannot use a compliance allow list to monitor the host's network compliance.

---

**Note** The system counts MAC-only hosts separately from hosts identified by both IP addresses and MAC addresses. All IP addresses associated with a host are counted together as one host.

---

### Reaching the Host Limit and Deleting Hosts

The network discovery policy controls what happens when you detect a new host after you reach the host limit; you can drop the new host, or replace the host that has been inactive for the longest time. You can also set the period after which the system removes a host from the network map due to inactivity. Although you can manually delete a host, an entire subnet, or all of your hosts from the network map, if the system detects activity associated with a deleted host, it re-adds the host.

## Cloud-delivered Firewall Management Center User Limit

A user is added to the Cloud-delivered Firewall Management Center user database when:

- The user is downloaded from a realm.
- A captive portal or RA-VPN user logs in.
- A user is detected from any identity source (for example, TS Agent).

A Cloud-delivered Firewall Management Center can store a maximum of 600,000 users in its host database but we recommend the following.

Number of devices managed by Security Cloud Control	Recommended number of users
1-50	100,000
51-300	300,000
301-1000	600,000

Only authoritative users are available for user control with access control policies.

The Cloud-delivered Firewall Management Center can store 600,000 sessions in its user database.

When the system detects a new, previously-undetected user after the limit has been reached, it prioritizes user data based on their identity source:

- If the new user is from a non-authoritative source, the system does not add the non-authoritative user to the database. To allow new users to be added, you must delete users manually or purge the database.
- If the new user is from an authoritative identity source, the system deletes the non-authoritative user who has remained inactive for the longest period of and adds the new authoritative user to the database.

If there are only authoritative users, the system deletes the authoritative user who has remained inactive for the longest period of time and adds the new user to the database.

Troubleshooting information can be found in [Troubleshoot User Control, on page 2628](#).

---

**Tip** Note that if you are using traffic-based detection, you can restrict user logging by protocol to help minimize username clutter and preserve space in the database. For example, you could prevent the system from adding users discovered in AIM, POP3, and IMAP traffic because you know it is traffic from specific contractors or visitors you do not want to monitor.

---

## User Limits for Microsoft Azure Active Directory Realms

### Microsoft Azure Active Directory User Limits

#### About user limits

Your management center model determines how many individual users you can monitor.

Note the following:

- The maximum number of *downloaded* users depends on your management center model.
- The maximum number of *concurrent* user sessions (that is, logins) depends on your managed device model. A single user can have multiple sessions from different unique IP addresses.

**Note** The system downloads all user sessions to all threat defense devices. If you have devices with different user concurrent user session limits, the threat defense with the smallest limit reports health warnings when its memory reaches the configured limit. (For example, if your management center manages a Firepower 2110 and a 4125, the 2110 reports health warnings when the number of concurrent user sessions approaches its maximum of 64,000.)

Refer to the following tables.

**Table 222: Maximum Downloaded Users by Management Center Model<sup>1</sup>**

Management Center Model	Number of Cisco Secure Dynamic Attributes Connector Connectors	Maximum Downloaded Users
Management Center Virtual (any supported hypervisor)	10	50,000
Management Center Virtual 300 (any supported hypervisor)	20	150,000

<sup>1</sup>—Management Center models are subject to end of life and end of sale. For more information, see [End-Of-Life and End-Of-Sale Notices](#).

**Table 223: Maximum Concurrent User Login Limits by Threat Defense**

Threat Defense Model	Maximum Concurrent User Logins
Threat Defense Virtual 5, 10, 20, 30, 50 (any supported hypervisor)	50,000
Firepower 1010, 1120, 1140, 1150 Firepower 2110, 2120, 2130 Secure Firewall 3110, 3120, 3130, 3140	50,000
Firepower 2140 Secure Firewall 3130, 3140	150,000
Firepower 4140, 4145, 4150 Firepower 9300 Secure Firewall 4215	225,000
Secure Firewall 4225, 4245	300,000

## CHAPTER 90

# Realms

---

The following topics describe realms and identity policies:

- [About Realms and Realm Sequences](#), on page 2441
- [License Requirements for Realms](#), on page 2448
- [Requirements and Prerequisites for Realms](#), on page 2448
- [Create a Proxy Sequence](#), on page 2448
- [Create a Microsoft Azure AD \(SAML\) Realm](#), on page 2450
- [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475
- [Create a Realm Sequence](#), on page 2488
- [Configure the Management Center for Cross-Domain-Trust: The Setup](#), on page 2489
- [Manage a Realm](#), on page 2497
- [Compare Realms](#), on page 2498
- [Troubleshoot Realms and User Downloads](#), on page 2498
- [History for Realms](#), on page 2504

## About Realms and Realm Sequences

*Realms* are connections between the Secure Firewall Management Center and the user accounts on the servers you monitor. They specify the connection settings and authentication filter settings for the server. Realms can:

- Specify the users and user groups whose activity you want to monitor.
- Query the user repository for user metadata on authoritative users, as well as some non-authoritative users: POP3 and IMAP users detected by traffic-based detection and users detected by traffic-based detection, a TS Agent, or ISE/ISE-PIC.

You can add multiple domain controllers as directories in a realm, but they must share the same basic realm information. The directories in a realm must be exclusively LDAP or exclusively Active Directory (AD) servers. After you enable a realm, your saved changes take effect next time the management center queries the server.

To perform user awareness, you must configure a realm for any of the [Supported Servers for Realms](#). The system uses these connections to query the servers for data associated with POP3 and IMAP users, and to collect data about LDAP users discovered through traffic-based detection.

The system uses the email addresses in POP3 and IMAP logins to correlate with LDAP users on an Active Directory or OpenLDAP. For example, if a managed device detects a POP3 login for a user with the same email address as an LDAP user, the system associates the LDAP user's metadata with that user.

To perform user control, you can configure any of the following:

- A realm or realm sequence for an Active Directory server, or for ISE/ISE-PIC

---

**Note** Configuring a Microsoft AD realm or realm sequence is optional if you plan to configure SGT ISE attribute conditions but not user, group, realm, Endpoint Location, or Endpoint Profile conditions; or if you use your identity policy only to filter network traffic.

---

- A realm or realm sequence for a Microsoft AD server for the TS Agent.
- For captive portal, an LDAP realm.

A realm sequence is not supported for LDAP.

You can nest Microsoft AD groups and the management center downloads those groups and the users they contain. You can optionally restrict which groups and users get downloaded as discussed in [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).

### About User Synchronization

You can configure a realm or realm sequence to establish a connection between the management center and an LDAP or Microsoft AD server to retrieve user and user group metadata for certain detected users:

- LDAP and Microsoft AD users authenticated by captive portal or reported by ISE/ISE-PIC. This metadata can be used for user awareness and user control.
- POP3 and IMAP user logins detected by traffic-based detection, if those users have the same email address as an LDAP or AD user. This metadata can be used for user awareness.

The management center obtains the following information and metadata about each user:

- LDAP user name
- First and last names
- Email address
- Department
- Telephone number

---

**Important** To reduce latency between the management center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the management center.

For example, if your management center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

---

### About User Activity Data

User activity data is stored in the user activity database and user identity data is stored in the users database. If your access control parameters are too broad, the management center obtains information on as many users as it can and reports the number of users it failed to retrieve in the Tasks tab page of the Message Center.

To optionally limit the subnets on which a managed device watches for user awareness data, you can use the **configure identity-subnet-filter** command as discussed in the [Cisco Secure Firewall Threat Defense Command Reference](#).

**Note** If you remove a user that has been detected by the system from your user repository, the management center does *not* remove that user from its users database; you must manually delete it. However, your LDAP changes *are* reflected in access control rules when the management center next updates its list of authoritative users.

## Realms and Trusted Domains

When you configure a Microsoft Active Directory (AD) *realm* in the management center, it is associated with a Microsoft Active Directory or LDAP *domain*.

A grouping of Microsoft Active Directory (AD) domains that trust each other is commonly referred to as a *forest*. This trust relationship can enable domains to access each other's resources in different ways. For example, a user account defined in domain A can be marked as a member of a group defined in domain B.

### The system and trusted domains

The system supports AD forests that are configured in a trust relationship. There are several types of trust relationships; this guide discusses two-way, transitive forest trust relationships. The following simple example shows two forests: **forest.example.com** and **eastforest.example.com**. Users and groups in each forest can be authenticated by AD in the other forest, provided you configure the forests that way.

If you set up the system with one realm for each domain and one directory for each domain controller, the system can discover up to 100,000 [foreign security principals](#) (users and groups). If these foreign security principals match a user downloaded in another realm, then they can be used in access control policy.

You need not configure a realm for any domain that has no users you wish to use in access control policies.

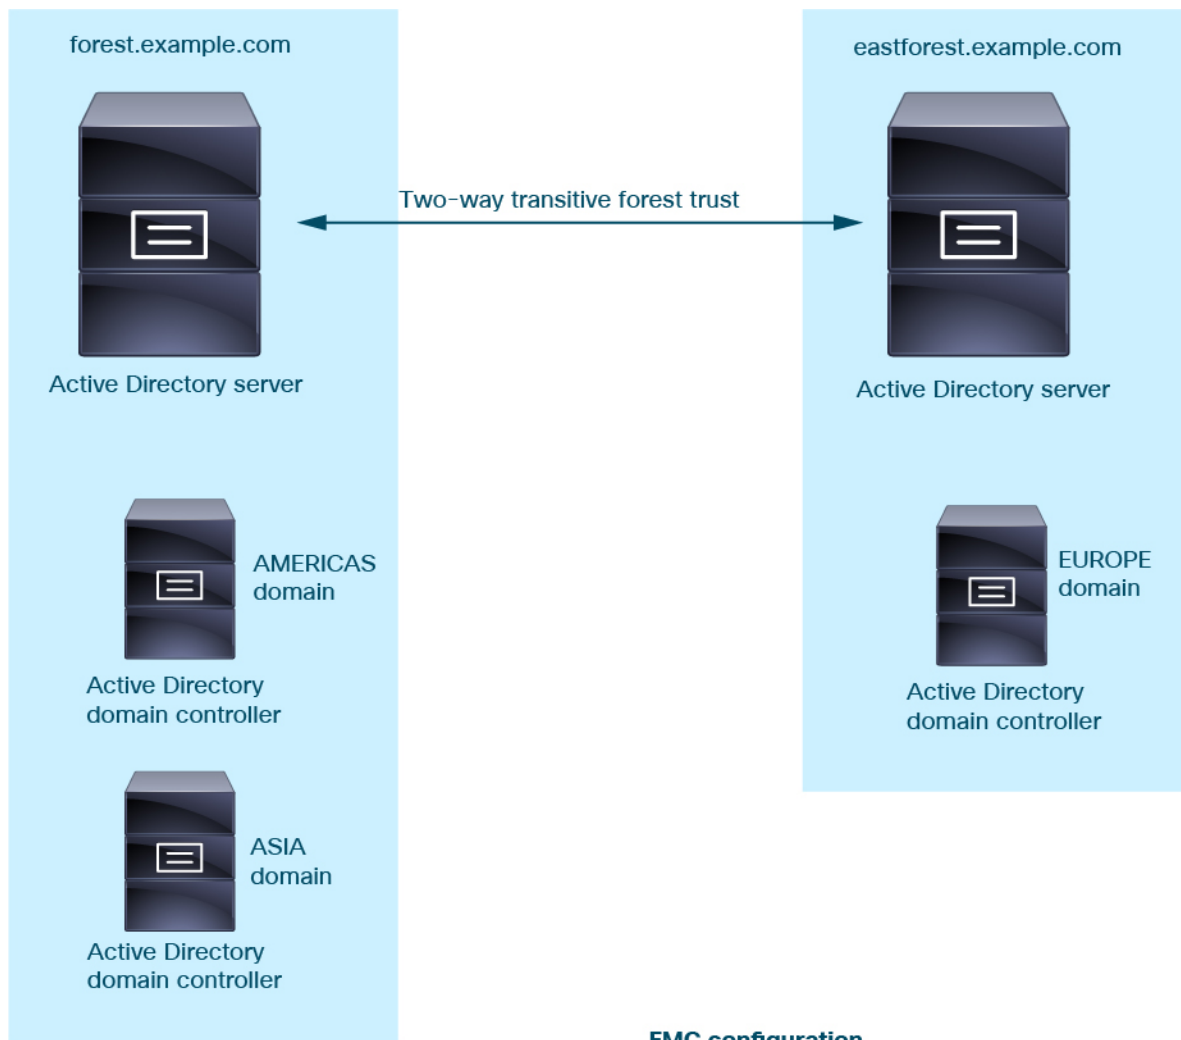

To continue the example, suppose you have three AD forests (one of which could be a subdomain or an independent forest), all set up as two-way transitive forest relationships, all users and groups are available in

all three forests as well as in the system. (As in the preceding example, all three AD domains must be set up as realms and all domain controllers must be configured as directories in those realms.)

Finally, you can set up the management center to be able to enforce identity policies on users and groups in a two-forest system with two-way transitive forest trust. Suppose each forest has at least one domain controller, each of which authenticates different users and groups. For the management center to be able to enforce identity policies on those users and groups, you must set up each domain containing relevant users as management center realm and each domain controller as management center directory in the respective realm.

Failure to properly configure the management center prevents some of the users and groups from being able to be used in policies. You will see warnings when you try to synchronize users and groups in that case.

**FMC configuration**

**Realm:** forest.example.com  
**Directory:** AMERICAS.forest.example.com  
**Directory:** ASIA.forest.example.com  
**Realm:** eastforest.example.com  
**Directory:** EUROPE.eastforest.example.com

Using the preceding example, set up the management center as follows:

- Realm for any domain in **forest.example.com** that contains users you want to control with access control policies
  - Directory in the realm for **AMERICAS.forest.example.com**
  - Directory in the realm for **ASIA.forest.example.com**
- Realm for any domain in **eastforest.example.com** that contains users you want to control with access control policies

- Directory in the realm for **EUROPE.eastforest.example.com**

**Note** The management center uses the AD field **msDS-PrincipalName** to resolve references to find user and group names in each domain controller. **msDS-PrincipalName** returns a NetBIOS name.

## Supported Servers for Realms

You can configure realms to connect to the following types of servers, providing they have TCP/IP access from the management center:

Server Type	Supported for ISE/ISE-PIC data retrieval?	Supported for TS Agent data retrieval?	Supported for captive portal data retrieval?
Microsoft Active Directory on Windows Server 2012, 2016, and 2019	Yes	Yes	Yes
OpenLDAP on Linux	No	No	Yes

An Active Directory Global Catalog server is *not supported* as a realm directory. For more information about the Global Catalog Server, see [Global Catalog](#) on learn.microsoft.com.

**Note** If the TS Agent is installed on a Microsoft Active Directory Windows Server shared with another passive authentication identity source (ISE/ISE-PIC), the management center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the management center.

Note the following about your server group configurations:

- To perform user control on user groups or on users in groups, you must configure user groups on the LDAP or Active Directory server.
- Group names cannot start with **S-** because it is used internally by LDAP.

Neither group names nor organizational unit names can contain special characters like asterisk (\*), equals (=), or backslash (\); otherwise, users in those groups or organizational units are not downloaded and are not available for identity policies.

- To configure an Active Directory realm that includes or excludes users who are members of a sub-group on your server, note that Microsoft recommends that Active Directory has no more than 5000 users per group in Windows Server 2012. For more information, see Active Directory Maximum Limits—Scalability on [MSDN](#).

If necessary, you can modify your Active Directory server configuration to increase this default limit and accommodate more users.

- To uniquely identify the users reported by a server in your Remote Desktop Services environment, you must configure the Cisco Terminal Services (TS) Agent. When installed and configured, the TS Agent assigns unique ports to individual users so the system can uniquely identify those users. (Microsoft changed the name *Terminal Services* to *Remote Desktop Services*.)

For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

## Supported Server Object Class and Attribute Names

The servers in your realms *must* use the attribute names listed in the following table for the management center to retrieve user metadata from the servers. If the attribute names are incorrect on your server, the management center cannot populate its database with the information in that attribute.

**Table 224: Map of attribute names to Secure Firewall Management Center fields**

Metadata	Management Center Attribute	LDAP ObjectClass	Active Directory Attribute	OpenLDAP Attribute
LDAP user name	Username	<ul style="list-style-type: none"> <li>• user</li> <li>• in OpenLDAP</li> </ul>	samaccountname	cn uid
first name	First Name		givenname	givenname
last name	Last Name		sn	sn
email address	Email		mail userprincipalname (if mail has no value)	mail
department	Department		department distinguishedname (if department has no value)	ou
telephone number	Phone		telephonenumber	telephonenumber

**Note** The LDAP ObjectClass for groups is `group`, `groupOfNames`, (`group-of-names` for Active Directory) or `groupOfUniqueNames`.

For more information about ObjectClasses and attributes, see the following references:

- Microsoft Active Directory:
  - ObjectClasses: All Classes on [MSDN](#)
  - Attributes: All Attributes on [MSDN](#)
- OpenLDAP: [RFC 4512](#)

# Create a Proxy Sequence

A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)

Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over.

---

**Note** To use a proxy sequence with a SAML - Azure AD realm, the managed device must run version 7.4.2 or later.

---

## Before you begin

You must add at least two managed devices to Security Cloud Control, all of which must be able to communicate with Active Directory or ISE/ISE-PIC.

## Procedure

- Step 1** Log in to the management center if you have not already done so.
- Step 2** Click **Integration > Other Integrations > Realms > Proxy Sequence**.
- Step 3** Click **Add Proxy Sequence**.
- Step 4** In the **Name** field, enter a name to identify the proxy sequence.
- Step 5** (Optional.) In the **Description** field, enter a description for the proxy sequence.
- Step 6** Under Proxies, click **Add (+)**.
- Step 7** Click the name of each managed device to add to the sequence.  
To narrow your search, enter all or part of a realm name in **Filter** field.
- Step 8** Click **OK**.
- Step 9** In the Add Proxy Sequence dialog box, drag and drop the proxies in the order in which you want Security Cloud Control to search for them.  
The following figure shows an example of a proxy sequence consisting of two proxies. The top proxy will be searched for users before the bottom proxy. Both proxies must be able to communicate with either Active Directory or ISE/ISE-PIC.

- Step 10** Click **Save**.

## What to do next

See [Create an Identity Policy](#), on page 2611.

# Create a Microsoft Azure AD (SAML) Realm

You can use a Microsoft Azure Active Directory (AD) realm for either passive authentication or active authentication.

## Passive authentication

*Passive authentications* occur when a user authenticates with Cisco ISE.

You have the following options, depending on your choice of user and group repository:

- To use Cisco ISE as a repository for users and to perform passive authentication using Azure AD. For more information, see:
  - [About Azure AD and Cisco ISE with Resource Owned Password Credentials, on page 2451](#)
  - [About Azure AD and Cisco ISE with TEAP/EAP-TLS, on page 2452](#)
- To download groups from Azure AD.

For more information about setting up Azure AD, see [Configure Microsoft Azure Active Directory for Passive Authentication, on page 2453](#).

## Active authentication

*Active authentications* occur when a user authenticates through preconfigured managed devices. Captive portal is another name for active authentication. Active authentication generally uses the same user repositories as passive authentication (the exceptions being ISE/ISE-PIC, and TS Agent, and the Passive Identity Agent, which are passive only).

To use Microsoft Azure AD as a captive portal requires users to authenticate with Azure AD. We refer to the realm as a Security Assertion Markup Language (SAML) realm because SAML is used to establish a trust relationship between:

- A *service provider* (the Secure Firewall Threat Defense device or devices to which authentication requests are sent).
- An *identity provider* (Microsoft Azure AD).

SAML is an open standard developed by the OASIS standards body; for more information, see the [SAML Overview](#).

For more information, see [How to Create a Microsoft Azure AD \(SAML\) Realm for Active Authentication \(Captive Portal\), on page 2461](#).

## How to Create a Microsoft Azure AD Realm for Passive Authentication

This topic discusses the high-level tasks of creating a Microsoft Azure AD (SAML) realm for passive authentication use with the Cisco Security Cloud Control.

## Procedure

	Command or Action	Purpose
<b>Step 1</b>	Enable the Cisco Secure Dynamic Attributes Connector.	The Cisco Secure Dynamic Attributes Connector is required to use a realm. You can do it first or you can enable it when you create the realm. .
<b>Step 2</b>	Configure Microsoft Azure AD.	Several configuration tasks are required, including setting up an event hub, giving your application permission to the Microsoft Graph API, and enabling the audit log.  See <a href="#">Configure Microsoft Azure Active Directory for Passive Authentication, on page 2453</a> .
<b>Step 3</b>	Configure Cisco ISE.	The way you configure ISE depends on how users authenticate with your system. For more information, see <a href="#">How to Configure ISE for Microsoft Azure AD (SAML)Microsoft Azure AD, on page 2453</a> .
<b>Step 4</b>	Create a Cisco ISE identity source.	The identity source enables ISE to communicate with the Secure Firewall Management Center.
<b>Step 5</b>	Get the information required to configure your Microsoft Azure AD realm.	This information includes client and tenant IDs, client secret, and other information store in Microsoft Azure AD.
<b>Step 6</b>	Configure and verify your realm.	Test the realm's configuration before you start to use it in access control policies.  Create a Microsoft Azure AD (SAML) realm as discussed in <a href="#">Create a Microsoft Azure AD (SAML) Realm, on page 2450</a>
<b>Step 7</b>	Create access control policies and rules using your Microsoft Azure AD (SAML) realm.	Unlike other types of realms, you do not need to create an identity policy or associate the identity policy with an access control policy.  See <a href="#">Creating a Basic Access Control Policy, on page 1832</a> and <a href="#">Create and Edit Access Control Rules, on page 1863</a> .

### What to do next

See [About Azure AD and Cisco ISE with Resource Owned Password Credentials, on page 2451](#).

## About Azure AD and Cisco ISE with Resource Owned Password Credentials

The following figure summarizes an Azure AD realm with Cisco ISE and resource owned password credentials (ROPC):

With ROPC,

1. The user logs in with a user name (or email address) and password using a VPN client like Cisco Secure Client.
2. The client ID, client secret, user name, password, and scopes are sent to Azure AD.
3. Tokens are sent from Azure AD to Cisco ISE, which sends user sessions to the Secure Firewall Management Center.

For details about configuring Cisco ISE, see [Configure ISE 3.0 REST ID with Azure Active Directory](#).

Additional resource: [Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials](#) on learn.microsoft.com.

## About Azure AD and Cisco ISE with TEAP/EAP-TLS

Tunnel Extensible Authentication Protocol (TEAP), defined by [RFC7170](#), can be used with ISE and the Cisco Security Cloud Control as follows:

The following is based on [Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory](#):

1. The user's certificate is sent to ISE through EAP-TLS or TEAP with EAP-TLS as the inner method.
2. ISE evaluates the user's certificate (validity period, trusted certificate authority, certificate revocation list, and so on).
3. ISE takes the certificate subject name (CN) and performs a look-up to the Azure Graph API to fetch the user's groups and other attributes. This is referred to by Azure as User Principal name (UPN).
4. ISE authorization policies are evaluated against the user's attributes returned from Azure.

## How to Configure ISE for Microsoft Azure AD (SAML)Microsoft Azure AD

In a Microsoft Azure AD (SAML)Microsoft Azure AD realm, it's the responsibility of ISE to send user sessions (login, logout) to the management center. This topic discusses how to set up ISE for use with an Azure AD realm.

### Resource owned password credentials authentication

To use ISE with Microsoft Azure AD (SAML)Microsoft Azure ADMicrosoft Azure AD implemented through Representational State Transfer (REST) Identity (ID) service with the help of Resource Owner Password Credentials (ROPC), see [Configure ISE 3.0 REST ID with Azure Active Directory](#).

### TEAP/EAP-TLS

To use ISE with authorization policies based on Azure AD group membership and other user attributes with EAP-TLS or TEAP as the authentication protocols, see [Configure Cisco ISE 3.2 EAP-TLS with Microsoft Azure Active Directory](#).

### What to do next

[Get Required Information For Your Microsoft Azure AD Realm, on page 2455](#)

## Configure Microsoft Azure Active Directory for Passive Authentication

This topic provides basic information about how to set up a Microsoft Azure Active Directory (AD) as a realm you can use with the Security Cloud Control. We expect you to already be familiar with Azure AD; if not, consult documentation or a support resource before you get started.

### Give your application the Microsoft Graph permission

Grant your Azure AD application the following permissions to Microsoft Graph as discussed in [Authorization and the Microsoft Graph Security API](#) on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the Security Cloud Control to download users and groups from Azure AD the first time.

*Required information from this step* for setting up the Azure AD realm in the Security Cloud Control:

- Name of the app you registered

- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

### Set up an event hub

Set up the event hub as discussed in [Quickstart: Create an event hub using Azure portal](#) on the Microsoft site. The Security Cloud Control uses the event hub audit log to download periodic updates to users and groups.

More information: [Features and terminology in Azure Event Hubs](#).

---

**Important** You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

---

*Required information from this step* for setting up the Azure AD realm in the Security Cloud Control:

- **Namespace Name**
- **Connection string—primary key**
- **Event Hub Name**
- **Consumer group Name**

### Enable the audit log

Enable the audit log as discussed in [Tutorial: Stream Azure Active Directory logs to an Azure event hub](#) on the Microsoft site.

### Configure Cisco ISE for Azure AD

To send user session information to the Security Cloud Control, configure Cisco ISE for Azure AD as discussed in [Configure ISE 3.0 REST ID with Azure Active Directory](#).

### What to do next

See [How to Configure ISE for Microsoft Azure AD \(SAML\)Microsoft Azure AD, on page 2453](#).

## Configure Azure AD Basic Settings

### Give your application the Microsoft Graph permission

Grant your Azure AD application the following permissions to Microsoft Graph as discussed in [Authorization and the Microsoft Graph Security API](#) on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the management center to download users and groups from Azure AD the first time.

*Required information from this step* for setting up the Azure AD realm in the management center:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

### Set up an event hub

Set up the event hub as discussed in [Quickstart: Create an event hub using Azure portal](#) on the Microsoft site. The management center uses the event hub audit log to download periodic updates to users and groups.

More information: [Features and terminology in Azure Event Hubs](#).

---

**Important** You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

---

*Required information from this step* for setting up the Azure AD realm in the Cisco Security Cloud Control:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

### Enable the audit log

Enable the audit log as discussed in [Tutorial: Stream Azure Active Directory logs to an Azure event hub](#) on the Microsoft site.

## Get Required Information For Your Microsoft Azure AD Realm

This task explains how to get the information required to set up a Microsoft Azure AD realm in the Cisco Security Cloud Control. You might have already obtained this information when you set up Microsoft Azure AD as discussed in [Configure Microsoft Azure Active Directory for Passive Authentication, on page 2453](#).

### Procedure

- 
- Step 1** Log in to <https://portal.azure.com/> as a user with at least the Product Designer role.
  - Step 2** At the top of the page, click **Microsoft Entra ID**.
  - Step 3** In the left column, click **App Registrations**.
  - Step 4** If necessary, filter the list of displayed apps to show the one you want to use.
  - Step 5** Click the name of your app.

Display name : docs-test

Application (client) ID : 7 [redacted]c11

Object ID : [redacted]1b9

Directory (tenant) ID : [redacted]90

Supported account types : [My organization only](#)

Client credentials : 0 certificate\_1 secret

Redirect URIs : [Add a Redirect URI](#)

Application ID URI : [Add an Application ID URI](#)

Managed application in L... : docs-test

**Step 6** Click **Copy** (📄) next to the following values on this page and paste those values to a text file.

- **Application (Client) ID**
- **Directory (tenant) ID**

**Step 7** Click **Client Credentials**.

**Step 8** Unless you already know the client secret *value* (as opposed to the client *secret ID*), you must create a new client secret as follows:

- Click **New Client Secret**.
- Enter the required information in the provided fields.
- Click **Add**.
- Click **Copy** (📄) next to Value as the following figure shows.

Description	Expires	Value
cisco-pubs	12/6/2023	[redacted]9c... 184... 2e0e

**Step 9** From <https://portal.azure.com/>, click **Event Hubs** > **(name of an event hub)**.

**Step 10** In the right pane, click **Copy** (📄) next to the value of **Host name** and paste the value to the clipboard. This is your event hub host name.

azure-ad-events- [redacted] Event Hubs Namespace

Search

Event Hub Delete Refresh Feedback

Overview

- Activity log
- Access control (IAM)
- Tags
- Diagnose and solve problems
- Events

Settings

- Shared access policies
- Scale

Essentials

Resource group ([move](#))

Status: Active

Location: East US

Subscription ([move](#)): [Microsoft Azure Enterprise](#)

Subscription ID: [redacted]

Host name: [redacted].windows.net

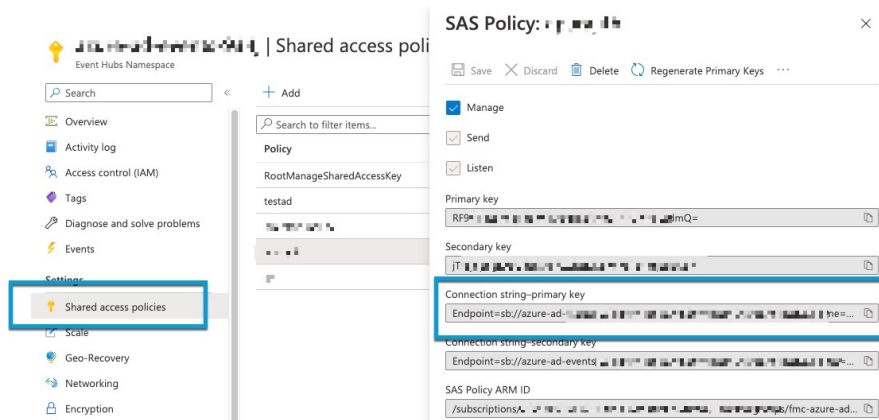

Copy to clipboard

**Step 11** Write down or copy to a text file the name of the event hub (same as the **Event Hubs Namespace** at the top of the page).

**Step 12** In the left pane, under Settings, click **Shared access policies**.

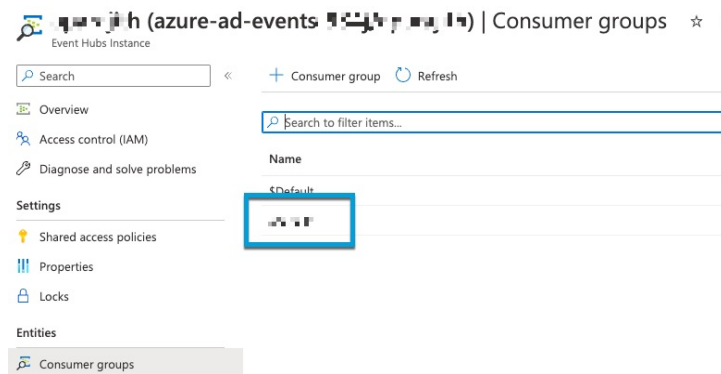

**Step 13** Click the name of a policy.

**Step 14** Click **Copy** (📄) next to **Connection string-primary key**.

**Step 15** Click **Overview > Entities > Event Hubs > (name of an event hub) > Entities > Consumer Groups**.

Write down the following value or copy it to the clipboard. This is your consumer group name.

**Step 16** In the left pane, click **Overview**.

**Step 17** Click **Copy** (📄) next to **Namespace**.

This is your event hubs topic name.

## Create a Microsoft Azure AD (SAML) Realm for Passive Authentication

The following topics discuss how to run the multi-step wizard required to create a Microsoft Azure AD (SAML) realm for passive authentication.

You can use a Microsoft Azure Active Directory (AD) realm with Cisco ISE to authenticate users and get user sessions for user control. We get groups from Azure AD and logged-in user session data from Cisco ISE.

You have the following options:

- Resource owned password credentials (ROPC): Enables users to log in with a client like Cisco Secure Client using a user name and password. ISE sends user sessions to the Secure Firewall Management Center. For more information, see [About Azure AD and Cisco ISE with Resource Owned Password Credentials, on page 2451](#).

Additional resource: [Microsoft identity platform and OAuth 2.0 Resource Owner Password Credentials on learn.microsoft.com](#).

- Extensible Authentication Protocol (EAP) Chaining with Tunnel-based Extensible Authentication Protocol (TEAP) and Transport Layer Security (TLS), abbreviated EAP/TEAP-TLS: TEAP is a tunnel-based EAP method that establishes a secure tunnel and executes other EAP methods under the protection of that secured tunnel. ISE is used to validate user credentials and to send user sessions to the Secure Firewall Management Center. For more information, see [About Azure AD and Cisco ISE with TEAP/EAP-TLS, on page 2452](#).

To configure the realm, complete all tasks in the following order:

1. [Configure Azure AD Basic Settings, on page 2454](#).
2. Get required information for your realm as discussed in [Get Required Information For Your Microsoft Azure AD Realm, on page 2455](#).
3. [Microsoft Azure AD \(SAML\) Realm: SAML Details, on page 2458](#).

## Microsoft Azure AD (SAML) Realm: SAML Details

This task discusses the first step in a multi-step wizard that creates a Microsoft Azure AD (SAML) realm. You must complete all steps in the wizard to set up your realm. The steps are different depending on whether you create the realm for active or passive authentication.

### Before you begin

Complete all of the following tasks before you create your realm:

- (Passive authentication with Cisco ISE only.) If you're using Cisco ISE as the repository for users and groups, set up ISE:
  - [About Azure AD and Cisco ISE with Resource Owned Password Credentials, on page 2451](#)
  - [About Azure AD and Cisco ISE with TEAP/EAP-TLS, on page 2452](#)
- To use Azure AD as the repository for users and groups, see [Configure Microsoft Azure Active Directory for Passive Authentication, on page 2453](#).
- Get required information for your realm as discussed in [Get Required Information For Your Microsoft Azure AD Realm, on page 2455](#).

## Procedure

- Step 1** Log in to Cisco Security Cloud Control.
- Step 2** Click **Policies > FTD Policies**.
- Step 3** Click **Integration > Other Integrations > Realms**.
- Step 4** From the list, click **SAML - Azure AD**.
- Step 5** Enter the following information.

Item	Description
<b>Name</b>	Unique name to identify the realm.
<b>Description</b>	(Optional.) Description of the realm.
<b>Identity Provider</b>	Always displays <b>Azure AD</b> .
<b>Configuration Type</b>	Click one of the following: <ul style="list-style-type: none"> <li>• <b>Passive Authentication with ISE</b> for passive authentication.</li> <li>• <b>Passive authentication or captive portal with Azure AD</b> for to use Azure AD as a user store for either passive authentication or active authentication (that is, captive portal).</li> </ul>

- Step 6** Click Next.

### What to do next

One of the following:

- Passive authentication: [Microsoft Azure AD \(SAML\) Realm: Azure AD Details, on page 2459](#).
- Active authentication: [Microsoft Azure AD \(SAML\) Realm: SAML Service Provider \(SP\) Metadata, on page 2472](#).

### Microsoft Azure AD (SAML) Realm: Azure AD Details

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

## Procedure

- Step 1** Continue from the preceding step in the wizard.
- Step 2** Enter the following information.

Item	Description
<b>Name</b>	Enter a unique name to identify this realm.
<b>Client Secret</b>	Enter the information you found as discussed in: <ul style="list-style-type: none"> <li>Passive authentication: <a href="#">How to Create a Microsoft Azure AD Realm for Passive Authentication</a>, on page 2450</li> <li>Active authentication: <a href="#">Get Required Information For Your Microsoft Azure AD Realm (Active Authentication Only)</a>, on page 2467</li> </ul>
<b>Tenant ID</b>	
<b>Event Hubs Host Name</b>	
<b>Event Hub Name</b>	
<b>Event Hub Connection String</b>	
(Optional.) <b>User Groups</b>	Slide to <b>Slider enabled</b> (  ) to specify groups to include or exclude from policy.
(Optional.) <b>Excluded User Groups</b>	If you enter one or more group names in this field, all groups and users they contain <i>except</i> these are downloaded and available for user awareness and user control.  Enter one group name per line followed by a line break. Group names are case-sensitive.
(Optional.) <b>Included User Groups</b>	If you enter one or more group names in this field, only those groups and users they contain are downloaded and user data is available for user awareness and user control.  Enter one group name per line followed by a line break. Group names are case-sensitive.

**Step 3** Click **Test**.  
Make sure the test connection succeeds before you continue to the next step.

**Step 4** Click **Next**.

### Microsoft Azure AD (SAML) Realm: User Session Timeout

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

This option sets the number of seconds before an inactive session is terminated by the system.

### Procedure

**Step 1** Continue from the preceding step in the wizard.

**Step 2** Enter the following information.

Item	Description
<b>ISE users</b>	Default is 1440 minutes (24 hours).

Item	Description
Captive portal users	Default is 1440 minutes (24 hours).

After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the management center as Unknown (except for **Failed Captive Portal Users**).

**Step 3** Click **Save**.

## How to Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal)

This topic discusses the high-level tasks of creating a Microsoft Azure Active Directory (AD) realm for use with the Cisco Security Cloud Control.

### Before you begin

If you enabled Change Management, you must open or edit, assign, and approve a ticket for each of the following objects before you can create the realm:

- Base URL
- Service provider certificate enrollment (PKCS12 format)
- Identity provider certificate enrollment (manual format)
- The realm itself (create and assign the ticket until realm creation is complete, then approve it)

For more information, see [Opening a Ticket for Configuration Changes, on page 215](#) and [Policies and Objects that Support Change Management, on page 209](#).

### Procedure

	Command or Action	Purpose
<b>Step 1</b>	Create a fully-qualified host name (FQDN) using your DNS server and upload the Threat Defense's internal certificate to the Cisco Security Cloud Control. You can consult a resource such as <a href="#">this one</a> if you've never done it before. Specify the IP address of a routed interface on one of the devices managed by your Cisco Security Cloud Control.	Consult a DNS server reference.
<b>Step 2</b>	Enable the Cisco Secure Dynamic Attributes Connector.	The Cisco Secure Dynamic Attributes Connector is required to use a Microsoft Azure AD realm. You can do it first or you can enable it when you create the realm. .

	Command or Action	Purpose
<b>Step 3</b>	Create a network object with an associated internal certificate.	See <a href="#">Creating Network Objects</a> , on page 1499.
<b>Step 4</b>	Get a signed certificate and upload it to the Secure Firewall Threat Defense to which Azure AD authentication requests will be sent.	<p>The certificate should be signed by a trusted Certificate Authority (CA) and delivered to you in <b>.p12</b> format (also referred to as <b>PKCS#12</b>; see also this article on <a href="#">ssl.com</a>).</p> <p>For background, see the section on public key infrastructure in <a href="#">Cisco Secure Firewall Management Center Device Configuration Guide</a> or <a href="#">stackoverflow.com</a>.</p> <p>To upload the signed certificate, see <a href="#">Installing a Certificate Using a PKCS12 File</a>, on page 1582.</p>
<b>Step 5</b>	Configure Microsoft Azure AD basic settings.	<p>Several configuration tasks are required, including setting up an event hub, giving your application permission to the Microsoft Graph API, and enabling the audit log.</p> <p>See <a href="#">Configure Azure AD Basic Settings</a>, on page 2454.</p>
<b>Step 6</b>	Create a single sign-on (SSO) app in Azure AD.	<p>The SSO app enables users that request access to a protected network resource to authenticate with Azure AD. The SSO app has both the federation XML that you can use to simplify realm creation as well as the identity provider certificate the Secure Firewall Threat Defense requires to security authenticate with Azure AD.</p> <p>See <a href="#">Configure a Single Sign-On (SSO) App in Azure AD</a>, on page 2464.</p>
<b>Step 7</b>	Get the information required to configure your Microsoft Azure AD realm.	<p>This information includes client and tenant IDs, client secret, and other information store in Microsoft Azure AD.</p> <p>See <a href="#">Get Required Information For Your Microsoft Azure AD Realm</a>, on page 2455.</p>
<b>Step 8</b>	Configure a decryption policy with a <b>Decrypt - Resign</b> rule for the Azure Authentication Service so users can access web pages using the HTTPS protocol.	<p>The Microsoft Azure AD realm can authenticate users only if the HTTPS traffic is decrypted before the traffic is sent to the realm. The Microsoft Azure AD realm itself is seen by the system as the <b>Azure Authentication Service</b> application.</p> <p><a href="#">Create a Decryption Rule with Decrypt - Resign Action</a>, on page 2466.</p>

	Command or Action	Purpose
<b>Step 9</b>	Create identity policy with an active authentication rule.	The identity policy enables selected users in your realm access resources after authenticating with the SAML realm.  For more information, see <a href="#">Create an Identity Policy, on page 2611</a> .
<b>Step 10</b>	Create access control policies and rules using your Microsoft Azure AD realm.	Unlike other types of realms, you do not need to create an identity policy or associate the identity policy with an access control policy.  See <a href="#">Creating a Basic Access Control Policy, on page 1832</a> and <a href="#">Create and Edit Access Control Rules, on page 1863</a> .
<b>Step 11</b>	Associate the identity and decryption policies with the access control policy from step 3.	This final step enables the system to authenticate users with the Microsoft Azure AD realm.  For more information, see <a href="#">Associating Other Policies with Access Control, on page 1844</a> .

**What to do next**

See [Configure Azure AD Basic Settings, on page 2454](#).

## Configure Azure AD Basic Settings

**Give your application the Microsoft Graph permission**

Grant your Azure AD application the following permissions to Microsoft Graph as discussed in [Authorization and the Microsoft Graph Security API](#) on the Microsoft site:

- Reader role
- User.Read.All permission
- Group.Read.All permission

This permission enables the management center to download users and groups from Azure AD the first time.

*Required information from this step* for setting up the Azure AD realm in the management center:

- Name of the app you registered
- **Application (client) ID**
- **Client secret**
- **Directory (tenant) ID**

### Set up an event hub

Set up the event hub as discussed in [Quickstart: Create an event hub using Azure portal](#) on the Microsoft site. The management center uses the event hub audit log to download periodic updates to users and groups.

More information: [Features and terminology in Azure Event Hubs](#).

---

**Important** You must choose the **Standard** pricing tier or better. If you choose **Basic**, the realm cannot be used.

---

*Required information from this step* for setting up the Azure AD realm in the Cisco Security Cloud Control:

- Namespace **Name**
- **Connection string—primary key**
- Event Hub **Name**
- Consumer group **Name**

### Enable the audit log

Enable the audit log as discussed in [Tutorial: Stream Azure Active Directory logs to an Azure event hub](#) on the Microsoft site.

## Configure a Single Sign-On (SSO) App in Azure AD

This topic discusses how to create an app in Microsoft Azure AD to handle single sign-on (SSO) from Azure AD when a network user attempts to access a protected network.

### Create the app

In the Microsoft Azure AD portal, click **Enterprise Applications** on the home page and follow the instructions in [Configure Microsoft Entra SSO](#) on learn.microsoft.com.

The following figure shows part of the SSO app configuration. You must provide some of the information on this page when you configure the Microsoft Azure AD (SAML) realm. For more information, see [Get Required Information For Your Microsoft Azure AD Realm \(Active Authentication Only\)](#), on page 2467.

## Set up Single Sign-On with SAML

An SSO implementation based on federation protocols improves security, reliability, and end user experiences and is easier to implement. Choose SAML single sign-on whenever possible for existing applications that do not use OpenID Connect or OAuth. [Learn more.](#)

Read the [configuration guide](#) for help integrating `aparajith_azure_saml`.

The screenshot shows the configuration page for a SAML-based application. It is divided into three numbered sections:

- Basic SAML Configuration:**
  - Identifier (Entity ID): `https://[redacted]/saml/sp/metadata/Azure`
  - Reply URL (Assertion Consumer Service URL): `https://[redacted]/+CSCOE+/saml/sp/acs?tokenname=[redacted]`
  - Sign on URL: `https://samltoolkit.azurewebsites.net/`
  - Relay State (Optional): `Optional`
  - Logout URL (Optional): `Optional`
- Attributes & Claims:**
  - givenname: `user.givenname`
  - surname: `user.surname`
  - emailaddress: `user.mail`
  - name: `user.userprincipalname`
  - Unique User Identifier: `user.userprincipalname`
- SAML Certificates:**
  - Token signing certificate: `[redacted]`
  - Status: `Active`
  - Thumbprint: `DE3B7E[redacted]85A7`

### (Optional.) Upload the service provider metadata

If you already configured the Microsoft Azure AD (SAML) realm, click Upload metadata file at the top of the page to quickly provide configuration values for the SSO app.

The following figure shows an example.

This screenshot shows the same configuration page as above, but with a blue box highlighting the 'Upload metadata file' button at the top of the configuration section. The configuration values are different, reflecting a test environment:

- Identifier (Entity ID): `https://inside.ntd-test.cisco.com/saml/sp/metadata/Azure`
- Reply URL (Assertion Consumer Service URL): `https://inside.ntd-test.cisco.com/+CSCOE+/saml/sp/acs?tokenname=[redacted]`

### Add users and groups to the SSO app

Add users and groups to your app as discussed in [Add a user account to an enterprise application](#) on [learn.microsoft.com](https://learn.microsoft.com)

### What to do next

See [Get Required Information For Your Microsoft Azure AD Realm \(Active Authentication Only\)](#), on page 2467.

## Create a Decryption Rule with Decrypt - Resign Action

This part of the procedure discusses how to create a decryption policy to decrypt and resign traffic before the traffic reaches the SAML realm. The realm can authenticate traffic only after it has been decrypted.

### Before you begin

### Procedure

- Step 1** If you haven't done so already, log in to the Cisco Security Cloud Control.
- Step 2** If you haven't done so already, create an internal certificate authority object to decrypt TLS/SSL traffic as discussed in [PKI, on page 1500](#).
- Step 3** Click **Policies > FTD Policies**.
- Step 4** Click **Policies > Access Control > Decryption**.
- Step 5** Click **New Policy**.
- Step 6** Enter a **Name** and choose a **Default Action** for the policy. Default actions are discussed in [Decryption Policy Default Actions, on page 2352](#).
- Step 7** Click **Save**.
- Step 8** Click **Add Rule**.
- Step 9** Enter a **Name** for the rule.
- Step 10** From the **Action** list, choose **Decrypt - Resign**.
- Step 11** From the **with** list, choose your service provider certificate object.
- Step 12** Click the **Applications** tab page.
- Step 13** In the Available Applications section, enter **Azure Authentication Service** in the search field.
- Step 14** Click **Azure Authentication** and click **Add to Rule**.  
The following figure shows an example.

The screenshot shows the 'Add Rule' configuration interface. At the top, the 'Name' field is 'Rule for Azure AD Decryption', 'Enabled' is checked, and 'Insert' is set to 'below rule'. The 'Action' is 'Decrypt - Resign' with 'IntCADecryption' as the certificate object and 'Replace Key Only' checked. Below this, there are tabs for 'Zones', 'Networks', 'VLAN Tags', 'Users', 'Applications', 'Ports', 'Category', 'Certificate', 'DN', 'Cert Status', 'Cipher Suite', 'Version', and 'Logging'. The 'Applications' tab is selected, showing a search for 'azure authentication ser' and a list of available applications including 'Azure Authentication Service'.

- Step 15** (Optional.) Set other options as discussed in [Decryption Rule Conditions, on page 2372](#).

- Step 16** Click **Add**.
- Step 17** At the top of the page, click **Save**.

### What to do next

## Get Required Information For Your Microsoft Azure AD Realm (Active Authentication Only)

This task explains how to get the information required to set up a Microsoft Azure AD realm in the management center.

### Procedure

- Step 1** Log in to <https://portal.azure.com/> as a user with at least the Product Designer role.
- Step 2** At the top of the page, click **Microsoft Entra ID**.
- Step 3** In the left column, click **App Registrations**.
- Step 4** If necessary, filter the list of displayed apps to show the one you want to use.
- Step 5** Click the name of your app.

- Step 6** Click **Copy** (📄) next to the following values on this page and paste those values to a text file.
- **Application (Client) ID**
  - **Directory (tenant) ID**

- Step 7** Click **Client Credentials**.

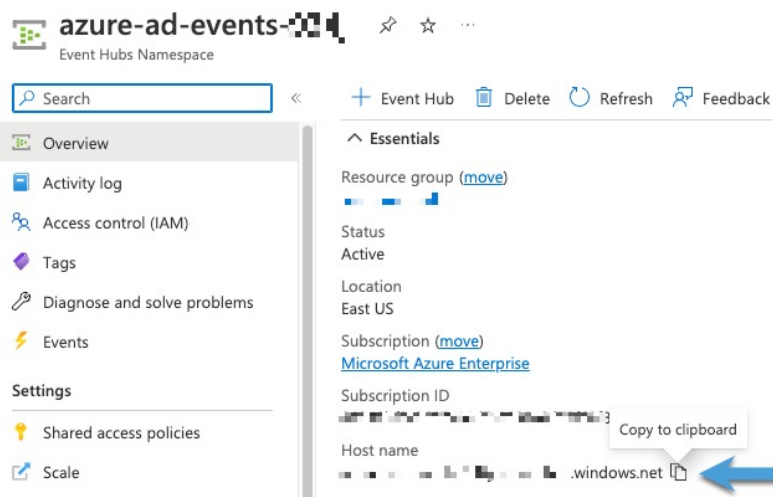

- Step 8** Unless you already know the client secret *value* (as opposed to the client *secret ID*), you must create a new client secret as follows:

- Click **New Client Secret**.
- Enter the required information in the provided fields.
- Click **Add**.
- Click **Copy** (📄) next to Value as the following figure shows.

- Step 9** From <https://portal.azure.com/>, click **Event Hubs** > (name of an event hub).

**Step 10** In the right pane, click **Copy** (📄) next to the value of **Host name** and paste the value to the clipboard. This is your event hub host name.

**Step 11** Write down or copy to a text file the name of the event hub (same as the **Event Hubs Namespace** at the top of the page).

**Step 12** In the left pane, under Settings, click **Shared access policies**.

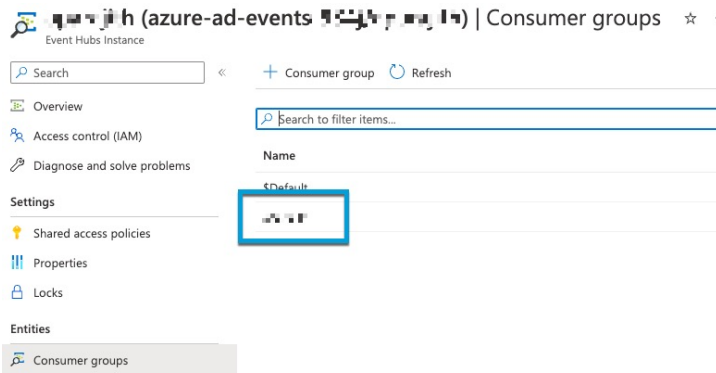

**Step 13** Click the name of a policy.

**Step 14** Click **Copy** (📄) next to **Connection string-primary key**.

**Step 15** Click **Overview > Entities > Event Hubs > (name of an event hub) > Entities > Consumer Groups**.

Write down the following value or copy it to the clipboard. This is your consumer group name.

**Step 16** In the left pane, click **Overview**.

**Step 17** Click **Copy** (📄) next to **Namespace**.

This is your event hubs topic name.

**Step 18** Return to the home page and log in if necessary: <https://portal.azure.com/#home>.

**Step 19** Click **Microsoft Entra ID**.

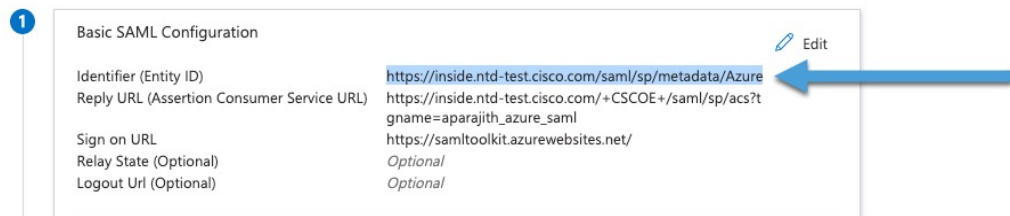

**Step 20** In the left pane, click **Enterprise Applications**.

**Step 21** If necessary, filter the list of applications to locate yours.

**Step 22** Click the name of your enterprise application.

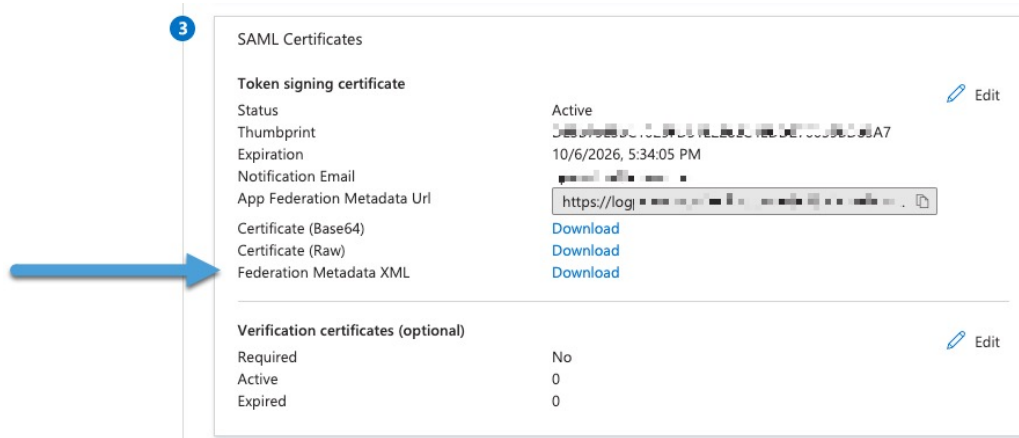

**Step 23** Click **Get Started** under Set up single sign on.

**Step 24** On your SSO app page, copy the value of Identifier (Entity ID) to the clipboard. The following figure shows an example.

**Step 25** On your SSO app page, click the **Download** link next to Federation Metadata XML, as the following figure shows.

The following figure shows an example.

**Step 26** If you've already set up your SSO app, *you can stop here*. The Federation Metadata XML contains all the information required to configure the identity provider in the Secure Firewall Management Center.

**Step 27** (Optional if you already downloaded the federation XML.) Click **Copy** (📄) next to both of the following values and save them to a text file. The following figure shows an example.

### What to do next

See [Create a Decryption Rule with Decrypt - Resign Action, on page 2466](#).

## Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal)

The following topics discuss how to run the multi-step wizard required to create a Microsoft Azure AD (SAML) realm for active authentication.

In active authentication (also referred to as *captive portal*), Microsoft Azure AD is the user store. When a user tries to access a protected resource as defined in access control rules, the user must authenticate with Microsoft Azure AD first.

To configure the realm, complete all tasks in the following order:

1. [Configure Azure AD Basic Settings, on page 2454](#).
2. [Configure a Single Sign-On \(SSO\) App in Azure AD, on page 2464](#).
3. [Get Required Information For Your Microsoft Azure AD Realm \(Active Authentication Only\), on page 2467](#)

## Microsoft Azure AD (SAML) Realm: SAML Details

This task discusses the first step in a multi-step wizard that creates a Microsoft Azure AD (SAML) realm. You must complete all steps in the wizard to set up your realm. The steps are different depending on whether you create the realm for active or passive authentication.

### Before you begin

Complete all of the following tasks before you create your realm:

- (Passive authentication with Cisco ISE only.) If you're using Cisco ISE as the repository for users and groups, set up ISE:
  - [About Azure AD and Cisco ISE with Resource Owned Password Credentials, on page 2451](#)
  - [About Azure AD and Cisco ISE with TEAP/EAP-TLS, on page 2452](#)
- To use Azure AD as the repository for users and groups, see [Configure Microsoft Azure Active Directory for Passive Authentication, on page 2453](#).
- Get required information for your realm as discussed in [Get Required Information For Your Microsoft Azure AD Realm, on page 2455](#).

## Procedure

- 
- Step 1** Log in to Cisco Security Cloud Control.
- Step 2** Click **Policies > FTD Policies**.
- Step 3** Click **Integration > Other Integrations > Realms**.
- Step 4** From the list, click **SAML - Azure AD**.
- Step 5** Enter the following information.

Item	Description
<b>Name</b>	Unique name to identify the realm.
<b>Description</b>	(Optional.) Description of the realm.
<b>Identity Provider</b>	Always displays <b>Azure AD</b> .
<b>Configuration Type</b>	Click one of the following: <ul style="list-style-type: none"> <li>• <b>Passive Authentication with ISE</b> for passive authentication.</li> <li>• <b>Passive authentication or captive portal with Azure AD</b> for to use Azure AD as a user store for either passive authentication or active authentication (that is, captive portal).</li> </ul>

- Step 6** Click **Next**.
-

**What to do next**

One of the following:

- Passive authentication: [Microsoft Azure AD \(SAML\) Realm: Azure AD Details, on page 2459.](#)
- Active authentication: [Microsoft Azure AD \(SAML\) Realm: SAML Service Provider \(SP\) Metadata, on page 2472.](#)

**Microsoft Azure AD (SAML) Realm: SAML Service Provider (SP) Metadata**

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

**Before you begin**

Complete the tasks discussed in [Microsoft Azure AD \(SAML\) Realm: SAML Details, on page 2458](#)

**Procedure**

**Step 1** Continue from [Microsoft Azure AD \(SAML\) Realm: SAML Details, on page 2458.](#)

**Step 2** Enter the following information.

Item	Description
<b>Base URL</b>	From the list, click the network object you previously created. Network users are directed to this URL when they try to access protected network resources.  You can also click <b>Add (+)</b> to create an object now.
<b>Entity ID</b>	Your SSO app's entity ID.
<b>Assertion Consumer Services (ACS) URL</b>	Automatically generated from the preceding values.
<b>Service Provider Certificate</b>	From the list, click the certificate to use to decrypt requests to the Secure Firewall Threat Defense.  You can also click <b>Add (+)</b> to create an object now.
<b>Download Service Provider Metadata</b>	(Optional.) Download the metadata associated with the service provider (that is, managed device) to simplify configuring your Microsoft Azure AD SSO app.

**Step 3** Click **Next**.

**What to do next**

[Microsoft Azure AD \(SAML\) Realm: SAML Identity Provider \(IdP\) Metadata, on page 2473.](#)

## Microsoft Azure AD (SAML) Realm: SAML Identity Provider (IdP) Metadata

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

### Before you begin

Complete the tasks discussed in [Microsoft Azure AD \(SAML\) Realm: SAML Service Provider \(SP\) Metadata, on page 2472](#).

### Procedure

- Step 1** Continue from [Microsoft Azure AD \(SAML\) Realm: SAML Service Provider \(SP\) Metadata, on page 2472](#).
- Step 2** If you previously downloaded the Azure AD SSO app's federation XML, click **Upload XML** and upload it now. You can then skip the next step.
- Step 3** Enter the following information.

Item	Description
<b>Entity ID</b>	Enter your identity provider's entity ID.
<b>Single Sign on (SSO) URL</b>	Enter the app's SSO URL.
<b>IdP Certificate</b>	From the list, click the certificate to use to authenticate with Microsoft Azure AD.  You can also click <b>Add (+)</b> to create an object now.

- Step 4** Click **Next**.

### What to do next

[Microsoft Azure AD \(SAML\) Realm: SAML Details, on page 2458](#).

## Microsoft Azure AD (SAML) Realm: Azure AD Details

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

### Procedure

- Step 1** Continue from the preceding step in the wizard.
- Step 2** Enter the following information.

Item	Description
<b>Name</b>	Enter a unique name to identify this realm.

Item	Description
Client Secret	Enter the information you found as discussed in: <ul style="list-style-type: none"> <li>Passive authentication: <a href="#">How to Create a Microsoft Azure AD Realm for Passive Authentication, on page 2450</a></li> <li>Active authentication: <a href="#">Get Required Information For Your Microsoft Azure AD Realm (Active Authentication Only), on page 2467</a></li> </ul>
Tenant ID	
Event Hubs Host Name	
Event Hub Name	
Event Hub Connection String	
(Optional.) User Groups	Slide to <b>Slider enabled</b> (  ) to specify groups to include or exclude from policy.
(Optional.) Excluded User Groups	If you enter one or more group names in this field, all groups and users they contain <i>except</i> these are downloaded and available for user awareness and user control.  Enter one group name per line followed by a line break. Group names are case-sensitive.
(Optional.) Included User Groups	If you enter one or more group names in this field, only those groups and users they contain are downloaded and user data is available for user awareness and user control.  Enter one group name per line followed by a line break. Group names are case-sensitive.

**Step 3** Click **Test**.  
Make sure the test connection succeeds before you continue to the next step.

**Step 4** Click **Next**.

## Microsoft Azure AD (SAML) Realm: User Session Timeout

This task discussed one page in a multi-page wizard to enable you to create a Microsoft Azure AD (SAML) realm.

This option sets the number of seconds before an inactive session is terminated by the system.

### Procedure

**Step 1** Continue from the preceding step in the wizard.

**Step 2** Enter the following information.

Item	Description
ISE users	Default is 1440 minutes (24 hours).
Captive portal users	Default is 1440 minutes (24 hours).

After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the management center as Unknown (except for **Failed Captive Portal Users**).

**Step 3** Click **Save**.

---

## Create an LDAP Realm or an Active Directory Realm and Realm Directory

If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the management center. For more information, see [Realm Fields, on page 2478](#).

The following procedure enables you to create a *realm* (a connection between the management center and an Active Directory realm) and a *directory* (a connection between the management center and an LDAP server or an Active Directory domain controller).

(Recommended.) To connect securely from the management center to your Active Directory server, first perform the following tasks:

- [Export the Active Directory Server's Root Certificate, on page 2485](#)
- [Find the Active Directory Server's Name, on page 2485](#)

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, see [2020 LDAP channel binding and LDAP signing requirement for Windows](#) on the Microsoft support site.

For more information about realm and directory configuration fields, see [Realm Fields, on page 2478](#) and [Realm Directory and Synchronize fields, on page 2482](#).

A step-by-step example of setting up a realm with cross-domain trust is shown in [Configure the Management Center for Cross-Domain-Trust: The Setup, on page 2489](#).

An Active Directory Global Catalog server is *not supported* as a realm directory. For more information about the Global Catalog Server, see [Global Catalog](#) on learn.microsoft.com.

**Note** You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

---

If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the management center. For more information, see [Realm Fields, on page 2478](#).

### Before you begin

If you're using Kerberos authentication for captive portal, see the following section before you begin: [Prerequisites for Kerberos Authentication, on page 2477](#).

If you enabled Change Management, you must open or edit, assign, and approve a ticket for each of the following objects before you can create the realm:

- If you're connecting securely to Microsoft AD or LDAP, the server's trusted certificate authority
- The realm itself

For more information, see [Opening a Ticket for Configuration Changes, on page 215](#) and [Policies and Objects that Support Change Management, on page 209](#).

If you are managing devices with Cisco Security Cloud Control (Security Cloud Control), create a proxy sequence first as discussed in [Create a Proxy Sequence, on page 2448](#)

---

**Important** To reduce latency between the management center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the management center.

For example, if your management center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

---

### Procedure

- 
- Step 1** Log in to the Secure Firewall Management Center.
- Step 2** Click **Integration > Other Integrations > Realms**.
- Step 3** To create a new realm, choose from **Add Realm** drop-down list.
- Step 4** To perform other tasks (such as enable, disable, or delete a realm), see [Manage a Realm, on page 2497](#).
- Step 5** Enter realm information as discussed in [Realm Fields, on page 2478](#).
- Step 6** (Optional.) From the **Proxy** list, click a managed device or proxy sequence to communicate with ISE/ISE-PIC if Security Cloud Control is unable to do so. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.
- Step 7** In the Directory Server Configuration section, enter directory information as discussed in [Realm Directory and Synchronize fields, on page 2482](#).
- Step 8** (Optional.) To configure another domain for this realm, click **Add another directory**.
- Step 9** Click **Configure Groups and Users**.  
Enter the following information:

Information	Description
<b>AD Primary Domain</b>	Domain for the Active Directory server where users should be authenticated. For additional information, see <a href="#">Realm Fields, on page 2478</a> .
<b>Base DN</b>	The directory tree on the server where the management center should begin searching for user data.

Information	Description
<b>Group DN</b>	The directory tree on the server where the management center should begin searching for group data.
<b>Proxy</b>	From the list, click one or more managed devices or a proxy sequence. These devices must be able to communicate with Active Directory or ISE/ISE-PIC to retrieve user data for identity policies.
<b>Load Groups</b>	Click to load groups from the Active Directory server. If no groups are displayed, enter or edit information in the <b>AD Primary Domain</b> , <b>Base DN</b> , and <b>Group DN</b> fields and click <b>Load Groups</b> .  For more information about those fields, see <a href="#">Realm Fields, on page 2478</a> .
Available Groups section	Limit the groups to use in policy by moving them to either the <b>Included Groups and Users</b> or <b>Excluded Groups and Users</b> list.  Moving one group to the <b>Included Groups and Users</b> list, for example, allows that group only to be used in policy but excludes all other groups.  Groups in the <b>Excluded Groups and Users</b> and the users they contain are excluded from excluded from user awareness and control. All other groups and users <i>are</i> available.  For more information, see <a href="#">Realm Directory and Synchronize fields, on page 2482</a> .

- Step 10** Click the **Realm Configuration** tab.
- Step 11** Enter **Group Attribute**, and (if you use Kerberos authentication for captive portal) enter **AD Join Username** and **AD Join Password**. For more information, see [Realm Directory and Synchronize fields, on page 2482](#).
- Step 12** If you use Kerberos authentication, click **Test**. If the test fails, wait a short time and try again.
- Step 13** Enter user session timeout values, in minutes, for **ISE/ISE-PIC Users**, **Terminal Server Agent Users**, **Captive Portal Users**, **Failed Captive Portal Users**, and **Guest Captive Portal Users**.
- Step 14** When you're finished configuring the realm, click **Save**.

#### What to do next

- [Configure the Management Center for Cross-Domain-Trust: The Setup, on page 2489](#)
- [Synchronize Users and Groups, on page 2487](#)
- Edit, delete, enable, or disable a realm; see [Manage a Realm, on page 2497](#).
- [Compare Realms, on page 2498](#).
- Optionally, monitor the task status; see *Viewing Task Messages* in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Prerequisites for Kerberos Authentication

If you're using Kerberos to authentication captive portal users, keep the following in mind.

**Hostname character limit**

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: [Naming conventions in Active Directory for computers, domains, sites, and OUs](#).

**DNS response character limit**

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in [RFC 6891 section-6.2.5](#).

## Realm Fields

The following fields are used to configure a realm.

**Realm Configuration Fields**

These settings apply to all Active Directory servers or domain controllers (also referred to as *directories*) in a realm.

**Name**

A unique name for the realm.

- To use the realm in identity policies, the system supports alphanumeric and special characters.
- To use the realm in RA VPN configurations, the system supports alphanumeric, hyphen (-), underscore (\_), and plus (+) characters.

**Description**

(Optional.) Enter a description of the realm.

**Type**

The type of realm, **AD** for Microsoft Active Directory, **LDAP** for other supported LDAP repositories, or **Local**. For a list of supported LDAP repositories, see [Supported Servers for Realms, on page 2446](#). You can authenticate captive portal users with an LDAP repository; all others require Active Directory.

---

**Note** Only captive portal supports an LDAP realm.

---

The realm type **LOCAL** is used for configuring local user settings. The LOCAL realm is used in remote access user authentication.

Add the following Local User Information for the LOCAL realm:

- **Username**—Name of the local user.
- **Password**—Local user password.
- **Confirm Password**—Confirm the local user password.

---

**Note** Click **Add another local user** to add more users to the LOCAL realm.

You can add more users after creating the realm and update password for the local users. You can also create multiple LOCAL realms but cannot disable them.

---

### AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

---

**Note** You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

---

### AD Join Username and AD Join Password

(Available on the **Realm Configuration** tab page when you edit a realm.)

For Microsoft Active Directory realms intended for Kerberos captive portal active authentication, the distinguished username and password of any Active Directory user with appropriate rights to create a Domain Computer account in the Active Directory domain.

Keep the following in mind:

- DNS must be able to resolve the domain name to an Active Directory domain controller's IP address.
- The user you specify must be able to join computers to the Active Directory domain.
- The user name must be fully qualified (for example, **administrator@mydomain.com**, *not administrator*).

If you choose **Kerberos** (or **HTTP Negotiate**, if you want Kerberos as an option) as the **Authentication Protocol** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

---

**Note** The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as [Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet](#) or [Password Storage Cheat Sheet](#) on the Open Web Application Security Project website.

We recommend SHA-256 for communicating with Active Directory.

---

## Directory Username and Directory Password

The distinguished username and password for a user with appropriate access to the user information you want to retrieve.

Note the following:

- For some versions of Microsoft Active Directory, specific permissions might be required to read users and groups. Consult the documentation provided with Microsoft Active Directory for details.
- For OpenLDAP, the user's access privileges are determined by the `<level>` parameter discussed in section 8 of the [OpenLDAP specification](#). The user's `<level>` should be `auth` or better.
- The user name must be fully qualified (for example, `administrator@mydomain.com`, *not* `administrator`).

---

**Note** The SHA-1 hash algorithm is not secure for storing passwords on your Active Directory server and should not be used. For more information, consult a reference such as [Migrating your Certification Authority Hashing Algorithm from SHA1 to SHA2 on Microsoft TechNet](#) or [Password Storage Cheat Sheet](#) on the Open Web Application Security Project website.

We recommend SHA-256 for communicating with Active Directory.

---

## Base DN

(Optional.) The directory tree on the server where the Secure Firewall Management Center should begin searching for user data. If you don't specify a **Base DN**, the system retrieves the top-level DN provided you can connect to the server.

Typically, the base distinguished name (DN) has a basic structure indicating the company domain name and operational unit. For example, the Security organization of the Example company might have a base DN of `ou=security,dc=example,dc=com`.

## Group DN

(Optional.) The directory tree on the server where the Secure Firewall Management Center should search for users with the group attribute. A list of supported group attributes is shown in [Supported Server Object Class and Attribute Names, on page 2447](#). If you don't specify a **Group DN**, the system retrieves the top-level DN provided you can connect to the server.

**Note** Following is the list of characters the system *supports* in users, groups, DNs in your directory server. Using any characters other than the following could result in the system failing to download users and groups.

Entity	Supported characters
User name	<b>a-z A-Z 0-9 ! # \$ % ^ &amp; ( ) _ - { } ' . ~ `</b>
Group name	<b>a-z A-Z 0-9 ! # \$ % ^ &amp; ( ) _ - { } ' . ~ `</b>
Base DN and Group DN	<b>a-z A-Z 0-9 ! @ \$ % ^ &amp; * ( ) _ - . ~ `</b>

A space is not supported anywhere in a user name, including at the end.

### Proxy

From the list, click one or more managed devices or a proxy sequence. These devices must be able to communicate with Active Directory or ISE/ISE-PIC to retrieve user data for identity policies.

The following fields are available when you edit an existing realm.

### User Session Timeout

(Available on the **Realm Configuration** tab page when you edit a realm.)

Enter the number of minutes before user sessions time out. The default is 1440 (24 hours) after the user's login event. After the timeout is exceeded, the user's session ends; if the user continues to access the network without logging in again, the user is seen by the management center as Unknown (except for **Failed Captive Portal Users**).

In addition, if you set up ISE/ISE-PIC without a realm and the timeout is exceeded, a workaround is required. For more information, contact [Cisco TAC](#).

You can set timeout values for the following:

- **User Agent and ISE/ISE-PIC Users:** Timeout for users tracked by the user agent or by ISE/ISE-PIC, which are types of passive authentication.

The timeout value you specify does *not* apply to pxGrid SXP session topic subscriptions (for example, destination SGT mappings). Instead, session topic mappings are preserved as long as there is no delete or update message for a given mapping from ISE.

For more information about ISE/ISE-PIC, see [The ISE/ISE-PIC Identity Source, on page 2533](#).

- **Terminal Services Agent Users:** Timeout for users tracked by the TS Agent, which is a type of passive authentication. For more information, see [The Terminal Services \(TS\) Agent Identity Source, on page 2605](#).
- **Captive Portal Users:** Timeout for users who successfully log in using the captive portal, which is a type of active authentication. For more information, see [The Captive Portal Identity Source, on page 2563](#).
- **Failed Captive Portal Users:** Timeout for users who do not successfully log in using the captive portal. You can configure the **Maximum login attempts** before the user is seen by the management center as Failed Auth User. A Failed Auth User can optionally be granted access to the network using access control policy and, if so, this timeout value applies to those users.

For more information about failed captive portal logins, see [Captive Portal Fields, on page 2577](#).

- **Guest Captive Portal Users:** Timeout for users who log in to the captive portal as a guest user. For more information, see [The Captive Portal Identity Source, on page 2563](#).

## Realm Directory and Synchronize fields

### Realm Directory Fields

These settings apply to individual servers (such as Active Directory domain controllers) in a realm.

#### Hostname / IP Address

Fully qualified host name of the Active Directory domain controller machine. To find the fully qualified name, see [Find the Active Directory Server's Name, on page 2485](#).

If you're using Kerberos for authenticating captive portal, also make sure you understand the following:

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: [Naming conventions in Active Directory for computers, domains, sites, and OUs](#).

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in [RFC 6891 section-6.2.5](#).

#### Port

The server's port.

#### Encryption

(Strongly recommended.) The encryption method to use:

- **STARTTLS**—encrypted LDAP connection
- **LDAPS**—encrypted LDAP connection
- **None**—unencrypted LDAP connection (unsecured traffic)

To communicate securely with an Active Directory server, see [Connect Securely to Active Directory, on page 2484](#).

#### CA Certificate

The TLS/SSL certificate to use for authentication to the server. You must configure **STARTTLS** or **LDAPS** as the **Encryption** type to use a TLS/SSL certificate.

If you are using a certificate to authenticate, the name of the server in the certificate must match the server **Hostname / IP Address**. For example, if you use 10.10.10.250 as the IP address but **computer1.example.com** in the certificate, the connection fails.

#### Interface used to connect to Directory server

Required only for RA VPN authentication so the Secure Firewall Threat Defense can connect securely to your Active Directory server. This interface is not used for downloading users and groups, however.

You can choose only a routed interface group. For more information, see [Interface, on page 1494](#).

Click one of the following:

- **Resolve via route lookup:** Use routing to connect to the Active Directory server.
- **Choose an interface:** Choose a specific managed device interface group to connect to the Active Directory server.

## User Synchronize Fields

### AD Primary Domain

For Microsoft Active Directory realms only. Domain for the Active Directory server where users should be authenticated.

---

**Note** You must specify a unique **AD Primary Domain** for every Microsoft Active Directory (AD) realm. Although the system allows you to specify the same **AD Primary Domain** for different Microsoft AD realms, the system won't function properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group. The system prevents you from specifying more than one realm with the same **AD Primary Domain** because users and groups won't be identified properly. This happens because system assigns a unique ID to every user and group in each *realm*; therefore, the system cannot definitively identify any particular user or group.

---

### Enter query to look for users and groups

#### Base DN:

(Optional.) The directory tree on the server where the management center should begin searching for user data.

Typically, the base distinguished name (DN) has a basic structure indicating the company domain name and operational unit. For example, the Security organization of the Example company might have a base DN of **ou=security,dc=example,dc=com**.

#### Group DN:

(Optional.) The directory tree on the server where the management center should search for users with the group attribute. A list of supported group attributes is shown in [Supported Server Object Class and Attribute Names, on page 2447](#).

---

**Note** Neither the group name nor the organizational unit name can contain special characters like asterisk (\*), equals (=), backslash (\) because users in those groups are not downloaded and cannot be used in identity policies.

---

### Load Groups

Enables you to download users and groups for user awareness and user control.

### Available Groups, Add to Include, Add to Exclude

Limits the groups that can be used in policy.

- Groups that are displayed in the **Available Groups** field are available for policy unless you move groups to the **Included Groups and Users** or **Excluded Groups and Users** field.
- If you move groups to the **Included Groups and Users** field, only those groups and users they contain are downloaded and user data is available for user awareness and user control.
- If you move groups to the **Excluded Groups and Users** field, all groups and users they contain *except* these are downloaded and available for user awareness and user control.
- To include users from groups that are not included, enter the user name in the field below **User Inclusion** and click **Add**.
- To exclude users from groups that are not excluded, enter the user name in the field below **User Exclusion** and click **Add**.

---

**Note** The users that are downloaded to the management center is calculated using the formula  $R = I - (E+e) + i$ , where

- R is list of downloaded users
  - I is included groups
  - E is excluded groups
  - e is excluded users
  - i is included users
- 

#### Synchronize Now

Click to synchronize groups and users with AD.

#### Begin automatic synchronization at

Enter the time and time interval at which to download users and groups from AD.

## Connect Securely to Active Directory

To create a secure connection between an Active Directory server and the management center (which we strongly recommend), you must perform all of the following tasks:

- Export the Active Directory server's root certificate.
- Import the root certificate into the management center as a trusted CA certificate **Objects > Object Management > PKI > Trusted CAs**).
- Find the Active Directory server's fully qualified name.
- Create the realm directory.

See one of the following tasks for more information.

#### Related Topics

[Export the Active Directory Server's Root Certificate](#), on page 2485

[Find the Active Directory Server's Name](#), on page 2485

[Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475

## Find the Active Directory Server's Name

To configure a realm directory in the management center, you must know the fully qualified server name, which you can find as discussed in the procedure that follows.

### Before you begin

You must log in to the Active Directory server as a user with sufficient privileges to view the computer's name.

### Procedure

- 
- |               |                                                                                                                                                  |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Log in to the Active Directory server.                                                                                                           |
| <b>Step 2</b> | Click <b>Start</b> .                                                                                                                             |
| <b>Step 3</b> | Right-click <b>This PC</b> .                                                                                                                     |
| <b>Step 4</b> | Click <b>Properties</b> .                                                                                                                        |
| <b>Step 5</b> | Click <b>Advanced System Settings</b> .                                                                                                          |
| <b>Step 6</b> | Click the <b>Computer Name</b> tab.                                                                                                              |
| <b>Step 7</b> | Note the value of <b>Full computer name</b> .<br>You must enter this exact name when you configure the realm directory in the management center. |
- 

### What to do next

[Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475.](#)

### Related Topics

[Export the Active Directory Server's Root Certificate, on page 2485](#)

## Export the Active Directory Server's Root Certificate

The task that follows discusses how to export the Active Directory server's root certificate, which is required to connect securely to the management center to obtain user identity information.

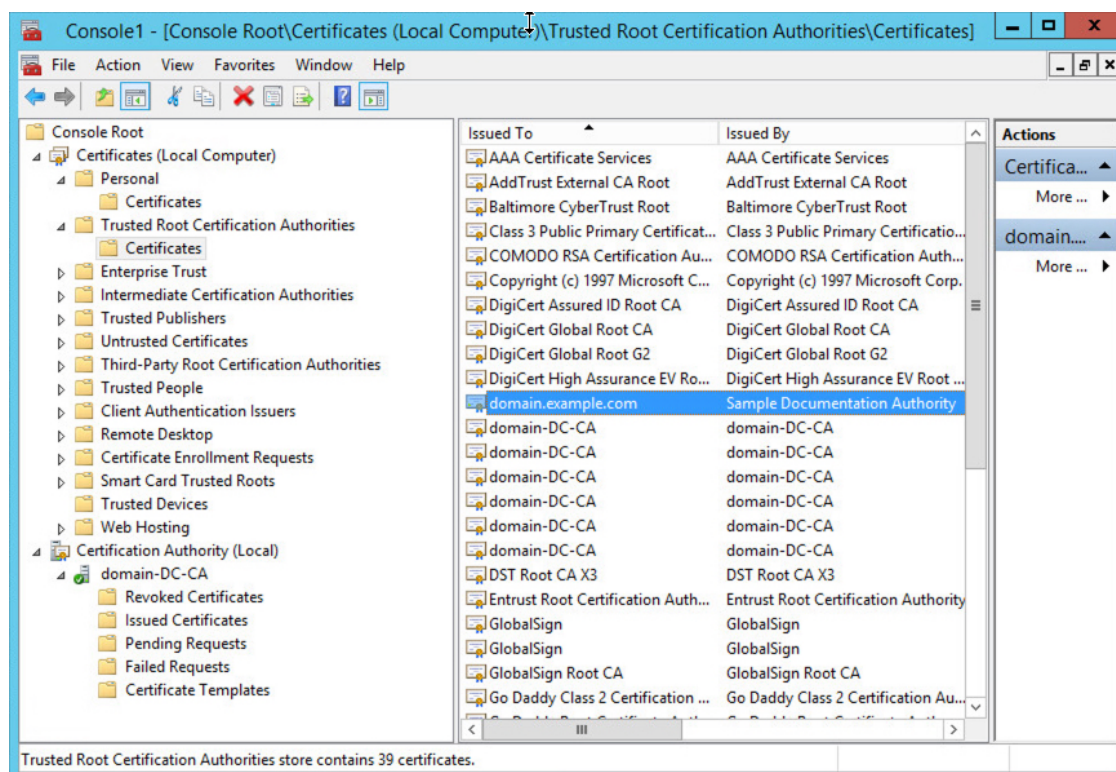

### Before you begin

You must know the name of your Active Directory server's root certificate. The root certificate might have the same name as the domain or the certificate might have a different name. The procedure that follows shows one way you can find the name; there could be other ways, however.

### Procedure

- 
- |               |                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Following is one way to find the name of the Active Directory Server's root certificate; consult Microsoft documentation for more information: <ol style="list-style-type: none"><li>Log in to the Active Directory server as a user with privileges to run the Microsoft Management Console.</li><li>Click <b>Start</b> and enter <b>mmc</b>.</li><li>Click <b>File &gt; Add/Remove Snap-in</b></li></ol> |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

- d) From the Available Snap-ins list in the left pane, click **Certificates (local)**.
- e) Click **Add**.
- f) At the Certificates snap-in dialog box, click **Computer Account** and click **Next**.
- g) At the Select Computer dialog box, click **Local Computer** and click **Finish**.
- h) *Windows Server 2012 only*. Repeat the preceding steps to add the Certification Authority snap-in.
- i) Click **Console Root > Trusted Certification Authorities > Certificates**.  
The server's trusted certificates are displayed in the right pane. The following figure is only an example for Windows Server 2012; yours will probably look different.

## Step 2 Export the certificate using the **certutil** command.

This is only one way to export the certificate. It's a convenient way to export the certificate, especially if you can run a web browser and connect to the management center from the Active Directory server.

- a) Click **Start** and enter **cmd**.
- b) Enter the command **certutil -ca.cert certificate-name**.  
The server's certificate is displayed on the screen.
- c) Copy the entire certificate to the clipboard, starting with **-----BEGIN CERTIFICATE-----** and ending with **-----END CERTIFICATE-----** (including those strings).

## What to do next

Import the Active Directory server's certificate into the management center as a Trusted CA Certificate as discussed in [Adding a Trusted CA Object, on page 1506](#).

**Related Topics**

[Find the Active Directory Server's Name](#), on page 2485

## Synchronize Users and Groups

*Synchronizing* users and groups means the management center queries the realms and directories you configured for groups and users in those groups. All users the management center finds can be used in identity policies.

If issues are found, you most likely need to add a realm that contains users and groups the management center cannot load. For details, see [Realms and Trusted Domains](#), on page 2443.

**Before you begin**

Create a management center *realm* for each Active Directory domain and a management center *directory* for each Active Directory domain controller in each forest. See [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.

You must create a realm only for domains that have users you want to use in user control.

You can nest Microsoft AD groups and the management center downloads those groups and the users they contain. You can optionally restrict which groups and users get downloaded as discussed in [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.

**Procedure**

- 
- Step 1** If you haven't done so already, log in to the management center.
- Step 2** Click **Integration** > **Other Integrations** > **Realms**.
- Step 3** Next to each realm, click **Download** (↓).
- Step 4** To see the results, click the **Sync Results** tab.  
The Realms column indicates whether or not there were issues synchronizing users and groups in Active Directory forests. Look for the following indicators next to each realm.

Indicator in Realms column	Meaning
(nothing)	All users and groups synchronized without error. No action is necessary.
<b>Yellow Triangle</b> (⚠)	There were issues synchronizing users and groups. Make sure you added a realm for each Active Directory domain and a directory for each Active Directory domain controller.  For more details, see <a href="#">Troubleshoot Cross-Domain Trust</a> , on page 2501.

---

# Create a Realm Sequence

The following procedure enables you to create a realm sequence, which is an ordered list of realms the system searches when it applies identity policy. You add a realm sequence to an identity rule exactly the same way as you add a realm; the difference is that the system searches all the realms in the order specified in the realm sequence when applying an identity policy.

## Before you begin

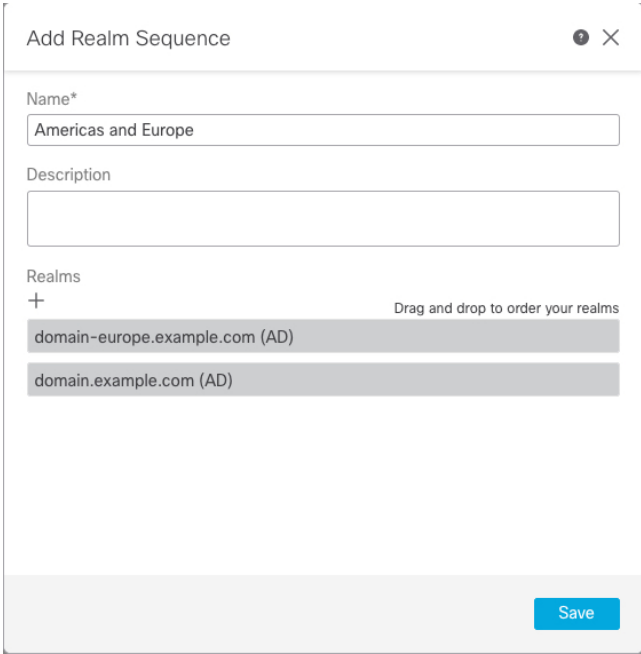

You must create and enable at least two realms, each corresponding to a connection with an Active Directory server. You cannot create realm sequences for LDAP realms.

Create a realm as discussed in [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.

## Procedure

---

- Step 1** Log in to the management center if you have not already done so.
- Step 2** Click **Integration > Other Integrations > Realms > Realm Sequences**.
- Step 3** Click **Add Sequence**.
- Step 4** In the **Name** field, enter a name to identify the realm sequence.
- Step 5** (Optional.) In the **Description** field, enter a description for the realm sequence.
- Step 6** Under Realms, click **Add (+)**.
- Step 7** Click the name of each realm to add to the sequence.  
To narrow your search, enter all or part of a realm name in **Filter** field.
- Step 8** Click **OK**.
- Step 9** In the Add Realm Sequence dialog box, drag and drop the realms in the order in which you want the system to search for them.  
The following figure shows an example of a realm sequence consisting of two realms. The **domain-europe.example.com** realm will be searched for users before the **domain.example.com** realm.

Add Realm Sequence

Name\*

Americas and Europe

Description

Realms

+ Drag and drop to order your realms

domain-europe.example.com (AD)

domain.example.com (AD)

Save

**Step 10** Click **Save**.

#### What to do next

See [Create an Identity Policy, on page 2611](#).

## Configure the Management Center for Cross-Domain-Trust: The Setup

This is an introduction to several topics that walk you through configuring the management center with two realms with cross-domain trust.

This step-by-step example involves two forests: **forest.example.com** and **eastforest.example.com**. The forests are configured so that certain users and groups in each forest can be authenticated by Microsoft AD in the other forest.

Following is the example setup used in this example.

Using the preceding example, you would set up the management center as follows:

- Realm and directory for any domain in **forest.example.com** that contains users you want to control with access control policy
- Realm and directory for any domain in **eastforest.example.com** that contains users you want to control with access control policy

Each realm in the example has one domain controller, which is configured in the management center as a directory. The directories in this example are configured as follows:

- **forest.example.com**
  - Base distinguished name (DN) for users: **ou=UsersWest,dc=forest,dc=example,dc=com**
  - Base DN for groups: **ou=EngineeringWest,dc=forest,dc=example,dc=com**
- **eastforest.example.com**
  - Base DN for users: **ou=EastUsers,dc=eastforest,dc=example,dc=com**
  - Base DN for groups: **ou=EastEngineering,dc=eastforest,dc=example,dc=com**

### Related Topics

[Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 1: Configure Realms and Directories](#), on page 2490

## Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 1: Configure Realms and Directories

This is the first task in a step-by-step procedure that explains how to configure the management center to recognize Active Directory servers configured in a cross-domain trust relationship, which is an increasingly common configuration for enterprise organizations. For an overview of this sample configuration, see [Configure the Management Center for Cross-Domain-Trust: The Setup](#), on page 2489.

If you set up the system with one realm for each domain and one directory for each domain controller, the system can discover up to 100,000 [foreign security principals](#) (users and groups). If these foreign security principals match a user downloaded in another realm, then they can be used in access control policy.

### Before you begin

You must configure Microsoft Active Directory servers in a cross-domain trust relationship; see [Realms and Trusted Domains, on page 2443](#) for more information.

If you authenticate users with LDAP, you *cannot* use this procedure.

### Procedure

---

- Step 1** Log in to the management center.
- Step 2** Click **Integration** > **Other Integrations** > **Realms**.
- Step 3** Choose from **Add Realm** drop-down list. .
- Step 4** Enter the following information to configure **forest.example.com**.

**Add New Realm**

Name\*  Description

Type  AD Primary Domain   
E.g. domain.com

Directory Username\*  Directory Password\*   
E.g. user@domain.com

Base DN  Group DN   
E.g. ou=group,dc=cisco,dc=com

Proxy

**Directory Server Configuration**

192.168.0.200:389

Hostname/IP Address\*  Port\*

Encryption  CA Certificate

Interface used to connect to Directory server ⓘ

Resolve via route lookup

Choose an interface

Default: Management/Diagnostic Interface

✔ Test connection succeeded

[Add another directory](#)

**Note** The **Directory Username** can be any user in the Active Directory domain; no special permissions are required.

The **Interface used to connect to Directory server** can be any interface that can connect to the Active Directory server.

- Step 5** **Proxy** is an optional managed device or proxy sequence to communicate with ISE/ISE-PIC if Security Cloud Control is unable to do so. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.
- Step 6** Click **Test** and make sure the test succeeds before you continue.
- Step 7** Click **Configure Groups and Users**.
- Step 8** If your configuration was successful, the next page is displayed similar to the following.

**Note** If groups and users were not downloaded, verify the values in the **Base DN** and **Groups DN** fields and click **Load Groups**.

There are other optional configurations available on this page; for more information about them, see [Realm Fields, on page 2478](#) and [Realm Directory and Synchronize fields, on page 2482](#).

- Step 9** If you made changes on this page or tab pages, click **Save**.
- Step 10** Click **Integration > Other Integrations > Realms**.
- Step 11** Click **Add Realm**.
- Step 12** Enter the following information to configure **eastforest.example.com**.

### Related Topics

[Configure the management center for Cross-Domain-Trust Step 2: Synchronize Users and Groups](#), on page 2495

## Configure the management center for Cross-Domain-Trust Step 2: Synchronize Users and Groups

After you configure two or more Active Directory servers that have a cross-domain trust relationship, you must download users and groups. That process exposes possible issues with the Active Directory configuration (for example, groups or users downloaded for one Active Directory domain but not the other).

### Before you begin

Make sure you have performed the tasks discussed in [Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 1: Configure Realms and Directories](#), on page 2490.

### Procedure

- Step 1** Log in to the management center.
- Step 2** Click **Integration** > **Other Integrations** > **Realms**.
- Step 3** At the end of the row of any realm in the cross-domain trust, click (Download Now), then click **Yes**.
- Step 4** Click **Check Mark** () (Notifications) > **Tasks**.

If groups and users fail to download, try again. If subsequent attempts fail, review your realm and directory setup as discussed in [Realm Fields, on page 2478](#) and [Realm Directory and Synchronize fields, on page 2482](#).

If you're using a proxy or proxy sequence, make sure all managed devices can communicate with Active Directory or ISE/ISE-PIC. If more than one managed device can communicate with ISE/ISE-PIC, we strongly recommend you set up a proxy sequence for the realm as discussed in [Create a Proxy Sequence, on page 2448](#)

**Step 5** Click **Integration > Other Integrations > Realms > Sync Results**.

---

### Related Topics

[Configure the management center for Cross-Domain-Trust Step 3: Resolve Issues](#), on page 2496

## Configure the management center for Cross-Domain-Trust Step 3: Resolve Issues

The final step in setting up cross-domain trust in the management center is to make sure users and groups are downloaded without errors. A typical reason why users and groups do not download properly is that the realms to which they belong have not been downloaded to the management center.

This topic discusses how to diagnose that a group referred in one forest to cannot be downloaded because the realm is not configured to find the group in the domain controller hierarchy.

### Before you begin

### Procedure

---

**Step 1** Log in to the management center if you have not already done so.

**Step 2** Click **Integration > Other Integrations > Realms > Sync Results**.

In the Realms column, if **Yellow Triangle** (▲) is displayed next to the name of a realm, you have issues that must be resolved. If not, your results are configured properly and you can quit.

**Step 3** Download users and groups again from the realms that display issues.

- a) Click the **Realms** tab.
- b) Click  (Download Now), then click **Yes**.

**Step 4** Click the **Sync Results** tab page.

If the **Yellow Triangle** (▲) is displayed in the Realms column, click **Yellow Triangle** (▲) next to the realm that has issues.

**Step 5** In the middle column, click either **Groups** or **Users** to find more information.

**Step 6** In the Groups or Users tab page, click **Yellow Triangle** (▲) to display more information.

The right column should display enough information you can isolate the source of the issue.

In the preceding example, **forest.example.com** includes a cross-domain group **CrossForestInvalidGroup** that contains another group **EastMarketingUsers** that was not downloaded by the management center. If, after synchronizing the **eastforest.example.com** realm again, the error does not resolve, it likely means that the Active Directory domain controller does not include **EastMarketingUsers**.

To resolve this issue, you can:

- Remove the **EastMarketingUsers** from **CrossForestInvalidGroup**, synchronize the **forest.example.com** realm again, and recheck.
- Remove the **ou=EastEngineering** value from the **Group DN** of the **eastforest.example.com** realm, which causes the management center to retrieve groups from the highest level in the Active Directory hierarchy, synchronize **eastforest.example.com**, and recheck.

## Manage a Realm

This section discusses how to perform various maintenance tasks for a realm using controls on the Realms page:

### Procedure

- Step 1** Log in to the management center if you haven't already done so.
- Step 2** Click **Integration > Other Integrations > Realms**.

- Step 3** To delete a realm, click **Delete** (🗑️).
  - Step 4** To edit a realm, click **Edit** (✎) next to the realm and make changes as described in [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).
  - Step 5** To enable a realm, slide **State** to the right; to disable a realm, slide it to the left.
  - Step 6** To download users and user groups, click **Download** (↓).
  - Step 7** To copy a realm, click **Copy** (📄).
  - Step 8** To compare realms, see [Compare Realms, on page 2498](#).
- 

## Compare Realms

You must be an Admin, Access Admin, Network Admin, or Security Approver to perform this task.

### Procedure

---

- Step 1** Log in to the management center.
  - Step 2** Click **Integration > Other Integrations > Realms**.
  - Step 3** Click **Compare Realms**.
  - Step 4** Choose **Compare Realm** from the **Compare Against** list.
  - Step 5** Choose the realms you want to compare from the **Realm A** and **Realm B** lists.
  - Step 6** Click **OK**.
  - Step 7** To navigate individually through changes, click **Previous** or **Next** above the title bar.
  - Step 8** (Optional.) Click **Comparison Report** to generate the realm comparison report.
  - Step 9** (Optional.) Click **New Comparison** to generate a new realm comparison view.
- 

## Troubleshoot Realms and User Downloads

If you notice unexpected server connection behavior, consider tuning your realm configuration, device settings, or server settings. For other related troubleshooting information, see:

- [Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues, on page 2559](#)
- [Troubleshoot the TS Agent Identity Source, on page 2606](#)
- [Troubleshoot the Captive Portal Identity Source, on page 2579](#)
- [Troubleshoot the Remote Access VPN Identity Source, on page 2602](#)
- [Troubleshoot User Control, on page 2628](#)

**Symptom: Users are not downloaded**

Possible causes follow:

- If you have the realm **Type** configured incorrectly, users and groups cannot be downloaded because of a mismatch between the attribute the system expects and what the repository provides. For example, if you configure **Type** as **LDAP** for a Microsoft Active Directory realm, the system expects the `uid` attribute, which is set to `none` on Active Directory. (Active Directory repositories use `sAMAccountName` for the user ID.)

**Solution:** Set the realm **Type** field appropriately: **AD** for Microsoft Active Directory or **LDAP** for another supported LDAP repository.

- Users in Active Directory groups that have special characters in the group or organizational unit name might not be available for identity policy rules. For example, if a group or organizational unit name contains the characters asterisk (\*), equals (=), or backslash (\), users in those groups are not downloaded and can't be used for identity policies.

**Solution:** Remove special characters from the group or organizational unit name.

**Important**

To reduce latency between the management center and your Active Directory domain controller, we strongly recommend you configure a realm directory (that is, domain controller) that is as close as possible geographically to the management center.

For example, if your management center is in North America, configure a realm directory that is also in North America. Failure to do so can cause problems such as timeout downloading users and groups.

**Symptom: Not all users in a realm are downloaded**

Possible causes follow:

- If you attempt to download more than the maximum number of users in any one realm, the download stops at the maximum number of users and a health alert is displayed. User download limits are set per Secure Firewall Management Center model.
- Every user must be a member of a group. Users that are members of no groups do not get downloaded.

**Symptom: Access control policy doesn't match group membership**

This solution applies to an AD domain that is in a trust relationship with other AD domains. In the following discussion, *external domain* means a domain other than the one to which the user logs in.

If a user belongs to a group defined in a trusted external domain, the management center doesn't track membership in the external domain. For example, consider the following scenario:

- Domain controllers 1 and 2 trust each other
- Group A is defined on domain controller 2
- User `mparvinder` in controller 1 is a member of Group A

Even though user `mparvinder` is in Group A, the management center access control policy rules specifying membership Group A don't match.

**Solution:** Create a similar group in domain controller 1 that contains has all domain 1 accounts that belong to group A. Change the access control policy rule to match any member of Group A or Group B.

**Symptom: Access control policy doesn't match child domain membership**

If a user belongs to a domain that is child of parent domain, Firepower doesn't track the parent/child relationships between domains. For example, consider the following scenario:

- Domain `child.parent.com` is child of domain `parent.com`
- User `mparvinder` is defined in `child.parent.com`

Even though user `mparvinder` is in a child domain, the Firepower access control policy matching the `parent.com` don't match `mparvinder` in the `child.parent.com` domain.

**Solution:** Change the access control policy rule to match membership in either `parent.com` or `child.parent.com`.

**Symptom: Realm or realm directory test fails**

The **Test** button on the directory page sends an LDAP query to the hostname or IP address you entered. If it fails, check the following:

- The **Hostname** you entered resolves to the IP address of an LDAP server or Active Directory domain controller.
- The **IP Address** you entered is valid.

The **Test AD Join** button on the realm configuration page verifies the following:

- DNS resolves the **AD Primary Domain** to an LDAP server or Active Directory domain controller's IP address.
- The **AD Join Username** and **AD Join Password** are correct.  
**AD Join Username** must be fully qualified (for example, `administrator@mydomain.com`, *not* `administrator`).
- The user has sufficient privileges to create a computer in the domain and join the management center to the domain as a Domain Computer.

**Symptom: User timeouts are occurring at unexpected times**

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your ISE/ISE-PIC server is synchronized with the time on the Secure Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

If you notice the system performing user timeouts at unexpected intervals, confirm that the time on your ISE/ISE-PIC, or TS Agent server is synchronized with the time on the Secure Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.

**Symptom: User data for previously-unseen ISE/ISE-PIC users is not displaying in the web interface**

After the system detects activity from an ISE/ISE-PIC or TS Agent user whose data is not yet in the database, the system retrieves information about them from the server. In some cases, the system requires additional

time to successfully retrieve this information from Microsoft Windows servers. Until the data retrieval succeeds, activity seen by the ISE/ISE-PIC, or TS Agent user is *not* displayed in the web interface.

Note that this can also prevent the system from handling the user's traffic using access control rules.

### Symptom: User data in events is unexpected

If you notice user or user activity events contain unexpected IP addresses, check your realms. The system does not support configuring multiple realms with the same **AD Primary Domain** value.

### Symptom: Users originating from terminal server logins are not uniquely identified by the system

If your deployment includes a terminal server and you have a realm configured for one or more servers connected to the terminal server, you must deploy the Cisco Terminal Services (TS) Agent to accurately report user logins in terminal server environments. When installed and configured, the TS Agent assigns unique ports to individual users so the system can uniquely identify those users in the web interface.

For more information about the TS Agent, see the *Cisco Terminal Services (TS) Agent Guide*.

## Troubleshoot Cross-Domain Trust

Typical issues with troubleshooting the management center configuration for cross-domain trust include the following:

- Not adding realms or directories for all forests that have shared groups.
- Configure a realm to exclude users from being downloaded and those users are referenced in a group in a different realm.
- Certain temporary issues.

### Understand the issues

If there are issues with the management center being able to synchronize users and groups with your Active Directory forests, the Sync Results tab page is displayed similar to the following.

The screenshot shows the 'Sync Results' tab in the Cisco Security Cloud Control interface. The page is divided into three main sections: 'Realms', 'Groups', and 'Users contained in the selected group'. Each section has a search bar and a list of items with error messages.

Section	Item	Error Message
Realms	forest.example.com	▲ forest.example.com E.g., Error message: this realm contains references to user or groups in another domain that have not been synchronized (downloaded with the system.) <a href="#">Learn more</a>
Groups	CrossForestGroup	▲ CrossForestGroup E.g., Error message: this group contains references to user or groups in another domain that have not been synchronized (downloaded with the system.) <a href="#">Learn more</a>
Users contained in the selected group	EASTFOREST0\EastMarketing	▲ EASTFOREST0\EastMarketing Check config for Realm and ensure you can sync user or group 'EASTFOREST0\EastMarketing' from that Realm.

The following table explains how to interpret the information.

Column	Meaning
Realms	<p>Displays all realms configured in the system. Click <b>Refresh</b> (🔄) to update the list of realms.</p> <p><b>Yellow Triangle</b> (⚠️) is displayed to indicate issues in the realm.</p> <p>Nothing is displayed next to a realm if all users and groups synchronized successfully.</p>
Groups	<p>Click <b>Groups</b> to display all groups in the realm. As with realms, <b>Yellow Triangle</b> (⚠️) is displayed to indicate issues.</p> <p>Click <b>Yellow Triangle</b> (⚠️) to see more detail about the issue.</p>
Users	Click <b>Users</b> to display all users, sorted by group.
Users contained in the selected group	Displays all users in the group you selected in the Groups column. Clicking <b>Yellow Triangle</b> (⚠️) displays more information to the right of the table.
Groups that contain selected user	Displays all groups the selected user belongs to. Clicking <b>Yellow Triangle</b> (⚠️) displays more information to the right of the table.
Error detail information (displayed to the right of the table).	<p>The system displays the NetBIOS forest name and group name it could not synchronize. Typical reasons the system cannot synchronize these users and groups follow:</p> <ul style="list-style-type: none"> <li>• <b>Problem:</b> The forest containing the groups and users do not have corresponding realms configured in the management center.</li> </ul> <p><b>Solution:</b> Add a realm for the forest that contains the group as discussed in <a href="#">Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475</a>.</p> <ul style="list-style-type: none"> <li>• <b>Problem:</b> You excluded groups from being downloaded to the management center.</li> </ul> <p><b>Solution:</b> Click the <b>Realms</b> tab page, click <b>Edit</b> (✎), then move the indicated group or user from the <b>Excluded Groups and Users</b> list.</p>

### Try downloading users and groups again

If there is a possibility the issues are temporary, download users and groups for all realms.

1. If you haven't done so already, log in to the management center.
2. Click **Integration > Other Integrations > Realms**.
3. Click **Download** (↓).
4. Click the **Sync Results** tab page.
5. If no indicator is displayed for entries in the Realms column, the issues have been resolved.

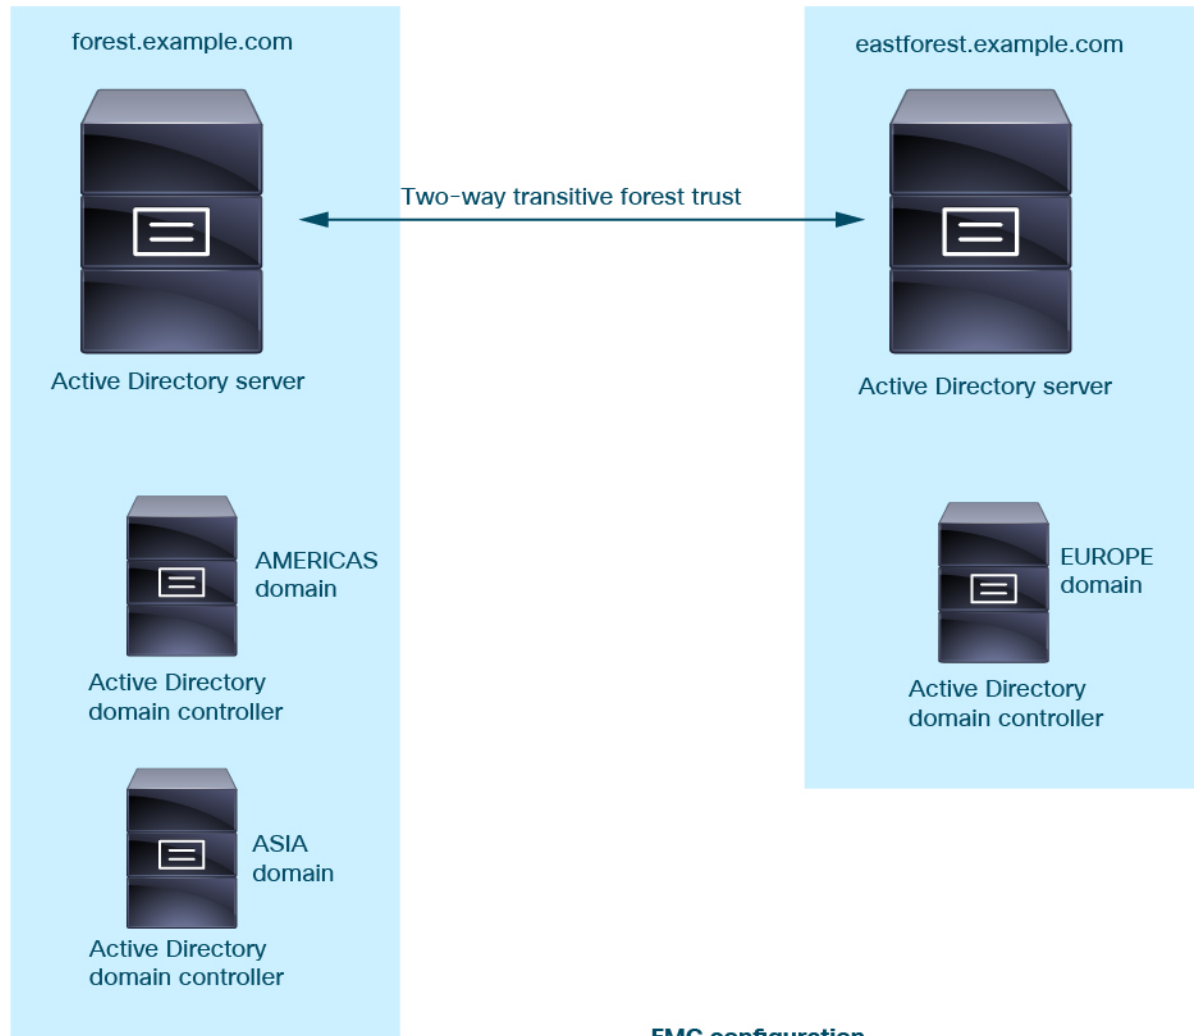

**Add a realm for all forests**

Make sure you configured:

- management center realm for each forest that has users you want to use in identity policies.
- management center directory for each domain controller in that forest with users you want to use in identity policies.

The following figure shows an example.

**FMC configuration**

**Realm:** forest.example.com  
**Directory:** AMERICAS.forest.example.com  
**Directory:** ASIA.forest.example.com  
**Realm:** eastforest.example.com  
**Directory:** EUROPE.eastforest.example.com

## History for Realms

Feature	Minimum Management Center	Minimum Threat Defense	Details
Microsoft Azure Active Directory (SAML) realms.	November 8, 2024	7.4.0	<p>You can now use Microsoft Azure Active Directory (AD) realms for active and passive authentication:</p> <ul style="list-style-type: none"> <li>• Active authentication using Azure AD: Use Azure AD as a captive portal.</li> <li>• Passive authentication using Cisco ISE (introduced in Version 7.4.0): The management center gets groups from Azure AD and logged-in user session data from ISE.</li> </ul> <p>We use SAML (Security Assertion Markup Language) to establish a trust relationship between a service provider (the devices that handle authentication requests) and an identity provider (Azure AD). For upgraded management centers, existing Azure AD realms are displayed as SAML - Azure AD realms.</p> <p><b>Upgrade impact.</b> If you had a Microsoft Azure AD realm configured before the upgrade, it is displayed as a SAML - Azure AD realm configured for passive authentication. All previous user session data is preserved.</p> <p>New/modified screens: <b>Integration &gt; Other Integrations &gt; Realms &gt; Add Realm &gt; SAML - Azure AD</b></p> <p>New/modified CLI commands: none</p> <p>See: <a href="#">Create a Microsoft Azure AD (SAML) Realm</a>.</p>
Proxy sequences.	Any	7.2.0	<p>Similar to a realm sequence, a proxy sequence is one or more managed devices that can communicate with Cisco Security Cloud Control in the event Cisco Security Cloud Control cannot communicate with the LDAP or Active Directory server.</p> <p>New/modified screens: <b>Integration &gt; Other Integrations &gt; Realms &gt; Proxy Sequence</b></p>
Cross-domain trust for Active Directory domains.	Any	7.0.0	<p>A grouping of Microsoft Active Directory (AD) domains that trust each other is commonly referred to as a <i>forest</i>. This trust relationship can enable domains to access each other's resources in different ways. For example, a user account defined in domain A can be marked as a member of a group defined in domain B.</p> <p>The management center can get users from Active Directory forests for identity rules.</p>
Realm sequences.	Any	6.7.0	<p>A <i>realm sequence</i> is an ordered list of two or more realms to which to apply identity rules. When you associate a realm sequence with an identity policy, the Firepower System searches the Active Directory domains in order from first to last as specified in the realm sequence.</p> <p>New/modified screens: <b>Integration &gt; Other Integrations &gt; Realms &gt; Realm Sequences</b></p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Realms for user control.	Any	Any	A realm is a connection between the management center either an Active Directory or LDAP user repository.

## CHAPTER 91

# User Control with the Passive Identity Agent

The following topics discuss how to configure and use the passive identity agent.

- [The Passive Identity Agent Identity Source](#), on page 2507
- [Deploy the Passive Identity Agent](#), on page 2508
- [How to Create a Passive Identity Agent Identity Source](#), on page 2513
- [Configure the Passive Identity Agent](#), on page 2515
- [Monitor the Passive Identity Agent](#), on page 2527
- [Manage the Passive Identity Agent](#), on page 2528
- [Troubleshoot the Passive Identity Agent](#), on page 2530
- [Security Requirements for the Passive Identity Agent](#), on page 2531
- [Internet Access Requirements for the Passive Identity Agent](#), on page 2531
- [History for the Passive Identity Agent](#), on page 2532

## The Passive Identity Agent Identity Source

The passive identity agent identity source sends session data from Microsoft Active Directory (AD) to the Cisco Security Cloud Control. All you need is a supported Microsoft AD setup as discussed in [About Realms and Realm Sequences](#), on page 2441.

---

**Note** You do not need to configure the Cisco Identity Services Engine (ISE) to use this identity source.

---

### Passive identity agent roles

The passive identity agent supports the following roles:

- **Standalone:** A passive identity agent that is not part of a redundant pair. A standalone agent can download users and groups from multiple Active Directory servers and domain controllers, provided the software is installed on all of them.
- **Primary:** (Primary agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

Handles all communication with the Cloud-delivered Firewall Management Center unless it stops communicating, in which case communication is handled by secondary agents.

- Secondary: (Secondary, or backup, agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

Monitors the health of the primary agent and takes over if the primary agent stops communicating with the Cloud-delivered Firewall Management Center.

### Passive identity agent system requirements

The passive identity agent requires the following:

- If you install it on a Windows Active Directory server, the server must run Windows Server 2008 or later.
- If you install it on a Windows client attached to the domain, the client must run Windows 8 or later.
- The system clock on all systems must be synchronized. We strongly recommend using the same NTP servers on all of them. This means:
  - The Security Cloud Control.  
For more information, see [Configure NTP Server](#).
  - All Windows Active Directory servers and domain controllers.
  - The machine on which the passive identity agent is installed.
- Security Cloud Control must run November 8, 2024 or later.
- You must enable Snort 3 on the Secure Firewall Threat Defense devices.

### Passive identity agent limitations

The passive identity agent the following limitations:

- Up to 10 agents simultaneously
- One passive identity agent identity source can monitor up to 50 AD directories
- Up to 300,000 concurrent user sessions
- IPv6 addresses are not supported

### Deploy the passive identity agent

For information about deployment options, see [Deploy the Passive Identity Agent, on page 2508](#).

## Deploy the Passive Identity Agent

You can install the Passive Identity Agent software on any machine that is part of a Microsoft Active Directory (AD) domain you want to use for user awareness and control. In other words, you can install it on any of the following:

- The Microsoft Active Directory server
- A domain controller

- A client connected to the network that is neither the directory server nor a domain controller

Any particular passive identity agent can monitor one or several Active Directory domain controllers in the same domain.

The machine on which the passive identity agent must communicate with the Cloud-delivered Firewall Management Center using the TLS/SSL protocol. For more information, see [Internet Access Requirements for the Passive Identity Agent](#), on page 2531.

### Types of agents

You can configure the following types of agents on the Microsoft AD directory server, domain controller, or on any client connected to the domain:

- Standalone agent: One agent that can monitor one or several Active Directory domain controllers in the same domain.
- Primary agent and secondary agent that can monitor one or several AD domain controllers in the same domain: To provide redundancy, you can install a primary and secondary agent on different machines. The primary is responsible for communicating with the Cloud-delivered Firewall Management Center but if communication fails, the secondary agent takes over.

See one of the following topics for more information.

### Related Topics

[Simple Passive Identity Agent Deployment](#), on page 2509

[Single Passive Identity Agent Monitoring Multiple Domain Controllers](#), on page 2510

[Multiple Passive Identity Agents Monitoring Multiple Domain Controllers](#), on page 2510

[Passive Identity Agent Primary/Secondary Agent Deployments](#), on page 2512

## Simple Passive Identity Agent Deployment

The following diagram shows the simplest passive identity agent deployment.

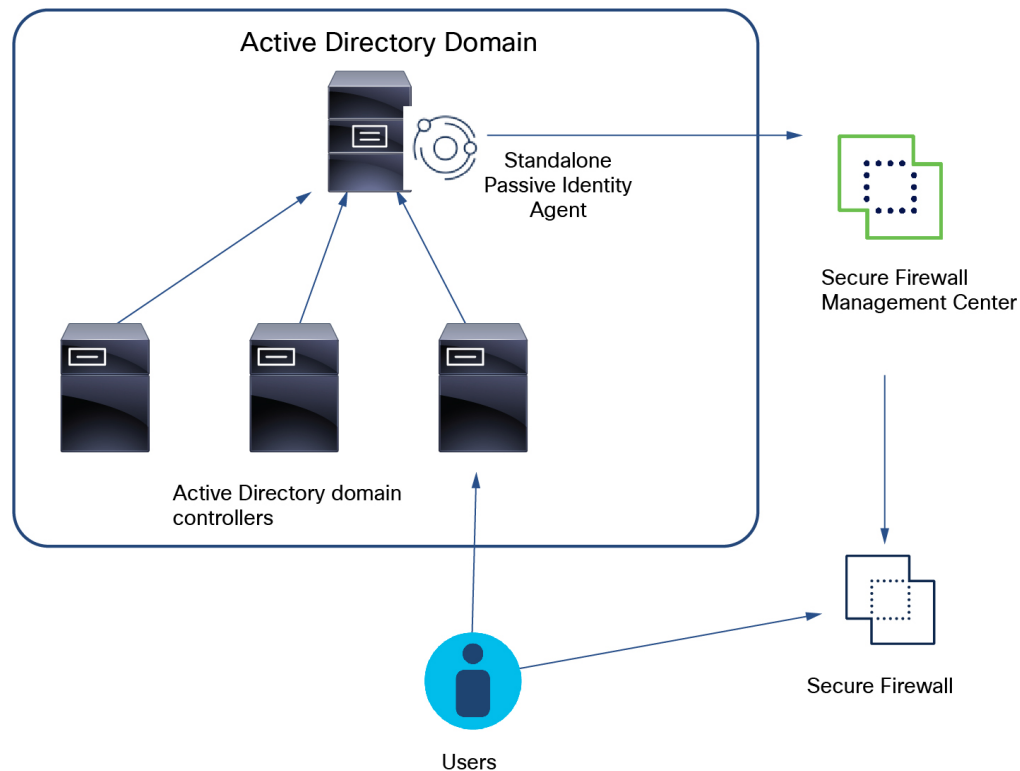

In the preceding example, a standalone passive identity agent is installed on the AD domain controller. Users log in and out of the AD domain and the agent sends user name and IP address information to the

Cloud-delivered Firewall Management Center. As users access the network, access control and identity policies deployed to the Secure Firewall Threat Defense determine whether or not, and how, access is allowed.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

## Single Passive Identity Agent Monitoring Multiple Domain Controllers

The following diagram shows a standalone passive identity agent that monitors several AD domain controllers.

In the preceding diagram, the standalone passive identity agent is installed on a client attached to the AD domain (or on the domain controller itself). Users log in to any domain controller and the agent sends user and IP address information to the Cloud-delivered Firewall Management Center. As users access the network, access control and identity policies deployed to the Secure Firewall Threat Defense determine whether or not, and how, access is allowed.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

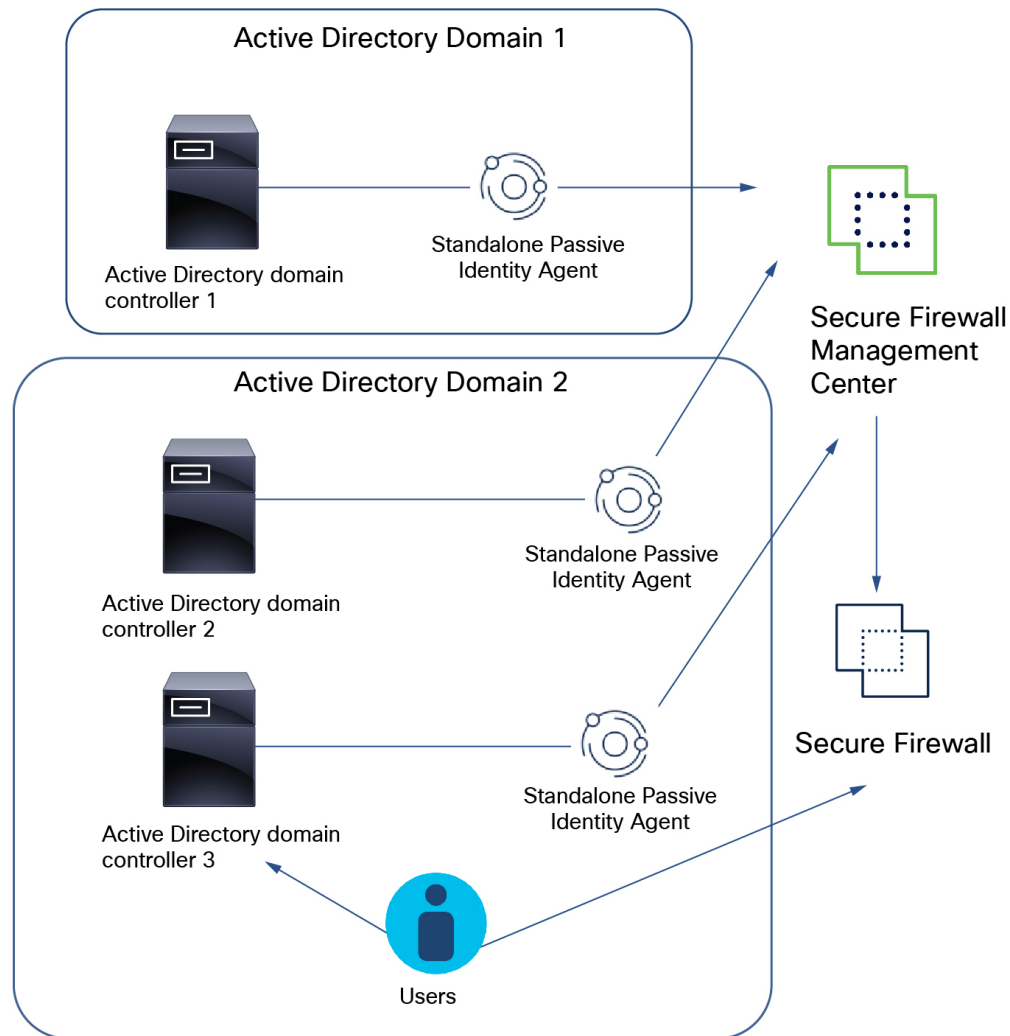

## Multiple Passive Identity Agents Monitoring Multiple Domain Controllers

The following figure shows standalone monitoring multiple AD domain controllers:

- In AD domain 1, a standalone passive identity agent installed on a machine attached to AD domain controller 1 sends user and IP address mapping data to the Cloud-delivered Firewall Management Center.

- In AD domain 2, standalone agents installed on AD domain controllers 1 and 2 send user and IP address mapping data to the Cloud-delivered Firewall Management Center.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

The preceding figure shows three passive identity agents, each configured as a standalone. To do this:

1. Create two Microsoft AD realms: one for each AD domain.

See [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.

2. For AD domain 2, create two directories, one for each domain controller.

3. Install the Passive Identity Agent software on a client that can log in to the domain.

Configure each passive identity agent individually to communicate with the Cloud-delivered Firewall Management Center on which you configure the passive identity agent source.

See [Install the Passive Identity Agent Software](#), on page 2524.

4. Create the passive identity agent identity source.

See [Create a Primary or Secondary Passive Identity Agent Identity Source](#), on page 2518.

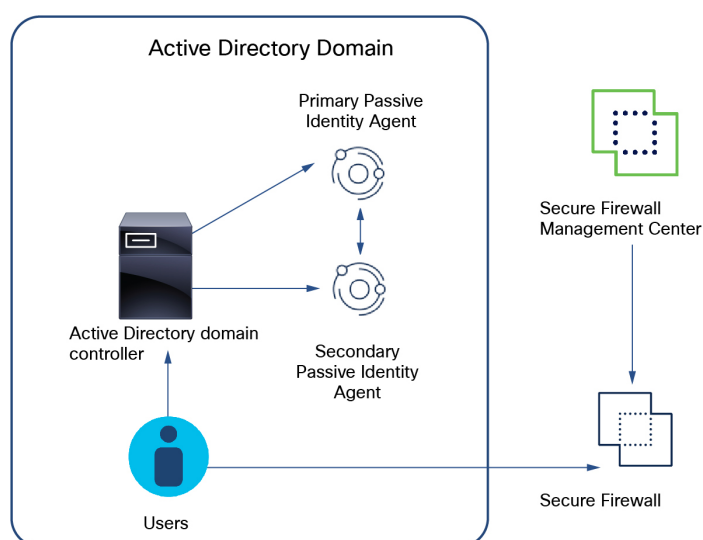

## Passive Identity Agent Primary/Secondary Agent Deployments

To provide redundancy and to avoid a single point of failure, you can configure primary and secondary passive identity agents in any of the ways shown in this topic.

You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.

### Single AD domain controller with primary and secondary agents

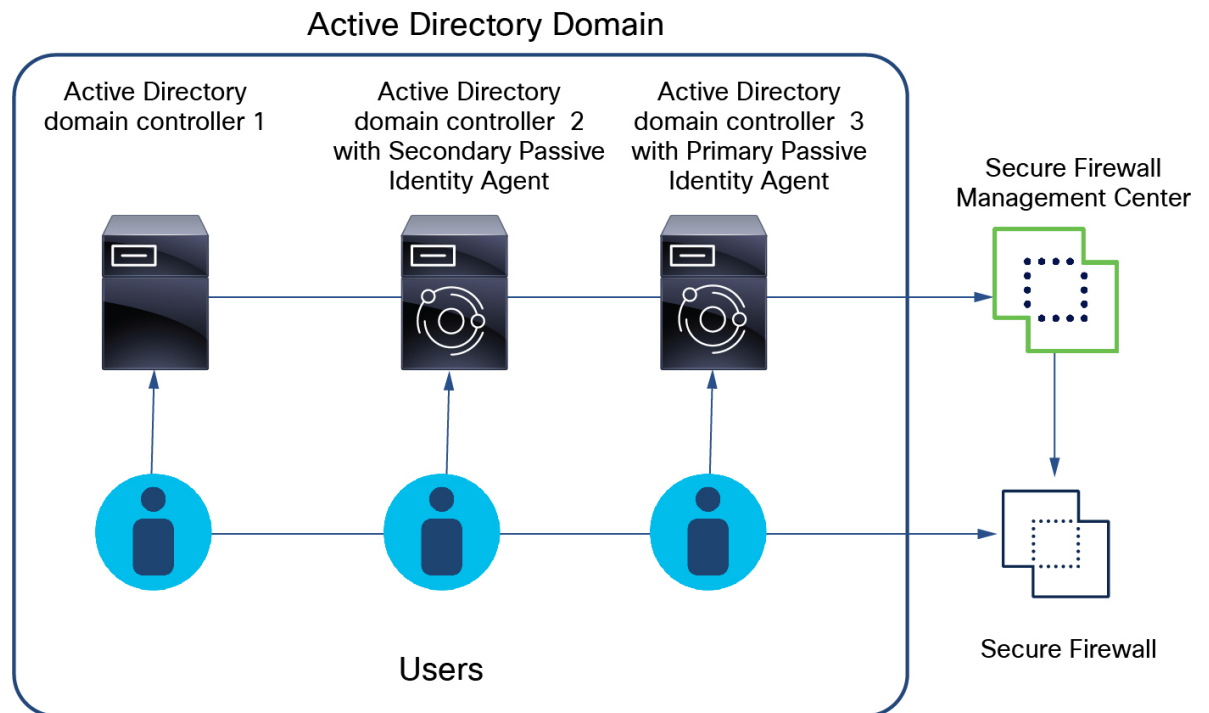

The following figure shows how to set up primary and secondary passive identity agents on one AD domain controller. If the primary agent fails, the secondary takes over.

To set this up:

1. Create a Microsoft AD realm that has one directory for the domain controller.  
See [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.
2. Install the passive identity agent software on any two network machines connected to the domain controller.  
Configure each passive identity agent individually to communicate with the Cloud-delivered Firewall Management Center on which you configure the passive identity agent source.  
See [Install the Passive Identity Agent Software](#), on page 2524.
3. Create the identity source.  
See [Create a Primary or Secondary Passive Identity Agent Identity Source](#), on page 2518.

### Multiple AD domain controllers, primary and secondary agents

The preceding figure shows how to configure primary and secondary agents to monitor three AD domain controllers. If the primary agent fails, the secondary agent takes over.

To set this up:

1. Create a Microsoft AD realm that has one directory for the domain controller.  
See [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.
2. Install the passive identity agent software on any machine connected to the domain controller.  
Configure each passive identity agent individually to communicate with the Cloud-delivered Firewall Management Center on which you configure the passive identity agent source.  
See [Install the Passive Identity Agent Software](#), on page 2524.
3. Create the identity source.  
See [Create a Primary or Secondary Passive Identity Agent Identity Source](#), on page 2518.

## How to Create a Passive Identity Agent Identity Source

The following provides high-level tasks required to configure the passive identity agent identity source in the Cloud-delivered Firewall Management Center and to deploy agent software to your Microsoft Active Directory (AD) servers.

## Procedure

	Command or Action	Purpose
<b>Step 1</b>	Create a realm for your Microsoft AD domain and domain controllers.	<p><i>Realms</i> are connections between the Cloud-delivered Firewall Management Center and the user accounts on the servers you monitor. They specify the connection settings and authentication filter settings for the server.</p> <p>For more information, see <a href="#">Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475</a>.</p>
<b>Step 2</b>	Create a passive identity agent identity source.	<p>The identity source allows the Cloud-delivered Firewall Management Center and passive identity agent to communicate with each other. Create standalone, primary, or secondary agents, depending on your needs.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• <a href="#">About Passive Identity Agent Roles, on page 2520</a></li> <li>• <a href="#">Create a Passive Identity Agent Identity Source, on page 2515</a></li> </ul>
<b>Step 3</b>	Create a passive identity agent user on the Cloud-delivered Firewall Management Center.	<p>We provide a role sufficient for the agent and manager to communicate with each other. We recommend using that role and no other for the passive identity agent user.</p>
<b>Step 4</b>	Install the passive identity agent software.	<p>The way you install the agent depends on your deployment.</p> <p>You can install a passive identity agent on the AD domain controller, directory server, or on any client connected to the domain you wish to monitor.</p> <p>For more information, see:</p> <ul style="list-style-type: none"> <li>• <a href="#">Deploy the Passive Identity Agent, on page 2508</a></li> <li>• <a href="#">Install the Passive Identity Agent Software, on page 2524</a></li> </ul>

### What to do next

[Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).

# Configure the Passive Identity Agent

The following topics discuss how to configure the passive identity agent.

## Related Topics

[Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475

[Create a Passive Identity Agent Identity Source](#), on page 2515

[Create a Cisco Security Cloud Control User for the Passive Identity Agent](#), on page 2521

[Install the Passive Identity Agent Software](#), on page 2524

## Create a Microsoft Active Directory Realm

The passive identity agent requires you to create a Microsoft Active Directory (AD) realm and directories in the Cloud-delivered Firewall Management Center as discussed in [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.

## Create a Passive Identity Agent Identity Source

This task discusses how to create a passive identity agent that sends user session activity to the Cloud-delivered Firewall Management Center.

### Before you begin

Complete the following:

- Review passive identity agent roles as discussed in [About Passive Identity Agent Roles](#), on page 2520.
- Create a Microsoft AD realm as discussed in [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.

### Procedure

- 
- Step 1** Log in to the Cisco Security Cloud Control.
- Step 2** Click **Objects > Other FTD Objects**.
- Step 3** **Integration > Other Integrations > Identity Sources**
- Step 4** Click **Passive Identity Agent**.
- Step 5** Click **Create Agent**.
- Step 6** In the Configure Agent dialog box, enter the following information:

Item	Description
<b>Name</b>	Enter a unique name to identify this passive identity agent.
<b>Description</b>	Enter an optional description.

Item	Description
<b>Role</b>	<p>Click one of the following:</p> <ul style="list-style-type: none"> <li>• <b>Primary:</b> The agent responsible for communicating with the Cisco Security Cloud Control. Not available if you choose <b>Standalone</b>.</li> <li>• <b>Secondary:</b> Becomes the primary if the primary loses contact with the Cisco Security Cloud Control. Not available if you choose <b>Standalone</b>.</li> <li>• <b>Standalone:</b> If there is only one passive identity agent.</li> </ul> <p>For more information about roles, see <a href="#">About Passive Identity Agent Roles</a>, on page 2520.</p>

**Step 7** Continue with:

- [Create a Standalone Passive Identity Agent Identity Source](#), on page 2516
- [Create a Primary or Secondary Passive Identity Agent Identity Source](#), on page 2518

## Create a Standalone Passive Identity Agent Identity Source

This task discusses how to configure a standalone passive identity agent.

### Before you begin

Complete the tasks discussed in [Create a Passive Identity Agent Identity Source](#), on page 2515.

### Procedure

**Step 1** In the Configure Agent dialog box, enter the following information:

Item	Description
<b>Role</b>	Click <b>Standalone</b> .
<b>Domain Controller</b>	From the list, select the check box next to each domain controller that has a passive identity agent you wish to use for identity management and user control.

The following figure shows an example of a standalone passive identity agent identity source.

### Configure Agent ?

**Name \***

**Description**

**Role**

**Note** The passive identity agent won't be active until you create a user and install the software.

### What to do next

- See [Create a Cisco Security Cloud Control User for the Passive Identity Agent, on page 2521](#)
- [Install the Passive Identity Agent Software, on page 2524](#)

## Create a Primary or Secondary Passive Identity Agent Identity Source

The following task continues from [Create a Passive Identity Agent Identity Source, on page 2515](#).

### Before you begin

Complete the tasks discussed in [Create a Passive Identity Agent Identity Source, on page 2515](#).

### Procedure

**Step 1** In the Configure Agent dialog box, enter the following information:

Item	Description
<b>Role</b>	<p>Click one of the following:</p> <ul style="list-style-type: none"> <li>• <b>Primary:</b> The agent responsible for communicating with the Secure Firewall Management Center.</li> <li>• <b>Secondary:</b> Becomes the primary if the primary loses contact with the Secure Firewall Management Center.</li> </ul> <p>For more information about roles, see <a href="#">About Passive Identity Agent Roles, on page 2520</a>.</p>
<b>Primary Agent Hostname/IP Address</b>	<p>(Primary agent only.) Enter the fully qualified domain name or IP address of the server on which the primary passive identity agent is installed.</p> <p>The passive identity agent supports IPv4 addresses and fully qualified domain names only. IPv6 addresses are not supported.</p>
<b>Secondary Agent Hostname/IP Address</b>	<p>(Secondary agent only.) Enter the fully qualified host name or IP address of the server on which the secondary passive identity agent is installed.</p> <p>The passive identity agent supports IPv4 addresses and fully qualified domain names only. IPv6 addresses are not supported.</p>
<b>Primary Agent</b>	<p>(Secondary agent only.) From the list, click the name of the primary passive identity agent.</p>
<b>Domain Controller</b>	<p>(Primary agent only.) From the list, select the check box next to each domain controller that has a passive identity agent you wish to use for identity management and user control.</p>

The following figure shows an example of a primary agent:

**Note** The passive identity agent won't be active until you create a user and install the software.

### What to do next

- See [Create a Cisco Security Cloud Control User for the Passive Identity Agent, on page 2521](#)
- See [Install the Passive Identity Agent Software, on page 2524](#)

## About Passive Identity Agent Roles

The passive identity agent has the following roles:

- **Standalone:** A passive identity agent that is not part of a redundant pair. A standalone agent can download users and groups from multiple Active Directory servers and domain controllers, provided the software is installed on all of them.
- **Primary:** (Primary agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

Handles all communication with the Cloud-delivered Firewall Management Center unless it stops communicating, in which case communication is handled by secondary agents.

- **Secondary:** (Secondary, or backup, agent in a redundant pair.) Can be installed on a Microsoft AD domain controller, directory server, or any network client.

Monitors the health of the primary agent and takes over if the primary agent stops communicating with the Cloud-delivered Firewall Management Center.

The can monitor several AD domain controllers that art part of the same domain.

## Create a Cisco Security Cloud Control User for the Passive Identity Agent

This task discusses how to create a Secure Firewall Management Center user with sufficient permissions to communicate with the passive identity agent.

---

**Note** Use *only* the **Passive Identity User** role for the passive identity agent user. In particular, *do not* use the **Administrator** role for the passive identity agent because **Administrator** will be logged off at a regular basis as the passive identity agent communicates with the Secure Firewall Management Center.

---

### Before you begin

Complete the tasks discussed in [Create a Passive Identity Agent Identity Source, on page 2515](#).

---

**Note** You *cannot* use external authentication with the Passive Identity Agent.

---

### Procedure

- 
- Step 1** Log in to the Cisco Security Cloud Control.
  - Step 2** Click **System** (⚙) > **Users** > **Users**.
  - Step 3** Click **Create User**.
  - Step 4** Create the user as discussed in [Add or Edit an Internal User](#) in the *Cisco Secure Firewall Management Center Administration Guide*.
  - Step 5** Select the **Passive Identity User** role.  
The following figure shows an example.

### User Configuration

User Name

Real Name

Email Address

Authentication  Use External Authentication Method

Password

Confirm Password

Maximum Number of Failed Logins  (0 = Unlimited)

Minimum Password Length

Days Until Password Expiration  (0 = Unlimited)

Days Before Password Expiration Warning

Options

- Force Password Reset on Login
- Check Password Strength
- Exempt from Browser Session Timeout

### User Role Configuration

Default User Roles

- Administrator
- External Database User (Read Only)
- Security Analyst
- Security Analyst (Read Only)
- Security Approver
- Intrusion Admin
- Access Admin
- Network Admin
- Maintenance User
- Discovery Admin
- Threat Intelligence Director (TID) User
- Passive Identity User

**Note** Do not choose a role for the passive identity agent user other than **Passive Identity User** because the agent will not function properly.

**Step 6** Click **Save**.

### What to do next

[Install the Passive Identity Agent Software, on page 2524.](#)

## Troubleshoot the Passive Identity Agent

This topic discusses how you can troubleshoot the passive identity agent software on your Windows AD domain controller or directory server.

### (Optional.) Set the log level

By default, the passive identity agent logs at the INFO level. To optionally change the log level, open **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config** in a text editor, save the file, and restart the Cisco Passive Identity Agent service.

### Do not rename the logging service

Do not rename **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config**; otherwise, the passive identity agent will stop generating log files. Do not remove or change the **.exe.config** file extension.

### View log files

Passive identity agent log files are stored in plain text format in the agent's installation directory: **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent**.

Use Notepad or another text editor to view these files. Log files rotate after reaching 10MB in size.

### Use the Microsoft Active Directory event viewer

In the event you are not seeing user sessions in the Cisco Security Cloud Control, you can look on your Microsoft Active Directory server's event viewers for the following Kerberos-related events:

- 4770
- 4768

For general information about audit policy, see [Audit Policy Recommendations](#) on learn.microsoft.com.

For more information about Windows Group Policy Object settings, see [Group Policy Objects](#) on learn.microsoft.com.

## Get an API Token for the Passive Identity Agent

This task discusses how to get the API token, which is used by the passive identity agent to authenticate with the cloud-delivered Firewall Management Center. It applies *only* to using the passive identity agent with the cloud-delivered Firewall Management Center.

### Required role:

- Super Admin
- Admin

## Procedure

- 
- Step 1** Log in to Cisco Security Cloud Control.
- Step 2** Click **Administration > Integrations & Migration > Cloud Services**.
- Step 3** Check the box next to the cloud-delivered Firewall Management Center with which you want to use the passive identity agent.
- Step 4** In the right pane, click **Passive Identity**.
- Step 5** Copy the token to the clipboard.
- 

### What to do next

[Install the Passive Identity Agent Software, on page 2524.](#)

## Install the Passive Identity Agent Software

This task discusses how to install the passive identity agent software. For a simple installation, you can install it on your Microsoft Active Directory (AD) domain controller; for other options, see [Deploy the Passive Identity Agent, on page 2508](#).

### Before you begin

See [Get an API Token for the Passive Identity Agent, on page 2523](#).

Make sure your systems meet the following requirements:

- If you install it on a Windows Active Directory server, the server must run Windows Server 2008 or later.
- If you install it on a Windows client attached to the domain, the client must run Windows 8 or later.
- The system clock on all systems must be synchronized. We strongly recommend using the same NTP servers on all of them. This means:
  - The Security Cloud Control.  
For more information, see [Configure NTP Server](#).
  - All Windows Active Directory servers and domain controllers.
  - The machine on which the passive identity agent is installed.
- Security Cloud Control must run November 8, 2024 or later.
- You must enable Snort 3 on the Secure Firewall Threat Defense devices.

## Procedure

- 
- Step 1** Download the passive identity agent from [software.cisco.com](https://software.cisco.com).

**Step 2** Log in as a member of the Administrators group to the machine on which to install the passive identity agent.

**Step 3** Double-click **CiscoPassiveIdentityAgentInstaller-1.0.msi**.

**Step 4** Click **Next**.

**Step 5** Choose a folder in which to install the passive identity agent and click **Next**.

The default installation folder is **Program Files(Program Files (x86))\Cisco\Cisco Passive Identity Agent**.

**Step 6** Click **Next**.

**Step 7** Click **Install**.

**Step 8** When the installation is done, click **Finish** and optionally check the box to start the passive identity agent.

**Step 9** When the passive identity agent starts, click the **On-Prem** tab if you are using the agent with an on-premises Secure Firewall Management Center (physical or virtual) or click the **Cloud** tab if you are using the agent with Security Cloud Control.

**Step 10** In the Cisco Passive Agent dialog box, enter the following information:

Item	Description
<b>FMC FQDN / IP Address</b>	Enter the fully qualified domain name or IP address of the Cloud-delivered Firewall Management Center on which you created the passive identity agent identity source.  The passive identity agent supports IPv4 addresses and fully qualified domain names only. IPv6 addresses are not supported.
<b>Token</b>	Enter the API token you found in <a href="#">Get an API Token for the Passive Identity Agent, on page 2523</a> .
<b>Agent</b>	Click the list to locate the domain controller of the passive identity agent you created previously on the Cisco Security Cloud Control.

**Step 11** Click the **Agent** list.

**Step 12** From the list, click the name of the domain controller to monitor.

**Step 13** Click **Test**.

The following figure shows an example.

Cisco Passive Identity Agent 1.0.0-3

Secure Firewall Management Center

Enter the fully qualified domain name or IP address of the Secure Management Center this agent communicates with.

**Step 14** Only if the test succeeds, click **Save**.

### What to do next

- Specify users to control and other options using an identity policy as described in [Create an Identity Policy, on page 2611](#).
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in [Associating Other Policies with Access Control, on page 1844](#).
- Deploy your identity and access control policies to managed devices as discussed in [Deploy Configuration Changes, on page 240](#).
- Monitor user activity .

## Uninstall the Passive Identity Agent Software

This task discusses how to uninstall the passive identity agent software from your Microsoft AD servers.

## Procedure

- 
- Step 1** Log in as an administrator to the machine on which the passive identity agent is installed.
  - Step 2** Search for Add or Remove Programs.
  - Step 3** Click **Cisco Passive Identity Agent**.
  - Step 4** Click **Uninstall**.
  - Step 5** You are required to confirm the uninstallation.
- 

# Monitor the Passive Identity Agent

The passive identity agent indicates whether or not it can communicate with the Cisco Security Cloud Control and other agents if it's configured as primary-secondary. You can view the status at **Integration > Other Integrations > Identity Sources**.

## Deployments

A standalone passive identity agent is represented as follows.

A primary-secondary pair is represented as follows.

The following table explains the meaning of the indicators.

Object	Meaning
	Cloud-delivered Firewall Management Center
	Standalone Passive Identity Agent
	Active Directory domain controller
	Primary agent
	Secondary agent

### Status indicators and colors

The passive identity agent indicates status using lines (that indicate whether communication with the Cloud-delivered Firewall Management Center is active or standby) and colors (that indicate whether or not communication is successful).

The following table shows the meanings of lines and colors:

Object	Meaning
Solid line	The agent that is responsible for communicating with the Cloud-delivered Firewall Management Center.
Dashed line	Primary/secondary configuration only. The agent that is acting as the backup agent. In the event of a communication failure between the active (solid line) agent, this agent communicates with the Cloud-delivered Firewall Management Center.
Green 	Agent communication is normal.
Amber 	Agent has never successfully communicated with the Cloud-delivered Firewall Management Center. A newly created agent line is orange and remains so until configuration is complete.
Red 	Communication is failing. To resolve the issues: <ul style="list-style-type: none"> <li>• Check sure the network connections between agents and the Cloud-delivered Firewall Management Center.</li> <li>• Make sure you have completed configuring the system (Microsoft AD server, domain controllers, and the Cloud-delivered Firewall Management Center).</li> </ul> For more information, see <a href="#">How to Create a Passive Identity Agent Identity Source</a> , on page 2513.

## Manage the Passive Identity Agent

### Related Topics

[Edit Passive Identity Agents](#), on page 2529

[Delete a Standalone Passive Identity Agent](#), on page 2529

[Delete Primary and Secondary Passive Identity Agents](#), on page 2529

[Uninstall the Passive Identity Agent Software](#), on page 2526

## Edit Passive Identity Agents

This task discusses how to edit passive identity agents you previously configured in the Cisco Security Cloud Control.

### Procedure

---

- Step 1** Log in to the Cisco Security Cloud Control.
  - Step 2** Click **Objects > Other FTD Objects**.
  - Step 3** **Integration > Other Integrations > Identity Sources**
  - Step 4** Click **Edit** (✎) next to the agent to edit.
  - Step 5** Make the desired changes.
  - Step 6** Click **Save**.
- 

## Delete a Standalone Passive Identity Agent

This task discusses how to delete a standalone passive identity agent.

### Procedure

---

- Step 1** Log in to the Cisco Security Cloud Control.
  - Step 2** Click **Objects > Other FTD Objects**.
  - Step 3** **Integration > Other Integrations > Identity Sources**
  - Step 4** Click **Edit** (✎) next to the agent to delete.
  - Step 5** Click **Delete**.
  - Step 6** You are required to confirm the action.
- 

## Delete Primary and Secondary Passive Identity Agents

This task discusses how to delete primary and secondary passive identity agents. You must delete a secondary agent before you can delete a primary agent.

### Procedure

---

- Step 1** Log in to the Cisco Security Cloud Control.
- Step 2** Click **Objects > Other FTD Objects**.
- Step 3** **Integration > Other Integrations > Identity Sources**

- Step 4** Click **Passive Identity Agent**.
  - Step 5** Click **Edit** (✎) next to a secondary agent to delete.
  - Step 6** Click **Delete**.
  - Step 7** You are required to confirm the action.
  - Step 8** If you wish to delete a primary agent, first delete all secondary agents.
- 

## Troubleshoot the Passive Identity Agent

This topic discusses how you can troubleshoot the passive identity agent software on your Windows AD domain controller or directory server.

### (Optional.) Set the log level

By default, the passive identity agent logs at the INFO level. To optionally change the log level, open **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config** in a text editor, save the file, and restart the Cisco Passive Identity Agent service.

### Do not rename the logging service

Do not rename **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent\CiscoPassiveIdentityAgentService.exe.config**; otherwise, the passive identity agent will stop generating log files. Do not remove or change the **.exe.config** file extension.

### View log files

Passive identity agent log files are stored in plain text format in the agent's installation directory: **C:\Program Files\Program Files (x86)\Cisco\Cisco Passive Identity Agent**.

Use Notepad or another text editor to view these files. Log files rotate after reaching 10MB in size.

### Use the Microsoft Active Directory event viewer

In the event you are not seeing user sessions in the Cisco Security Cloud Control, you can look on your Microsoft Active Directory server's event viewers for the following Kerberos-related events:

- [4770](#)
- [4768](#)

For general information about audit policy, see [Audit Policy Recommendations](#) on learn.microsoft.com.

For more information about Windows Group Policy Object settings, see [Group Policy Objects](#) on learn.microsoft.com.

## Security Requirements for the Passive Identity Agent

To safeguard the system, you should install the passive identity agent on a protected internal network. Although the passive identity agent is configured to have only the necessary services and ports available, you must make sure that attacks cannot reach it.

If the passive identity agent and the Security Cloud Control reside on the same network, you can connect the Security Cloud Control to the same protected internal network as the passive identity agent.

Regardless of how you deploy your appliances, inter-system communication is encrypted. However, you must still take steps to ensure that communications between appliances cannot be interrupted, blocked, or tampered with; for example, with a distributed denial of service (DDoS) or man-in-the-middle attack.

## Internet Access Requirements for the Passive Identity Agent

By default, the passive identity agent is configured to communicate with the Firepower System over the internet using HTTPS on port 443/tcp (HTTPS). If you do not want the passive identity agent to have direct access to the internet, you can configure a proxy server.

If your Cloud-delivered Firewall Management Center cannot communicate with the machine on which the passive identity agent is installed, you must use a proxy with the HTTPS protocol enabled.

The way you do this is up to you; for example, you might have a commercial proxy and use a Windows system proxy with HTTPS enabled to communicate with it.

The following information informs you of the ports the passive identity agent use to communicate with each other, with the Security Cloud Control, and with Microsoft Active Directory.

**Table 225: Passive Identity Agent port requirements**

Port	Reason
443	Communicate with the Security Cloud Control.
135	Communicate with Microsoft Active Directory using the MSRPC protocol.
9095	Communicate with each other using the UDP protocol.

# History for the Passive Identity Agent

Table 226: History for the Passive Identity Agent

Feature	Minimum Management Center	Minimum Threat Defense	Details
Passive Identity Agent	November 8, 2024	7.6	<p>This feature is introduced.</p> <p>The passive identity agent identity source sends session data from Microsoft Active Directory (AD) to the management center. Passive identity agent software is supported on:</p> <ul style="list-style-type: none"> <li>• Microsoft AD server (Windows Server 2008 or later)</li> <li>• Microsoft AD domain controller (Windows Server 2008 or later)</li> <li>• Any client connected to the domain you want to monitor (Windows 8 or later)</li> </ul> <p>See: <a href="#">User Control With the Passive Identity Agent</a>.</p>

## CHAPTER 92

# User Control with ISE/ISE-PIC

The following topics discuss how to perform user awareness and user control with ISE/ISE-PIC:

- [The ISE/ISE-PIC Identity Source, on page 2533](#)
- [License Requirements for ISE/ISE-PIC, on page 2535](#)
- [Requirements and Prerequisites for ISE/ISE-PIC, on page 2535](#)
- [ISE/ISE-PIC Guidelines and Limitations, on page 2535](#)
- [How to Configure ISE/ISE-PIC for User Control, on page 2538](#)
- [Configure ISE/ISE-PIC, on page 2541](#)
- [Configure ISE for User Control, on page 2547](#)
- [Ways to Configure the Cisco Identity Services Engine \(Cisco ISE\) Identity Source, on page 2550](#)
- [Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues, on page 2559](#)
- [History for ISE/ISE-PIC, on page 2561](#)

## The ISE/ISE-PIC Identity Source

You can integrate your Cisco Identity Services Engine (ISE) or ISE Passive Identity Connector (ISE-PIC) deployment with the system to use ISE/ISE-PIC for passive authentication.

ISE/ISE-PIC is an authoritative identity source, and provides user awareness data for users who authenticate using Active Directory (AD), LDAP, RADIUS, or RSA. Additionally, you can perform user control on Active Directory users. ISE/ISE-PIC does not report failed login attempts or the activity of ISE Guest Services users.

In addition to user awareness and control, if you use ISE Cisco ISE to define and use security group tags (SGT) for classifying traffic in a Cisco TrustSec network, you can write access control rules that use SGT as both source and destination matching criteria. This enables you to block or allow access based on security group membership rather than IP addresses or network objects. For more information, see [Configure Dynamic Attributes Conditions, on page 1872](#). Also see [ISE/ISE-PIC Guidelines and Limitations, on page 2535](#).

---

**Note** The system does not parse IEEE 802.1x machine authentication but it *does* parse 802.1x user authentication. If you are using 802.1x with ISE, you must include user authentication. 802.1x machine authentication will not provide a user identity to the management center that can be used in policy.

---

For more information on Cisco ISE/ISE-PIC, see the [Cisco Identity Services Engine Passive Identity Connector Administrator Guide](#) or the [Cisco Identity Services Engine Administrator Guide](#).

**Note** We strongly recommend you use the latest version of ISE/ISE-PIC to get the latest feature set and the most number of issue fixes.

## Source and Destination Security Group Tag (SGT) Matching

If you use Cisco ISE to define and use security group tags (SGT) for classifying traffic in a Cisco TrustSec network, you can write access control rules that use SGT as both source and destination matching criteria. This enables you to block or allow access based on security group membership rather than IP addresses or network objects. For more information, see [Configure Dynamic Attributes Conditions, on page 1872](#).

Matching on SGT tags provides the following benefits:

- The management center can subscribe to Security Group Tag eXchange Protocol (SXP) mappings from ISE.

ISE uses SXP to propagate the IP-to-SGT mapping database to managed devices. When you configure management center to use an ISE server, you enable the option to listen to the SXP topic from ISE. This causes the management center to learn about the security group tags and mappings directly from ISE. The management center then publishes SGTs and mappings to managed devices.

The SXP Topic receives security group tags based on static and dynamic mappings learned through the SXP protocol between ISE and other SXP compliant devices (like switches).

You can create security group tags in ISE and assign host or network IP addresses to each tag. You can also assign SGTs to user accounts, and the SGT is assigned to the user's traffic. If the switches and routers in the network are configured to do so, these tags then get assigned to packets as they enter the network controlled by ISE, the Cisco TrustSec cloud.

SXP is *not* supported by ISE-PIC.

- The management center and managed devices can learn about SGT mappings without deploying additional policy. (In other words, you can view connection events for SGT mappings without deploying an access control policy.)
- Supports Cisco TrustSec, which enables you to segment your network to protect critical business assets.
- When a managed device evaluates SGT as a traffic matching criteria for an access control rule, it uses the following priority:

1. The source SGT tag defined in the packet, if any.

For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.

For the SGT tag to be in the packet, the switches and routers in the network must be configured to add them. See the ISE documentation for information on how to implement this method.

2. The SGT assigned to the user session, as downloaded from the ISE session directory. The SGT can be matched to source or destination.
3. The SGT-to-IP address mapping downloaded using SXP. If the IP address is in the range for an SGT, then the traffic matches the access control rule that uses the SGT. The SGT can be matched to source or destination.

Examples:

- In ISE, create an SGT tag named Guest Users and associate it with the 192.0.2.0/24 network.  
For example, you could use Guest Users as a source SGT condition in your access control rule and restrict access to certain URLs, web site categories, or networks from anyone who accesses your network.
- In ISE, create an SGT tag named Restricted Networks and associate it with the 198.51.100.0/8 network.  
For example, you could use Restricted Networks as a destination SGT rule condition and block access from Guest Users and other networks that have users who are not authorized to access the network.

## ISE/ISE-PIC Guidelines and Limitations

Use the guidelines discussed in this section when configuring ISE/ISE-PIC.

#### ISE/ISE-PIC Version and Configuration Compatibility

Your ISE/ISE-PIC version and configuration affects its integration and interaction with the Secure Firewall Management Center, as follows:

- We strongly recommend you use the latest version of ISE/ISE-PIC to get the latest feature set.

- Synchronize the time on the ISE/ISE-PIC server and the Secure Firewall Management Center. Otherwise, the system might perform user timeouts at unexpected intervals.
- To implement user control using ISE or ISE-PIC data, configure and enable a realm for the ISE server assuming the pxGrid persona as described in [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).
- Each Secure Firewall Management Center host name that connects to an ISE server must be unique; otherwise, the connection to one of the Secure Firewall Management Centers will be dropped.
- If you configure ISE/ISE-PIC to monitor a large number of user groups, the system might drop user mappings based on groups due to managed device memory limitations. As a result, rules with realm or user conditions might not perform as expected.

For any device running version 6.7 or later, you can optionally use the **configure identity-subnet-filter** command to limit the subnets that the managed device monitors. For more information, see the [Cisco Secure Firewall Threat Defense Command Reference](#).

Alternatively, you can configure a network object and apply that object as an Identity Mapping Filter in the identity policy. See [Create an Identity Policy, on page 2611](#).

For the specific versions of ISE/ISE-PIC that are compatible with this version of the system, see the [Cisco Firepower Compatibility Guide](#).

### IPv6 support

- Compatible versions of ISE/ISE-PIC version 2.x include support for IPv6-enabled endpoints.
- Version 3.0 (patch 2) and later of ISE/ISE-PIC enables IPv6 communication between ISE/ISE-PIC and the management center.

### Proxy sequence

A *proxy sequence* is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)

Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over.

### Approve clients in ISE

Before a connection between the ISE server and the management center succeeds, you must manually approve the clients in ISE. (Typically, there are two clients: one for the connection test and another for ISE agent.)

You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the *Cisco Identity Services Engine Administrator Guide*.

### Unreachable sessions are removed

If a user session in ISE/ISE-PIC is reported as unreachable, the Secure Firewall Management Center prunes that session so another user with the same IP cannot match the unreachable user's identity rules. You can control this behavior in ISE/ISE-PIC by going to **Providers > Endpoint Probes** and clicking one of the following:

- **Enabled** to cause ISE/ISE-PIC to monitor endpoint connections and therefore to cause the Secure Firewall Management Center to prune a session from an unreachable user.

- **Disabled** to cause ISE/ISE-PIC to ignore endpoint connections.

### Security Group Tags (SGT)

A Security Group Tag (SGT) specifies the privileges of a traffic source within a trusted network. Cisco ISE and Cisco TrustSec use a feature called Security Group Access (SGA) to apply SGT attributes to packets as they enter the network. These SGTs correspond to a user's assigned security group within ISE or TrustSec. If you configure ISE as an identity source, the Firepower System can use these SGTs to filter traffic.

Security Group Tags can be used both as source and destination matching criteria in access control rules.

---

**Note** To implement user control using only the ISE SGT attribute tag, you do not need to configure a realm for the ISE server. ISE SGT attribute conditions can be configured in policies with or without an associated identity policy.

---

---

**Note** In some rules, custom SGT conditions can match traffic tagged with SGT attributes that were *not* assigned by ISE. This is not considered user control, and works only if you are not using ISE/ISE-PIC as an identity source; see [Custom SGT Conditions](#).

---

To match destination SGT tags in addition to source SGT tags, the following apply:

Required ISE version: 2.6 patch 6 or later, 2.7 patch 2 or later

Router support: Any Cisco router that supports SGT inline tagging over Ethernet. For more information, consult a reference such as the [Cisco Group Based Policy Platform and Capability Matrix Release](#)

Limitations:

- Quality of Service (QoS) policy uses source SGT matching only; it does *not* use destination SGT matching
- RA-VPN does not receive SGT mappings directly through RADIUS

### ISE and High Availability

When the primary ISE/ISE-PIC server fails, the following occurs:

As a result of the integration with pxGrid v2, the management center round-robins between both configured ISE hosts until one accepts the connection.

If the connection is lost, the management center resumes round-robin attempts to the connected hosts.

### Endpoint Location (or Location IP)

An Endpoint Location attribute is the IP address of the network device that used ISE to authenticate the user, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Location (Location IP)**.

### ISE Attributes

Configuring an ISE connection populates the Secure Firewall Management Center database with ISE attribute data. You can use the following ISE attributes for user awareness and user control. This is not supported with ISE-PIC.

### Endpoint Profile (or Device Type)

An Endpoint Profile attribute is the user's endpoint device type, as identified by ISE.

You must configure and deploy an identity policy to control traffic based on **Endpoint Profile (Device Type)**.

## How to Configure ISE/ISE-PIC for User Control

You can use ISE/ISE-PIC in any of the following configurations:

- With a realm, identity policy, and associated access control policy.

Use a realm to control *user* access to network resources in policy. You can still use ISE/ISE-PIC Security Group Tags (SGT) metadata in your policies.

- With an access control policy only. No realm or identity policy are necessary.

Use this method to control network access using SGT metadata alone.

### Related Topics

[How to Configure ISE/ISE-PIC Without a Realm](#), on page 2538

[How to Configure ISE/ISE-PIC for User Control Using a Realm](#), on page 2539

## How to Configure ISE/ISE-PIC Without a Realm

This topic provides a high-level overview of tasks you must complete to configure ISE to be able to allow or block access to the network using SGT tags.

### Procedure

	Command or Action	Purpose
<b>Step 1</b>	SGT matching: Enable SXP on ISE.	This enables the management center to receive updates from ISE when SGT metadata changes.
<b>Step 2</b>	Export system certificates from ISE/ISE-PIC.	The certificates are required to connect securely between the ISE/ISE-PIC pxGrid, monitoring (MNT) servers and the management center. See <a href="#">Export Certificates from the ISE/ISE-PIC Server for Use in the Management Center</a> , on page 2544
<b>Step 3</b>	Import the certificates in the management center.	The certificates must be imported as follows:

	Command or Action	Purpose
		<ul style="list-style-type: none"> <li>pxGrid client certificate: internal certificate with key (<b>Objects &gt; Object Management &gt; PKI &gt; Internal Certs</b>)</li> <li>pxGrid server certificate: trusted CA (<b>Objects &gt; Object Management &gt; PKI &gt; Trusted CAs</b>)</li> <li>MNT certificate: trusted CA</li> </ul>
<b>Step 4</b>	Create the ISE/ISE-PIC identity source.	The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC. See <a href="#">Configure ISE for User Control, on page 2547</a> .
<b>Step 5</b>	Create an access control rule.	The access control rule specifies an action to take (for example, allow or block) if traffic matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See <a href="#">Introduction to Access Control Rules, on page 1853</a> .
<b>Step 6</b>	Deploy the access control policy to managed devices.	Before your policy can take effect, it must be deployed to managed devices. See <a href="#">Deploy Configuration Changes, on page 240</a> .

**What to do next**

[Export Certificates from the ISE/ISE-PIC Server for Use in the Management Center, on page 2544](#)

## How to Configure ISE/ISE-PIC for User Control Using a Realm

**Before you begin**

This topic provides a high-level overview of tasks you must complete to configure ISE/ISE-PIC for user control and to be able to allow or block user or group access to the network. Users and groups can be stored in any server listed in [Supported Servers for Realms, on page 2446](#).

**Procedure**

	Command or Action	Purpose
<b>Step 1</b>	Destination SGT only: Enable SXP on ISE.	This enables the management center to receive updates from ISE when SGT metadata changes.
<b>Step 2</b>	Export system certificates from ISE/ISE-PIC.	The certificates are required to connect securely between the ISE/ISE-PIC pxGrid,

	Command or Action	Purpose
		<p>monitoring (MNT) servers and the management center. See the following:</p> <ul style="list-style-type: none"> <li>pxGrid server and MNT server certificate: <a href="#">Export Certificates from the ISE/ISE-PIC Server for Use in the Management Center, on page 2544</a></li> <li>pxGrid client certificate: <a href="#">Generate a Self-Signed Certificate, on page 2546</a></li> </ul>
<b>Step 3</b>	Import the certificates in the management center.	<p>The certificates must be imported as follows:</p> <ul style="list-style-type: none"> <li>pxGrid client certificate: internal certificate with key (<b>Objects &gt; Object Management &gt; PKI &gt; Internal Certs</b>)</li> <li>pxGrid server certificate: trusted CA (<b>Objects &gt; Object Management &gt; PKI &gt; Trusted CAs</b>)</li> <li>MNT certificate: trusted CA</li> </ul>
<b>Step 4</b>	(Optional.) Create a proxy sequence for use with the realm and also with ISE/ISE-PIC.	<p>A <i>proxy sequence</i> is one or more managed devices that can be used to communicate with an LDAP, Active Directory, or ISE/ISE-PIC server. It is necessary only if Security Cloud Control cannot communicate with your Active Directory or ISE/ISE-PIC server. (For example, Security Cloud Control might be in a public cloud but Active Directory or ISE/ISE-PIC might be in a private cloud.)</p> <p>Although you can use one managed device as a proxy sequence, we strongly recommend you set up two or more so that, in the event one managed device cannot communicate with Active Directory or ISE/ISE-PIC, another managed device can take over.</p>
<b>Step 5</b>	Create a realm.	<p>You must create a realm only to control access to the network by the users and groups you choose.</p> <p>See <a href="#">Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475</a>.</p>
<b>Step 6</b>	Download users and groups, and enable the realm.	<p>Downloading users and groups enables you to use them in access control rules. See <a href="#">Synchronize Users and Groups, on page 2487</a>.</p>

	Command or Action	Purpose
<b>Step 7</b>	Create the ISE/ISE-PIC identity source.	The ISE/ISE-PIC identity source enables you to control user activity using Security Group Tags (SGT) provided by ISE/ISE-PIC. See <a href="#">Configure ISE for User Control, on page 2547</a> .
<b>Step 8</b>	Create an identity policy.	An identity policy is a container for one or more identity rules. See <a href="#">Create an Identity Policy, on page 2611</a> .
<b>Step 9</b>	Create an identity rule.	An identity rule specifies how a realm is used to control access to the network by users and groups. See <a href="#">Create an Identity Rule, on page 2618</a> .
<b>Step 10</b>	Associate the identity policy with an access control policy.	This enables the access control policy to use users and groups in the realm.
<b>Step 11</b>	Create an access control rule.	The access control rule specifies an action to take (for example, allow or block) if traffic matches the rule criteria. You can use source and destination SGT metadata as matching criteria in the access control rule. See <a href="#">Introduction to Access Control Rules, on page 1853</a> .
<b>Step 12</b>	Deploy the access control policy to managed devices.	Before your policy can take effect, it must be deployed to managed devices. See <a href="#">Deploy Configuration Changes, on page 240</a> .

### What to do next

[Export Certificates from the ISE/ISE-PIC Server for Use in the Management Center, on page 2544](#)

## Configure ISE/ISE-PIC

The following topics discuss how to configure the ISE/ISE-PIC server for use with identity policies in the management center.

The topics discuss how to:

- Export certificates from the ISE/ISE-PIC server to authenticate with the management center.
- Publish SXP topics so the management center can be updated with Security Group Tags (SGT) on the ISE server.

### Related Topics

[Configure Security Groups and SXP Publishing in ISE, on page 2542](#)

[Export Certificates from the ISE/ISE-PIC Server for Use in the Management Center, on page 2544](#)

## Configure Security Groups and SXP Publishing in ISE

There is a lot of configuration that you must do in Cisco Identity Services Engine (ISE) to create the TrustSec policy and security group tags (SGT). Please look at the ISE documentation for more complete information on implementing TrustSec.

The following procedure picks out the highlights of the core settings you must configure in ISE for the threat defense device to be able to download and apply static SGT-to-IP address mappings, which can then be used for source and destination SGT matching in access control rules. See the ISE documentation for detailed information.

The screen shots in this procedure are based on ISE 2.4. The exact paths to these features might change in subsequent releases, but the concepts and requirements will be the same. Although ISE 2.4 or later is recommended, and preferably 2.6 or later, the configuration should work starting with ISE 2.2 patch 1.

### Before you begin

You must have the ISE Plus license to publish SGT-to-IP address static mappings and to get user session-to-SGT mappings so that the threat defense device can receive them.

### Procedure

---

**Step 1** Choose **Work Centers > TrustSec > Settings > SXP Settings**, and select the **Publish SXP Bindings on PxGrid** option.

This option makes ISE send the SGT mappings out using SXP. You must select this option for the threat defense device to “hear” anything from listing to the SXP topic. This option must be selected for the threat defense device to get static SGT-to-IP address mapping information. It is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.

The screenshot shows the 'SXP Settings' page in the Cisco ISE administration console. The breadcrumb trail is: Home > Context Visibility > Operations > Policy > Administration > Work Centers > TrustSec > SXP > Settings. The 'Publish SXP bindings on PxGrid' checkbox is checked and highlighted with a red box. Other settings include 'Add radius mappings into SXP IP SGT mapping table' (checked), 'Global Password' (masked with asterisks), and a section for 'Timers' with input fields for: Minimum Acceptable Hold Time (120), Reconciliation Timer (120), Minimum Hold Time (90), Maximum Hold Time (180), and Retry Open Timer (120). Buttons for 'Set Default' and 'Save' are at the bottom right.

**Step 2** Choose **Work Centers > TrustSec > SXP > SXP Devices**, and add a device.

This does not have to be a real device, you can even use the management IP address of the threat defense device. The table simply needs at least one device to induce ISE to publish the static SGT-to-IP address mappings. This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.

The screenshot shows the 'SXP Devices' page in the Cisco ISE administration console. The breadcrumb trail is: Home > Context Visibility > Operations > Policy > Administration > Work Centers > TrustSec > Components > SXP > SXP Devices. The page displays a table of SXP devices with the following data:

Name	IP Address	Status	Peer Role	Pass...	Negot...	SX...	Connected To	Duration [d...	SXP Domain
FDM	192.168.0.20	OFF	BOTH	NONE		V4	ISE	24:01:15:05	default

**Step 3** Choose **Work Centers > TrustSec > Components > Security Groups** and verify there are security group tags defined. Create new ones as necessary.

**Security Groups**

For Policy Export go to [Administration > System > Backup & Restore > Policy Export Page](#)

Icon	Name	SGT (Dec / Hex)	Description
	Point_of_Sale_Systems	10/000A	Point of Sale Security Group
	Production_Servers	11/000B	Production Servers Security Group
	Production_Users	7/0007	Production User Security Group
	Quarantined_Systems	255/00FF	Quarantine Security Group

**Step 4** Choose **Work Centers > TrustSec > Components > IP SGT Static Mapping** and map host and network IP addresses to the security group tags.

This step is not necessary if you simply want to use SGT tags defined in the packets, or SGTs that are assigned to a user session.

**IP SGT static mapping**

0 Selected

IP address/Host	SGT	Mapping group	Deploy via	Deploy to
<input type="checkbox"/> 192.168.1.0/24	AppServer (16/0010)		default	[No Devices]
<input type="checkbox"/> 192.168.1.101	AppServer (16/0010)		default	[No Devices]
<input type="checkbox"/> 192.168.2.102	DataCenter (17/0011)		default	[No Devices]
<input type="checkbox"/> 192.168.7.0/24	Production_Users (7/0007)		default	[No Devices]
<input type="checkbox"/> 192.168.8.0/24	Production_Servers (11/000B)		default	[No Devices]

## Export Certificates from the ISE/ISE-PIC Server for Use in the Management Center

The following sections discuss how to:

- Export system certificates from the ISE/ISE-PIC server.

These certificates are required to securely connect to the ISE/ISE-PIC server. You might need to export one, or as many as three, certificates, depending on how your ISE system is set up:

- One certificate for the pxGrid server
  - One certificate for the monitoring (MNT) server
  - One certificate, including the private key, for the pxGrid client (that is, the management center)  
Unlike the first two certificates, this is a self-signed certificate.
- Import these certificates into the management center:
    - pxGrid client certificate: internal certificate with key (**Objects > Object Management > PKI > Internal Certs**)
    - pxGrid server certificate: trusted CA (**Objects > Object Management > PKI > Trusted CAs**)
    - MNT certificate: trusted CA

### Related Topics

[Export a System Certificate](#), on page 2545

[Import ISE/ISE-PIC Certificates](#), on page 2546

## Export a System Certificate

You can export a system certificate or a certificate and its associated private key. If you export a certificate and its private key for backup purposes, you can reimport them later if needed.

### Before you begin

To perform the following task, you must be a Super Admin or System Admin.

### Procedure

- 
- Step 1** In the Cisco ISE GUI, click the **Menu** icon () and choose **Administration > System > Certificates > System Certificates**.
- Step 2** Check the check box next to the certificate that you want to export and click **Export**.
- Step 3** Choose whether to export only the certificate, or the certificate and its associated private key.
- Tip** We do not recommend exporting the private key that is associated with a certificate because its value may be exposed. If you must export a private key (for example, when you export a wildcard system certificate to be imported into the other Cisco ISE nodes for inter-node communication), specify an encryption password for the private key. You must specify this password while importing this certificate into another Cisco ISE node to decrypt the private key.
- Step 4** Enter the password if you have chosen to export the private key. The password should be at least eight characters long.
- Step 5** Click **Export** to save the certificate to the file system that is running your client browser.

If you export only the certificate, the certificate is stored in the PEM format. If you export both the certificate and private key, the certificate is exported as a .zip file that contains the certificate in the PEM format and the encrypted private key file.

---

## Generate a Self-Signed Certificate

Add a new local certificate by generating a self-signed certificate. Cisco recommends that you only employ self-signed certificates for your internal testing and evaluation needs. If you plan to deploy Cisco ISE in a production environment, use CA-signed certificates whenever possible to ensure more uniform acceptance around a production network.

---

**Note** If you use a self-signed certificate and you want to change the hostname of your Cisco ISE node, log in to the administration portal of the Cisco ISE node, delete the self-signed certificate that has the old hostname, and generate a new self-signed certificate. Otherwise, Cisco ISE continues to use the self-signed certificate with the old hostname.

---

### Before you begin

To perform the following task, you must be a Super Admin or System Admin.

### Procedure

---

**Step 1** In the Cisco ISE GUI, click the **Menu** icon (☰) and choose **Administration > System > Certificates > System Certificates**.

To generate a self-signed certificate from a secondary node, choose **Administration > System > Server Certificate**.

**Step 2** In the ISE-PIC GUI, click the **Menu** icon (☰) and choose **Certificates > System Certificates**.

**Step 3** Click **Generate Self Signed Certificate** and enter the details in the window displayed.

**Step 4** Check the check boxes in the **Usage** area based on the service for which you want to use this certificate.

**Step 5** Click **Submit** to generate the certificate.

To restart the secondary nodes, from the CLI, enter the following commands in the following order:

- a) **application stop ise**
  - b) **application start ise**
- 

## Import ISE/ISE-PIC Certificates

This procedure is optional. You can also import ISE server certificates when you create the ISE/ISE-PIC identity source as discussed in [Configure ISE for User Control, on page 2547](#).

### Before you begin

Export certificates from the ISE/ISE-PIC server as discussed in [Export a System Certificate, on page 2545](#). The certificates and key must be present on the machine from which you log in to the management center.

You must import the certificates as follows:

- pxGrid client certificate: internal certificate with key (**Objects > Object Management > PKI > Internal Certs**)
- pxGrid server certificate: trusted CA (**Objects > Object Management > PKI > Trusted CAs**)
- MNT certificate: trusted CA

### Procedure

- 
- |                |                                                                                  |
|----------------|----------------------------------------------------------------------------------|
| <b>Step 1</b>  | Log in to the management center if you have not already done so.                 |
| <b>Step 2</b>  | Click <b>Objects &gt; Object Management</b> .                                    |
| <b>Step 3</b>  | Expand <b>PKI</b> .                                                              |
| <b>Step 4</b>  | Click <b>Internal Certs</b> .                                                    |
| <b>Step 5</b>  | Click <b>Add Internal Cert</b> .                                                 |
| <b>Step 6</b>  | Follow the prompts on your screen to import the certificate and private key.     |
| <b>Step 7</b>  | Click <b>Trusted CAs</b> .                                                       |
| <b>Step 8</b>  | Click <b>Add Trusted CA</b> .                                                    |
| <b>Step 9</b>  | Follow the prompts on your screen to import the pxGrid server certificate.       |
| <b>Step 10</b> | Repeat the preceding steps, if necessary, to import the MNT server's trusted CA. |
- 

### What to do next

[Configure ISE for User Control, on page 2547](#)

## Configure ISE for User Control

The following procedure discusses how to configure the ISE/ISE-PIC identity source. You must be in the global domain to perform this task.

### Threat Defense Feature History:

7.2—Optionally add a proxy, which is a connection to one or more cCisco Security Cloud Control in the event Cisco Security Cloud Control cannot communicate with the ISE/ISE-PIC server. .

### Before you begin

- To get user sessions from a Microsoft Active Directory Server or supported LDAP server, configure and enable a realm for the Cisco ISE server, assuming the pxGrid persona, as discussed in [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).

- To get all mappings that are defined in Cisco ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:
  - To use the SGT information in the packets only, and not use mappings downloaded from Cisco ISE, skip the steps discussed in [Create and Edit Access Control Rules, on page 1863](#). Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.
  - To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the Cisco ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.
- (Advanced configuration only.) Export certificates from the ISE/ISE-PIC server and optionally import them into the management center as discussed in [Export Certificates from the ISE/ISE-PIC Server for Use in the Management Center, on page 2544](#).
- To publish SXP topics so the management center can be updated with Security Group Tags (SGT) on the ISE server, see [Configure ISE/ISE-PIC, on page 2541](#).

## Procedure

- 
- Step 1** Log in to the management center.
- Step 2** Click **Integration > Other Integrations > Identity Sources**.
- Step 3** Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.
- Note** To disable the connection, click **None**.
- Step 4** Enter a **Primary Host Name/IP Address** and, optionally, a **Secondary Host Name/IP Address**.
- Step 5** Click the appropriate certificate authorities from the **pxGrid Server CA** and **MNT Server CA** lists, and the appropriate certificate from the **pxGrid Client Certificate** list. You can also click **Add (+)** to add a certificate.
- Note** The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.
- Step 6** (Optional.) Enter an **ISE Network Filter** using CIDR block notation.
- Step 7** In the **Subscribe To** section, check the following:
- **Session Directory Topic** to receive ISE user session information from the ISE server.
  - **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.
- Step 8** (Optional.) From the **Proxy** list, click either a managed device or a proxy sequence. If Security Cloud Control cannot communicate with your ISE/ISE-PIC server, you can choose either a managed device or proxy sequence to do it. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.
- Step 9** To test the connection, click **Test**.
- If the test fails, click **Additional Logs** for more information about the connection failure.
-

### What to do next

- Specify users to control and other options using an identity policy as described in [Create an Identity Policy, on page 2611](#).
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in [Associating Other Policies with Access Control, on page 1844](#).
- Use Security Group Tags (SGT) from Cisco ISE as dynamic attributes in access control policies.  
For more information, see [Configure Dynamic Attributes Conditions, on page 1872](#).
- Deploy your identity and access control policies to managed devices as discussed in [Deploy Configuration Changes, on page 240](#).
- Monitor user activity .

- [Internal Certificate Objects, on page 1508](#)

## ISE/ISE-PIC Configuration Fields

The following fields are used to configure a connection to /ISE-PIC.

### Primary and Secondary Host Name/IP Address

The hostname or IP address for the primary and, optionally, the secondary pxGrid ISE servers.

The ports used by the host names you specify must be reachable by both ISE and the management center.

### pxGrid Server CA

The trusted certificate authority for the pxGrid framework. If your deployment includes a primary and a secondary pxGrid node, the certificates for both nodes must be signed by the same certificate authority.

### MNT Server CA

The trusted certificate authority for the ISE certificate when performing bulk downloads. If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.

### pxGrid Client Certificate

The internal certificate and key that the Secure Firewall Management Center must provide to /ISE-PIC to connect to /ISE-PIC or to perform bulk downloads.

---

**Note** The **pxGrid Client Certificate** must include the [clientAuth](#) extended key usage value, or it must not include any extended key usage values.

---

### ISE Network Filter

An optional filter you can set to restrict the data that ISE reports to the Secure Firewall Management Center. If you provide a network filter, ISE reports data from the networks within that filter. You can specify a filter in the following ways:

- Leave the field blank to specify **any**.
- Enter a single IPv4 address block using CIDR notation.
- Enter a list of IPv4 address blocks using CIDR notation, separated by commas.

---

**Note** This version of the system does not support filtering using IPv6 addresses, regardless of your ISE version.

---

#### Subscribe to:

**Session Directory Topic:** Check this box to subscribe to user session information from the ISE server. Includes SGT and endpoint metadata.

**SXP Topic:** Check this box to subscribe to SXP mappings from the ISE server.

#### Proxy

You can optionally choose either a managed device or a proxy sequence to communicate with ISE/ISE-PIC if Security Cloud Control is unable to do so. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.

## Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source

You can configure the Cisco ISE identity source in any of the following ways:

- Quick configuration (new): *Cisco ISE only; not supported for ISE-PIC*. Enter the user name and password of a user in at least the External RESTful Services (ERS) Operator group. The Secure Firewall Management Center logs into the Cisco ISE Primary Authentication Node (PAN), downloads the certificates, and configures the identity source. You have the option of saving the ISE configuration for later use.

For more information about groups, see the section on Cisco ISE Administrator Groups in the [Cisco Identity Services Engine Administrator Guide](#).

For details, see [Quick Configuration, on page 2552](#).

- Advanced configuration (old): Same as previous Secure Firewall Management Center releases and works for both Cisco ISE and ISE-PIC. You must get certificates and other information from your ISE/ISE-PIC server as discussed in [Configure ISE/ISE-PIC, on page 2541](#).

For details about advanced configuration, see [Cisco ISE Advanced Configuration, on page 2556](#).

#### Related Topics

[About Cisco ISE Quick Configuration](#), on page 2551

[Cisco ISE Advanced Configuration](#), on page 2556

## About Cisco ISE Quick Configuration

Complete these tasks first: [Prerequisites for ISE Quick Configuration, on page 2551](#).

You must have the following information:

- Fully qualified domain name or IP address of the policy administration node (PAN).
- User name and password of a user in at least the External RESTful Services (ERS) Operator group.

Note the following about SGT-to-IP mappings and SXP:

- To get all mappings that are defined in Cisco ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:
  - To use the SGT information in the packets only, and not use mappings downloaded from Cisco ISE, skip the steps discussed in [Create and Edit Access Control Rules, on page 1863](#). Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.
  - To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the Cisco ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.

## Prerequisites for ISE Quick Configuration

For ISE quick configuration to succeed, you must do both of the following as an ISE administrator:

- Enable External RESTful Services (ERS) (read/write), Open API (read/write), and *disable* the Cross-Site Request Forgery (CSRF) check

Go to  > **Administration** > **System** > **Settings** > **API Settings** > **API Service Settings**

For more information, see [Enable API Service](#) in the [Cisco Identity Services Engine Administrator Guide](#).

The following figure shows an example.

## API Settings

Overview **API Service Settings** API Gateway Settings

∨ API Service Settings for Administration Node

- ERS (Read/Write)
- Open API (Read/Write)

∨ CSRF Check ( only for ERS Settings )

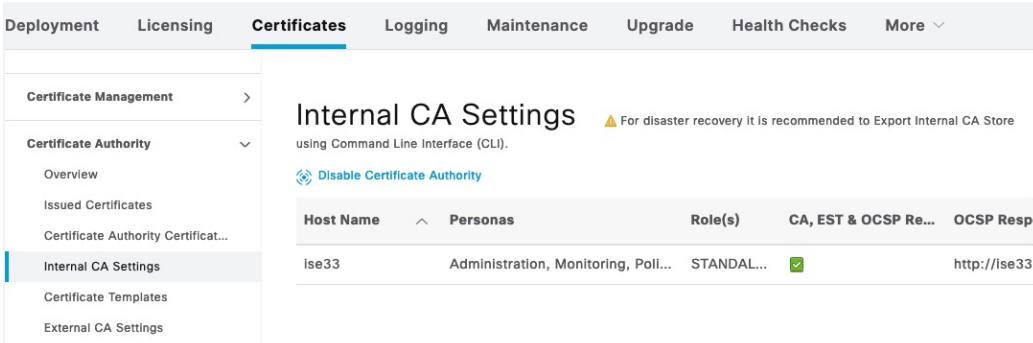

- Enable CSRF Check for Enhanced Security (Not compatible with pre ISE 2.3 Clients)
- Disable CSRF For ERS Request (compatible with ERS clients older than ISE 2.3)

- Slide **ERS (Read/Write)** to **Enabled**.
- Enable the certificate authority

Go to  > **Administration** > **System** > **Certificates** > **Certificate Authority** > **Internal CA Settings**

For more information, see [Internal CA Settings](#) in the [Cisco Identity Services Engine Administrator Guide](#).

The following figure shows an example.

Host Name	Personas	Role(s)	CA, EST & OCSP Re...	OCSP Respo
ise33	Administration, Monitoring, Poli...	STANDAL...	<input checked="" type="checkbox"/>	http://ise33.

## Quick Configuration

This task discusses how to configure Cisco ISE (but not ISE-PIC) by entering a user name and password. The Secure Firewall Management Center then logs in to ISE and downloads the necessary certificates to authenticate the two applications.

### Threat Defense Feature History:

7.6—This feature is introduced.

### Before you begin

See the following topics first:

- [About Cisco ISE Quick Configuration, on page 2551](#)
- [Prerequisites for ISE Quick Configuration, on page 2551](#)

### Procedure

---

- Step 1** Log in to the management center.
- Step 2** Click **Integration > Other Integrations > Identity Sources**.
- Step 3** Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.
- Note** To disable the connection, click **None**.
- Step 4** Click **Quick Configuration (New)**.
- Step 5** In the **Primary PAN FQDN/IP Address** field, enter the fully qualified domain name or IP address of the policy administration node (PAN). Do *not* enter a scheme (such as **https://**).
- Step 6** In the **Username** field, enter the user name of a user in at least the ERS Operator group.
- For more information about groups, see the section on Cisco ISE Administrator Groups in the [Cisco Identity Services Engine Administrator Guide](#).
- Step 7** In the **Password** field, enter the user's password.
- Step 8** (Optional.) Enter an **ISE Network Filter** using CIDR block notation.
- Step 9** In the **Subscribe To** section, check the following:
- **Session Directory Topic** to receive ISE user session information from the ISE server.
  - **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.
- Step 10** (Optional.) From the **Proxy** list, click either a managed device or a proxy sequence. If Security Cloud Control cannot communicate with your ISE/ISE-PIC server, you can choose either a managed device or proxy sequence to do it. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.
- Step 11** To test the connection, click **Test**.
- Step 12** (Optional.) After a successful test, click **Save this Config** at the top of the page to save the configuration on the Secure Firewall Management Center.
- 

### What to do next

- Specify users to control and other options using an identity policy as described in [Create an Identity Policy, on page 2611](#).
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in [Associating Other Policies with Access Control, on page 1844](#).

- Use Security Group Tags (SGT) from Cisco ISE as dynamic attributes in access control policies.  
For more information, see [Configure Dynamic Attributes Conditions, on page 1872](#).
- Deploy your identity and access control policies to managed devices as discussed in [Deploy Configuration Changes, on page 240](#).
- Monitor user activity .

### Related Topics

## ISE Quick Configuration Results

### Initial information page for an untrusted certificate

When you enter required information in the **Quick Configuration (New)** tab page, the system first checks to see if the certificate was signed by a trusted authority. If not, a page similar to the following is displayed.

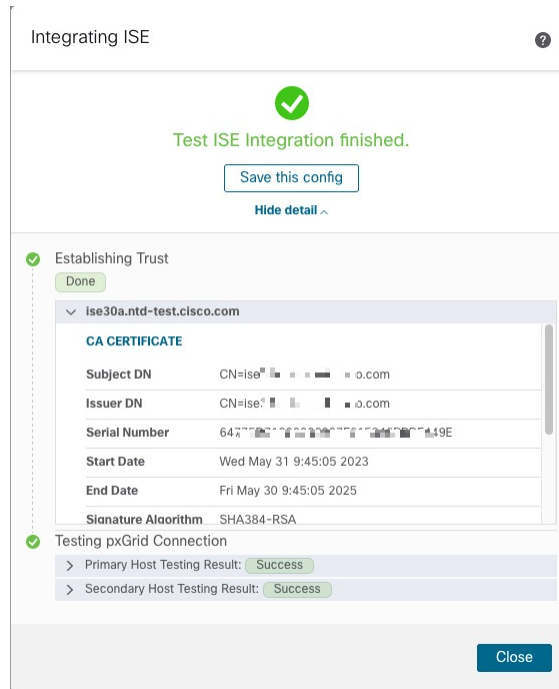

You have the following options:

- Click **Accept** for the Secure Firewall Management Center to trust the certificate and continue authenticating with ISE.
- Click **Decline** to quit without authenticating with ISE.

You can then verify the ISE configuration on the **Quick Configuration (New)** tab page and try again.

### Successful ISE integration

If the Secure Firewall Management Center was able to authenticate successfully with the information you provided, a page similar to the following is displayed.

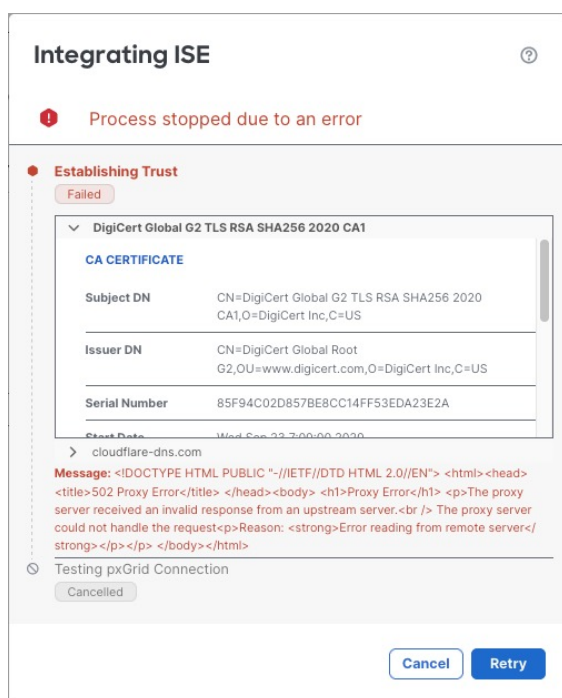

Click **Save this Config** to save it and be able to use the identity source in the future.

Optionally expand one of the lists under Testing pxGrid Connection to display certificates downloaded from those sources.

### Unsuccessful ISE integration

If the Secure Firewall Management Center fails to authenticate with ISE for any reason, a page similar to the following is displayed.

The error messages are displayed in red text.

You have the following options:

- If the error is temporary (for example, a temporarily network issue), click **Retry**.
- To try again with different ISE credentials, click **Cancel**.

## Cisco ISE Advanced Configuration

The following procedure discusses how to configure the ISE/ISE-PIC identity source. You must be in the global domain to perform this task.

### Threat Defense Feature History:

7.2—Optionally add a proxy, which is a connection to one or more cCisco Security Cloud Control in the event Cisco Security Cloud Control cannot communicate with the ISE/ISE-PIC server. .

### Before you begin

- To get user sessions from a Microsoft Active Directory Server or supported LDAP server, configure and enable a realm for the Cisco ISE server, assuming the pxGrid persona, as discussed in [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.
- To get all mappings that are defined in Cisco ISE, including SGT-to-IP address mappings published through SXP, use the procedure that follows. As an alternative, you have the following options:

- To use the SGT information in the packets only, and not use mappings downloaded from Cisco ISE, skip the steps discussed in [Create and Edit Access Control Rules, on page 1863](#). Note that in this case, you can use SGT tags as a source condition only; these tags will never match destination criteria.
- To use SGT in packets and user-to-IP-address/SGT mappings only, do not subscribe to the SXP topic in the Cisco ISE identity source, and do not configure ISE to publish SXP mappings. You can use this information for both source and destination matching conditions.
- (Advanced configuration only.) Export certificates from the ISE/ISE-PIC server and optionally import them into the management center as discussed in [Export Certificates from the ISE/ISE-PIC Server for Use in the Management Center, on page 2544](#).
- To publish SXP topics so the management center can be updated with Security Group Tags (SGT) on the ISE server, see [Configure ISE/ISE-PIC, on page 2541](#).

## Procedure

- 
- Step 1** Log in to the management center.
- Step 2** Click **Integration > Other Integrations > Identity Sources**.
- Step 3** Click **Identity Services Engine** for the **Service Type** to enable the ISE connection.
- Note** To disable the connection, click **None**.
- Step 4** Enter a **Primary Host Name/IP Address** and, optionally, a **Secondary Host Name/IP Address**.
- Step 5** Click the appropriate certificate authorities from the **pxGrid Server CA** and **MNT Server CA** lists, and the appropriate certificate from the **pxGrid Client Certificate** list. You can also click **Add (+)** to add a certificate.
- Note** The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.
- Step 6** (Optional.) Enter an **ISE Network Filter** using CIDR block notation.
- Step 7** In the **Subscribe To** section, check the following:
- **Session Directory Topic** to receive ISE user session information from the ISE server.
  - **SXP Topic** to receive updates to SGT-to-IP mappings when available from the ISE server. This option is required to use destination SGT tagging in access control rules.
- Step 8** (Optional.) From the **Proxy** list, click either a managed device or a proxy sequence. If Security Cloud Control cannot communicate with your ISE/ISE-PIC server, you can choose either a managed device or proxy sequence to do it. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.
- Step 9** To test the connection, click **Test**.
- If the test fails, click **Additional Logs** for more information about the connection failure.
-

### What to do next

- Specify users to control and other options using an identity policy as described in [Create an Identity Policy, on page 2611](#).
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in [Associating Other Policies with Access Control, on page 1844](#).
- Use Security Group Tags (SGT) from Cisco ISE as dynamic attributes in access control policies.  
For more information, see [Configure Dynamic Attributes Conditions, on page 1872](#).
- Deploy your identity and access control policies to managed devices as discussed in [Deploy Configuration Changes, on page 240](#).
- Monitor user activity .

## ISE/ISE-PIC Configuration Fields

The following fields are used to configure a connection to /ISE-PIC.

### Primary and Secondary Host Name/IP Address

The hostname or IP address for the primary and, optionally, the secondary pxGrid ISE servers.

The ports used by the host names you specify must be reachable by both ISE and the management center.

### pxGrid Server CA

The trusted certificate authority for the pxGrid framework. If your deployment includes a primary and a secondary pxGrid node, the certificates for both nodes must be signed by the same certificate authority.

### MNT Server CA

The trusted certificate authority for the ISE certificate when performing bulk downloads. If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.

### pxGrid Client Certificate

The internal certificate and key that the Secure Firewall Management Center must provide to /ISE-PIC to connect to /ISE-PIC or to perform bulk downloads.

---

**Note** The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.

---

### ISE Network Filter

An optional filter you can set to restrict the data that ISE reports to the Secure Firewall Management Center. If you provide a network filter, ISE reports data from the networks within that filter. You can specify a filter in the following ways:

- Leave the field blank to specify **any**.

- Enter a single IPv4 address block using CIDR notation.
- Enter a list of IPv4 address blocks using CIDR notation, separated by commas.

**Note** This version of the system does not support filtering using IPv6 addresses, regardless of your ISE version.

#### Subscribe to:

**Session Directory Topic:** Check this box to subscribe to user session information from the ISE server. Includes SGT and endpoint metadata.

**SXP Topic:** Check this box to subscribe to SXP mappings from the ISE server.

#### Proxy

You can optionally choose either a managed device or a proxy sequence to communicate with ISE/ISE-PIC if Security Cloud Control is unable to do so. For example, your Security Cloud Control might be in a public cloud but the ISE/ISE-PIC server might be on an internal intranet.

#### Related Topics

[Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues](#), on page 2559

## Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues

### Troubleshoot Cisco TrustSec issues

A device interface can be configured to propagate Security Group Tags (SGTs) either from ISE/ISE-PIC or from a Cisco device on the network (referred to as Cisco TrustSec.) On the device management page (**Devices > Device Management**), the **Propagate Security Group Tag** check box for an interface is checked after a device reboot. If you do not want the interface to propagate TrustSec data, uncheck the box.

### Troubleshoot ISE/ISE-PIC issues

For other related troubleshooting information, see [Troubleshoot Realms and User Downloads, on page 2498](#) and [Troubleshoot User Control, on page 2628](#).

If you experience issues with the ISE or ISE-PIC connection, check the following:

- The pxGrid Identity Mapping feature in ISE must be enabled before you can successfully integrate ISE with the system.
- When the primary server fails, you must manually promote the secondary to primary; there is no automatic failover.
- Before a connection between the ISE server and the management center succeeds, you must manually approve the clients in ISE. (Typically, there are two clients: one for the connection test and another for ISE agent.)

You can also enable **Automatically approve new accounts** in ISE as discussed in the chapter on Managing users and external identity sources in the [Cisco Identity Services Engine Administrator Guide](#).

- The **pxGrid Client Certificate** must include the **clientAuth** extended key usage value, or it must not include any extended key usage values.
- The time on your ISE server must be synchronized with the time on the Secure Firewall Management Center. If the appliances are not synchronized, the system may perform user timeouts at unexpected intervals.
- If your deployment includes a primary and a secondary pxGrid node,
  - The certificates for both nodes must be signed by the same certificate authority.
  - The ports used by the host name must be reachable by both the ISE server and by the management center.
- If your deployment includes a primary and a secondary MNT node, the certificates for both nodes must be signed by the same certificate authority.

To exclude subnets from receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE, use the **configure identity-subnet-filter** {**add** | **remove**} command. You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.

If you experience issues with user data reported by ISE or ISE-PIC, note the following:

- After the system detects activity from an ISE user whose data is not yet in the database, the system retrieves information about them from the server. Activity seen by the ISE user is *not* handled by access control rules, and is *not* displayed in the web interface until the system successfully retrieves information about them in a user download.
- You cannot perform user control on ISE users who were authenticated by an LDAP, RADIUS, or RSA domain controller.
- The management center does not receive user data for ISE Guest Services users.
- If ISE monitors the same users as TS Agent, the management center prioritizes the TS Agent data. If the TS Agent and ISE report identical activity from the same IP address, only the TS Agent data is logged to the management center.
- Your ISE version and configuration impact how you can use ISE in the system. For more information, see [The ISE/ISE-PIC Identity Source, on page 2533](#).
- If you have management center high availability configured and the primary fails, see the section on ISE and high availability in [ISE/ISE-PIC Guidelines and Limitations, on page 2535](#).
- ISE-PIC does not provide ISE attribute data.
- ISE-PIC cannot perform ISE ANC remediations.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see [RFC 959](#).

If you experience issues with supported functionality, see [The ISE/ISE-PIC Identity Source, on page 2533](#) for more information about version compatibility.

**ISE/ISE-PIC user timeout**

If you're setting up ISE/ISE-PIC without a realm, be aware there is a user session timeout that affects how users are seen by the management center. For more information, see [Realm Fields, on page 2478](#).

## History for ISE/ISE-PIC

Feature	Minimum Management Center	Minimum Threat Defense	Details
Quick configuration	2024MMDD	7.6.0	<p>You can optionally configure ISE using only the user name and password of a user in the External RESTful Services (ERS) Operator group. <i>(This feature is available for ISE only, not ISE-PIC.)</i></p> <p><b>Upgrade impact.</b> Any ISE or ISE-PIC identity source you created before upgrade is still available on the <b>Advanced Configuration (Old)</b> tab page. Quick configuration affects only new ISE identity sources created after the upgrade.</p> <p>New/modified screens: <b>Integration &gt; Other Integrations &gt; Identity Sources &gt; Identity Services Engine</b>. There are two tab pages: <b>Quick Configuration (New)</b> and <b>Advanced Configuration (Old)</b>.</p> <p>New/modified CLI commands: none</p>
Proxy	Any	7.2.0	<p>One or more managed devices that can communicate with Cisco Security Cloud Control in the event Cisco Security Cloud Control cannot communicate with the ISE/ISE-PIC server.</p> <p><b>New/updated screen: Integration &gt; Other Integrations &gt; Realms &gt; Proxy Sequence</b></p>
pxGrid 2.0 is the default for supported ISE/ISE-PIC versions	Any	6.7.0	<p>Note the following:</p> <ul style="list-style-type: none"> <li>Supported ISE/ISE-PIC versions: 2.6 patch 6 or later, 2.7 patch 2 or later</li> <li>Adaptive Network Control (ANC) policies replace Endpoint Protection Service (EPS) remediations. If you have EPS policies configured in the management center, you must migrate them to use ANC.</li> </ul>
Optionally exclude subnets from receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE. You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.	Any	6.7.0	<p>New command: <b>configure identity-subnet-filter {add   remove}</b></p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Destination Security Group Tag matching (SGT)	Any	6.5.0	<p>Feature introduced. Enables you to use ISE SGT tags for both source and destination matching criteria in access control rules.</p> <p>SGT tags are tag-to-host/network mappings obtained by ISE.</p> <p>New/modified screens:</p> <ul style="list-style-type: none"> <li>• New options to configure Destination SGT matching: <ul style="list-style-type: none"> <li><b>System &gt; Integration &gt; Identity Sources &gt; ISE/ISE-PIC</b> <ul style="list-style-type: none"> <li>• <b>Session Directory Topic:</b> Subscribe to ISE user session information.</li> <li>• <b>SXP Topic:</b> Subscribe to SGT tag updates on the ISE server.</li> </ul> </li> <li>• New and renamed columns in <b>Analysis &gt; Connections &gt; Events</b> <ul style="list-style-type: none"> <li>• Renamed: Security Groups Tags renamed to Source SGT</li> <li>• New: Destination SGT</li> </ul> </li> </ul> </li> </ul>
Integration with ISE-PIC	Any	6.2.1	You can now use data from ISE-PIC.
SGT tags for user control.	Any	6.2.0	You no longer need to create a realm or identity policy to perform user control based on ISE Security Group Tag (SGT) data.
Integration with ISE.	Any	6.0	Feature introduced. By subscribing to Cisco's Platform Exchange Grid (PxGrid), the Firepower Management Center can download additional user data, device type data, device location data, and Security Group Tags (SGTs) —a method used by ISE to provide network access control).

## CHAPTER 93

# User Control with Captive Portal

- [The Captive Portal Identity Source, on page 2563](#)
- [License Requirements for Captive Portal, on page 2564](#)
- [Requirements and Prerequisites for Captive Portal, on page 2564](#)
- [Captive Portal Guidelines and Limitations, on page 2564](#)
- [How to Configure the Captive Portal for User Control, on page 2567](#)
- [Troubleshoot the Captive Portal Identity Source, on page 2579](#)
- [History for Captive Portal, on page 2580](#)

## The Captive Portal Identity Source

Captive portal is one of the authoritative identity sources supported by the system. Captive portal is an active authentication method where users authenticate onto the network using a managed device. (RA-VPN is another type of active authentication.) Active authentication differs from passive authentication in that the user is presented with a login page by the managed device, whereas passive authentication queries the authentication realm (for example, Microsoft AD) to authenticate the user.

You typically use captive portal to require authentication to access the internet or to access restricted internal resources; you can optionally configure guest access to resources. After the system authenticates captive portal users, it handles their user traffic according to access control rules. Captive portal performs authentication on HTTP and HTTPS traffic only.

---

**Note** To use a Microsoft Azure AD (SAML) realm for captive portal, see [Create a Microsoft Azure AD \(SAML\) Realm for Active Authentication \(Captive Portal\), on page 2470](#).

---

---

**Note** HTTPS traffic must be decrypted before captive portal can perform authentication.

---

Captive portal also records failed authentication attempts. A failed attempt does not add a new user to the list of users in the database. The user activity type for failed authentication activity reported by captive portal is **Failed Auth User**.

The authentication data gained from captive portal can be used for user awareness and user control.

**Related Topics**

[How to Configure the Captive Portal for User Control](#), on page 2567

## About Hostname Redirect

(Snort 3 only.) An active authentication identity rule redirects to the captive portal port using its configured interface. Because the redirect is typically done to an IP address, the user gets an untrusted certificate error and because this behavior is similar to a man-in-the-middle attack, users might be reluctant to accept the untrusted certificate.

To avoid this problem, you can configure the captive portal to use the managed device's fully-qualified domain name (FQDN). With a properly configured certificate, users will not get an untrusted certificate error, and the authentication will be more seamless and appear to be more secure.

Control

## Requirements and Prerequisites for Captive Portal

**Supported Domains**

Any

**User Roles**

- Admin
- Access Admin
- Network Admin

## Captive Portal Guidelines and Limitations

When you configure and deploy captive portal in an identity policy, users from specified realms authenticate using threat defense to access your network.

---

**Note** When a remote access VPN user has already actively authenticated through a managed device acting as a secure gateway, captive portal active authentication will not occur, even if configured in an identity policy.

---

### Use a Microsoft Azure AD (SAML) realm as a captive portal

To use a Microsoft Azure AD (SAML) realm as a captive portal, see [How to Create a Microsoft Azure AD \(SAML\) Realm for Active Authentication \(Captive Portal\)](#), on page 2461.

### Captive portal and policies

You configure captive portal in your identity policy and invoke active authentication in your identity rules. Identity policies are associated with access control policies and access control policies define access to resources in the network. For example, you might exclude users in the US-West/Finance group to access Engineering servers or you can prohibit users from accessing nonsecure applications on the network.

You configure some captive portal identity policy settings on the identity policy's **Active Authentication** tab page and configure the rest in the identity rule associated with the access control policy.

An active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected. In each case the system transparently enables or disables TLS/SSL decryption, which restarts the Snort process.

---

**Caution** Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior](#), on page 234 for more information.

---

When the captive portal authenticates users that match an identity rule, any user in a Microsoft Active Directory or LDAP group that has not been downloaded is identified as Unknown. To avoid users being identified as Unknown, configure the realm or realm sequence to download users in all groups you expect to authenticate with captive portal. Unknown users are handled according to the associated access control policy; if the access control policy is configured to block Unknown users, these users are blocked.

To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

For more information about synchronizing users and groups, see [Synchronize Users and Groups](#), on page 2487.

### Routed interface required

Captive portal active authentication can be performed only by a device with a routed interface configured. If you are configuring an identity rule for captive portal and your captive portal device contains inline and routed interfaces, you must configure interface rule conditions in the access control policy to target only the routed interfaces on the device.

If the identity policy associated with your access control policy contains one or more captive portal identity rules and you deploy the policy on the Security Cloud Control that manages one or more devices with routed interfaces configured, the policy deployment succeeds and the routed interfaces perform active authentication.

### Required certificate and certificate authorities

Before you can use the captive portal for user control and awareness, you must have all of the following:

- To authenticate with Microsoft AD, export the server's root certificate and import it into the Security Cloud Control as a trusted CA certificate.
- An internal certificate object for authenticating with the managed device to which the identity policy is deployed.
- An internal certificate authority for the required decryption rule.

### Captive portal requirements and limitations

Note the following requirements and limitations:

- Captive portal does not support HTTP/3 QUIC connections.
- The system supports up to 20 captive portal logins per second.
- There is a maximum five minute limit between failed login attempts for a failed login attempt to be counted toward the count of maximum login attempts. The five minute limit is not configurable. (Maximum login attempts are displayed in connection events: **Analysis > Connections > Events**.)  
If more than five minutes elapse between failed logins, the user is redirected to captive portal for authentication and will not be designated a failed login user or a guest user, and will not be reported to the Security Cloud Control.
- Captive portal does not negotiate TLS v1.0 connections.  
Only TLS v1.1, v1.2, and TLS 1.3 connections are supported.
- You *cannot* use a realm sequence with the captive portal.
- The only way to be sure a user logs out is for the user to close and reopen the browser. Unless that happens, in some cases, the user can log out of captive portal and be able to access the network without authenticating again using the same browser.
- If a realm is created for a parent domain and the managed device detects a login to a child of that parent domain, the user's subsequent logout is not detected by the managed device.
- Your access control rule must allow traffic destined for the IP address and port of the device you plan to use for captive portal.
- To perform captive portal active authentication on HTTPS traffic, you must use a decryption policy to decrypt the traffic from the users you want to authenticate. You cannot decrypt the traffic in the connection between a captive portal user's web browser and the captive portal daemon on the managed device; this connection is used to authenticate the captive portal user.
- To limit the amount of non-HTTP or HTTPS traffic that is allowed through the managed device, you should enter typical HTTP and HTTPS ports in the identity policy's **Ports** tab page.

The managed device changes a previously unseen user from **Pending** to **Unknown** when it determines that the incoming request does not use the HTTP or HTTPS protocol. As soon as the managed device changes a user from **Pending** to another state, access control, Quality of Service, and decryption policies can be applied to that traffic. If your other policies don't permit non-HTTP or HTTPS traffic, configuring ports on the captive portal identity policy can prevent undesired traffic from being allowed through the managed device.

### Kerberos prerequisites

If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: [Naming conventions in Active Directory for computers, domains, sites, and OUs](#).

DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in [RFC 6891 section-6.2.5](#).

## How to Configure the Captive Portal for User Control

### Before you begin

To use the captive portal for active authentication, you must set up an LDAP realm; or a Microsoft AD realm or realm sequence; Microsoft Azure AD (SAML) realm; access control policy; an identity policy; a decryption policy; and associate the identity and decryption policies with the same access control policy. Finally, you must deploy the policies to managed devices. This topic provides a high-level summary of those tasks.

---

**Note** To use a Microsoft Azure AD (SAML) realm as a captive portal, see [How to Create a Microsoft Azure AD \(SAML\) Realm for Active Authentication \(Captive Portal\)](#), on page 2461.

---

Perform the following tasks first:

- Confirm that your Security Cloud Control manages one or more devices with a *routed* interface configured.
- To use encrypted authentication with the captive portal, either create a PKI object for the authenticating managed device or have your certificate data and key available on the machine from which you're accessing the Security Cloud Control. To create a PKI object, see [PKI](#), on page 1500.

### Procedure

---

**Step 1** Create and enable an LDAP realm; or a Microsoft AD realm and optionally realm sequence as discussed in the following topics:

- [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475
- (Optional.) [Create a Realm Sequence](#), on page 2488
- [Synchronize Users and Groups](#), on page 2487

A realm sequence is not supported for the captive portal.

To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

For more information, see [Synchronize Users and Groups](#), on page 2487.

**Step 2** Get required certificates and certificate authorities.  
You must have all of the following:

- To authenticate with Microsoft AD, export the server's root certificate and import it into the Secure Firewall Management Center as a trusted CA certificate.
- An internal certificate object for authenticating with the managed device to which the identity policy is deployed.
- An internal certificate authority for the required decryption rule.

**Step 3** Create a network object with an associated trusted certificate authority.

See [Configure the Captive Portal Part 1: Create a Network Object, on page 2569](#).

**Step 4** Create identity policy with an active authentication rule.

The identity policy enables selected users in your realm access resources after authenticating with the captive portal.

For more information, see [Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2570](#).

**Step 5** Configure an access control rule for the captive portal that allows traffic on the captive portal port (by default, TCP 885).

You can choose any available TCP port for the captive portal to use. Whatever your choice, you must create a rule that allows traffic on that port.

For more information, see [Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule, on page 2572](#).

**Step 6** Add another access control rule to allow users in the selected realm or realm sequence to access resources using the captive portal.

For more information, see [Configure the Captive Portal Part 4: Create a User Access Control Rule, on page 2573](#).

**Step 7** Configure a decryption policy with a **Decrypt - Resign** rule for the **Unknown** user so captive portal users can access web pages using the HTTPS protocol.

The captive portal can authenticate users only if the HTTPS traffic is decrypted before the traffic is sent to the captive portal. The captive portal itself is seen by the system as the **Unknown** user.

[Captive Portal Example: Create a Decryption Policy with an Outbound Rule, on page 2574](#)

**Step 8** Associate the identity and decryption policies with the access control policy from step 3.

This final step enables the system to authenticate users with the captive portal.

For more information, see [Configure Captive Portal Part 6: Associate Identity and Decryption Policies with the Access Control Policy, on page 2576](#).

---

### What to do next

See [Configure the Captive Portal Part 1: Create a Network Object, on page 2569](#).

### Related Topics

[Exclude Applications from Captive Portal, on page 2578](#)

[PKI](#), on page 1500

[Troubleshoot the Captive Portal Identity Source](#), on page 2579

[Snort Restart Scenarios](#), on page 232

## Configure the Captive Portal Part 1: Create a Network Object

This task discusses how to start configuring the captive portal as an identity source.

### Before you begin

(Snort 3 only.) Create a fully-qualified host name (FQDN) using your DNS server and upload the Threat Defense's internal certificate to the management center. You can consult a resource such as [this one](#) if you've never done it before. Specify the IP address of a routed interface on one of the devices managed by your management center.

For more information about the network object, see [Redirect to Host Name Network Rule Conditions](#), on page 2614.

### Procedure

- 
- Step 1** If you haven't already done so, log in to your management center.
  - Step 2** Click **Objects > Object Management**.
  - Step 3** Expand **PKI**.
  - Step 4** Click **Internal Certs**.
  - Step 5** Click **Add Internal Cert**.
  - Step 6** In the **Name** field, enter a name to identify the internal cert (for example, **MyCaptivePortal**).
  - Step 7** In the **Certificate Data** field, either paste the certificate or use the **Browse** button to locate it.  
  
The certificate Common Name must exactly match the FQDN with which you want captive portal users to authenticate.
  - Step 8** In the **Key** field, either paste the certificate's private key or use the **Browse** button to locate it.
  - Step 9** If the certificate is encrypted, select the **Encrypted** check box and enter the password in the adjacent field.
  - Step 10** Click **Save**.
  - Step 11** Click **Network**.
  - Step 12** Click **Add Network > Add Object**.
  - Step 13** In the **Name** field, enter a name to identify the object (for example, **MyCaptivePortalNetwork**).
  - Step 14** Click **FDQN** and, in the field, enter the name of the captive portal's FDQN.
  - Step 15** Click an option for **Lookup**.

The following figure shows an example.

### New Network Object ?

---

Name

Description

Network  
 Host  Range  Network  FQDN

**Note:**  
You can use FQDN network objects in access, prefilter and translated destination in NAT rules only.

Lookup:

Allow Overrides

**Step 16** Click **Save**.

#### What to do next

[Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2570](#)

## Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule

### Before you begin

This multi-part procedure shows how to set up the captive portal using the default TCP port 885 and using a management center server certificate for both the captive portal and for TLS/SSL decryption. Each part of this example explains one task required to enable the captive portal to perform active authentication.

If you follow all the steps in this procedure, you can configure captive portal to work for users in your domains. You can optionally perform additional tasks, which are discussed in each part of the procedure.

For an overview of the entire procedure, see [How to Configure the Captive Portal for User Control, on page 2567](#).

## Procedure

- Step 1** Log in to the management center if you have not already done so.
- Step 2** Click **Policies > Access Control > Identity** and create or edit an identity policy.
- Step 3** (Optional.) Click **Add Category** to add a category for the captive portal identity rules and enter a **Name** for the category.
- Step 4** Click the **Active Authentication** tab.
- Step 5** Choose the appropriate **Server Certificate** from the list or click **Add (+)** to add a certificate.
- Note** Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.
- Step 6** From the **Redirect to Host Name** field, click the network object you previously created or click **Add (+)**.
- Step 7** Enter **885** in the **Port** field and specify the **Maximum login attempts**.
- Step 8** (Optional.) Choose an **Active Authentication Response Page** as described in [Captive Portal Fields, on page 2577](#).

The following figure shows an example.

The screenshot displays the configuration interface for Active Authentication. It features a tabbed interface with 'Active Authentication' selected. The configuration includes several fields with red asterisks indicating they are required:

- Server Certificate:** A dropdown menu set to 'CaptivePortalCert' with a plus sign to add more.
- Redirect to Host Name:** A dropdown menu set to 'CaptivePortalNetwork' with a plus sign and a warning icon indicating it is 'Supported only in Snort 3.0 and above'.
- Port:** A text input field containing '885', with a note '(885 or 1025 - 65535)'.
- Maximum login attempts:** A text input field containing '3', with a note '(0 or greater. Use 0 to indicate unlimited login attempts)'.

Below the fields is the **Active Authentication Response Page** section, which includes a note: 'This page will be displayed if a user triggers an identity rule with HTTP Response Page as the Authentication Type.' A dropdown menu is set to 'System-provided'.

A legend at the bottom indicates: '\* Required when using Active Authentication'.

- Step 9** Click **Save**.
- Step 10** Click **Rules**.
- Step 11** Click **Add Rule** to add a new captive portal identity policy rule, or click **Edit (✎)** to edit an existing rule.
- Step 12** Enter a **Name** for the rule.
- Step 13** From the **Action** list, choose **Active Authentication**.
- Step 14** Click **Realm & Settings**.
- Step 15** From the **Realms** list, choose a realm to use for user authentication.  
A realm sequence is not supported.
- Step 16** (Optional.) Check **Identify as Guest if authentication cannot identify user**. For more information, see [Captive Portal Fields, on page 2577](#).
- Step 17** Choose an **Authentication Protocol** from the list.

- Step 18** (Optional.) To exempt specific application traffic from captive portal, see [Exclude Applications from Captive Portal, on page 2578](#).
- Step 19** Add conditions to the rule (port, network, and so on) as discussed in [Identity Rule Conditions, on page 2613](#).
- Step 20** Click **Add**.
- Step 21** At the top of the page, click **Save**.

---

### What to do next

Continue with [Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule, on page 2572](#).

## Update a Custom Authentication Form

After you upgrade to version 7.4.1 (or later) from an earlier release, you must add the following line to a custom authentication form for users to see a list of domains when they authenticate with captive portal. (This task is always required if you use the HTTP Response Page authentication type; if users authenticate with a realm using another authentication type, this task is optional.)

On the **Active Authentication** tab page of your identity rule, click **Edit** (✎) and enter the following in the part of the form that requires the user to log in:

```
<select name="realm" id="realm"></select>
```

## Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule

This part of the procedure shows how to create an access control rule that allows the captive portal to communicate with clients using TCP port 885, which is the captive portal's default port. You can choose another port if you wish, but the port must match the one you chose in [Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2570](#).

### Before you begin

For an overview of the entire captive portal configuration, see [How to Configure the Captive Portal for User Control, on page 2567](#).

### Procedure

- 
- Step 1** Log in to the management center if you have not already done so.
  - Step 2** If you haven't done so already, create a certificate for the captive portal as discussed in [PKI, on page 1500](#).
  - Step 3** Click **Policies > Access Control > Access Control** and create or edit an access control policy.
  - Step 4** Click **Add Rule**.
  - Step 5** Enter a **Name** for the rule.
  - Step 6** Choose **Allow** from the **Action** list.
  - Step 7** Click **Ports**.
  - Step 8** From the **Protocol** list under the **Selected Destination Ports** field, choose **TCP**.
  - Step 9** In the **Port** field, enter **885**.
  - Step 10** Click **Add** next to the **Port** field.

The following figure shows an example.

The screenshot shows the 'Add Rule' configuration page. The 'Name' field is 'Captive portal rule' and is checked as 'Enabled'. The 'Action' is set to 'Allow'. The 'Time Range' is 'None'. The 'Ports' tab is selected, showing 'Available Ports' on the left and 'Selected Source Ports' and 'Selected Destination Ports' on the right. At the bottom, there is a section for adding ports with 'Protocol' set to TCP (6) and 'Port' set to 885. The 'Add' button for this port is circled in red.

**Step 11** Click **Add** at the bottom of the page.

### What to do next

Continue with [Configure the Captive Portal Part 4: Create a User Access Control Rule, on page 2573](#).

## Configure the Captive Portal Part 4: Create a User Access Control Rule

This part of the procedure discusses how to add an access control rule that enables users in a realm to authenticate using captive portal.

### Before you begin

For an overview of the entire captive portal configuration, see [How to Configure the Captive Portal for User Control, on page 2567](#).

### Procedure

- Step 1** In the rule editor, click **Add Rule**.
- Step 2** Enter a **Name** for the rule.
- Step 3** Choose **Allow** from the **Action** list.
- Step 4** Click **Users**.
- Step 5** In the **Available Realms** list, click the realms to allow.
- Step 6** If no realms display, click **Refresh** (↻).

- Step 7** In the **Available Users** list, choose the users to add to the rule and click **Add to Rule**.
- Step 8** (Optional.) Add conditions to the access control policy as discussed in [Identity Rule Conditions, on page 2613](#).
- Step 9** Click **Add**.
- Step 10** On the access control rule page, click **Save**.
- Step 11** In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.
- 

### What to do next

[Captive Portal Example: Create a Decryption Policy with an Outbound Rule, on page 2574](#)

## Captive Portal Example: Create a Decryption Policy with an Outbound Rule

This part of the procedure discusses how to create a decryption policy to decrypt and resign traffic before the traffic reaches the captive portal. The captive portal can authenticate traffic only after it has been decrypted.

### Before you begin

You must have an internal certificate authority (CA) for your outbound server; in other words, the managed device that decrypts the traffic for captive portal users to authenticate. This certificate must be different from the *internal certificate* you use to authenticate the captive portal with the managed device.

### Procedure

---

- Step 1** Click **Policies > Access Control > Decryption**.
- Step 2** Click **New Policy**.
- Step 3** Give the policy a unique **Name** and, optionally, a **Description**.
- Step 4** Click the **Outbound Connections** tab.

Create Decryption Policy
? ✕

**1** A decryption policy is not required to only perform application or URL discovery; instead, you can use TLS 1.3 Server Identity Discovery on the access control policy.

Name\*

Description

Outbound Connections (User Protection)
Inbound Connections (Server Protection)

**How Outbound Protection Works**

Outbound protection matches traffic based on the referenced internal CA certificate's signature algorithm type, in addition to any configured rule conditions.

The diagram illustrates the decryption process. It shows a flow from a SOURCE (represented by a laptop icon) to a DESTINATION (represented by a cloud icon). In the middle, there is a green circle labeled 'DECRYPT RE-SIGN'. Arrows indicate the direction of traffic. Above the flow, there is a padlock icon and the text 'DECRYPTION EXCLUSIONS', indicating that certain traffic is excluded from decryption.

Internal CA [Download](#)

A rule will be auto-created for the selected certificate authority.

CaptivePortalCA ✎ ✕
Associated: 2 Networks, 1 Port

[See how to configure](#)

Cancel Save

- Step 5** Upload or choose certificates for the rules.  
The system creates one rule per combination of CA and networks/ports.
- Step 6** (Optional.) Choose networks and ports.  
For more information:
- [Decryption Rule Conditions, on page 2372](#)
  - [Network Rule Conditions, on page 1065](#)
  - [Port Rule Conditions, on page 1067](#)
- Step 7** Click **Save**.
- Step 8** Click **Edit** (✎) next to the decryption policy you just created.
- Step 9** Click **Edit** (✎) next to the decryption rule for captive portal.
- Step 10** Click **Users**.
- Step 11** Above the **Available Realms** list, click **Refresh** (↻).
- Step 12** In the **Available Realms** list, click **Special Identities**.

**Step 13** In the **Available Users** list, click **Unknown**.

**Step 14** Click **Add to Rule**.

The following figure shows an example.

**Step 15** (Optional.) Set other options as discussed in [Decryption Rule Conditions](#), on page 2372.

**Step 16** Click **Add**.

### What to do next

[Configure Captive Portal Part 6: Associate Identity and Decryption Policies with the Access Control Policy](#), on page 2576

## Configure Captive Portal Part 6: Associate Identity and Decryption Policies with the Access Control Policy

This part of the procedure discusses how to associate the identity policy and TLS/SSL **Decrypt - Resign** rule with the access control policy you created earlier. After this, users can authenticate using the captive portal.

### Before you begin

For an overview of the entire captive portal configuration, see [How to Configure the Captive Portal for User Control](#), on page 2567.

### Procedure

**Step 1** Click **Policies > Access Control > Access Control** and edit the access control policy you created as discussed in [Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule](#), on page 2572. If **View** (👁)

appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Step 2** Either create a new access control policy or edit an existing policy.
- Step 3** At the top of the page, click the word **Identity**.
- Step 4** From the list, choose the name of your identity policy and, at the top of the page, click **Save**.
- Step 5** Repeat the preceding steps to associate your captive portal decryption policy with the access control policy.
- Step 6** If you haven't done so already, target the policy at managed devices as discussed in [Setting Target Devices for an Access Control Policy](#), on page 1838.

---

### What to do next

- Deploy your identity and access control policies to managed devices as discussed in [Deploy Configuration Changes](#), on page 240.
- Monitor user activity .

## Captive Portal Fields

Use the following fields to configure captive portal on the **Active Authentication** tab page of your identity policy. See also [Identity Rule Fields](#), on page 2620 and [Exclude Applications from Captive Portal](#), on page 2578.

### Server Certificate

An internal certificate presented by the captive portal daemon.

---

**Note** Captive portal does *not* support the use of Digital Signature Algorithm (DSA) or Elliptic Curve Digital Signature Algorithm (ECDSA) certificates.

---

### Port

The port number to use for the captive portal connection. You must set up your access control rule with a TCP port to use for the captive portal, then associate the identity policy with that access control policy. For more information, see [Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule](#), on page 2572.

### Maximum login attempts

The maximum allowed number of failed login attempts before the system denies a user's login request.

### Active Authentication Response Page

The system-provided or custom HTTP response page you want to display to captive portal users. After you select an **Active Authentication Response Page** in your identity policy active authentication settings, you also must configure one or more identity rules with **HTTP Response Page** as the **Authentication Protocol**.

The system-provided HTTP response page includes **Username** and **Password** fields, a list of realms if you chose to authenticate with a realm sequence, as well as a **Login as guest** button to allow users to access the network as guests. To display a single login method, configure a custom HTTP response page.

An example of what users see when logging in with a response page is shown in [Create a Sample Identity Policy with an Active Authentication Rule, on page 2623](#).

Choose the following options:

- To use a generic response, click **System-provided**. You can click **View** (👁) to view the HTML code for this page.
- To create a custom response, click **Custom**. A window with system-provided code is displayed that you can replace or modify. When you are done, save your changes. You can edit a custom page by clicking **Edit** (✎).

### Related Topics

[Internal Certificate Objects](#), on page 1508

## Exclude Applications from Captive Portal

You can select applications (identified by their HTTP `User-Agent` strings) and exempt them from captive portal active authentication. This allows traffic from the selected applications to pass through the identity policy without authenticating.

---

**Note** Only applications with the **User-Agent Exclusion Tag** are displayed in this list.

---

### Procedure

- 
- Step 1** If you haven't done so already, log in to the management center.
- Step 2** Click **Policies > Access Control > Identity**.
- Step 3** Edit the identity policy that contains the captive portal rule.
- Step 4** On **Realm & Settings** tab page, expand **HTTP User Agent Exclusions**.
- In the first column, select the check box next to each item to filter applications, then one or more applications, and click **Add to Rule**.  
Check boxes are ANDed together.
  - To narrow the filters that are displayed, type a search string in the **Search by name** field; this is especially useful for categories and tags. To clear the search, click **Clear** (✕).
  - To refresh the filters list and clear any selected filters, click **Reload** (🔄).
- Note** The list displays 100 applications at a time.
- Step 5** Choose the applications that you want to add to the filter from the **Available Applications** list:
- To narrow the individual applications that appear, enter a search string in the **Search by name** field. To clear the search, click **Clear** (✕).
  - Use paging at the bottom of the list to browse the list of individual available applications.

- To refresh the applications list and clear any selected applications, click **Reload** (↻).

**Step 6** Add the selected applications to exclude from external authentication. You can click and drag, or you can click **Add to Rule**. The result is the combination of the application filters you selected.

---

#### What to do next

- Continue configuring the identity rule as described in [Create an Identity Rule, on page 2618](#).

## Troubleshoot the Captive Portal Identity Source

For other related troubleshooting information, see [Troubleshoot Realms and User Downloads, on page 2498](#) and [Troubleshoot User Control, on page 2628](#).

If you experience issues with captive portal, check the following:

- The time on your captive portal managed device must be synchronized with the time on the management center.
- If you have DNS resolution configured and you create an identity rule to perform **Kerberos** (or **HTTP Negotiate**, if you want Kerberos as an option) captive portal, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the hostname you provided when configuring DNS.

For more information, see [About Hostname Redirect, on page 2564](#).

- If you're using Kerberos authentication, the managed device's host name must be less than 15 characters (it's a NetBIOS limitation set by Windows); otherwise, captive portal authentication fails. You set the managed device host name when you set up the device. For more information, see an article like this one on the Microsoft documentation site: [Naming conventions in Active Directory for computers, domains, sites, and OUs](#).
- DNS must return a response of 64KB or less to the hostname; otherwise, the AD connection test fails. This limit applies in both directions and is discussed in [RFC 6891 section-6.2.5](#).
- If the captive portal is configured correctly but the redirect to an IP address or fully-qualified domain name (FQDN) fails, disable endpoint security software. This type of software can interfere with the redirection.
- If you select **Kerberos** (or **HTTP Negotiate**, if you want Kerberos as an option) as the **Authentication Type** in an identity rule, the **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.
- If you select **HTTP Basic** as the **Authentication Type** in an identity rule, users on your network might not notice their sessions time out. Most web browsers cache the credentials from **HTTP Basic** logins and use the credentials to seamlessly begin a new session after an old session times out.
- If the connection between your management center and a managed device fails, no captive portal logins reported by the device can be identified during the downtime, unless the users were previously seen and downloaded to the management center. The unidentified users are logged as Unknown users on the

management center. After the downtime, the Unknown users are reidentified and processed according to the rules in your identity policy.

- If the device you want to use for captive portal contains both inline and routed interfaces, you must configure a zone condition in your captive portal identity rules to target only the routed interfaces on the captive portal device.
- The host name of the managed device must be less than 15 characters for Kerberos authentication to succeed.
- The only way to be sure a user logs out is to close and reopen the browser. Unless that happens, in some cases, the user can log out of captive portal and be able to access the network without authenticating again using the same browser.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see [RFC 959](#).
- When the captive portal authenticates users that match an identity rule, any user in a Microsoft Active Directory or LDAP group that has not been downloaded is identified as Unknown. To avoid users being identified as Unknown, configure the realm or realm sequence to download users in all groups you expect to authenticate with captive portal. Unknown users are handled according to the associated access control policy; if the access control policy is configured to block Unknown users, these users are blocked.

To make sure the system downloads all users in a realm or realm sequence, make sure the groups are in the Available Groups list in the realm's configuration.

For more information, see [Synchronize Users and Groups, on page 2487](#).

## History for Captive Portal

Feature	Minimum Management Center	Minimum Threat Defense	Details
Hostname redirect.	Any	7.1.0 with Snort 3	You can use a network object that contains the fully-qualified host name (FQDN) of the interface that captive portal can use for active authentication requests.
Guest login.	Any	6.1.0	Users can log in as guest using captive portal.
Captive portal.	Any	6.0.0	Feature introduced. You can use the captive portal to require users to enter their credentials when prompted in a browser window. The mapping also allows policies to be based on a user or group of users.

## CHAPTER 94

# User Control with the pxGrid Cloud Identity Source

---

The following topics discuss how to configure and use the pxGrid Cloud Identity Source.

- [About the pxGrid Cloud Identity Source, on page 2581](#)
- [How to Configure a pxGrid Cloud Identity Source, on page 2583](#)
- [Enable pxGrid Cloud Service in Cisco ISE, on page 2586](#)
- [Register Cisco ISE with the Cisco DNA Portal, on page 2586](#)
- [Register the pxGrid Cloud Connection with Cisco ISE, on page 2588](#)
- [Create and Subscribe to the Firewall Management Center Application, on page 2590](#)
- [Create a pxGrid Cloud Identity Source, on page 2591](#)
- [Create Dynamic Attributes Filters for the pxGrid Cloud Identity Source, on page 2595](#)
- [Create Access Control Rules Using Dynamic Attributes Filters, on page 2597](#)
- [History for the pxGrid Cloud Identity Source, on page 2599](#)

## About the pxGrid Cloud Identity Source

The Cisco Identity Services Engine (Cisco ISE) pxGrid Cloud Identity Source enables you to use subscription and user data from Cisco ISE in cloud-delivered Firewall Management Center access control rules.

The pxGrid cloud identity source enables the use of constantly changing dynamic objects from ISE to be used for user control in access control policies in the cloud-delivered Firewall Management Center.

The pxGrid cloud identity source also uses:

- The Cisco Platform Exchange Grid (pxGrid), which enables multivendor, cross-platform network system collaboration in things like security monitoring and detection systems, network policy platforms, asset and configuration management, identity, and access management. pxGrid Cloud is the cloud-based interface to Cisco ISE.

More information about pxGrid can be found in resources such as:

- [Cisco Platform Exchange Grid \(pxGrid\) on cisco.com](#)
- [What is PxGrid? on devnet](#)

- The Cisco Digital Network Architecture (Cisco DNA) delivers automation, security, predictive monitoring, and a policy-driven approach. It provides end-to-end network visibility and uses network insights to optimize network performance and deliver the best user and application experience.

To use the pxGrid cloud identity source with the Cisco Security Cloud Control, you must [Create a Cisco DNA Portal account](#).

- [Cisco Platform Exchange Grid \(pxGrid\)](#) on cisco.com
- [What is pxGrid?](#) on devnet
- [Cisco Platform Exchange Grid Cloud](#) on devnet

#### Prerequisites:

- *ISE-PIC is not supported*
- Cisco ISE 3.1 patch 3 and all later patches and versions

#### What to do next

See [How the pxGrid Cloud Identity Source Identity Source Works, on page 2582](#)

## Limitations of the pxGrid Cloud Identity Source

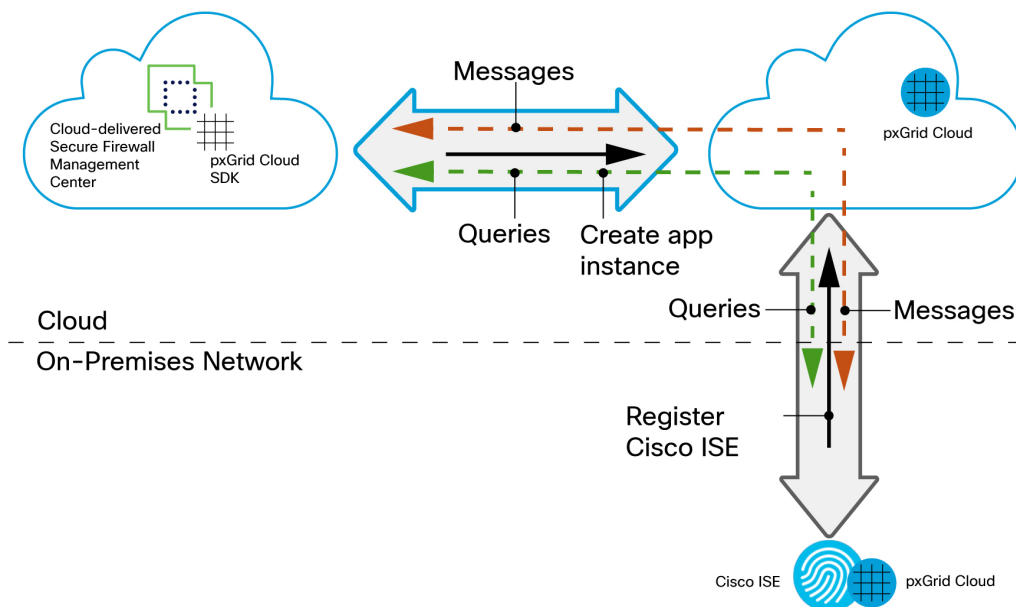

Before you set up the pxGrid cloud identity source, note the following:

- pxGrid Cloud supports only the `us-west-2` region
- You cannot use the following in access control rules: SGT, endpoint, and location IP.

## How the pxGrid Cloud Identity Source Identity Source Works

The following figure shows how the identity source works.

Your cloud-delivered Firewall Management Center uses the pxGrid Cloud SDK to programmatically retrieve user information from an on-premises Cisco ISE server so these users can be used in identity policies on the cloud-delivered Firewall Management Center.

To authorize and authenticate this data exchange, you must:

1. In Cisco ISE, enable the use of pxGrid Cloud.
2. Register Cisco ISE as a product in pxGrid Cloud, which authenticates Cisco ISE and pxGrid Cloud and enables them to communicate with each other.

The authentication process requires you to paste a one-time password (OTP) from pxGrid Cloud into Cisco ISE.

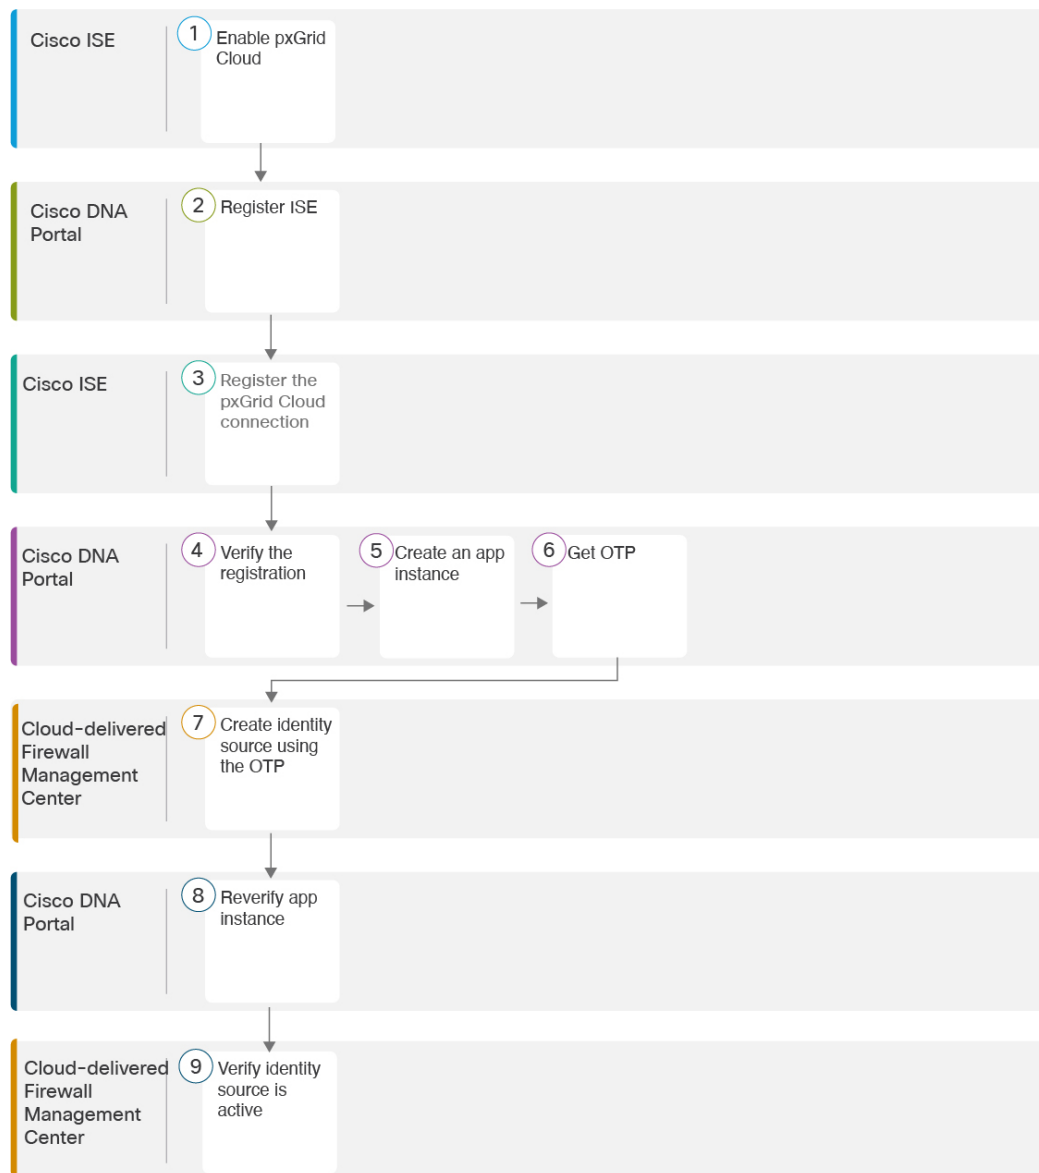

3. In pxGrid Cloud, create an "app instance" that generates an OTP for you to use in the cloud-delivered Firewall Management Center to authenticate the two with each other.
4. After completing all the preceding tasks, the cloud-delivered Firewall Management Center (which includes the pxGrid Cloud SDK) can query ISE using pxGrid Cloud and retrieve sessions containing user information.
5. Many types of dynamic objects can be filtered and sent to the cloud-delivered Firewall Management Center as dynamic objects to be used in access control rules. These include: SGT, endpoint profile, posture status, and machine authentication.

We retrieve user information from Cisco ISE and group information from either Microsoft Active Directory or Azure Active Directory.

## How to Configure a pxGrid Cloud Identity Source

Before you begin, create a [Cisco DNA Portal](#) account.

The following figure shows the steps to configure a pxGrid cloud identity source using Cisco ISE, the Cisco DNA Portal, and cloud-delivered Firewall Management Center.

- 1 [Enable pxGrid Cloud Service in Cisco ISE, on page 2586](#)
- 2 [Register Cisco ISE with the Cisco DNA Portal, on page 2586](#)
- 3 [Register the pxGrid Cloud Connection with Cisco ISE, on page 2588](#)
- 4 [Create and Subscribe to the Firewall Management Center Application, on page 2590](#)
- 5 [Create the Identity Source, on page 2592](#)
- 6 [Verify It's Working, on page 2594](#)

Table 227: Configure a pxGrid cloud identity source

1	Cisco ISE	<p>Enable the pxGrid Cloud in Cisco ISE.</p> <p>pxGrid Cloud enables you to subscribe to offers and to register apps (in this case, the cloud-delivered Firewall Management Center) for secure data exchange in a cloud environment.</p> <p>For more information, see <a href="#">Enable pxGrid Cloud Service in Cisco ISE, on page 2586</a>.</p>
2	Cisco DNA Portal	<p>Register Cisco ISE in the Cisco DNA portal and authenticate communication between Cisco ISE and the Cisco DNA Portal.</p> <p>For more information, see <a href="#">Register Cisco ISE with the Cisco DNA Portal, on page 2586</a>.</p>
3 4	Cisco ISE, Cisco DNA Portal	<p>Register the pxGrid Cloud with Cisco ISE and verify the registration.</p> <p>For more information, see <a href="#">Register the pxGrid Cloud Connection with Cisco ISE, on page 2588</a>.</p>
5 6	Cisco DNA Portal, cloud-delivered Firewall Management Center	<p>Create an application instance in the Cisco DNA Portal and get the one-time password (OTP).</p> <p>The application instance enables the cloud-delivered Firewall Management Center to authenticate with Cisco ISE using the pxGrid Cloud service.</p> <p>The OTP, required for the next step, expires in 60 minutes.</p>
7	Cloud-delivered Firewall Management Center	<p>Create the pxGrid cloud identity source using the OTP you got in the previous step.</p> <p>Linking the app enables the cloud-delivered Firewall Management Center to authenticate with ISE and the Cisco DNA Portal so it can receive user data from Cisco ISE.</p> <p>For more information, see <a href="#">Create the Identity Source, on page 2592</a>.</p>
8	Cisco DNA Portal	<p>Reverify the application instance.</p> <p><a href="#">Activate the App Instance, on page 2593</a>.</p>
9	Cloud-delivered Firewall Management Center	<p>Verify the identity source is active.</p> <p><a href="#">Verify It's Working, on page 2594</a>.</p>

After you have completed all the preceding tasks, you can:

- Create dynamic attributes filters, which define what dynamic objects are sent to the cloud-delivered Firewall Management Center.
- For more information, see [Create Dynamic Attributes Filters, on page 1913](#).
- After you configure the pxGrid cloud identity source, you can use any of the following in access control rules:
    - Dynamic objects
    - Microsoft AD user and groups
    - Azure AD users and groups

See [Enable pxGrid Cloud Service in Cisco ISE, on page 2586](#).

# Enable pxGrid Cloud Service in Cisco ISE

## Before you begin

- Ensure that you install and activate the Advantage license tier in your Cisco ISE deployment.
- The pxGrid Cloud agent creates an outbound HTTPS connection to Cisco pxGrid Cloud. Therefore, you must configure Cisco ISE proxy settings if the customer network uses a proxy to reach the internet. To configure proxy settings in Cisco ISE, click the **Menu** icon (☰) and choose **Administration > System > Settings > Proxy**.
- The Cisco ISE Trusted Certificates Store must include the root CA certificate required to validate the server certificate presented by Cisco pxGrid Cloud. Ensure that the **Trust for Authentication of Cisco Services** option is enabled for this root CA certificate. To enable **Trust for Authentication of Cisco Services**, navigate to **Administration > System > Certificates**

## Procedure

- 
- Step 1** In the Cisco ISE GUI, click the **Menu** icon (☰) and choose **Administration > System > Deployment**.
  - Step 2** Click the node on which you want to enable the pxGrid Cloud service.
  - Step 3** In the **General Settings** tab, enable the **pxGrid** service.
  - Step 4** Check the **Enable pxGrid Cloud** check box.

The pxGrid Cloud service can be enabled on two nodes to enable high availability.

**Note** You can enable the **pxGrid Cloud** option only when the **pxGrid** service is enabled on that node.

---

# Register Cisco ISE with the Cisco DNA Portal

This task discusses how to register Cisco ISE as an app in the Cisco DNA Portal and to authenticate communication between the Cisco DNA Portal and Cisco ISE.

## Procedure

- 
- Step 1** Log in to the [Cisco DNA Portal](#).
  - Step 2** If prompted, choose an account to use.
  - Step 3** On the Welcome page, click the **My Products** tab.

The following figure shows an example.

The screenshot shows the Cisco DNA Portal interface. At the top, there is a navigation bar with the Cisco logo and 'DNA Portal' text. Below the navigation bar, there is a welcome message: 'Welcome to Cisco DNA Portal' followed by the hashtag '#GetMoreWithCisco' and the text 'Activate Cisco Network Experience Applications for your Cisco products. On-board new capabilities and get more out of your network.' Below this, there is a 'SUMMARY' section with three metrics: '1 Regions', '0 Applications', and '0 Products'. Below the summary, there are two tabs: 'My Applications' and 'My Products', with 'My Products' being the active tab. The main content area displays the message 'No Products Registered' and 'You do not have any registered products. Please register.' with a blue 'Register' button.

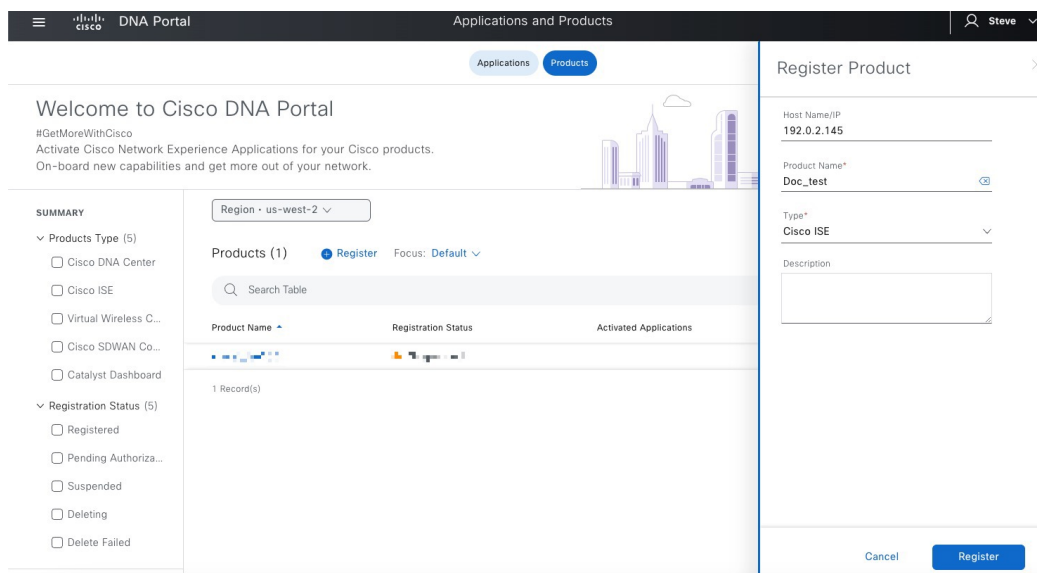

**Step 4** Click **Register**.

**Step 5** From the **Region** list, click **us-west-2**, as the following figure shows.

**Note** **us-west-2** is the only supported region at this time.

**Step 6** Click **Register**.  
The following figure shows a sample registration page.

**Step 7** Enter the following information.

- **Host Name/IP:** (Optional.) Enter the ISE server's fully qualified host name or IP address. If you enter an IP address, omit the scheme (for example, **https://**) and the port, if any.
- **Product Name:** Enter a unique name to identify this server.
- **Type:** From the list, click **Cisco ISE**.
- **Description:** Enter an optional description.

**Step 8** Click **Register**.

**Step 9** Generate a one-time password (OTP) in any of the following ways:

- If you've previously registered ISE apps and see yours listed, click **Generate OTP** in the **Actions** column; you'll need it in the next part of this procedure.
- If you're registering your app now, the OTP is displayed. Click  to copy it to the clipboard; you'll need it in the next part of this procedure.

### What to do next

See [Create and Subscribe to the Firewall Management Center Application](#), on page 2590.

## Register the pxGrid Cloud Connection with Cisco ISE

This task discusses how to register the pxGrid Cloud connection with Cisco ISE, which enables pxGrid Cloud to send user data to the pxGrid cloud identity source in Cisco Security Cloud Control.

## Before you begin

Complete the tasks discussed in [Enable pxGrid Cloud Service in Cisco ISE, on page 2586](#).

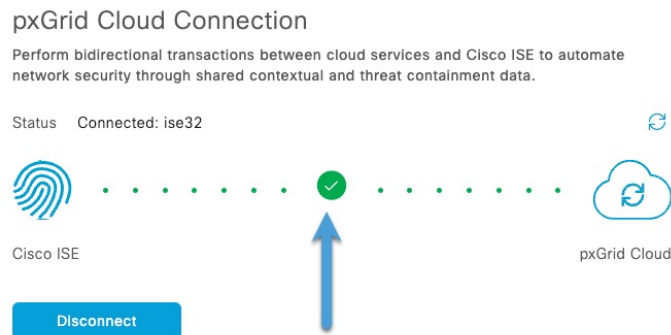

## Procedure

- Step 1** Log in to Cisco ISE as an administrator.
- Step 2** Click  > **Administration** > **pxGrid Services** > **Client Management**.
- Step 3** Click the **pxGrid Cloud Policy** tab.
- Step 4** Make sure all services are enabled with read/write privileges.
- Step 5** In the left navigation bar, click **pxGrid Cloud Connection**.
- Step 6** Click **Setup Connection** as the following figure shows.

- Step 7** Paste the OTP value in the provided field.
- Step 8** Click **Connect**.

A green check mark like the following confirms that connection was successful.

- Step 9** Confirm the setup has been successful so far:
- Log in to the Cisco DNA Portal.
  - Click the **Products** tab.
  - Click **Refresh** as the following figure shows.

d) Verify that **Registered** is displayed as the status of your product.

### What to do next

Continue with [Create an App Instance, on page 2591](#).

## Create and Subscribe to the Firewall Management Center Application

This topic discusses how to register Cisco ISE with the pxGrid cloud identity source and activate your Firewall Management Center application with the Cisco ISE product. You can subscribe to ISE's Session Directory subscriptions and enable the cloud-delivered Firewall Management Center to get user data for user control.

### Before you begin

You must have already performed this task: [Register Cisco ISE with the Cisco DNA Portal, on page 2586](#).

### Procedure

- Step 1** Log in to the [Cisco DNA Portal](#).
- Step 2** Click **Applications**.
- Step 3** Click **Firewall Management Center**, then click **Activate**.  
The following figure shows an example.

- Step 4** Accept the agreement and click **Subscribe**.  
After subscribing, you must copy the provided OTP to the clipboard and use it in 60 minutes or less to complete the next step in this process.

### What to do next

[Create an App Instance, on page 2591](#)

# Create a pxGrid Cloud Identity Source

The following tasks discuss how to create a pxGrid cloud identity source using Cisco ISE, the Cisco DNA Portal, and Cisco Security Cloud Control. You must complete all tasks in the order shown; in some cases, there is a time limit due to the expiration of a required One-Time Password (OTP).

## Related Topics

- [Create an App Instance](#), on page 2591
- [Create the Identity Source](#), on page 2592
- [Activate the App Instance](#), on page 2593
- [Verify It's Working](#), on page 2594

## Create an App Instance

This task is one of several tasks you have to perform to create a pxGrid cloud identity source to send user session data to the cloud-delivered Firewall Management Center.

There is a one-hour time limit on the one-time password (OTP) required to complete this procedure successfully. You do not need to log in to Cisco ISE.

### Before you begin

Complete all of the following tasks first:

- [Enable pxGrid Cloud Service in Cisco ISE](#), on page 2586
- [Register Cisco ISE with the Cisco DNA Portal](#), on page 2586
- [Register the pxGrid Cloud Connection with Cisco ISE](#), on page 2588
- [Create and Subscribe to the Firewall Management Center Application](#), on page 2590

## Procedure

- Step 1** Log in to the [Cisco DNA portal](#).
- Step 2** In the Cisco DNA Portal, go to **Applications and Products** as the following figure shows:

- Step 3** Click **Manage** next to **Firepower Management Center**.
- Step 4** Click **Add**.
- Step 5** Click **Create a New One**.

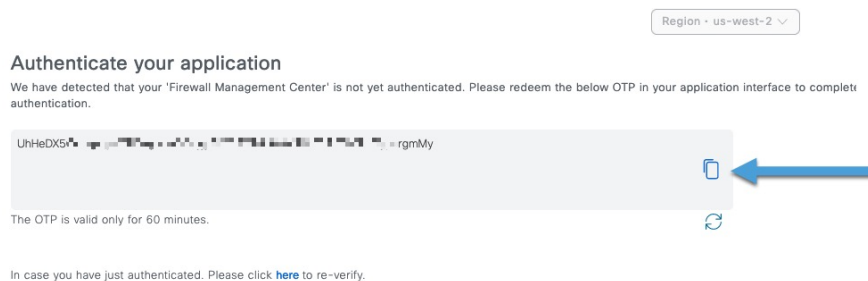

The following figure shows an example.

### Choose Application Instance

Select which Application Instance you would like to connect your product to. Not seeing the Instance that you want? [Create a New One](#)

**Step 6** Click the copy button next to the displayed OTP as the following figure shows:

**Step 7** Copy the OTP to a text file; it expires in 60 minutes.

**Step 8** Continue with [Create the Identity Source, on page 2592](#).

## Create the Identity Source

This task is one of several required to create a pxGrid cloud identity source to send user session data to the cloud-delivered Firewall Management Center.

### Before you begin

Complete the task discussed in [Create an App Instance, on page 2591](#).

### Procedure

- 
- Step 1** Log in to Cisco Security Cloud Control as a user with the Super Admin role.
  - Step 2** Click **Tools & Settings > Firewall Management Center > Devices > Integrations > Other Integrations > Identity Sources**.
  - Step 3** Click **Identity Services Engine (pxGrid Cloud)**.
  - Step 4** Click **Create pxGrid Cloud Instance**.
  - Step 5** The following figure shows an example.

Create pxGrid App Instance ?

Name \*

Description

OTP (One-Time Password) \* [How to get OTP](#)

OTP Enables you to set up your pxGrid Tenant

[Cancel](#) [Save](#)

**Step 6** Enter the following information.

Value	Description
<b>Name</b>	(Required.) Enter a name to uniquely identify this connector.
<b>Description</b>	Optional description.
<b>OTP (One-Time Password)</b>	Enter the OTP you obtained in the preceding steps.

**Step 7** Continue with [Activate the App Instance, on page 2593](#).

## Activate the App Instance

This task discusses how to create a pxGrid cloud identity source to send user session data to the cloud-delivered Firewall Management Center.

There is a one-hour time limit on the one-time password (OTP) required to complete this procedure successfully. You do not need to log in to Cisco ISE.

### Before you begin

Complete the task discussed in [Create the Identity Source, on page 2592](#).

### Procedure

- Step 1** Log in to the [Cisco DNA Portal](#).
- Step 2** Reverify the app by clicking the word **here** as the following figure shows.

Authenticate your application

We have detected that your 'Firewall Management Center' is not yet authenticated. Please redeem the below OTP in your application interface to complete authentication.

Lup\* \* \* \* \* 3RX

The OTP is valid only for 60 minutes.

In case you have just authenticated. Please click [here](#) to re-verify.

- Step 3** Click the name of the application instance you just created in cloud-delivered Firewall Management Center.
- Step 4** Click **Next**.
- Step 5** Click the name of the Cisco ISE product and click **Next**.
- Step 6** Select the check box next to each scope. The following figure shows an example.

Configure Access Control

Choose the functional capabilities and API Access control to be allowed for application "Firewall Management Center" on this products "SteveJISE2".

**CAPABILITIES**

Select All

Adaptive Network Control (ANC) configuration

ISE Session directory

Echo service topics used for testing

TrustSec related topics (Configuration, SXP, etc.)

**API ACCESS**

There are no API groups configured for this application.

- Step 7** Click **Next**.
- Step 8** Review the displayed information for accuracy. Make sure all scopes are selected.
- Step 9** Click **Activate**.
- Step 10** Continue with [Verify It's Working, on page 2594](#).

## Verify It's Working

This task discusses how to create a pxGrid cloud identity source to send user session data to the cloud-delivered Firewall Management Center.

There is a one-hour time limit on the one-time password (OTP) required to complete this procedure successfully. To do that, you must log in to both cloud-delivered Firewall Management Center and the Cisco DNA Portal at the same time. You do not need to log in to Cisco ISE.

### Before you begin

Complete the tasks discussed in [Activate the App Instance, on page 2593](#).

## Procedure

- 
- Step 1** Log in to Security Cloud Control.
- Step 2** Wait a few minutes for the identity source to be activated then click **Refresh**.
- Step 3** After the identity source has been activated, click **Save**.
- 

### What to do next

Complete the following tasks:

- Create dynamic attributes filters, which define what dynamic objects are sent to the cloud-delivered Firewall Management Center.

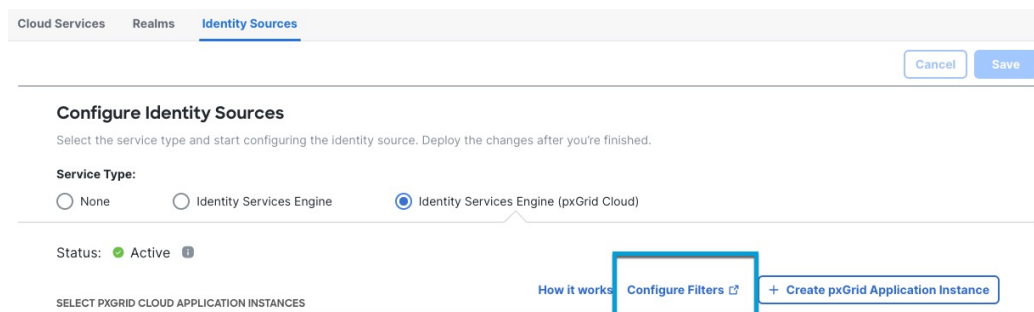

For more information, see [Create Dynamic Attributes Filters, on page 1913](#).

# Create Dynamic Attributes Filters for the pxGrid Cloud Identity Source

Dynamic attributes filters determine which dynamic objects are sent to the cloud-delivered Firewall Management Center for use in access control policies. We recommend setting up dynamic attributes filters for the pxGrid cloud identity source that specify clients that are in compliance with posture and for clients that are not in compliance with posture. You can create other dynamic attributes filter as you desire.

## Procedure

- 
- Step 1** Log in to Cisco Security Cloud Control.
- Step 2** Click **Objects > Other FTD Objects**.
- Step 3** Click **Integration > Other Integrations > Identity Sources**.
- Step 4** Click **Identity Services Engine (pxGrid Cloud)**.
- Step 5** Click **Configure Filters** as the following figure shows.

- Step 6** On the Dynamic Attributes Connector page, click the **Dynamic Attributes Filter** tab.

**Step 7** Do any of the following:

- Add a new filter: click Add icon (  ).
- Edit or delete a filter: Click **More** (  ), then click **Edit** or **Delete** at the end of the row.

**Step 8** Enter the following information.

Item	Description
Name	Unique name to identify the dynamic filter (as a dynamic object) in access control policy and in the ((CDO)) Object Manager ( <b>External Attributes</b> > <b>Dynamic Object</b> ).
Connector	From the list, click <b>pxGrid Cloud</b> .
Query	<ul style="list-style-type: none"> <li>• Add a new query: click Add icon (  ).</li> <li>• Edit or delete a query: Click <b>More</b> (  ), then click <b>Edit</b> or <b>Delete</b> at the end of the row.</li> </ul>

**Step 9** To add or edit a query, enter the following information.

Item	Description
Key	Click a key from the list. Keys are fetched from the connector. A typical key for the pxGrid Cloud Identity Source is <b>PostureStatus</b> .
Operation	Click one of the following: <ul style="list-style-type: none"> <li>• <b>Equals</b> to exactly match the key to the value.</li> <li>• <b>Contains</b> to match the key to the value if any part of the value matches.</li> </ul>
Values	Click either <b>Any</b> or <b>All</b> and click one or more values from the list. Click <b>Add another value</b> to add values to your query.

**Step 10** Click **Show Preview** to display a list of networks or IP addresses returned by your query.

**Step 11** When you're finished, click **Save**.

The following figure shows two sample dynamic attributes filters: one for clients whose posture is compliant and the other for clients whose posture is non-compliant.

#	Name	Connector	Query	Actions
1	posture_compliant	pxGrid Cloud (External)	PostureStatus eq 'Compliant'	⋮
2	posture_noncompliant	pxGrid Cloud (External)	PostureStatus eq 'NonCompliant'	⋮

- Step 12** (Optional.) Verify the dynamic object in the Cisco Security Cloud Control.
- Log in to Cisco Security Cloud Control.
  - Click **Policies > FTD Policies**.
  - Click **Objects > Object Management**.
  - In the left pane, click **External Attributes > Dynamic Object**.  
The dynamic attribute query you created should be displayed as a dynamic object.

---

#### What to do next

[Create Access Control Rules Using Dynamic Attributes Filters, on page 1916](#)

## Create Access Control Rules Using Dynamic Attributes Filters

This topic discusses how to create access control rules using dynamic objects (these dynamic objects are named after the dynamic attributes filters you created previously).

#### Before you begin

Create dynamic attributes filters as discussed in [Create Dynamic Attributes Filters, on page 1913](#).

---

**Note** You cannot create dynamic attributes filters for AWS, Azure, Azure Service Tags, Cisco Multicloud Defense, Generic Text, GitHub, Google Cloud, and Outlook 365, pxGrid cloud identity source, vCenter, Webex, and Zoom). These types of cloud objects provide their own IP addresses.

---

#### Procedure

- 
- Step 1** Log in to Security Cloud Control.
  - Step 2** Click **Policies > FTD Policies**.
  - Step 3** Click **Edit** (✎) next to an access control policy.
  - Step 4** Click **Add Rule**.
  - Step 5** Click the **Dynamic Attributes** tab.
  - Step 6** In the Available Attributes section, from the list, click **Dynamic Objects**.  
The following figure shows an example.

The preceding example shows a dynamic object named `FinanceNetwork` that corresponds to the dynamic attribute filter created in the Cisco Secure Dynamic Attributes Connector.

**Step 7**

Add the desired object to source or destination attributes.

**Step 8**

Add other conditions to the rule if desired.

**What to do next**

[Dynamic Attributes Rule Conditions](#) in the *Cisco Secure Firewall Management Center Device Configuration Guide*.

## History for the pxGrid Cloud Identity Source

Feature	Minimum Secure Firewall Threat Defense Version	Details
pxGrid Cloud Identity Source.	November 8, 2024	<p>The Cisco Identity Services Engine (Cisco ISE) pxGrid Cloud Identity Source enables you to use subscription and user data from Cisco ISE in cloud-delivered Firewall Management Center access control rules.</p> <p>The pxGrid cloud identity source enables the use of constantly changing dynamic objects from ISE to be used for user control in access control policies in the cloud-delivered Firewall Management Center.</p> <p>New/updated screens: <b>Integration &gt; Other Integrations &gt; Identity Sources &gt; Identity Services Engine (pxGrid Cloud)</b></p> <p>See: <a href="#">User Control with the pxGrid Cloud Identity Source</a></p>

## CHAPTER 95

# User Control with Remote Access VPN

The following topics discuss how to perform user awareness and user control with Remote Access VPN:

- [The Remote Access VPN Identity Source, on page 2601](#)
- [Configure RA VPN for User Control, on page 2602](#)
- [Troubleshoot the Remote Access VPN Identity Source, on page 2602](#)

## The Remote Access VPN Identity Source

Secure Client is the only client supported on endpoint devices for remote VPN connectivity to threat defense devices.

When you set up a secure VPN gateway as discussed in [Create a New Remote Access VPN Policy, on page 1686](#), you can set up an identity policy for those users and associate the identity policy with an access control policy, provided your users are in an Active Directory repository.

---

**Note** If you use remote access VPN with User Identity and RADIUS as the identity source, you must configure the realm (**Objects > Object Management > AAA Server > RADIUS Server Group**).

---

The login information provided by a remote user is validated by an LDAP or AD realm or a RADIUS server group. These entities are integrated with the Secure Firewall Threat Defense secure gateway.

---

**Note** If users authenticate with remote access VPN using Active Directory as the authentication source, users must log in using their username; the format `domain\username` or `username@domain` fails. (Active Directory refers to this username as the *logon name* or sometimes as `sAMAccountName`.) For more information, see [User Naming Attributes](#) on MSDN.

---

If you use RADIUS to authenticate, users can log in with any of the preceding formats.

---

Once authenticated via a VPN connection, the remote user takes on a *VPN Identity*. This VPN Identity is used by *identity policies* on the Secure Firewall Threat Defense secure gateway to recognize and filter network traffic belonging to that remote user.

Identity policies are associated with access control policies, which determine who has access to network resources. It is in this way that the remote user blocked or allowed to access your network resources.

### Related Topics

- [VPN Overview](#), on page 1605
- [Remote Access VPN Overview](#), on page 1675
- [VPN Basics](#), on page 1606
- [Remote Access VPN Features](#), on page 1676
- [Guidelines and Limitations for Remote Access VPNs](#), on page 1682
- [Create a New Remote Access VPN Policy](#), on page 1686

## Configure RA VPN for User Control

### Before you begin

- Create a realm as discussed in [Create an LDAP Realm or an Active Directory Realm and Realm Directory](#), on page 2475.
- To use authentication, authorization, and auditing (AAA), set up a RADIUS server group as discussed in [Add a RADIUS Server Group](#), on page 1463.

### Procedure

- 
- Step 1** Log in to the management center.
  - Step 2** Click **Devices > VPN > Remote Access**.
  - Step 3** See [Create a New Remote Access VPN Policy](#), on page 1686.
- 

### What to do next

- Specify users to control and other options using an identity policy as described in [Create an Identity Policy](#), on page 2611.
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in [Associating Other Policies with Access Control](#), on page 1844.
- Deploy your identity and access control policies to managed devices as discussed in [Deploy Configuration Changes](#), on page 240.
- Monitor VPN user traffic .

## Troubleshoot the Remote Access VPN Identity Source

- For other related troubleshooting information, see [Troubleshoot Realms and User Downloads](#), on page 2498 and [Troubleshoot User Control](#), on page 2628.
- If you experience issues with Remote Access VPN, check the connection between your management center and a managed device. If the connection fails, all Remote Access VPN logins reported by the

device cannot be identified during the downtime, unless the users were previously seen and downloaded to the management center.

The unidentified users are logged as Unknown users on the management center. After the downtime, the Unknown users are re identified and processed according to the rules in your identity policy.

- The host name of the managed device must be less than 15 characters for Kerberos authentication to succeed.
- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see [RFC 959](#).

## Not Observing Correct Settings for VPN Statistics

This task discusses steps you must take after either enabling or disabling the **VPN Statistics** setting in a health policy. Failure to perform this task means managed devices have a health policy with incorrect settings.

### Procedure

- Step 1** Log in to the Secure Firewall Management Center if you haven't already done so.
- Step 2** Click **System** (⚙) > **Health** > **Policy**.
- Step 3** Under Firewall Threat Defense Health Policies, click **Edit** (✎) next to a policy to edit.

Firewall Threat Defense Health Policies			
Policy Name	Domain	Applied To	Last Modified
Initial_Health_Policy 2023-03-28 16:26:02 Initial Health Policy2	Global	1 devices	2023-05-02 11:34:50 Last modified by admin

- Step 4** On the **Health Modules** tab page, scroll down to locate **VPN Statistics**.
- Step 5** Verify the VPN statistics setting is correct or change it if necessary.
- Step 6** If you changed the setting, click **Save**, then click **Cancel** to return to the health policy.
- Step 7** Under Firewall Threat Defense Health Policies, click **Deploy health policy** (📄) to apply the policy.
- Step 8** In the **Policy Assignments & Deploy** dialog box, move the devices to which to deploy the health policy to the **Selected Devices** field.

Policy Assignments & Deploy

Select devices to which the policy has to be applied.

Available Devices

Selected Devices

ftd74-50

>>

<<

Cancel Apply

- Step 9** Click **Apply**.  
A message is displayed when the health policy is deployed.
- Step 10** After the health policy has finished deploying, click **Policies > Access Control** to edit an access control policy.
- Step 11** Click **Edit** (✎) next to a policy to edit.
- Step 12** Make a minor change to the policy, such as changing its name.
- Step 13** Save the access control policy.
- Step 14** Deploy configuration changes..
-

## CHAPTER 96

# User Control with TS Agent

To use the TS Agent as an identity source for user awareness and user control, install and configure the TS Agent software as discussed in the [Cisco Terminal Services \(TS\) Agent Guide](#).

### What to do next:

- Specify users to control and other options using an identity policy as described in [Create an Identity Policy, on page 2611](#).
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in [Associating Other Policies with Access Control, on page 1844](#).
- Deploy your identity and access control policies to managed devices as discussed in [Deploy Configuration Changes, on page 240](#).
- Monitor user activity.
- [The Terminal Services \(TS\) Agent Identity Source, on page 2605](#)
- [TS Agent Guidelines, on page 2606](#)
- [User Control with TS Agent, on page 2606](#)
- [Troubleshoot the TS Agent Identity Source, on page 2606](#)
- [History for TS Agent, on page 2607](#)

## The Terminal Services (TS) Agent Identity Source

The TS Agent is a passive authentication method and one of the authoritative identity sources supported by the system. A Windows Terminal Server performs the authentication, and the TS Agent reports it to a standalone or high availability management center.

When installed on Windows Terminal Servers, the TS Agent assigns a unique port range to individual users as they log in or log out of a monitored network. The management center uses the unique port to identify individual users in the system. You can use one TS Agent to monitor user activity on one Windows Terminal Server and send encrypted data to a management center.

The TS Agent does not report failed login attempts. The data gained from the TS Agent can be used for user awareness and user control.

## TS Agent Guidelines

The TS Agent requires a multi-step configuration, and includes the following:

1. A Windows Terminal Server with the TS Agent installed and configured.
2. One or more identity realms targeting the users your server is monitoring.

You install the TS Agent on a Microsoft Windows Terminal Server. For detailed information about the multi-step TS Agent installation and configuration and a complete discussion of the server and system requirements, see the [Cisco Terminal Services \(TS\) Agent Guide](#).

TS Agent data is visible in the Users, User Activity, and Connection Event tables and can be used for user awareness and user control.

---

**Note** If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the management center prioritizes the TS Agent data. If the TS Agent and another passive identity source report activity by the same IP address, only the TS Agent data is logged to the management center.

---

## User Control with TS Agent

To use the TS Agent as an identity source for user awareness and user control, install and configure the TS Agent software as discussed in the [Cisco Terminal Services \(TS\) Agent Guide](#).

### What to do next:

- Specify users to control and other options using an identity policy as described in [Create an Identity Policy, on page 2611](#).
- Associate the identity rule with an access control policy, which filters and optionally inspects traffic, as discussed in [Associating Other Policies with Access Control, on page 1844](#).
- Deploy your identity and access control policies to managed devices as discussed in [Deploy Configuration Changes, on page 240](#).
- Monitor user activity.

## Troubleshoot the TS Agent Identity Source

For other related troubleshooting information, see [Troubleshoot Realms and User Downloads, on page 2498](#) and [Troubleshoot User Control, on page 2628](#).

If you experience issues with the TS Agent integration, check:

- You must synchronize the time on your TS Agent server with the time on the management center.
- If the TS Agent monitors the same users as another passive authentication identity source (ISE/ISE-PIC), the management center prioritizes the TS Agent data. If the TS Agent and a passive identity source report activity by the same IP address, only the TS Agent data is logged to the management center.

- Active FTP sessions are displayed as the **Unknown** user in events. This is normal because, in active FTP, the server (not the client) initiates the connection and the FTP server should not have an associated user name. For more information about active FTP, see [RFC 959](#).

For more troubleshooting information, see the [Cisco Terminal Services \(TS\) Agent Guide](#).

## History for TS Agent

Feature	Minimum Management Center	Minimum Threat Defense	Details
TS Agent communicates with the Cisco Security Cloud Control	Any	7.2.0	By applying a token from Cisco Security Cloud Control, the TS Agent can get user login sessions in the same way as for the Cisco Security Cloud Control.
TS Agent for user control.	Any	6.2.0	<p>Feature introduced. Firepower now provides the ability to better identify individual users in shared environments, such as Citrix's Virtual Desktop Infrastructure (VDI), to accurately enforce user-based policy rules on the firewall. Users are identified by ports used.</p> <p>The TS Agent software is updated independently of the Firepower Management Center. For more information, see:</p> <ul style="list-style-type: none"> <li>• <i>Cisco Terminal Services (TS) Agent Guide</i> available on <a href="#">cisco.com</a></li> <li>• <a href="#">Cisco Firepower Compatibility Guide</a></li> </ul>

## CHAPTER 97

# User Identity Policies

---

The following topics discuss how to create and manage identity rules and identity policies:

- [About Identity Policies, on page 2609](#)
- [License Requirements for Identity Policies, on page 2610](#)
- [Requirements and Prerequisites for Identity Policies, on page 2610](#)
- [Create an Identity Policy, on page 2611](#)
- [Identity Rule Conditions, on page 2613](#)
- [Create an Identity Rule, on page 2618](#)
- [Sample Identity Policies and Rules, on page 2620](#)
- [Manage an Identity Policy, on page 2627](#)
- [Manage an Identity Rule, on page 2628](#)
- [Troubleshoot User Control, on page 2628](#)

## About Identity Policies

Identity policies contain identity rules. Identity rules associate sets of traffic with a realm and an authentication method: passive authentication, active authentication, or no authentication.

With the exception noted in the following paragraphs, you must configure realms and authentication methods you plan to use before you can invoke them in your identity rules:

- You configure realms outside of your identity policy, at **System > Integration > Realms**. For more information, see [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).
- You configure ISE/ISE-PIC, a passive authentication identity source, at **System > Integration > Identity Sources**. For more information, see [Configure ISE for User Control, on page 2547](#). For more information, see [Ways to Configure the Cisco Identity Services Engine \(Cisco ISE\) Identity Source, on page 2550](#).
- You configure the TS Agent, a passive authentication identity source, outside the system. For more information, see the *Cisco Terminal Services (TS) Agent Guide*.
- You configure captive portal, an active authentication identity source, within the identity policy. For more information, see [How to Configure the Captive Portal for User Control, on page 2567](#).
- You configure Remote Access VPN, an active authentication identity source, in Remote Access VPN policies. For more information, see [Remote Access VPN Authentication, on page 1678](#).

After you add multiple identity rules to a single identity policy, order the rules. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles the traffic.

You can also filter traffic by network object, which limits the network each device monitors in the event your devices are at or near their memory limits.

After you configure one or more identity policies, you must associate one identity policy with your access control policy. When traffic on your network matches the conditions in your identity rule, the system associates the traffic with the specified realm and authenticates the users in the traffic using the specified identity source.

If you do not configure an identity policy, the system does not perform user authentication.

#### **Exception to creating an identity policy**

An identity policy is not required if all of the following are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies. For more information, see [ISE SGT vs Custom SGT Rule Conditions](#).

## Create an Identity Policy

This task discusses how to create an identity policy.

### Before you begin

An identity policy is required to use users and groups in a realm in access control policies. Create and enable one or more realms as described in [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).

(Optional.) If a particular managed device monitors a large number of user groups, the system might drop user mappings based on groups due to managed device memory limitations. As a result, rules with realm or user conditions might not perform as expected. Provided the devices run version 6.7 or later, you can configure the identity rule to monitor traffic by one network or network group object only. To create a network object, see [Creating Network Objects, on page 1499](#).

An identity policy is not required if all of the following are true:

- You use the ISE/ISE-PIC identity source.
- You do not use users or groups in access control policies.
- You use Security Group Tags (SGT) in access control policies. For more information, see [ISE SGT vs Custom SGT Rule Conditions](#).

### Procedure

- 
- Step 1** Log in to the management center.
  - Step 2** Click **Policies > Access Control > Identity** and click **New Policy**.
  - Step 3** Enter a **Name** and, optionally, a **Description**.
  - Step 4** Click **Save**.
  - Step 5** To add a rule to the policy, click **Add Rule** as described in [Create an Identity Rule, on page 2618](#).
  - Step 6** To create a rule category, click **Add Category**.
  - Step 7** To configure captive portal active authentication, click **Active Authentication** and see [Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2570](#).
  - Step 8** (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add (+)** to create a new network object.
  - Step 9** Click **Save** to save the identity policy.
- 

### What to do next

- Add rules to your identity policy that specify which users to match and other options; see [Create an Identity Rule, on page 2618](#).

- Associate the identity policy with an access control policy to allow or block selected users from accessing specified resources; see [Associating Other Policies with Access Control, on page 1844](#).
- (Not required for Microsoft Azure AD realms.) Deploy configuration changes to managed devices; see [Deploy Configuration Changes, on page 240](#).

If you encounter issues, see [Troubleshoot User Control, on page 2628](#).

### Related Topics

[Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule, on page 2570](#)

[Create an Identity Mapping Filter, on page 2612](#)

[Captive Portal Fields, on page 2577](#)

[Troubleshoot User Control, on page 2628](#)

## Create an Identity Mapping Filter

An identity mapping filter can be used to limit the networks to which an identity rule applies. For example, if your management center manages FTDs that have a limited amount of memory, you can limit the networks they monitor.

You can also optionally exclude subnets from the following:

- Receiving user-to-IP and Security Group Tag (SGT)-to-IP mappings from ISE.

You should typically do this for lower-memory managed devices to prevent Snort identity health monitor memory errors.

### Before you begin

Perform the following tasks:

1. Create a realm, which is required for an identity policy. See [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).
2. Create an identity policy. See [Create an Identity Policy, on page 2611](#).
3. Create a network object or network group object as discussed in [Creating Network Objects, on page 1499](#). The network object or group you create should define the network you want managed devices to monitor in identity policies.

### Procedure

- 
- Step 1** Log in to the management center.
- Step 2** Click **Policies > Identity**.
- Step 3** Click **Edit** (✎).
- Step 4** Click the **Identity Source** tab.
- Step 5** From the **Identity Mapping Filter** list, choose the name of a network object to use as a filter .
- To create a new network object, see [Creating Network Objects, on page 1499](#).

**Note** To restrict traffic to IPv6 addresses, you must add at least one address, network, or group to the filter.

**Step 6** Click **Save**.

**Step 7** (Not required for Microsoft Azure AD realms.) Deploy configuration changes to managed devices; see [Deploy Configuration Changes, on page 240](#).

---

### What to do next

(Not required for Microsoft Azure AD realms.) Associate the identity policy with an access control policy as discussed in [Associating Other Policies with Access Control, on page 1844](#).

To check or change ISE identity mapping filters (also referred to as *subnet filters*), use the following commands:

```
show identity-subnet-filter
configure identity-subnet-filter { add | remove } subnet
```

## Identity Rule Conditions

Rule conditions enable you to fine-tune your identity policy to target the users and networks you want to control. See one of the following sections for more information.

### Related Topics

[Security Zone Rule Conditions, on page 1965](#)

[Network Rule Conditions, on page 1065](#)

[VLAN Tags Rule Conditions, on page 1867](#)

[Port Rule Conditions, on page 1067](#)

[Realm & Settings Rule Conditions, on page 2616](#)

## Security Zone Rule Conditions

Security zones segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices.

Zone rule conditions control traffic by its source and destination security zones. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

Just as all interfaces in a zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

---

**Tip** Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

---

## Network Rule Conditions

Network rule conditions control traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

---

**Note** You *cannot* use FQDN network objects in identity rules.

---

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

## Redirect to Host Name Network Rule Conditions

(Snort 3.0 only.)—You can use a network object that contains the fully-qualified host name (FQDN) of the interface that captive portal can use for active authentication requests.

The FQDN must resolve to the IP address of one of the interfaces on a managed device. By using an FQDN, you can assign a certificate for active authentication that the client will recognize, thus avoiding the untrusted certificate warning users get when being redirected to a managed device's IP address.

The certificate can specify one FQDN, a wildcard FQDN, or multiple FQDNs in the Subject Alternate Names (SAN) in the certificate.

If an identity rule requires active authentication for a user, but you do not specify a redirect FQDN, the user is redirected to the captive portal port on the managed device interface to which they are connected.

If you do not supply a Redirect to Host Name FQDN, the HTTP Basic, HTTP Response Page, and NTLM authentication methods redirect the user to the captive portal using the IP address of the interface. However, for HTTP Negotiate, the user is redirected using the fully-qualified DNS name *firewall-hostname.directory-server-domain-name*. To use HTTP Negotiate without a Redirect to Host Name FQDN, you must also update your DNS server to map this name to the IP addresses of all inside interfaces where you are requiring active authentication. Otherwise, the redirection cannot complete, and users cannot authenticate.

We recommend that you always provide a Redirect to Host Name FQDN to ensure consistent behavior regardless of authentication method.

## VLAN Tags Rule Conditions

---

**Note** VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

---

VLAN rule conditions control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic. The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note the following Q-in-Q support:

- Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

## Port Rule Conditions

Port conditions allow you to control traffic by its source and destination ports.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

### Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic.

Application filtering is also recommended for applications, like threat defense, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

### Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

## Port, Protocol, and ICMP Code Rule Conditions

Port conditions match traffic based on the source and destination ports. Depending on the rule type, “port” can represent any of the following:

- TCP and UDP—You can control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP(6)/22.
- ICMP—You can control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.

- Protocol—You can control traffic using other protocols that do not use ports.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

### Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic. Note that application filtering is not available in prefilter rules.

Application filtering is also recommended for applications, like FTP, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

### Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

### Matching Non-TCP Traffic with Port Conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although you can configure port conditions to match non-TCP traffic, there are some restrictions:

- Access control rules—For Classic devices, you can match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, you can add only network-based conditions: zone, IP address, port, and VLAN tag. Also, the system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For threat defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support TCP port conditions only.
- ICMP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies sent in response to ICMP echo requests are ignored. For a rule to match on any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

## Realm & Settings Rule Conditions

The **Realm & Settings** tab page enables you to choose a realm or realm sequence to which to apply the identity rule. If you are using captive portal, you have additional options.

### Authentication Realm

From the **Realm** list, click a realm or realm sequence.

The realm or realm sequence containing the users you want to perform the specified **Action** on. You must fully configure a realm or realm sequence before selecting it as the realm in an identity rule.

---

**Note** If remote access VPN is enabled and your deployment is using a RADIUS server group for VPN authentication, make sure you specify the realm associated with this RADIUS server group.

---

### Active authentication only: other options

If you either choose **Active Authentication** as the authentication type or if you check the box, **Use active authentication if passive or VPN identity cannot be established**, you have the following options.

#### Use active authentication if passive or VPN identity cannot be established

(Passive authentication rule only.) Selecting this option authenticates users using captive portal active authentication if a passive or a VPN authentication fails to identify them. You must configure an Active Authentication rule in your identity policy in order to select this option. (That is, users must authenticate using the captive portal.)

If you disable this option, users that do not have a VPN identity or that passive authentication cannot identify are identified as Unknown.

Also see the discussion of the **Authentication Realm** list later in this topic,

#### Identify as Special Identities/Guest if authentication cannot identify user

Selecting this option allows users who fail captive portal active authentication the specified number of times to access your network as a guest. These users appear in the management center identified by their username (if their username exists on the AD or LDAP server) or by **Guest** (if their user name is unknown). Their realm is the realm specified in the identity rule. (By default, the number of failed logins is 3.)

This field is displayed only if you configure **Active Authentication** (that is, captive portal authentication) as the rule **Action**.

### Authentication Protocol

The method to use to perform captive portal active authentication. .

The selections vary depending on the type of realm, LDAP or AD:

- Choose **HTTP Basic** if you want to authenticate users using an unencrypted HTTP Basic Authentication (BA) connection. Users log in to the network using their browser's default authentication pop-up window.

Most web browsers cache the credentials from **HTTP Basic** logins and use the credentials to seamlessly begin a new session after an old session times out.

- Choose **NTLM** to authenticate users using a NT LAN Manager (NTLM) connection. This selection is available only when you select an AD realm. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent authentication is not configured, users log in to the network using their browser's default authentication pop-up window.
- Choose **Kerberos** to authenticate users using a Kerberos connection. This selection is available only when you select an AD realm for a server with secure LDAP (LDAPS) enabled. If transparent authentication is configured in a user's browser, the user is automatically logged in. If transparent authentication is not configured, users log in to the network using their browser's default authentication pop-up window.

---

**Note** The **Realm** you select must be configured with an **AD Join Username** and **AD Join Password** to perform Kerberos captive portal active authentication.

---

---

**Note** If you are creating an identity rule to perform Kerberos captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN must match the host name you provided when configuring DNS.

For threat defense devices, the FQDN must resolve to the IP address of the routed interface used for captive portal.

---

- Choose **HTTP Negotiate** to allow the captive portal server to choose between HTTP Basic, Kerberos, or NTLM for the authentication connection. This type is available only when you select an AD realm.

---

**Note** The **Realm** you choose must be configured with an **AD Join Username** and **AD Join Password** for **HTTP Negotiate** to choose Kerberos captive portal active authentication.

---

---

**Note** If you are creating an identity rule to perform **HTTP Negotiate** captive portal and you have DNS resolution configured, you must configure your DNS server to resolve the fully qualified domain name (FQDN) of the captive portal device. The FQDN of the device you are using for captive portal must match the hostname you provided when configuring DNS.

---

- Choose **HTTP Response Page** to enable users to choose a realm to log in to.

You can optionally customize the response page; for example, to conform to company style standards.

## Create an Identity Rule

For details about configuration options for identity rules, see [Identity Rule Fields, on page 2620](#).

### Before you begin

You must create and enable a realm or realm sequence.

- Create a Microsoft Active Directory realm and realm directory as discussed in [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).
- (Microsoft AD realm only.) Download users and groups and enable the realm as discussed in [Synchronize Users and Groups, on page 2487](#).

- Create a Microsoft Azure AD (SAML) realm as discussed in [Create a Microsoft Azure AD \(SAML\) Realm, on page 2450](#).
- (Optional.) Create a realm sequence as discussed in [Create a Realm Sequence, on page 2488](#).
- Rules are evaluated top-down. For a connection that matches the specified network criteria of a given rule, the user is evaluated against the identity realm specified in the rule. If the user is not part of that realm, they will be marked as unknown, and no further rules in the identity policy will be evaluated. Thus, if you have more than one realm that needs to be evaluated, be sure to use realm sequences instead of a single realm.

**Caution**

Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include a decryption policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

**Procedure**

- 
- Step 1** Log in to the management center.
  - Step 2** Click **Policies > Access Control > Identity**.
  - Step 3** Click **Edit** (✎) next to the identity policy to which to add the identity rule.  
If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
  - Step 4** Click **Add Rule**.
  - Step 5** Enter a **Name**.
  - Step 6** If the Specified rule is applicable, check the check box of **Enabled**.
  - Step 7** To add the rule to an existing category, indicate where you want to **Insert** the rule. To add a new category, click **Add Category**.
  - Step 8** Choose a rule **Action** from the list.
  - Step 9** If you're configuring captive portal, see [How to Configure the Captive Portal for User Control, on page 2567](#).
  - Step 10** (Optional) To add conditions to the identity rule, see [Identity Rule Conditions, on page 2613](#).
  - Step 11** Click **Add**.
  - Step 12** In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste. Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.
  - Step 13** Click **Save**.
-

### What to do next

- Deploy configuration changes.

## Identity Rule Fields

Use the following fields to configure identity rules.

### Enabled

Enabling this option enables the identity rule in the identity policy. Unselecting this option disables the identity rule.

### Action

Specify the type of authentication you want to perform on the users in the specified realm: **Passive Authentication** (default), **Active Authentication**, or **No Authentication**. You must fully configure the authentication method, or *identity source*, before selecting it as the action in an identity rule.

Additionally, if VPN is enabled (configured on at least one managed device), remote access VPN sessions are actively authenticated by VPN. Other sessions use the rule action. This means that, if VPN is enabled, VPN identity determination is performed first for all sessions regardless of the selected action. If a VPN identity is found on the specified realm, this is the identity source used. No additional captive portal active authentication is done, even if selected.

If the VPN identity source is not found, the process continues according to the specified action. You cannot restrict the identity policy to VPN authentication only because if the VPN identity is not found, the rule is applied according to the selected action.

### Caution

Adding the first or removing the last active authentication rule when TLS/SSL decryption is disabled (that is, when the access control policy does not include an SSL policy) restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

Note that an active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

For information about which passive and active authentication methods are supported in your version of the system, see [About User Identity Sources, on page 2424](#).

## Sample Identity Policies and Rules

The following sections provide examples of configuring an identity policy with either a passive authentication rule or an active authentication rule. In addition, because you can authenticate users with active authentication using either realms or realm sequences, separate examples are provided.

*Active authentication* means the user authenticates using the captive portal; the user enters network credentials before being allowed to access allowed resources. (RA-VPN is another type of active authentication but it cannot be used together with captive portal authentication. For more information, see [The Remote Access VPN Identity Source, on page 2601](#).)

*Passive authentication* covers all other types. Passive authentication includes using Microsoft Active Directory realms, Microsoft Azure Active Directory realms, Cisco Identity Services Engine, and others.

### Assumptions

The examples use the following assumptions:

- Microsoft Active Directory (AD) realm named forest.example.com with two child domains configured in a trust relationship:
  - US-West
  - US-East
- A realm sequence named US that includes both realms
- Passive authentication rule that authenticates users with a realm sequence
- Two active authentication rules:
  - One rule that authenticates users with a realm and uses the NTLM authentication protocol
  - One rule that authenticates users with a realm sequence and uses the HTTP Response Page authentication protocol
- Each sample identity rule is associated with a different identity policy

### Passive authentication identity rules

When you configure a Passive Authentication identity rule, you can choose to authenticate users either with LDAP, a Microsoft Active Directory realm, or a Microsoft AD realm sequence. You can use a realm to authenticate with any authentication type; realm sequence restricts the authentication types you can use. For an example, see [Create an Identity Policy with a Passive Authentication Rule, on page 2621](#).

### Active authentication identity rules

When you configure an Active Authentication identity rule, you can choose to authenticate users either with LDAP, a Microsoft Active Directory realm, or a Microsoft AD realm sequence. You can use a realm to authenticate with any authentication type; realm sequence restricts the authentication types you can use.

You can also authenticate users with a Microsoft Active Directory realm sequence except for the following authentication types:

- NTLM
- Kerberos
- HTTP Negotiate

For an example, see [Create a Sample Identity Policy with an Active Authentication Rule, on page 2623](#).

## Create an Identity Policy with a Passive Authentication Rule

This task discusses how to create an identity policy with a passive authentication rule that authenticates users using the US realm sequence. If a user is not found in the first realm in the sequence, the system searches the

other realms in the sequence in the order listed in the realm sequence. If a user is still not found in the realm or realm sequence, the user is identified as Unknown.

You can optionally authenticate a user with the captive portal (that is, active authentication) if the user is not found in any realm in the sequence. For more information, see [Captive Portal Guidelines and Limitations](#), on page 2564.

## Procedure

- Step 1** Log in to the management center.
- Step 2** Click **Policies > Access Control > Identity**.
- Step 3** Click **New Policy**.
- Step 4** Enter a **Name** for the policy and an optional **Description**.
- Step 5** Click **Save**.
- Step 6** Click **Add Rule**.
- Step 7** Enter a **Name** for the rule.
- Step 8** From the list, click **Passive Authentication**.
- Step 9** Click the **Realms & Settings** tab page.
- Step 10** From the list, click the name of a realm or realm sequence.

The following figure shows an example.

The screenshot shows the 'Add Rule' configuration page. The 'Name' field contains 'Passive rule', 'Enabled' is checked, and 'Authentication Protocol' is set to 'HTTP Basic'. The 'Authentication Realm' dropdown menu is open, displaying a list of realms: 'US-East (AD)', 'US-West (AD)', 'LDAP (LDAP)', and 'US (Sequence)'. The 'US-East (AD)' option is highlighted. A message below the dropdown indicates 'or VPN identity cannot be established'. At the bottom of the form, there are 'Cancel' and 'Add' buttons.

- If you choose a realm (such as **US-East** in the example), the system searches that realm for users to match the rule. If a user is not found, the user is identified as Unknown.
- If you choose a realm sequence (**US (Sequence)** in the example), users are searched in every realm in the sequence in the order specified in the sequence. If the user is not found, the user is identified as Unknown.
- You can also choose an LDAP realm.

- For additional ways to authenticate the user, check **Use active authentication if passive or VPN identity cannot be established**. For more information, see [Captive Portal Guidelines and Limitations, on page 2564](#).

The following figure shows a sample passive identity policy configured to search for users in the US realm sequence.

The screenshot shows the 'Add Rule' configuration interface. At the top, the rule name is 'Passive rule', it is checked as 'Enabled', and is categorized under 'Standard Rules'. The 'Authentication Protocol' is set to 'HTTP Basic'. Below this, the 'Authentication Realm' is set to 'US (Sequence)'. There is a checkbox labeled 'Use active authentication if passive or VPN identity cannot be established' which is currently unchecked. At the bottom right, there are 'Cancel' and 'Add' buttons, with 'Add' being the primary action.

- Step 11** (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add (+)** to create a new network object.
- Step 12** Set identity rule conditions as discussed in [Identity Rule Conditions, on page 2613](#).
- Step 13** Associate the identity rule with an access control rule as discussed in [Associating Other Policies with Access Control, on page 1844](#).
- Step 14** Deploy configuration changes to managed devices; see [Deploy Configuration Changes, on page 240](#).

## Create a Sample Identity Policy with an Active Authentication Rule

The associated tasks show an examples of configuring an identity policy with an **Active Authentication** rule where authentication is performed using either a realm or a realm sequence.

The differences follow:

- *Realm* enables you to use any supported authentication type (currently, **HTTP Basic**, **NTLM**, **Kerberos**, **HTTP Negotiate**, or **HTTP Response Page**).
- *Realm sequence* limits you to only the **HTTP Basic** or **HTTP Response Page** authentication types.

Users who authenticate with a realm sequence and the HTTP Response Page authentication type see the following by default:

The user can authenticate in any of the following ways:

- If a list of realms in the realm sequence is displayed (as shown), the user must enter their user name and password in the provided fields and click the name of their realm from the list.
- If realms are not displayed in a list, the user can enter their credentials in `username@domain` format.

Users who authenticate with a realm and the HTTP Basic authentication page see the following:

The user must enter their user name in `username@domain` format.

## Procedure

- 
- Step 1** Log in to the management center.
  - Step 2** Click **Policies > Access Control > Identity**.
  - Step 3** Click **New Policy**.
  - Step 4** Enter a **Name** for the policy and an optional **Description**.
  - Step 5** Click **Save**.
  - Step 6** Click the **Active Authentication** tab.
  - Step 7** Enter the following information:
    - **Server Certificate:** From the list, click an internal certificate object to use for secure connection to the Threat Defense device, or click **Add (+)** to add one.

- **Redirect to Host Name:** (Optional.) From the list, click a network object to which to redirect captive portal requests. If you omit this value, requests redirect to the IP address of the managed device. You can click **Add** (+) to create a new network object. For more information, see [Redirect to Host Name Network Rule Conditions, on page 2614](#).

Managed devices must have Snort 3 enabled to use this option.

- **Port:** Enter a port for the captive portal to use. This port must be unique for the captive portal and must match an access control rule you set up as discussed in [Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule, on page 2572](#). (Default is 885.)
- **Maximum login attempts:** Enter the maximum number of login attempts before login fails. (Default is 3.)
- **Active Authentication Response Page:** Choose a system-provided or custom login page for captive portal users. For more information about your options, see [Captive Portal Fields, on page 2577](#).

- Step 8** Click **Save** to save your changes to the identity policy.
- Step 9** Click the **Rules** tab.
- Step 10** Click **Add Rule**.
- Step 11** Enter a **Name** for the rule.
- Step 12** From the list, click **Active Authentication**.
- Step 13** Click the **Realms & Settings** tab page and continue with one of the following sections.

---

### What to do next

Continue with one of the following sections:

- [Active Authentication Using a Realm, on page 2625](#)
- [Active Authentication Using a Realm Sequence, on page 2626](#)

## Active Authentication Using a Realm

This task discusses how to authenticate captive portal users with a realm and any available authentication protocol (currently, **HTTP Basic**, **NTLM**, **Kerberos**, **HTTP Negotiate**, or **HTTP Response Page**).

### Before you begin

Complete the task discussed in [Create a Sample Identity Policy with an Active Authentication Rule, on page 2623](#).

### Procedure

- 
- Step 1** Continue from [Create a Sample Identity Policy with an Active Authentication Rule, on page 2623](#).
  - Step 2** On the **Realms & Settings** tab page, click **US-East**.
  - Step 3** From the **Authentication Protocol** list, click **NTLM**.

The following figure shows an example.

If you choose a realm (such as in the example), the system searches that realm for users to match the rule. If a user is not found, the user is identified as Unknown.

- Step 4** Click **Add**.
- Step 5** (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add (+)** to create a new network object.
- Step 6** Set identity rule conditions as discussed in [Identity Rule Conditions, on page 2613](#).
- Step 7** Associate the identity rule with an access control rule as discussed in [Associating Other Policies with Access Control, on page 1844](#).
- Step 8** Deploy configuration changes to managed devices; see [Deploy Configuration Changes, on page 240](#).

## Active Authentication Using a Realm Sequence

This task discusses how to authenticate captive portal users with a realm sequence, which restricts you to the **HTTP Basic** or **HTTP Response Page** authentication protocols.

### Before you begin

Complete the task discussed in [Create a Sample Identity Policy with an Active Authentication Rule, on page 2623](#).

### Procedure

- Step 1** Continue from [Create a Sample Identity Policy with an Active Authentication Rule, on page 2623](#).
- Step 2** On the **Realms & Settings** tab page, click the name of a realm from the list.
- Step 3** From the list, click **US-East**.
- Step 4** From the **Protocol** list, click **HTTP Response Page**.

The following figure shows an example.

If you choose a realm sequence (such as in the example), the system searches realms in the sequence in the order specified in the realm sequence. The first realm in the sequence can be referred to as the *default* realm; it's the realm that is used if the user does not change it. If a user is not found, the user is identified as Unknown.

(Only if you upgraded to version 7.4.1 from an earlier version.) Edit the HTTP response page so it shows the list of realms in the sequence as discussed in [Update a Custom Authentication Form, on page 2572](#).

- Step 5** Click **Add**.
- Step 6** (Optional.) To filter traffic by network object, click the **Identity Source** tab. From the list, click the network object to use to filter traffic for this identity policy. Click **Add** (+) to create a new network object.
- Step 7** Set identity rule conditions as discussed in [Identity Rule Conditions, on page 2613](#).
- Step 8** Associate the identity rule with an access control rule as discussed in [Associating Other Policies with Access Control, on page 1844](#).
- Step 9** Deploy configuration changes to managed devices; see [Deploy Configuration Changes, on page 240](#).

## Manage an Identity Policy

### Procedure

- Step 1** Log in to the management center.
- Step 2** Click **Policies > Access Control > Identity**.
- Step 3** To delete a policy, click **Delete** (🗑️). If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** To edit a policy, click **Edit** (✎) next to the policy and make changes as described in [Create an Identity Policy, on page 2611](#). If **View** (👁️) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Step 5** To copy a policy, click **Copy** (📄).
- Step 6** To generate a report for the policy, click **Report** (📄) as described in [Generate Current Policy Reports, on page 253](#).
- Step 7** To compare policies, see [Compare Policies, on page 252](#).
- Step 8** To create a folder in which to organize policies, click **Add Category**.

---

**What to do next**

Deploy configuration changes.

## Manage an Identity Rule

### Procedure

- 
- Step 1** Log in to the management center.
- Step 2** Click **Policies > Access Control > Identity** .
- Step 3** Click **Edit** (✎) next to the policy you want to edit. If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** To edit an identity rule, click **Edit** (✎) and make changes as described in [Create an Identity Policy, on page 2611](#).
- Step 5** To delete an identity rule, click **Delete** (🗑).
- Step 6** To create a rule category, click **Add Category** and choose the position and the rule.
- Step 7** Click **Save**.

---

**What to do next**

- Deploy configuration changes.

## Troubleshoot User Control

If you notice unexpected user rule behavior, consider tuning your rule, identity source, or realm configurations. For other related troubleshooting information, see:

- [Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues, on page 2559](#)
- [Troubleshoot the TS Agent Identity Source, on page 2606](#)
- [Troubleshoot the Captive Portal Identity Source, on page 2579](#)
- [Troubleshoot Realms and User Downloads, on page 2498](#)

**Rules targeting realms, users, or user groups are not matching traffic**

If you configure a TS Agent or ISE/ISE-PIC device to monitor a large number of user groups, or if you have a very large number of users mapped to hosts on your network, the system may drop user records due to your management center user limit. As a result, rules with user conditions may not match traffic as expected.

**Rules targeting user groups or users within user groups are not matching traffic as expected**

If you configure a rule with a user group condition, your LDAP or Active Directory server must have user groups configured. The system cannot perform user group control if the server organizes the users in basic object hierarchy.

**Rules targeting users in secondary groups are not matching traffic as expected**

If you configure a rule with a user group condition that includes or excludes users who are members of a secondary group on your Active Directory server, your server may be limiting the number of users it reports.

By default, Active Directory servers limit the number of users they report from secondary groups. You must customize this limit so that all of the users in your secondary groups are reported to the management center and eligible for use in rules with user conditions.

**Rules are not matching users when seen for the first time**

After the system detects activity from a previously-unseen user, the system retrieves information about them from the server. Until the system successfully retrieves this information, activity seen by this user is *not* handled by matching rules. Instead, the user session is handled by the next rule it matches (or the policy's default action, if applicable).

For example, this might explain when:

- Users who are members of user groups are not matching rules with user group conditions.
- Users who were reported by a TS Agent or ISE device are not matching rules, when the server used for user data retrieval is an Active Directory server.

Note that this might also cause the system to delay the display of user data in event views and analysis tools.

**Rules are not matching all ISE/ISE-PIC users**

This is expected behavior. You can perform user control on ISE/ISE-PIC users who were authenticated by an Active Directory domain controller. You cannot perform user control on ISE/ISE-PIC users who were authenticated by an LDAP, RADIUS, or RSA domain controller.

**Users and groups using too much memory**

If processing users and groups is using too much memory, health alerts are displayed. Remember that all user sessions are propagated to all devices managed by the management center. If your management center manages devices with different amounts of memory, the device with the least amount of memory determines the number of user sessions the system can handle without errors.

It's not possible to tune memory allocated to identity processes; even if a device has available memory, it can report out-of-memory issues. If issues persist, you have the following options:

- Segregate lower capacity managed devices on subnets and configure ISE/ISE-PIC to not report passive authentication data to those subnets.

See the chapter on managing network devices in the *Cisco Identity Services Engine Administrator Guide*.

- Unsubscribe from Security Group Tags (SGTs).

For more information, see [Configure ISE for User Control, on page 2547](#).

- Upgrade your managed device to a model with more memory.

## PART **XXI**

# Network Discovery

- [Network Discovery Overview, on page 2633](#)
- [Host Identity Sources, on page 2641](#)
- [Application Detection, on page 2659](#)
- [Network Discovery Policies, on page 2679](#)

## CHAPTER 98

# Network Discovery Overview

---

The following topics discuss network discovery:

- [About Detection of Host, Application, and User Data, on page 2633](#)
- [Host and Application Detection Fundamentals, on page 2634](#)

## About Detection of Host, Application, and User Data

Network discovery policies can only be configured for Secure Firewall Threat Defense devices that send events to a Network Analytics Manager. (The Network Analytics Manager is an on-premises Secure Firewall Management Center that is configured to provide event analytics only.)

The system uses *network discovery* and *identity* policies to collect host, application, and user data for traffic on your network. You can use certain types of discovery and identity data to build a comprehensive map of your network assets, perform forensic analysis, behavioral profiling, access control, and mitigate and respond to the vulnerabilities and exploits to which your organization is susceptible.

### Host and Application Data

Host and application data is collected by host identity sources and application detectors according to the settings in your network discovery policy. Managed devices observe traffic on the network segments you specify.

For more information, see [Host and Application Detection Fundamentals, on page 2634](#).

### User Data

User data is collected by user identity sources according to the settings in your network discovery and identity policies. You can use the data for user awareness and user control.

For more information, see [About User Identity, on page 2423](#).

Logging discovery and identity data allows you to take advantage of many features in the system, including:

- Viewing the network map, which is a detailed representation of your network assets and topology that you can view by grouping hosts and network devices, host attributes, application protocols, or vulnerabilities.
- Performing application and user control; that is, writing access control rules using application, realm, user, user group, and ISE attribute conditions.
- Viewing host profiles, which are complete views of all the information available for your detected hosts.

- Viewing dashboards, which (among other capabilities) can provide you with an at-a-glance view of your network assets and user activity.
- Viewing detailed information on the discovery events and user activity logged by the system.
- Associating hosts and any servers or clients they are running with the exploits to which they are susceptible. This enables you to identify and mitigate vulnerabilities, evaluate the impact that intrusion events have on your network, and tune intrusion rule states so that they provide maximum protection for your network assets
- Alerting you by email, SNMP trap, or syslog when the system generates either an intrusion event with a specific impact flag, or a specific type of discovery event
- Monitoring your organization's compliance with an allow list of allowed operating systems, clients, application protocols, and protocols
- Creating correlation policies with rules that trigger and generate correlation events when the system generates discovery events or detects user activity
- Logging and using NetFlow connections, if applicable.

## Host and Application Detection Fundamentals

You can configure your network discovery policy to perform host and application detection.

For more information, see [Overview: Host Data Collection, on page 2641](#) and [Overview: Application Detection, on page 2659](#).

## Passive Detection of Operating System and Host Data

*Passive detection* is the system's default method of populating the network map by analyzing network traffic (and any exported NetFlow data). Passive detection provides contextual information about your network assets, such as operating systems and running applications.

If traffic from a monitored host does not offer conclusive evidence of the host's operating system, the network map displays the most likely operating system. For example, a NAT device may appear to be running several operating systems because of the hosts "behind" the NAT device. To make this most-likely determination, the system uses a confidence value it assigns to each detected operating system, and the amount of corroborating data among detected operating systems.

---

**Note** The system does not consider reported "unknown" applications and operating systems in its determination.

---

If passive detection inaccurately identifies your network assets, consider the placement of your managed devices. You can also augment the system's passive detection capabilities with custom operating-system fingerprints and custom application detectors. Or, you can use *active detection*, which is not based on traffic analysis, but instead allows you to directly update the network map using scan results or other information sources.

## Active Detection of Operating System and Host Data

*Active detection* adds host information collected by active sources to network maps. For example, you can use the Nmap scanner to actively scan the hosts that you target on your network. Nmap discovers operating systems and applications on hosts.

In addition, the host input feature allows you to actively add *host input data* to network maps. There are two different categories of host input data:

- *user input data*—Data added through the system user interface. You can modify a host's operating system or application identity through this interface.
- *host import input data*—Data imported using a command line utility.

The system retains one identity for each active source. When you run an Nmap scan instance, for example, the results of the previous scan are replaced with the new scan results. However, if you run an Nmap scan and then replace those results with data from a client whose results are imported through the command line, the system retains both the identities from the Nmap results and the identities from the import client. The system then uses the priorities set in the network discovery policy to determine which active identity to use as the current identity.

Note that user input is considered one source, even if it comes from different users. As an example, if UserA sets the operating system through the host profile, and then UserB changes that definition through the host profile, the definition set by UserB is retained, and the definition set by UserA is discarded. In addition, note that user input overrides all other active sources and is used as the current identity if it exists.

## Current Identities for Applications and Operating Systems

The *current identity* for an application or an operating system on a host is the identity that the system finds most likely to be correct.

The system uses the current identity for an operating system or application for the following purposes:

- to assign vulnerabilities to a host
- for impact assessment
- when evaluating correlation rules written against operating system identifications, host profile qualifications, and compliance allow lists
- for display in the Hosts and Servers table views in workflows
- for display in the host profile
- to calculate the operating system and application statistics on the Discovery Statistics page

The system uses source priorities to determine which active identity should be used as the current identity for an application or operating system.

For example, if a user sets the operating system to Windows 2003 Server on a host, Windows 2003 Server is the current identity. Attacks which target Windows 2003 Server vulnerabilities on that host are given a higher impact, and the vulnerabilities listed for that host in the host profile include Windows 2003 Server vulnerabilities.

The database may retain information from several sources for the operating system or for a particular application on a host.

The system treats an operating system or application identity as the current identity when the source for the data has the highest source priority. Possible sources have the following priority order:

1. user
2. scanner and application (set in the network discovery policy)
3. managed devices
4. NetFlow records

A new higher priority application identity will not override a current application identity if it has less detail than the current identity.

In addition, when an identity conflict occurs, the resolution of the conflict depends on settings in the network discovery policy or on your manual resolution.

## Current User Identities

When the system detects multiple logins to the same host by different users, the system assumes that only one user is logged into any given host at a time, and that the current user of a host is the last authoritative user login. If only non-authoritative user logins have been logged into the host, the last non-authoritative user login is considered the current user. If multiple users are logged in through remote sessions, the last user reported by the server is the user reported to the management center.

When the system detects multiple logins to the same host by the same user, the system records the first time that a user logs into a specific host and disregards subsequent logins. If an individual user is the only person who logs into a specific host, the only login that the system records is the original login.

If another user logs into that host, however, the system records the new login. Then, if the original user logs in again, his or her new login is recorded.

## Application and Operating System Identity Conflicts

An *identity conflict* occurs when the system reports a new passive identity that conflicts with the current active identity and previously reported passive identities. For example, the previous passive identity for an operating system is reported as Windows 2000, then an active identity of Windows XP becomes current. Next, the system detects a new passive identity of Ubuntu Linux 8.04.1. The Windows XP and the Ubuntu Linux identities are in conflict.

When an identity conflict exists for the identity of the host's operating system or one of the applications on the host, the system lists both conflicting identities as current and uses both for impact assessment until the conflict is resolved.

A user with Administrator privileges can resolve identity conflicts automatically by choosing to always use the passive identity or always use the active identity. Unless you disable automatic resolution of identity conflicts, identity conflicts are always automatically resolved.

A user with Administrator privileges can also configure the system to generate an event when an identity conflict occurs. That user can then set up a correlation policy with a correlation rule that uses an Nmap scan as a correlation response. When an event occurs, Nmap scans the host to obtain updated host operating system and application data.

## NetFlow Data

NetFlow is a Cisco IOS application that provides statistics on packets flowing through a router. It is available on Cisco networking devices and can also be embedded in Juniper, FreeBSD, and OpenBSD devices.

When NetFlow is enabled on a network device, a database on the device (the NetFlow cache) stores records of the flows that pass through the router. A flow, called a *connection* in the system, is a sequence of packets that represents a session between a source and destination host, using specific ports, protocol, and application protocol. The network device can be configured to export this NetFlow data. In this documentation, network devices configured in this way are called *NetFlow exporters*.

Managed devices can be configured to collect records from NetFlow exporters, generate unidirectional end-of-connection events based on the data in those records, and finally send those events to the management

center to be logged in the connection event database. You can also configure the network discovery policy to add host and application protocol information to the database based on the information in NetFlow connections.

You can use this discovery and connection data to supplement the data gathered directly by your managed devices. This is especially useful if you have NetFlow exporters monitoring networks that your managed devices cannot monitor.

## Requirements for Using NetFlow Data

Before you configure the system to analyze NetFlow data, you must enable the NetFlow feature on the routers or other NetFlow-enabled network devices you plan to use, and configure the devices to broadcast NetFlow data to a destination network where the sensing interface of a managed device is connected.

The system can parse both NetFlow version 5 and NetFlow version 9 records. NetFlow exporters **must** use one of those versions if you want to export the data to the system. In addition, the system requires that specific fields be present in the exported NetFlow templates and records. If your NetFlow exporters are using version 9, which you can customize, you **must** make sure that the exported templates and records contain the following fields, in any order:

- IN\_BYTES (1)
- IN\_PKTS (2)
- PROTOCOL (4)
- TCP\_FLAGS (6)
- L4\_SRC\_PORT (7)
- IPV4\_SRC\_ADDR (8)
- L4\_DST\_PORT (11)
- IPV4\_DST\_ADDR (12)
- LAST\_SWITCHED (21)
- FIRST\_SWITCHED (22)
- IPV6\_SRC\_ADDR (27)
- IPV6\_DST\_ADDR (28)

Because the system uses managed devices to analyze NetFlow data, your deployment must include at least one managed device that can monitor NetFlow exporters. At least one sensing interface on that managed device must be connected to a network where it can collect the exported NetFlow data. Because the sensing interfaces on managed devices do not usually have IP addresses, the system does not support the direct collection of NetFlow records.

Note that the Sampled NetFlow feature available on some network devices collects NetFlow statistics on only a subset of packets that pass through the devices. Although enabling this feature can improve CPU utilization on the network device, it may affect the NetFlow data you are collecting for analysis by the system.

## Differences between NetFlow and Managed Device Data

The traffic represented by NetFlow data is not directly analyzed. Instead, it converts exported NetFlow records into connection logs and host and application protocol data.

As a result, there are several differences between converted NetFlow data and the discovery and connection data gathered directly by your managed devices. You should keep these differences in mind when performing analysis that requires:

- Statistics on the number of detected connections
- Operating system and other host-related information (including vulnerabilities)
- Application data, including client information, web application information, and vendor and version server information
- Knowing which host in a connection is the initiator and which is the responder

### **Network Discovery Policy versus Access Control Policy**

You configure NetFlow data collection, including connection logging, using rules in the network discovery policy. Contrast this with connection logging for connections detected by managed devices, which you configure per access control rule.

### **Types of Connection Events**

Because NetFlow data collection is linked to networks rather than access control rules, you do not have granular control over which NetFlow connections the system logs.

NetFlow data cannot generate Security Intelligence events.

NetFlow-based connection events can be stored in the connection event database only; you cannot send them to the system log or an SNMP trap server.

### **Number of Connection Events Generated Per Monitored Session**

For connections detected directly by managed devices, you can configure the access control rule to log a bidirectional connection event at the beginning or end of a connection, or both.

In contrast, because exported NetFlow records contain unidirectional connection data, the system generates at least two connection events for each NetFlow record it processes. This also means that a summary's connection count is incremented by two for every connection based on NetFlow data, providing an inflated count of the number of connections that are actually occurring on your network.

Because the NetFlow exporter outputs records at a fixed interval even if a connection is still ongoing, long-running sessions can result in multiple exported records, each of which generates a connection event. For example, if the NetFlow exporter exports every five minutes, and a particular connection lasts twelve minutes, the system generates six connection events for that session:

- One pair of events for the first five minutes
- One pair for the second five minutes
- A final pair when the connection is terminated

### **Host and Operating System Data**

Hosts added to the network map from NetFlow data do not have operating system, NetBIOS, or host type (host vs network device) information. You can, however, manually set a host's operating system identity using the host input feature.

### Application Data

For connections detected directly by managed devices, the system can identify application protocols, clients, and web applications by examining the packets in the connection.

When the system processes NetFlow records, the system uses a port correlation in `/etc/sf/services` to extrapolate application protocol identity. However, there is no vendor or version information for those application protocols, nor do connection logs contain information on client or web applications used in the session. You can, however, manually provide this information using the host input feature.

Note that a simple port correlation means that application protocols running on non-standard ports may be unidentified or misidentified. Additionally, if no correlation exists, the system marks the application protocol as `unknown` in connection logs.

### Vulnerability Mappings

The system cannot map vulnerabilities to hosts monitored by NetFlow exporters, unless you use the host input feature to manually set either a host's operating system identity or an application protocol identity. Note that because there is no client information in NetFlow connections, you cannot associate client vulnerabilities with hosts created from NetFlow data.

### Initiator and Responder Information in Connections

For connections detected directly by managed devices, the system can identify which host is the initiator, or source, and which is the responder, or destination. However, NetFlow data does not contain initiator or responder information.

When the System processes NetFlow records, it uses an algorithm to determine this information based on the ports each host is using, and whether those ports are well-known:

- If both or neither port being used is a well-known port, the system considers the host using the lower-number port to be the responder.
- If only one of the hosts is using a well-known port, the system considers that host to be the responder.

For this purpose, a well-known port is any port that is either numbered from 1 to 1023, or that contains application protocol information in `/etc/sf/services` on the managed device.

In addition, for connections detected directly by managed devices, the system records two byte counts in the corresponding connection event:

- The **Initiator Bytes** field records bytes sent.
- The **Responder Bytes** field records bytes received.

Connection events based on unidirectional NetFlow records contain only one byte count, which the system assigns to either **Initiator Bytes** or **Responder Bytes**, depending on the port-based algorithm. The system sets the other field to 0. Note that if you are viewing connection summaries (aggregated connection data) of NetFlow records, both fields may be populated.

### NetFlow-only Connection Event Fields

A small number of fields are present only in connection events generated from NetFlow records.

## CHAPTER 99

# Host Identity Sources

---

The following topics provide information on host identity sources:

- [Overview: Host Data Collection, on page 2641](#)
- [Requirements and Prerequisites for Host Identity Sources, on page 2642](#)
- [Determining Which Host Operating Systems the System Can Detect, on page 2642](#)
- [Identifying Host Operating Systems, on page 2642](#)
- [Custom Fingerprinting, on page 2643](#)
- [Host Input Data, on page 2651](#)

## Overview: Host Data Collection

As the system passively monitors the traffic that travels through your network, it compares specific packet header values and other unique data from network traffic against established definitions (called *fingerprints*) to determine information about the hosts on your network, including:

- the number and types of hosts (including network devices such as bridges, routers, load balancers, and NAT devices)
- basic network topology data, including the number of hops from the discovery point on the network to the hosts
- the operating systems running on the hosts
- applications on the hosts and users associated with these applications

If the system cannot identify a host's operating system, you can create custom client or server fingerprints. The system uses these fingerprints to identify new hosts. You can map fingerprints to systems in the vulnerability database (VDB) to allow the appropriate vulnerability information to be displayed whenever a host is identified using the custom fingerprint.

---

**Note** In addition to collecting host data from monitored network traffic, the system can collect host data from exported NetFlow records, and you can actively add host data using Nmap scans and the host input feature.

---

# Requirements and Prerequisites for Host Identity Sources

## Model Support

Any.

## Supported Domains

Any, with the exception of custom fingerprinting, which is Leaf only.

## User Roles

- Admin
- Discovery Admin, except for third-party data and custom mappings.

# Determining Which Host Operating Systems the System Can Detect

To learn which exact operating systems the system can fingerprint, view the list of available fingerprints that is shown during the process of creating a custom OS fingerprint.

## Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
  - Step 2** Click **Custom Operating Systems**.
  - Step 3** Click **Create Custom Fingerprint**.
  - Step 4** View the lists of options in the drop-down lists in the **OS Vulnerability Mappings** section. These options are the operating systems that the system can fingerprint.
- 

## What to do next

As needed, see [Identifying Host Operating Systems, on page 2642](#).

# Identifying Host Operating Systems

If the system does not correctly identify a host's operating system (for example, it shows in the Host Profile as Unknown or is incorrectly identified), try the strategies below.

## Procedure

---

Try one of the following strategies:

- Check the Network Discovery Identity Conflict Settings.
  - Create a custom fingerprint for the host.
  - Run an Nmap scan against the host.
  - Import data into the network map, using the host input feature.
  - Manually enter operating system information.
- 

## Custom Fingerprinting

The system includes operating system *fingerprints* that the system uses to identify the operating system on each host it detects. However, sometimes the system cannot identify a host operating system or misidentifies it because no fingerprints exist that match the operating system. To correct this problem, you can create a *custom fingerprint*, which provides a pattern of operating system characteristics unique to the unknown or misidentified operating system, to supply the name of the operating system for identification purposes.

If the system cannot match a host's operating system, it cannot identify the vulnerabilities for the host, because the system derives the list of vulnerabilities for each host from its operating system fingerprint. For example, if the system detects a host running Microsoft Windows, the system has a stored Microsoft Windows vulnerability list that it adds to the host profile for that host based on the detected Windows operating system.

As an example, if you have several devices on your network running a new beta version of Microsoft Windows, the system cannot identify that operating system or map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for Microsoft Windows, you may want to create a custom fingerprint for one of the hosts to help identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for Microsoft Windows in the fingerprint to associate that list with each host that matches the fingerprint.

When you create a custom fingerprint, the management center lists the set of vulnerabilities associated with that fingerprint for any hosts running the same operating system. If the custom fingerprint you create does not have any vulnerabilities mappings in it, the system uses the fingerprint to assign the custom operating system information you provide in the fingerprint. When the system sees new traffic from a previously detected host, the system updates the host with the new fingerprint information. The system also uses the new fingerprint to identify any new hosts with that operating system the first time they are detected.

Before creating a custom fingerprint, you should determine why the host is not being identified correctly to decide whether custom fingerprinting is a viable solution.

You can create two types of fingerprints with the system:

- Client fingerprints, which identify operating systems based on the SYN packet that the host sends when it connects to a TCP application running on another host on the network.

- Server fingerprints, which identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application.

---

**Note** If both a client and server fingerprint match the same host, the client fingerprint is used.

---

After creating fingerprints, you must activate them before the system can associate them with hosts.

#### Related Topics

[Creating a Custom Fingerprint for Clients](#), on page 2646

[Creating a Custom Fingerprint for Servers](#), on page 2648

## Managing Fingerprints

After a fingerprint is created and activated, you can edit a fingerprint to make changes or add vulnerability mappings.

### Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
- Step 2** Click **Custom Operating Systems**. If the system is awaiting data to create a fingerprint, it automatically refreshes the page every 10 seconds until the fingerprint is created.
- Step 3** Manage your custom fingerprints:
- **Activate/Deactivate** — Activate or deactivate a fingerprint as described in [Activating and Deactivating Fingerprints](#), on page 2644.
  - **Create** — Create fingerprints as described in [Creating a Custom Fingerprint for Clients](#), on page 2646 and [Creating a Custom Fingerprint for Servers](#), on page 2648.
  - **Edit** — Edit a fingerprint as described in [Editing an Active Fingerprint](#), on page 2645 and [Editing an Inactive Fingerprint](#), on page 2645.
  - **Delete** — Click **Delete** (  ) next to the fingerprint you want to delete, and click **OK** to confirm. You can only delete deactivated fingerprints.
- 

## Activating and Deactivating Fingerprints

You must activate a custom fingerprint before the system can use it to identify hosts. After the new fingerprint is activated, the system uses it to re-identify previously discovered hosts and discover new hosts.

If you want to stop using a fingerprint, you can deactivate it. Deactivating a fingerprint causes a fingerprint to no longer be used, but allows it to remain on the system. When you deactivate a fingerprint, the operating system is marked as unknown for hosts that use the fingerprint. If the hosts are detected again and match a different active fingerprint, they are then identified by that active fingerprint.

Deleting a fingerprint removes it from the system completely. After deactivating a fingerprint, you can delete it.

## Procedure

- 
- Step 1** Choose **Policies** > **Network Discovery**.
  - Step 2** Click **Custom Operating Systems**.
  - Step 3** Click the slider next to the fingerprint you want to activate or deactivate.

**Note** The activate option is only available if the fingerprint you created is valid. If the slider is not available, try creating the fingerprint again.

---

## Editing an Active Fingerprint

If a fingerprint is *active*, you can modify the fingerprint name, description, custom operating system display, and map additional vulnerabilities to it.

You can modify the fingerprint name, description, custom operating system display, and map additional vulnerabilities to it.

## Procedure

- 
- Step 1** Choose **Policies** > **Network Discovery**.
  - Step 2** Click **Custom Operating Systems**
  - Step 3** Click **Edit** (✎) next to the fingerprint you want to edit.
  - Step 4** Modify the fingerprint name, description, and custom OS display, if necessary.
  - Step 5** If you want to delete a vulnerability mapping, click **Delete** next to the mapping in the **Pre-Defined OS Product Maps** section of the page.
  - Step 6** If you want to add additional operating systems for vulnerability mapping, choose the **Product** and, if applicable, **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** and then click **Add OS Definition**.  
  
The vulnerability mapping is added to the **Pre-Defined OS Product Maps** list.
  - Step 7** Click **Save**.
- 

## Editing an Inactive Fingerprint

If a fingerprint is *inactive*, you can modify all elements of the fingerprint and resubmit it to the Secure Firewall Management Center. This includes all properties you specified when creating the fingerprint, such as fingerprint type, target IP addresses and ports, vulnerability mappings, and so on. When you edit an inactive fingerprint and submit it, it is resubmitted to the system and, if it is a client fingerprint, you must resend traffic to the appliance before activating it. Note that you can choose only a single vulnerability mapping for an inactive fingerprint. After you activate the fingerprint, you can map additional operating systems and versions to its vulnerabilities list.

## Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
- Step 2** Click **Custom Operating Systems**.
- Step 3** Click **Edit** (✎) next to the fingerprint you want to edit.
- Step 4** Make changes to the fingerprint as necessary:
- If you are modifying a client fingerprint, see [Creating a Custom Fingerprint for Clients, on page 2646](#).
  - If you are modifying a server fingerprint, see [Creating a Custom Fingerprint for Servers, on page 2648](#).
- Step 5** Click **Save**.
- 

### What to do next

- If you modified a client fingerprint, remember to send traffic from the host to the appliance gathering the fingerprint.

## Creating a Custom Fingerprint for Clients

Client fingerprints identify operating systems based on the SYN packet a host sends when it connects to a TCP application running on another host on the network.

If the management center does not have direct contact with monitored hosts, you can specify a device that is managed by the management center and is closest to the host you intend to fingerprint when specifying client fingerprint properties.

Before you begin the fingerprinting process, obtain the following information about the host you want to fingerprint:

- The number of network hops between the host and the management center or the device you use to obtain the fingerprint. (Cisco strongly recommends that you directly connect the management center or the device to the same subnet that the host is connected to.)
- The network interface (on the management center or the device) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.
- Access to the host in order to generate client traffic.

## Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
- Step 2** Click **Custom Operating Systems**.
- Step 3** Click **Create Custom Fingerprint**.

- Step 4** From the **Device** drop-down list, choose the management center or the device that you want to use to collect the fingerprint.
- Step 5** Enter a **Fingerprint Name**.
- Step 6** Enter a **Fingerprint Description**.
- Step 7** From the **Fingerprint Type** list, choose **Client**.
- Step 8** In the **Target IP Address** field, enter an IP address of the host you want to fingerprint.
- Note that the fingerprint will only be based on traffic to and from the host IP address you specify, not any of the host's other IP addresses (if it has any).
- Step 9** In the **Target Distance** field, enter the number of network hops between the host and the device that you chose earlier to collect the fingerprint.
- Caution** This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.
- Step 10** From the **Interface** list, choose the network interface that is connected to the network segment where the host resides.
- Caution** Cisco recommends that you do **not** use the sensing interface on a managed device for fingerprinting for several reasons. First, fingerprinting does not work if the sensing interface is on a span port. Also, if you use the sensing interface on a device, the device stops monitoring the network for the amount of time it takes to collect the fingerprint. You can, however, use the management interface or any other available network interfaces to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.
- Step 11** If you want to display custom information in the host profile for fingerprinted hosts (or if the host you want to fingerprint does not reside in the **OS Vulnerability Mappings** section), choose **Use Custom OS Display** and provide the values you want to display for the following:
- In the **Vendor String** field, enter the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
  - In the **Product String** field, enter the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
  - In the **Version String** field, enter the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.
- Step 12** In the OS Vulnerability Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping.
- You must specify **Vendor** and **Product** values in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information.
- To map vulnerabilities for all versions of an operating system, specify only the **Vendor** and **Product** values.
- Note** Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

**Example:**

If you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the major version.

**Example:**

To add all versions of the Palm OS, you would choose **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

**Step 13**

Click **Create**.

The status briefly shows *New*, then switches to *Pending*, where it remains until traffic is seen for the fingerprint. Once traffic is seen, it switches to *Ready*.

The Custom Fingerprint status page refreshes every ten seconds until it receives data from the host in question.

**Step 14**

Using the IP address you specified as the target IP address, access the host you are trying to fingerprint and initiate a TCP connection to the appliance.

To create an accurate fingerprint, traffic **must** be seen by the appliance collecting the fingerprint. If you are connected through a switch, traffic to a system other than the appliance may not be seen by the system.

**Example:**

Access the web interface of the management center from the host you want to fingerprint or SSH into the management center from the host. If you are using SSH, use the command below, where `localIPv6address` is the IPv6 address specified in step 7 that is currently assigned to the host and `DCmanagementIPv6address` is the management IPv6 address of the management center. The Custom Fingerprint page should then reload with a “Ready” status.

```
ssh -b localIPv6address DCmanagementIPv6address
```

**What to do next**

- Activate the fingerprint as described in [Activating and Deactivating Fingerprints, on page 2644](#).

## Creating a Custom Fingerprint for Servers

Server fingerprints identify operating systems based on the SYN-ACK packet that the host uses to respond to an incoming connection to a running TCP application. Before you begin, you should obtain the following information about the host you want to fingerprint:

- The number of network hops between the host and the appliance you use to obtain the fingerprint. Cisco strongly recommends that you directly connect an unused interface on the appliance to the same subnet that the host is connected to.
- The network interface (on the appliance) that is connected to the network where the host resides.
- The actual operating system vendor, product, and version of the host.
- An IP address that is not currently in use and is authorized on the network where the host is located.

**Tip** If the management center does not have direct contact with monitored hosts, you can specify a managed device that is closest to the host you intend to fingerprint when specifying server fingerprint properties.

## Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
- Step 2** Click **Custom Operating Systems**.
- Step 3** Click **Create Custom Fingerprint**.
- Step 4** From the **Device** list, choose the management center or the managed device that you want to use to collect the fingerprint.
- Step 5** Enter a **Fingerprint Name**.
- Step 6** Enter a **Fingerprint Description**.
- Step 7** From the **Fingerprint Type** list, choose **Server** to display the server fingerprinting options.
- Step 8** In the **Target IP Address** field, enter an IP address of the host you want to fingerprint.
- Note that the fingerprint will only be based on traffic to and from the host IP address you specify, not any of the host's other IP addresses (if it has any).
- Caution** You can capture IPv6 fingerprints only with appliances running Version 5.2 and later.
- Step 9** In the **Target Distance** field, enter the number of network hops between the host and the device that you chose earlier to collect the fingerprint.
- Caution** This must be the actual number of physical network hops to the host, which may or may not be the same as the number of hops detected by the system.
- Step 10** From the **Interface** list, choose the network interface that is connected to the network segment where the host resides.
- Caution** Cisco recommends that you do **not** use the sensing interface on a managed device for fingerprinting for several reasons. First, fingerprinting does not work if the sensing interface is on a span port. Also, if you use the sensing interface on a device, the device stops monitoring the network for the amount of time it takes to collect the fingerprint. You can, however, use the management interface or any other available network interfaces to perform fingerprint collection. If you do not know which interface is the sensing interface on your device, refer to the *Installation Guide* for the specific model you are using to fingerprint.
- Step 11** Click **Get Active Ports**.
- Step 12** In the **Server Port** field, enter the port that you want the device chose to collect the fingerprint to initiate contact with, or choose a port from the **Get Active Ports** drop-down list.
- You can use any server port that you know is open on the host (for instance, 80 if the host is running a web server).
- Step 13** In the **Source IP Address** field, enter an IP address that should be used to attempt to communicate with the host.
- You should use a source IP address that is authorized for use on the network but is not currently being used, for example, a DHCP pool address that is currently not in use. This prevents you from temporarily knocking another host offline while you create the fingerprint.

You should exclude that IP address from monitoring in your network discovery policy while you create the fingerprint. Otherwise, the network map and discovery event views will be cluttered with inaccurate information about the host represented by that IP address.

- Step 14** In the **Source Subnet Mask** field, enter the subnet mask for the IP address you are using.
- Step 15** If the **Source Gateway** field appears, enter the default gateway IP address that should be used to establish a route to the host.
- Step 16** If you want to display custom information in the host profile for fingerprinted hosts or if the fingerprint name you want to use does not exist in the OS Definition section, choose **Use Custom OS Display** in the Custom OS Display section.

Provide the values you want to appear in host profiles for the following:

- In the **Vendor String** field, enter the operating system's vendor name. For example, the vendor for Microsoft Windows would be Microsoft.
- In the **Product String** field, enter the operating system's product name. For example, the product name for Microsoft Windows 2000 would be Windows.
- In the **Version String** field, enter the operating system's version number. For example, the version number for Microsoft Windows 2000 would be 2000.

- Step 17** In the OS Vulnerability Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping.

You must specify a Vendor and Product name in this section if you want to use the fingerprint to identify vulnerabilities for matching hosts or if you do not assign custom operating system display information.

To map vulnerabilities for all versions of an operating system, specify only the vendor and product name.

**Note** Not all options in the **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** drop-down lists may apply to the operating system you choose. In addition, if no definition appears in a list that matches the operating system you want to fingerprint, you can leave these values empty. Be aware that if you do not create any OS vulnerability mappings in a fingerprint, the system cannot use the fingerprint to assign a vulnerabilities list with hosts identified by the fingerprint.

**Example:**

If you want your custom fingerprint to assign the list of vulnerabilities from Redhat Linux 9 to matching hosts, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

**Example:**

To add all versions of the Palm OS, you would choose **PalmSource, Inc.** from the **Vendor** list, **Palm OS** from the **Product** list, and leave all other lists at their default settings.

- Step 18** Click **Create**.  
The Custom Fingerprint status page refreshes every ten seconds and should reload with a "Ready" status.

**Note** If the target system stops responding during the fingerprinting process, the status shows an `ERROR: No Response` message. If you see this message, submit the fingerprint again. Wait three to five minutes (the time period may vary depending on the target system), click **Edit** (✎) to access the Custom Fingerprint page, and then click **Create**.

### What to do next

- Activate the fingerprint as described in [Activating and Deactivating Fingerprints, on page 2644](#).

## Host Input Data

You can augment the network map by importing network map data from third parties. You can also use the host input feature by modifying operating system or application identities or deleting application protocols, protocols, host attributes, or clients using the web interface.

The system may reconcile data from multiple sources to determine the current identity of an operating system or application.

All data except third-party vulnerabilities is discarded when the affected host is removed from the network map. For more information on setting up scripts or import files, see the *Firepower System Host Input API Guide*.

To include imported data in impact correlations, you must map the data to the operating system and application definitions in the database.

## Requirements for Using Third-Party Data

You can import discovery data from third-party systems on your network. However, to enable features where intrusion and discovery data are used together, such as Cisco recommendations, adaptive profile updates, or impact assessment, you should map as many elements of it as possible to corresponding definitions. Consider the following requirements for using third-party data:

- If you have a third-party system that has specific data on your network assets, you can import that data using the host input feature. However, because third parties may name the products differently, you must map the third-party vendor, product, and versions to the corresponding Cisco product definition. After you map the products, you must enable vulnerability mappings for impact assessment in the management center configuration to allow impact correlation. For versionless or vendorless application protocols, you need to map vulnerabilities for the application protocols in the management center configuration.
- If you import patch information from a third party and you want to mark all vulnerabilities fixed by that patch as invalid, you must map the third-party fix name to a fix definition in the database. All vulnerabilities addressed by the fix will then be removed from hosts where you add that fix.
- If you import operating system and application protocol vulnerabilities from a third party and you want to use them for impact correlation, you must map the third-party vulnerability identification string to vulnerabilities in the database. Note that although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot import and map third-party client vulnerabilities. After the vulnerabilities are mapped, you must enable third-party vulnerability mappings for impact assessment in the management center configuration. To cause application protocols without vendor or version information to map to vulnerabilities, an administrative user must also map vulnerabilities for the applications in the management center configuration.
- If you import application data and you want to use that data for impact correlation, you must map the vendor string for each application protocol to the corresponding Cisco application protocol definition.

### Related Topics

[Mapping Third-Party Products, on page 2652](#)

[Mapping Third-Party Product Fixes](#), on page 2653

[Mapping Third-Party Vulnerabilities](#), on page 2654

[Creating Custom Product Mappings](#), on page 2655

## Third-Party Product Mappings

When you add data from third parties to the network map through the user input feature, you must map the vendor, product, and version names used by the third party to the Cisco product definitions. Mapping the products to Cisco definitions assigns vulnerabilities based on those definitions.

Similarly, if you are importing patch information from a third party, such as a patch management product, you must map the name for the fix to the appropriate vendor and product and the corresponding fix in the database.

### Mapping Third-Party Products

If you import data from a third party, you must map the Cisco product to the third-party name to assign vulnerabilities and perform impact correlation using that data. Mapping the product associates Cisco vulnerability information with the third-party product name, which allows the system to perform impact correlation using that data.

If you import data using the host input import feature, you can also use the AddScanResult function to map third-party products to operating system and application vulnerabilities during the import.

For example, if you import data from a third party that lists Apache Tomcat as an application and you know it is version 6 of that product, you could add a third-party map where:

- **Vendor Name** is set to `Apache`.
- **Product Name** is set to `Tomcat`.
- **Apache** is chosen from the **Vendor** drop-down list.
- **Tomcat** is chosen from the **Product** drop-down list.
- **6** is chosen from the **Version** drop-down list

This mapping would cause any vulnerabilities for Apache Tomcat 6 to be assigned to hosts with an application listing for Apache Tomcat.

Note that for versionless or vendorless applications, you must map vulnerabilities for the application types in the Secure Firewall Management Center configuration. Although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot import and map third-party client vulnerabilities.

---

**Tip** If you have already created a third-party mapping on another Secure Firewall Management Center, you can export it and then import it onto this management center. You can then edit the imported mapping to suit your needs.

---

### Procedure

---

**Step 1** Choose **Policies > Application Detectors**.

- Step 2** Click **User Third-Party Mappings**.
- Step 3** You have two choices:
- Create — To create a new map set, click **Create Product Map Set**.
  - Edit — To edit an existing map set, click **Edit** (✎) next to the map set you want to modify. If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Enter a **Mapping Set Name**.
- Step 5** Enter a **Description**.
- Step 6** You have two choices:
- Create — To map a third-party product, click **Add Product Map**.
  - Edit — To edit an existing third-party product map, **Edit** (✎) next to the map set you want to modify. If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 7** Enter the **Vendor String** used by the third-party product.
- Step 8** Enter the **Product String** used by the third-party product.
- Step 9** Enter the **Version String** used by the third-party product.
- Step 10** In the Product Mappings section, choose the operating system, product, and versions you want to use for vulnerability mapping from the **Vendor**, **Product**, **Major Version**, **Minor Version**, **Revision Version**, **Build**, **Patch**, and **Extension** fields.
- Example:**
- If you want a host running a product whose name consists of third-party strings to use the vulnerabilities from Red Hat Linux 9, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.
- Step 11** Click **Save**.

---

## Mapping Third-Party Product Fixes

If you map a fix name to a particular set of fixes in the database, you can then import data from a third-party patch management application and apply the fix to a set of hosts. When the fix name is imported to a host, the system marks all vulnerabilities addressed by the fix as invalid for that host.

### Procedure

---

- Step 1** Choose **Policies > Application Detectors**.
- Step 2** Click **User Third-Party Mappings**.
- Step 3** You have two choices:
- Create — To create a new map set, click **Create Product Map Set**.
  - Edit — To edit an existing map set, click **Edit** (✎) next to the map set you want to modify. If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Enter a **Mapping Set Name**.

**Step 5** Enter a **Description**.

**Step 6** You have two choices:

- **Create** — To map a third-party product, click **Add Fix Map**.
- **Edit** — To edit an existing third-party product map, click **Edit** (✎) next to it. If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 7** Enter the name of the fix you want to map in the **Third-Party Fix Name** field.

**Step 8** In the **Product Mappings** section, choose the operating system, product, and versions you want to use for fix mapping from the following fields:

- **Vendor**
- **Product**
- **Major Version**
- **Minor Version**
- **Revision Version**
- **Build**
- **Patch**
- **Extension**

**Example:**

If you want your mapping to assign the fixes from Red Hat Linux 9 to hosts where the patch is applied, choose **Redhat, Inc.** as the vendor, **Redhat Linux** as the product, and **9** as the version.

**Step 9** Click **Save** to save the fix map.

## Mapping Third-Party Vulnerabilities

To add vulnerability information from a third party to the VDB, you must map the third-party identification string for each imported vulnerability to any existing SVID, Bugtraq, or SID. After you create a mapping for the vulnerability, the mapping works for all vulnerabilities imported to hosts in the network map and allows impact correlation for those vulnerabilities.

You must enable impact correlation for third-party vulnerabilities to allow correlation to occur. For versionless or vendorless applications, you must also map vulnerabilities for the application types in the Secure Firewall Management Center configuration.

Although many clients have associated vulnerabilities, and clients are used for impact assessment, you cannot use third-party client vulnerabilities for impact assessment.

**Tip** If you have already created a third-party mapping on another Secure Firewall Management Center, you can export it and then import it onto this management center. You can then edit the imported mapping to suit your needs.

## Procedure

- 
- Step 1** Choose **Policies > Application Detectors**.
- Step 2** Click **User Third-Party Mappings**.
- Step 3** You have two choices:
- Create — To create a new vulnerability set, click **Create Vulnerability Map Set**.
  - Edit — To edit an existing vulnerability set, click **Edit** (✎) next to the vulnerability set. If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Add Vulnerability Map**.
- Step 5** Enter the third-party identification for the vulnerability in the **Vulnerability ID** field.
- Step 6** Enter a **Vulnerability Description**.
- Step 7** Optionally:
- Enter a Snort ID in the **Snort Vulnerability ID Mappings** field.
  - Enter a legacy vulnerability ID in the **SVID Mappings** field.
  - Enter a Bugtraq identification number in the **Bugtraq Vulnerability ID Mappings** field.
- Step 8** Click **Add**.

---

### Related Topics

[Enabling Network Discovery Vulnerability Impact Assessment](#), on page 2693

## Custom Product Mappings

You can use product mappings to ensure that servers input by a third party are associated with the appropriate Cisco definitions. After you define and activate the product mapping, all servers or clients on monitored hosts that have the mapped vendor strings use the custom product mappings. For this reason, you may want to map vulnerabilities for all servers in the network map with a particular vendor string instead of explicitly setting the vendor, product, and version for the server.

### Creating Custom Product Mappings

If the system cannot map a server to a vendor and product in the VDB, you can manually create the mapping. When you activate a custom product mapping, the system maps vulnerabilities for the specified vendor and product to all servers in the network map where that vendor string occurs.

---

**Note** Custom product mappings apply to all occurrences of an application protocol, regardless of the source of the application data (such as Nmap, the host input feature, or the system itself). However, if third-party vulnerability mappings for data imported using the host input feature conflicts with the mappings you set through a custom product mapping, the third-party vulnerability mapping overrides the custom product mapping and uses the third-party vulnerability mapping settings when the input occurs.

---

You create lists of product mappings and then enable or disable use of several mappings at once by activating or deactivating each list. When you specify a vendor to map to, the system updates the list of products to include only those made by that vendor.

After you create a custom product mapping, you must activate the custom product mapping list. After you activate a list of custom product mappings, the system updates all servers with occurrences of the specified vendor strings. For data imported through the host input feature, vulnerabilities update unless you have already explicitly set the product mappings for this server.

If, for example, your company modifies the banner for your Apache Tomcat web servers to read `Internal Web Server`, you can map the vendor string `Internal Web Server` to the vendor **Apache** and the product **Tomcat**, then activate the list containing that mapping, all hosts where a server labeled `Internal Web Server` occurs have the vulnerabilities for Apache Tomcat in the database.

---

**Tip** You can use this feature to map vulnerabilities to local intrusion rules by mapping the SID for the rule to another vulnerability.

---

## Procedure

- 
- Step 1** Choose **Policies > Application Detectors**.
  - Step 2** Click **Custom Product Mappings**
  - Step 3** Click **Create Custom Product Mapping List**.
  - Step 4** Enter a **Custom Product Mapping List Name**.
  - Step 5** Click **Add Vendor String**.
  - Step 6** In the **Vendor String** field, enter the vendor string that identifies the applications that should map to the chosen vendor and product values.
  - Step 7** Choose the vendor you want to map to from the **Vendor** drop-down list.
  - Step 8** Choose the product you want to map to from the **Product** drop-down list.
  - Step 9** Click **Add** to add the mapped vendor string to the list.
  - Step 10** Optionally, repeat steps 4 to 8 as needed to add additional vendor string mappings to the list.
  - Step 11** Click **Save**.
- 

### What to do next

- Activate the custom product mapping list. For more information, see [Activating and Deactivating Custom Product Mappings, on page 2657](#).

## Editing Custom Product Mapping Lists

You can modify existing custom product mapping lists by adding or removing vendor strings or changing the list name.

## Procedure

- 
- Step 1** Choose **Policies > Application Detectors**.
- Step 2** Click **Custom Product Mappings**.
- Step 3** Click **Edit** (✎) next to the product mapping list you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Make changes to the list as described in [Creating Custom Product Mappings, on page 2655](#).
- Step 5** When you finish, click **Save**.
- 

## Activating and Deactivating Custom Product Mappings

You can enable or disable use of an entire list of custom product mappings at once. After you activate a custom product mapping list, each mapping on that list applies to all applications with the specified vendor string, whether detected by managed devices or imported through the host input feature.

## Procedure

- 
- Step 1** Choose **Policies > Application Detectors**.
- Step 2** Click **Custom Product Mappings**.
- Step 3** Click the slider next to the custom product mapping list to activate or deactivate it.
- If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
-

## CHAPTER 100

# Application Detection

---

The following topics describe application detection:

- [Overview: Application Detection, on page 2659](#)
- [Requirements and Prerequisites for Application Detection, on page 2665](#)
- [Custom Application Detectors, on page 2665](#)
- [Viewing or Downloading Detector Details, on page 2674](#)
- [Sorting the Detector List, on page 2674](#)
- [Filtering the Detector List, on page 2675](#)
- [Navigating to Other Detector Pages, on page 2676](#)
- [Activating and Deactivating Detectors, on page 2677](#)
- [Editing Custom Application Detectors, on page 2677](#)
- [Deleting Detectors, on page 2678](#)

## Overview: Application Detection

When the system analyzes IP traffic, it attempts to identify the commonly used applications on your network. Application awareness is crucial to application control.

There are three types of applications that the system detects:

- *application protocols* such as HTTP and SSH, which represent communications between hosts
- *clients* such as web browsers and email clients, which represent software running on the host
- *web applications* such as MPEG video and Facebook, which represent the content or requested URL for HTTP traffic

The system identifies applications in your network traffic according to the characteristics specified in the detector. For example, the system can identify an application by an ASCII pattern in the packet header. In addition, Secure Socket Layers (SSL) protocol detectors use information from the secured session to identify the application from the session.

There are two sources of application detectors:

- *System-provided detectors* detect web applications, clients, and application protocols.

The availability of system-provided detectors for applications (and operating systems) depends on the version of the system software and the version of the VDB you have installed. Release notes and advisories

contain information on new and updated detectors. You can also import individual detectors authored by Professional Services.

- *Custom application protocol detectors* are user-created and detect web applications, clients, and application protocols.

You can also detect application protocols through *implied application protocol detection*, which infers the existence of an application protocol based on the detection of a client.

The system identifies only those application protocols running on hosts in your monitored networks, as defined in the network discovery policy. For example, if an internal host accesses an FTP server on a remote site that you are not monitoring, the system does not identify the application protocol as FTP. On the other hand, if a remote or internal host accesses an FTP server on a host you are monitoring, the system can positively identify the application protocol.

If the system can identify the client used by a monitored host to connect to a non-monitored server, the system identifies the client's corresponding application protocol, but does not add the protocol to the network map. Note that client sessions must include a response from the server for application detection to occur.

The system characterizes each application that it detects; see [Application Characteristics, on page 1821](#). The system uses these characteristics to create groups of applications, called *application filters*. Application filters are used to perform access control and to constrain search results and data used in reports and dashboard widgets.

You can also supplement application detector data using exported NetFlow records, Nmap active scans, and the host input feature.

#### Related Topics

[Best Practices for Configuring Application Control](#), on page 1820

[Application Detector Fundamentals](#), on page 2660

## Application Detector Fundamentals

The system uses *application detectors* to identify the commonly used applications on your network. Use the Detectors page (**Policies > Application Detectors**) to view the detector list and customize detection capability.

Whether you can modify a detector or change its state (active or inactive) depends on its type. The system uses only active detectors to analyze application traffic.

---

**Note** Cisco-provided detectors may change with system and VDB updates. See the release notes and advisories for information on updated detectors.

---

---

**Note** For Firepower application identification, the ports are not listed intentionally. The application's associate ports are not reported for any of Cisco's applications because most of the applications are port-agnostic. Our platform's detection capabilities can identify services running at any port in the network.

---

### Cisco-Provided Internal Detectors

*Internal detectors* are a special category of detectors for client, web application, and application protocol traffic. Internal detectors are delivered with system updates and are always on.

If an application matches against internal detectors designed to detect client-related activity and no specific client detector exists, a generic client may be reported.

### Cisco-Provided Client Detectors

*Client detectors* detect client traffic and are delivered via VDB or system update, or are provided for import by Cisco Professional Services. You can activate and deactivate client detectors. You can export a client detector only if you import it.

### Cisco-Provided Web Application Detectors

*Web application detectors* detect web applications in HTTP traffic payloads and are delivered via VDB or system update. Web application detectors are always on.

### Cisco-Provided Application Protocol (Port) Detectors

*Port-based application protocol detectors* use well-known ports to identify network traffic. They are delivered via VDB or system update, or are provided for import by Cisco Professional Services. You can activate and deactivate application protocol detectors, and view a detector definition to use it as the basis for a custom detector.

### Cisco-Provided Application Protocol (Firepower) Detectors

*Firepower-based application protocol detectors* analyze network traffic using Firepower application fingerprints and are delivered via VDB or system update. You can activate and deactivate application protocol detectors.

### Custom Application Detectors

*Custom application detectors* are pattern-based. They detect patterns in packets from client, web application, or application protocol traffic. You have full control over imported and custom detectors.

## Identification of Application Protocols in the Web Interface

The following table outlines how the system identifies detected application protocols:

**Table 228: System Identification of Application Protocols**

Identification	Description
application protocol name	<p>The management center identifies an application protocol with its name if the application protocol was:</p> <ul style="list-style-type: none"> <li>positively identified by the system</li> <li>identified using NetFlow data and there is a port-application protocol correlation in <code>/etc/sf/services</code></li> <li>manually identified using the host input feature</li> <li>identified by Nmap or another active source</li> </ul>

Identification	Description
pending	<p>The management center identifies an application protocol as <code>pending</code> if the system can neither positively nor negatively identify the application.</p> <p>Most often, the system needs to collect and analyze more connection data before it can identify a pending application.</p> <p>In the Application Details and Servers tables and in the host profile, the <code>pending</code> status appears only for application protocols where specific application protocol traffic was detected (rather than inferred from detected client or web application traffic).</p>
unknown	<p>The management center identifies an application protocol as <code>unknown</code> if:</p> <ul style="list-style-type: none"> <li>• the application does not match any of the system's detectors.</li> <li>• the application protocol was identified using NetFlow data, but there is no port-application protocol correlation in <code>/etc/sf/services</code>.</li> <li>• Snort has closed the session but it still persists in the device. Here, the traffic is allowed to pass through the firewall, but the application is not detected.</li> </ul>
blank	<p>All available detected data has been examined, but no application protocol was identified. In the Application Details and Servers tables and in the host profile, the application protocol is left blank for non-HTTP generic client traffic with no detected application protocol.</p>

## Implied Application Protocol Detection from Client Detection

If the system can identify the client used by a monitored host to access a non-monitored server, the management center infers that the connection is using the application protocol that corresponds with the client. (Because the system tracks applications only on monitored networks, connection logs usually do not include application protocol information for connections where a monitored host is accessing a non-monitored server.)

This process, or *implied application protocol detection*, has the following consequences:

- Because the system does not generate a New TCP Port or New UDP Port event for these servers, the server does not appear in the Servers table. In addition, you cannot trigger either discovery event alerts or correlation rules using the detection of these application protocol as a criterion.
- Because the application protocol is not associated with a host, you cannot view its details in host profiles, set its server identity, or use its information in host profile qualifications for traffic profiles or correlation rules. In addition, the system does not associate vulnerabilities with hosts based on this type of detection.

You can, however, trigger correlation events on whether the application protocol information is present in a connection. You can also use the application protocol information in connection logs to create connection trackers and traffic profiles.

## Host Limits and Discovery Event Logging

When the system detects a client, server, or web application, it generates a discovery event unless the associated host has already reached its maximum number of clients, servers, or web applications.

Host profiles display up to 16 clients, 100 servers, and 100 web applications per host.

Note that actions dependent on the detection of clients, servers, or web applications are unaffected by this limit. For example, access control rules configured to trigger on a server will still log connection events.

## Special Considerations for Application Detection

### SFTP

In order to detect SFTP traffic, the same rule must also detect SSH.

### Squid

The system positively identifies Squid server traffic when either:

- the system detects a connection from a host on your monitored network to a Squid server where proxy authentication is enabled, or
- the system detects a connection from a Squid proxy server on your monitored network to a target system (that is, the destination server where the client is requesting information or another resource).

However, the system cannot identify Squid service traffic if:

- a host on your monitored network connects to a Squid server where proxy authentication is disabled, or
- the Squid proxy server is configured to strip `Via:` header fields from its HTTP responses

### SSL Application Detection

The system provides application detectors that can use session information from a Secure Socket Layers (SSL) session to identify the application protocol, client application, or web application in the session.

When the system detects an encrypted connection, it marks that connection as either a generic HTTPS connection or as a more specific secure protocol, such as SMTPS, when applicable. When the system detects an SSL session, it adds `SSL client` to the **Client** field in connection events for the session. If it identifies a web application for the session, the system generates discovery events for the traffic.

For SSL application traffic, managed devices can also detect the common name from the server certificate and match that against a client or web application from an SSL host pattern. When the system identifies a specific client, it replaces `SSL client` with the name of the client.

Because the SSL application traffic is encrypted, the system can use only information in the certificate for identification, not application data within the encrypted stream. For this reason, SSL host patterns can sometimes only identify the company that authored the application, so SSL applications produced by the same company may have the same identification.

In some instances, such as when an HTTPS session is launched from within an HTTP session, managed devices detect the server name from the client certificate in a client-side packet.

To enable SSL application identification, you must create access control rules that monitor responder traffic. Those rules must have either an application condition for the SSL application or URL conditions using the URL from the SSL certificate. For network discovery, the responder IP address does not have to be in the networks to monitor in the network discovery policy; the access control policy configuration determines whether the traffic is identified. To identify detections for SSL applications, you can filter by the `SSL protocol` tag, in the application detectors list or when adding application conditions in access control rules.

### Referred Web Applications

Web servers sometimes refer traffic to other websites, which are often advertisement servers. To help you better understand the context for referred traffic occurring on your network, the system lists the web application that referred the traffic in the **Web Application** field in events for the referred session. The VDB contains a list of known referred sites. When the system detects traffic from one of those sites, the referring site is stored with the event for that traffic. For example, if an advertisement accessed via Facebook is actually hosted on Advertising.com, the detected Advertising.com traffic is associated with the Facebook web application. The system can also detect referring URLs in HTTP traffic, such as when a website provides a simple link to another site; in this case, the referring URL appears in the HTTP Referrer event field.

In events, if a referring application exists, it is listed as the web application for the traffic, while the URL is that for the referred site. In the example above, the web application for the connection event for that traffic would be Facebook, but the URL would be Advertising.com. A referred application may appear as the web application if no referring web application is detected, if the host refers to itself, or if there is a chain of referrals. In the dashboard, connection and byte counts for web applications include sessions where the web application is associated with traffic referred by that application.

Note that if you create a rule to act specifically on referred traffic, you should add a condition for the referred application, rather than the referring application. To block Advertising.com traffic referred from Facebook, for example, add an application condition to your access control rule for the Advertising.com application.

## Application Detection in Snort 2 and Snort 3

In Snort 2, you can enable or disable application detection through the constraints in the access control policies and through network filters in the network discovery policies. However, the constraints in access control policy can override the network filters and enable application detection. For example, if you have defined network filters in network discovery policy and when the access control policy has constraints such as SSL, URL SI, DNS SI, and so on, that requires application detection, then these network discovery filters are overridden and all networks are monitored for application detection. This Snort 2 functionality is not supported in Snort 3.

---

**Note** Snort 3 is now at parity with Snort 2, with respect to enabling AppID inspection exclusively on particular network subnets that are defined in the Network Discovery policy filters **if** no other configuration in the AC policy requires AppID to monitor all traffic.

---

In Snort 3, application detection is always enabled for all networks by default. To disable application detection, do the following:

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, click edit policy and delete the application rules.
  - Step 2** Choose **Policies > SSL**, click delete to delete the SSL policy.
  - Step 3** Choose **Policies > Network Discovery**, click delete to delete the network discovery policy.
  - Step 4** Choose **Policies > Access Control**, click **Edit** (✎) to the policy you want to edit and then click the **Security Intelligence > URLs** tab to delete the URLs Allow or Block list.
  - Step 5** As you cannot delete default DNS rules, choose **Policies > DNS**, click edit and uncheck the enabled box to disable the DNS policy.

- Step 6** In the access control policy, under the **Advanced** settings, disable the *Enable Threat Intelligence Director* and *Enable reputation enforcement on DNS traffic* options.
- Step 7** Save and deploy the access control policy.
-

## Custom Application Detectors

If you use a custom application on your network, you can create a custom web application, client, or application protocol detector that provides the system with the information it needs to identify the application. The type of application detector is determined by your selections in the **Protocol**, **Type**, and **Direction** fields.

Client sessions must include a responder packet from the server for the system to begin detecting and identifying application protocols in server traffic. Note that, for UDP traffic, the system designates the source of the responder packet as the server.

If you have already created a detector on another management center, you can export it and then import it onto this management center. You can then edit the imported detector to suit your needs. You can export and import custom detectors as well as detectors provided by Cisco Professional Services. However, you **cannot** export or import any other type of Cisco-provided detectors.

## Custom Application Detector and User-Defined Application Fields

You can use the following fields to configure custom application detectors and user-defined applications.

### Custom Application Detector Fields: General

Use the following fields to configure basic and advanced custom application detectors.

#### Application Protocol

The application protocol you want to detect. This can be a system-provided application or a user-defined application.

If you want the application to be available for exemption from active authentication (configured in your identity rules), you must select or create an application protocol with the **User-Agent Exclusion** tag.

### Description

A description for the application detector.

### Name

A name for the application detector.

### Detector Type

The type of detector, **Basic** or **Advanced**. Basic application detectors are created in the web interface as a series of fields. Advanced application detectors are created externally and uploaded as custom .lua files.

### Custom Application Detector Fields: Detection Patterns

Use the following fields to configure the detection patterns for basic custom application detectors.

#### Direction

The source of the traffic the detector should inspect, **Client** or **Server**.

#### Offset

The location in a packet, in bytes from the beginning of the packet payload, where the system should begin searching for the pattern.

Because packet payloads start at byte 0, calculate the offset by subtracting 1 from the number of bytes you want to move forward from the beginning of the packet payload. For example, to look for the pattern in the fifth bit of the packet, type 4 in the **Offset** field.

#### Pattern

The pattern string associated with the **Type** you selected.

#### Ports

The port of the traffic the detector should inspect.

#### Protocol

The protocol you want to detect. Your protocol selection determines whether the **Type** or the **URL** field displays.

The protocol (and, in some cases, your subsequent selections in the **Type** and **Direction** fields) determine the type of application detector you create: web application, client, or application protocol.

Detector Type	Protocol	Type or Direction
Web Application	HTTP	<b>Type</b> is <b>Content Type</b> or <b>URL</b>
	RTMP	Any
	SSL	Any

Detector Type	Protocol	Type or Direction
Client	HTTP	Type is <b>User Agent</b>
	SIP	Any
	TCP or UDP	<b>Direction is Client</b>
Application Protocol	TCP or UDP	<b>Direction is Server</b>

### Type

The type of pattern string you entered. The options you see are determined by the **Protocol** you selected. If you selected **RTMP** as the protocol, the **URL** field displays instead of the **Type** field.

**Note** If you select **User Agent** as the **Type**, the system automatically sets the **Tag** for the application to **User-Agent Exclusion**.

Type Selection	String Characteristics
<b>Ascii</b>	The string is ASCII encoded.
<b>Common Name</b>	The string is the value in the commonName field within the server response message.
<b>Content Type</b>	The string is the value in the content-type field within the server response header.
<b>Hex</b>	The string is in hexadecimal notation.
<b>Organizational Unit</b>	The string is the value in the organizationName field within the server response message.
<b>SIP Server</b>	The string is the value in the From field within the message header.
<b>SSL Host</b>	The string is the value in the server_name field within the ClientHello message.
<b>URL</b>	The string is a URL.  <b>Note</b> The detector assumes that the string you enter is a complete section of the URL. For example, entering <b>cisco.com</b> would match <b>www.cisco.com/support</b> and <b>www.cisco.com</b> , but not <b>www.wearecisco.com</b> .
<b>User Agent</b>	The string is the value in the user-agent field within the GET request header. It is also available for the SIP protocol and indicates that the string is the value in the User-Agent field within the SIP message header.

## URL

Either a full URL or a section of a URL from the swfURL field within the C2 message of a RTMP packet. This field displays instead of the **Type** field when you select **RTMP** as the **Protocol**.

---

**Note** The detector assumes that the string you enter is a complete section of the URL. For example, entering **cisco.com** would match **www.cisco.com/support** and **www.cisco.com**, but not **www.wearecisco.com**.

---

## User-Defined Application Fields

Use the following fields to configure user-defined applications within basic and advanced custom application detectors.

### Business Relevance

The likelihood that the application is used within the context of your organization's business operations, as opposed to recreationally: **Very High**, **High**, **Medium**, **Low**, or **Very Low**. Select the option that best describes the application.

### Categories

A general classification for the application that describes its most essential function.

### Description

A description for the application.

### Name

A name for the application.

### Risk

The likelihood that the application is used for purposes that might be against your organization's security policy: **Very High**, **High**, **Medium**, **Low**, or **Very Low**. Select the option that best describes the application.

### Tags

One or more predefined tags that provide additional information about the application. If you want an application to be available for exemption from active authentication (configured in your identity rules), you must add the **User-Agent Exclusion** tag to your application.

# Configuring Custom Application Detectors

You can configure basic or advanced custom application detectors.

## Procedure

---

- Step 1** Select **Policies > Application Detectors**.
- Step 2** Click **Create Custom Detector**.
- Step 3** Enter a **Name** and a **Description**.

- Step 4** Choose an **Application Protocol** from the application drop-down list. You have the following options:
- If you are creating a detector for an existing application protocol (for example, if you want to detect a particular application protocol on a non-standard port), select the application protocol from the drop-down list.
  - If you are creating a detector for a user-defined application, follow the procedure outlined in [Creating a User-Defined Application, on page 2669](#).
- Step 5** Click **Detector Type** as **Basic** or **Advanced**.
- Step 6** Click **OK**.
- Step 7** Configure **Detection Patterns** or **Detection Criteria** or **Encrypted Visibility Engine Process Assignments**:
- If you are configuring a basic detector, specify preset **Detection Patterns** as described in [Specifying Detection Patterns in Basic Detectors, on page 2670](#).
  - If you are configuring an advanced detector, specify custom **Detection Criteria** as described in [Specifying Detection Criteria in Advanced Detectors, on page 2671](#).
  - If you are configuring an encrypted visibility engine (EVE) detector, specify custom EVE process assignments as described in *Specifying EVE Process Assignments* section in this chapter.
- Caution** Advanced custom detectors are complex and require outside knowledge to construct valid .lua files. Incorrectly configured detectors could have a negative impact on performance or detection capability.
- Step 8** Optionally, use **Packet Captures** to test the new detector as described in [Testing a Custom Application Protocol Detector, on page 2673](#).
- Step 9** Click **Save**.
- Note** If you include the application in an access control rule, the detector is automatically activated and cannot be deactivated while in use.

---

**What to do next**

- Activate the detector as described in [Activating and Deactivating Detectors, on page 2677](#).

**Related Topics**

[Custom Application Detector and User-Defined Application Fields, on page 2665](#)

## Creating a User-Defined Application

Applications, categories, and tags created here are available in access control rules and in the application filter object manager as well.

---

**Caution** Creating a user-defined application immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior](#), on page 234 for more information.

---

### Before you begin

- Begin configuring your custom application protocol detector as described in [Configuring Custom Application Detectors](#), on page 2668.

### Procedure

- 
- Step 1** On the **Create A Custom Application Detector** dialog box, click **Add (+)** next to the **Application** field.
- Step 2** Type a **Name**.
- Step 3** Type a **Description**.
- Step 4** Select a **Business Relevance**.
- Step 5** Select a **Risk**.
- Step 6** Click **Add** next to **Categories** to add a category and type a new category name, or select an existing category from the **Categories** drop-down list.
- Step 7** Optionally, click **Add** next to **Tags** to add a tag and type a new tag name, or select an existing tag from the **Tags** drop-down list.
- Step 8** Click **OK**.
- 

### What to do next

- Continue configuring your custom application protocol detector as described in [Configuring Custom Application Detectors](#), on page 2668. You must save and activate the detector before the system can use it to analyze traffic.

### Related Topics

[Custom Application Detector and User-Defined Application Fields](#), on page 2665

## Specifying Detection Patterns in Basic Detectors

You can configure a custom application protocol detector to search application protocol packet headers for a particular pattern string. You can also configure detectors to search for multiple patterns; in that case the application protocol traffic must match all of the patterns for the detector to positively identify the application protocol.

Application protocol detectors can search for ASCII or hexadecimal patterns, using any offset.

### Before you begin

- Begin configuring your custom application protocol detector as described in [Configuring Custom Application Detectors, on page 2668](#).

### Procedure

- 
- Step 1** On the **Create Detector** page, in the **Detection Patterns** section, click **Add**.
- Step 2** Choose protocol type from the **Application** drop-down list.
- Step 3** Choose pattern type from the **Type** drop-down list.
- Step 4** Type a **Pattern** string that matches the **Type** you specified.
- Step 5** Optionally, type the **Offset** (in bytes).
- Step 6** Optionally, to identify application protocol traffic based on the port it uses, type a port from 1 to 65535 in the **Port(s)** field. To use multiple ports, separate them by commas.
- Step 7** Click a **Direction**: **Client** or **Server**.
- Step 8** Click **OK**.

**Tip** If you want to delete a pattern, click **Delete** (  ) next to the pattern you want to delete.

---

### What to do next

- Continue configuring your custom application protocol detector as described in [Configuring Custom Application Detectors, on page 2668](#). You must save and activate the detector before the system can use it to analyze traffic.

### Related Topics

[Specifying Detection Criteria in Advanced Detectors, on page 2671](#)

## Specifying Detection Criteria in Advanced Detectors

---

**Caution** Advanced custom detectors are complex and require outside knowledge to construct valid .lua files. Incorrectly configured detectors could have a negative impact on performance or detection capability.

---

---

**Caution** Do not upload .lua files from untrusted sources.

---

Custom .lua files contain your custom application detector settings. Creating custom .lua files requires advanced knowledge of the lua programming language and experience with Cisco's C-lua API. Cisco strongly recommends you use the following to prepare .lua files:

- third-party instruction and reference material for the lua programming language
- The Open Source Detectors Developers Guide: <https://www.snort.org/downloads>

- OpenAppID Snort community resources: <http://blog.snort.org/search/label/openappid>

---

**Note** The system does not support .lua files that reference system calls or file I/O.

---

#### Before you begin

- Begin configuring your custom application protocol detector as described in [Configuring Custom Application Detectors, on page 2668](#).
- Prepare to create a valid .lua file by downloading and studying the .lua files for comparable detectors. For more information about downloading detector files, see [Viewing or Downloading Detector Details, on page 2674](#).
- Create a valid .lua file that contains your custom application detector settings.

#### Procedure

- 
- Step 1** On the **Create Detector** page for an advanced custom application detector, in the **Detection Criteria** section, click **Add**.
- Step 2** Click **Browse...** to navigate to the **.lua** file and upload it.
- Step 3** Click **OK**.
- 

#### What to do next

- Continue configuring your custom application protocol detector as described in [Configuring Custom Application Detectors, on page 2668](#). You must save and activate the detector before the system can use it to analyze traffic.

#### Related Topics

[Specifying Detection Patterns in Basic Detectors, on page 2670](#)

## Specifying EVE Process Assignments

You can configure your own custom application detectors to map processes detected by the encrypted visibility engine (EVE) to new or existing applications.

#### Before you begin

- Begin configuring your custom application protocol detector as described in [Configuring Custom Application Detectors, on page 2668](#).

## Procedure

- 
- Step 1** On the Create Detector page, in the Encrypted Visibility Engine Process Assignments section, click **Add**.
- Step 2** Enter the **Process Name** and **Minimum Process Confidence** value.
- Note** You can enter text in the **Process Name** field and this is case-sensitive. The value should match the exact process name detected by EVE. The **Minimum Process Confidence** can be any number from 0 to 100. This is the number displayed in the **Encrypted Visibility Process Confidence Score** field in Connection Events.
- For information about the **Encrypted Visibility Process Confidence Score** field, see the section *Connection and Security Intelligence Event Fields* in the [Cisco Firepower Management Center Administration Guide](#).
- Step 3** Click **Save**.
- Step 4** In the Application Detector listing page, activate the detector that you created. For more information, see [Activating and Deactivating Detectors, on page 2677](#). When you activate the detector, the detector files are pushed to all the FTDs registered on the management center.
- 

### What to do next

- Continue configuring your custom application protocol detector as described in [Configuring Custom Application Detectors, on page 2668](#). You must save and activate the detector before the system can use it to analyze traffic.

## Testing a Custom Application Protocol Detector

If you have a packet capture (pcap) file that contains packets with traffic from the application protocol you want to detect, you can test a custom application protocol detector against that pcap file. Cisco recommends using a simple, clean pcap file without unnecessary traffic.

Pcap files must be 256 KB or smaller; if you try to test your detector against a larger pcap file, the management center automatically truncates it and tests the incomplete file. You must fix the unresolved checksums in a pcap before using the file to test a detector.

### Before you begin

- Configure your custom application protocol detector as described in [Configuring Custom Application Detectors, on page 2668](#).

## Procedure

- 
- Step 1** On the Create Detector page, in the Packet Captures section, click **Add**.
- Step 2** Browse to the pcap file in the pop-up window and click **OK**.

**Step 3** To test your detector against the contents of the pcap file, click **Evaluate** next to the pcap file. A message indicates whether the test succeeded.

**Step 4** Optionally, repeat steps 1 to 3 to test the detector against additional pcap files.

**Tip** To delete a pcap file, click **Delete** (  ) next to the file you want to delete.

---

#### What to do next

- Continue configuring your custom application protocol detector as described in [Configuring Custom Application Detectors, on page 2668](#). You must save and activate the detector before the system can use it to analyze traffic.

## Viewing or Downloading Detector Details

You can use the detectors list to view application detector details (all detectors) and download detector details (custom application detectors only).

### Procedure

---

**Step 1** To view application detector details, do one of the following:

- See the *Cisco Firepower Application Detector Reference* for the relevant VDB version at <https://www.cisco.com/c/en/us/support/security/defense-center/products-technical-reference-list.html>
- a. Select **Policies > Application Detectors**.
- b. Filter the list to find a particular detector.
- c. Click **Information** (  )

**Step 2** To download detector details for a custom application detector, click **Download** (  ).

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have the necessary permissions.

---

## Sorting the Detector List

By default, the Detectors page lists detectors alphabetically by name. An up or down arrow next to a column heading indicates that the page is sorted by that column in that direction.

## Procedure

- 
- Step 1** Select **Policies > Application Detectors**.
- Step 2** Click the appropriate column heading.
- 

# Filtering the Detector List

## Procedure

- 
- Step 1** Select **Policies > Application Detectors**.
- Step 2** Expand one of the filter groups described in [Filter Groups for the Detector List, on page 2675](#) and select the check box next to a filter. To select all filters in a group, right-click the group name and select **Check All**.
- Step 3** If you want to remove a filter, click **Remove** (✕) in the name of the filter in the **Filters** field or disable the filter in the filter list. To remove all filters in a group, right-click the group name and select **Uncheck All**.
- Step 4** If you want to remove all filters, click **Clear all** next to the list of filters applied to the detectors.
- 

## Filter Groups for the Detector List

You can use several filter groups, separately or in combination, to filter the list of detectors.

### Name

Finds detectors with names or descriptions containing the string you type. Strings can contain any alphanumeric or special character.

### Custom Filter

Finds detectors matching a custom application filter created on the object management page.

### Author

Finds detectors according to who created the detector. You can filter detectors by:

- any individual user who has created or imported a custom detector
- Cisco, which represents all Cisco-provided detectors *except* individually imported add-on detectors (you are the author for any detector that you import)
- **Any User**, which represents all detectors not provided by Cisco

**State**

Finds detectors according to their state, that is, **Active** or **Inactive**.

**Type**

Finds detectors according to the detector type, as described in [Application Detector Fundamentals](#), on page 2660.

**Protocol**

Finds detectors according to which traffic protocol the detector inspects.

**Category**

Finds detectors according to the categories assigned to the application they detect.

**Tag**

Finds detectors according to the tags assigned to the application they detect.

**Risk**

Finds detectors according to the risks assigned to the application they detect: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

**Business Relevance**

Finds detectors according to the business relevance assigned to the application they detect: **Very High**, **High**, **Medium**, **Low**, and **Very Low**.

## Navigating to Other Detector Pages

### Procedure

- 
- Step 1** Select **Policies > Application Detectors**.
  - Step 2** If you want to view the next page, click **Right Arrow** (>).
  - Step 3** If you want to view the previous page, click **Left Arrow** (<).
  - Step 4** If you want to view a different page, type the page number and press Enter.
  - Step 5** If you want to jump to the last page, click **Right End Arrow** (>|).
  - Step 6** If you want to jump to the first page, click **Left End Arrow** (|<).
-

# Activating and Deactivating Detectors

You must activate a detector before you can use it to analyze network traffic. By default, all Cisco-provided detectors are activated.

You can activate multiple application detectors for each port to supplement the system's detection capability.

When you include an application in an access control rule in a policy and that policy is deployed, if there is no active detector for that application, one or more detectors automatically activate. Similarly, while an application is in use in a deployed policy, you cannot deactivate a detector if deactivating leaves no active detectors for that application.

**Tip** For improved performance, deactivate any application protocol, client, or web application detectors you do not intend to use.

**Caution** Activating or deactivating a system or custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

## Procedure

- 
- Step 1** Select **Policies > Application Detectors**.
- Step 2** Click the slider next to the detector you want to activate or deactivate. If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Note** Some application detectors are required by other detectors. If you deactivate one of these detectors, a warning appears to indicate that the detectors that depend on it are also disabled.
- 

# Editing Custom Application Detectors

Use the following procedure to modify custom application detectors.

## Procedure

- 
- Step 1** Select **Policies > Application Detectors**.
- Step 2** Click **Edit** () next to the detector you want to modify. If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Make changes to the detector as described in [Configuring Custom Application Detectors, on page 2668](#).

**Step 4** You have the following saving options, depending on the state of the detector:

- To save an inactive detector, click **Save**.
- To save an inactive detector as a new, inactive detector, click **Save as New**.
- To save an active detector and immediately start using it, click **Save and Reactivate**.

**Caution** Saving and reactivating a custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

- To save an active detector as a new, inactive detector, click **Save as New**.

## Deleting Detectors

You can delete custom detectors as well as individually imported add-on detectors provided by Cisco Professional Services. You cannot delete any of the other Cisco-provided detectors, though you can deactivate many of them.

**Note** While a detector is in use in a deployed policy, you cannot delete the detector.

**Caution** Deleting an activated custom application detector immediately restarts the Snort process without going through the deploy process. The system warns you that continuing restarts the Snort process and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

### Procedure

**Step 1** Select **Policies > Application Detectors**.

**Step 2** Click **Delete** (  ) next to the detector you want to delete. If **View** (  ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 3** Click **OK**.

## CHAPTER 101

# Network Discovery Policies

The following topics describe how to create, configure, and manage network discovery policies:

- [Overview: Network Discovery Policies, on page 2679](#)
- [Requirements and Prerequisites for Network Discovery Policies, on page 2680](#)
- [Network Discovery Customization, on page 2680](#)
- [Network Discovery Rules, on page 2681](#)
- [Configuring Advanced Network Discovery Options, on page 2690](#)
- [Troubleshooting Your Network Discovery Strategy, on page 2698](#)

## Overview: Network Discovery Policies

The network discovery policy on the management center controls how the system collects data on your organization's network assets and which network segments and ports are monitored.

Network discovery policies can only be configured for Secure Firewall Threat Defense devices that send events to a Network Analytics Manager. (The Network Analytics Manager is an on-premises Secure Firewall Management Center that is configured to provide event analytics only.)

Discovery rules within the policy specify which networks and ports the system monitors to generate discovery data based on network data in traffic, and the zones to which the policy is deployed. Within a rule, you can configure whether hosts, applications, and non-authoritative users are discovered. You can create rules to exclude networks and zones from discovery. You can configure discovery of data from NetFlow exporters and restrict the protocols for traffic where user data is discovered on your network.

The network discovery policy has a single default rule in place, configured to discover applications from all observed traffic. The rule does not exclude any networks, zones, or ports, host and user discovery is not configured, and the rule is not configured to monitor a NetFlow exporter. This policy is deployed by default to any managed devices when they are registered to the management center. To begin collecting host or user data, you must add or modify discovery rules and re-deploy the policy to a device.

If you want to adjust the scope of network discovery, you can create additional discovery rules and modify or remove the default rule.

Remember that the access control policy for each managed device defines the traffic that you permit for that device and, therefore, the traffic you can monitor with network discovery. If you block certain traffic using access control, the system cannot examine that traffic for host, user, or application activity. For example, if an access control policy blocks access to social networking applications, the system cannot provide any discovery data on those applications.

If you enable traffic-based user detection in your discovery rules, you can detect non-authoritative users through user login activity in traffic over a set of application protocols. You can disable discovery in particular protocols across all rules if needed. Disabling some protocols can help avoid reaching the user limit associated with your management center model, reserving available user count for users from the other protocols.

Advanced network discovery settings allow you to manage what data is logged, how discovery data is stored, what indications of compromise (IOC) rules are active, what vulnerability mappings are used for impact assessment, and what happens when sources offer conflicting discovery data. You can also add sources for host input and NetFlow exporters to monitor.

## Requirements and Prerequisites for Network Discovery Policies

### Model Support

Any.

## Network Discovery Customization

The information about your network traffic collected by the system is most valuable to you when the system can correlate this information to identify the hosts on your network that are most vulnerable and most important.

As an example, if you have several devices on your network running a customized version of SuSE Linux, the system cannot identify that operating system and so cannot map vulnerabilities to the hosts. However, knowing that the system has a list of vulnerabilities for SuSE Linux, you may want to create a custom fingerprint for one of the hosts that can then be used to identify the other hosts running the same operating system. You can include a mapping of the vulnerability list for SuSE Linux in the fingerprint to associate that list with each host that matches the fingerprint.

The system also allows you to input host data from third-party systems directly into the network map, using the host input feature. However, third-party operating system or application data does not automatically map to vulnerability information. If you want to see vulnerabilities and perform impact correlation for hosts using third-party operating system, server, and application protocol data, you must map the vendor and version information from the third-party system to the vendor and version listed in the vulnerability database (VDB). You also may want to maintain the host input data on an ongoing basis. Note that even if you map application data to system vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

If the system cannot identify application protocols running on hosts on your network, you can create user-defined application protocol detectors that allow the system to identify the applications based on a port or a pattern. You can also import, activate, and deactivate certain application detectors to further customize the application detection capability.

You can also replace detection of operating system and application data using scan results from the Nmap active scanner or augment the vulnerability lists with third-party vulnerabilities. The system may reconcile data from multiple sources to determine the identity for an application.

## Configuring the Network Discovery Policy

### Procedure

---

**Step 1** Choose **Policies** > **Network Discovery**.

**Step 2** Configure the following components of your policy:

- Discovery rules — See [Configuring Network Discovery Rules](#), on page 2682.
  - Traffic-based detection for users — See [Configuring Traffic-Based User Detection](#), on page 2689.
  - Advanced network discovery options — See [Configuring Advanced Network Discovery Options](#), on page 2690.
  - Custom operating system definitions (fingerprints) — See [Creating a Custom Fingerprint for Clients](#), on page 2646 and [Creating a Custom Fingerprint for Servers](#), on page 2648.
- 

## Network Discovery Rules

Network discovery rules allow you to tailor the information discovered for your network map to include only the specific data you want. Rules in your network discovery policy are evaluated sequentially. You can create rules with overlapping monitoring criteria, but doing so may affect your system performance.

When you exclude a host or a network from monitoring, the host or network does not appear in the network map and no events are reported for it. However, when the host discovery rules for the local IP are disabled, the detection engine instances are impacted by a higher processing load, as it builds data from each flow afresh rather than using the existing host data.

We recommend that you exclude load balancers (or specific ports on load balancers) and NAT devices from monitoring. These devices may create excessive and misleading events, filling the database and overloading the management center. For example, a monitored NAT device might exhibit multiple updates of its operating system in a short period of time. If you know the IP addresses of your load balancers and NAT devices, you can exclude them from monitoring.

---

**Tip** The system can identify many load balancers and NAT devices by examining your network traffic.

---

In addition, if you need to create a custom server fingerprint, you should temporarily exclude from monitoring the IP address that you are using to communicate with the host you are fingerprinting. Otherwise, the network map and discovery event views will be cluttered with inaccurate information about the host represented by that IP address. After you create the fingerprint, you can configure your policy to monitor that IP address again.

Cisco also recommends that you **not** monitor the same network segment with NetFlow exporters and managed devices. Although ideally you should configure your network discovery policy with non-overlapping rules,

the system does drop duplicate connection logs generated by managed devices. However, you **cannot** drop duplicate connection logs for connections detected by both a managed device and a NetFlow exporter.

## Configuring Network Discovery Rules

You can configure discovery rules to tailor the discovery of host and application data to your needs.

---

**Tip** In most cases, we recommend restricting discovery to the addresses in RFC 1918.

---

### Before you begin

- Make sure you are logging connections for the traffic where you want to discover network data.
- If you want to collect exported NetFlow records, add a NetFlow Exporter as described in [Adding NetFlow Exporters to a Network Discovery Policy, on page 2694](#).
- If you will want to view discovery performance graphs, you must enable hosts, users, and applications in your discovery rule. Note that this may impact system performance.

### Procedure

---

**Step 1** Choose **Policies > Network Discovery**.

**Step 2** Click **Add Rule**.

**Step 3** Set the **Action** for the rule as described in [Actions and Discovered Assets, on page 2682](#).

**Step 4** Set optional discovery parameters:

- Restrict the rule action to specific networks; see [Restricting the Monitored Network, on page 2684](#).
- Restrict the rule action to traffic in specific zones; see [Configuring Zones in Network Discovery Rules, on page 2687](#).
- Exclude ports from monitoring; see [Excluding Ports in Network Discovery Rules, on page 2686](#).
- Configure the rule for NetFlow data discovery; see [Configuring Rules for NetFlow Data Discovery, on page 2684](#).

**Step 5** Click **Save**.

---

### What to do next

- Deploy configuration changes.

## Actions and Discovered Assets

When you configure a discovery rule, you must select an action for the rule. The effect of that action depends on whether you are using the rule to discover data from a managed device or from a NetFlow exporter.

The following table describes what assets are discovered by rules with the specified action settings in those two scenarios.

Table 229: Discovery Rule Actions

Action	Option	Managed Device	NetFlow Exporter
Exclude	--	Excludes the specified network from monitoring. If the source or destination host for a connection is excluded from discovery, the connection is recorded but discovery events are not created for excluded hosts.	Excludes the specified network from monitoring. If the source or destination host for a connection is excluded from discovery, the connection is recorded but discovery events are not created for excluded hosts.
Discover	Hosts	Adds hosts to the network map based on discovery events. (Optional, unless user discovery is enabled, then required.)	Adds hosts to the network map and logs connections based on NetFlow records. (Required)
Discover	Applications	Adds applications to the network map based on application detectors. Note that you cannot discover hosts or users in a rule without also discovering applications. (Required)	Adds application protocols to the network map based on NetFlow records and the port-application protocol correlation in <code>/etc/sf/services</code> . (Optional)
Discover	Users	Adds users to the users table and logs user activity based on traffic-based detection on the user protocols configured in the network discovery policy. (Optional)	n/a
Log NetFlow Connections	--	n/a	Logs NetFlow connections only. Does not discover hosts or applications.

If you want the rule to monitor managed device traffic, application logging is required. If you want the rule to monitor users, host logging is required. If you want the rule to monitor exported NetFlow records, you cannot configure it to log users, and logging applications is optional.

**Note** The system detects connections in exported NetFlow records based on the **Action** settings in the network discovery policy. The system detects connections in managed device traffic based on access control policy settings.

## Monitored Networks

A discovery rule causes discovery of monitored assets only in traffic to and from hosts in the specified networks. For a discovery rule, discovery occurs for connections that have at least one IP address within the networks specified, with events generated only for IP addresses within the networks to monitor. The default discovery rule discovers applications from all observed traffic (0.0.0.0/0 for all IPv4 traffic, and ::/0 for all IPv6 traffic).

If you configure a rule to handle NetFlow discovery and log only connections data, the system also logs connections to and from IP addresses in the specified networks. Note that network discovery rules provide the only way to log NetFlow network connections.

You can also use network object or object groups to specify the networks to monitor.

## Restricting the Monitored Network

Every discovery rule must include at least one network.

### Procedure

---

**Step 1** Choose **Policies** > **Network Discovery**.

**Step 2** Click **Add Rule**.

**Step 3** Click **Networks**, if it is not already open.

**Step 4** (Optional) Add network objects to the Available Networks list as described in [Creating Network Objects During Discovery Rule Configuration](#), on page 2685.

If you modify a network object used in the network discovery policy, the changes do not take effect for discovery until you deploy the configuration changes.

**Step 5** Specify a network:

- Choose a network from the **Available Networks** list. If the network does not immediately appear on the list, click **Reload** (↻).
- Enter the IP address into the text box below the Available Networks label.

**Step 6** Click **Add**.

**Step 7** Click **Save**.

---

### What to do next

- Deploy configuration changes.

## Configuring Rules for NetFlow Data Discovery

The system can use data from NetFlow exporters to generate connection and discovery events, and to add host and application data to the network map.

If you choose a NetFlow exporter in a discovery rule, the rule is limited to discovery of NetFlow data for the specified networks. Choose the NetFlow device to monitor before you configure other aspects of rule behavior, as the available rule actions change when you choose a NetFlow device. You cannot configure port exclusions for monitoring NetFlow exporters.

### Before you begin

- Add NetFlow-enabled devices to the network discovery policy; see [Adding NetFlow Exporters to a Network Discovery Policy](#), on page 2694.

### Procedure

---

**Step 1** Choose **Policies** > **Network Discovery**.

- Step 2** Click **Add Rule**.
- Step 3** Choose **NetFlow Device**.
- Step 4** From the **NetFlow Device** drop-down list, choose the IP address of the NetFlow exporter to be monitored.
- Step 5** Specify the type of NetFlow data you want the system managed device to collect:
- Connection only — Choose `Log NetFlow Connections` from the **Action** drop-down list.
  - Host, Application, and Connection — Choose `Discover` from the **Action** drop-down list. The system automatically checks the **Hosts** check box and enables collection of connection data. Optionally, you can check the **Application** check box to collect application data.
- Step 6** Click **Save**.
- 

#### What to do next

- Deploy configuration changes.

### Creating Network Objects During Discovery Rule Configuration

You can add new network objects to the list of available networks that appears in a discovery rule by adding them to the list of reusable network objects and groups.

#### Procedure

---

- Step 1** Choose **Policies > Network Discovery**.
- Step 2** In **Networks**, click **Add Rule**.
- Step 3** Click **Add (+)** next to **Available Networks**.
- Step 4** Create a network object as described in [Creating Network Objects, on page 1499](#).
- Step 5** Finish adding the network discovery rule as described in [Configuring Network Discovery Rules, on page 2682](#).
- 

### Port Exclusions

Just as you can exclude hosts from monitoring, you can exclude specific ports from monitoring. For example:

- Load balancers can report multiple applications on the same port in a short period of time. You can configure your network discovery rules so that they exclude that port from monitoring, such as excluding port 80 on a load balancer that handles a web farm.
- Your organization may use a custom client that uses a specific range of ports. If the traffic from this client generates excessive and misleading events, you can exclude those ports from monitoring. Similarly, you may decide that you do not want to monitor DNS traffic. In that case, you could configure your rules so that your discovery policy does not monitor port 53.

When adding ports to exclude, you can decide whether to use a reusable port object from the Available Ports list, add ports directly to the source or destination exclusion lists, or create a new reusable port and then move it into the exclusion lists.

---

**Note** You cannot exclude ports in rules handling NetFlow data discovery.

---

## Excluding Ports in Network Discovery Rules

You cannot exclude ports in rules handling NetFlow data discovery.

### Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
  - Step 2** Click **Add Rule**.
  - Step 3** Click **Port Exclusions**.
  - Step 4** Optionally, add port objects to the Available Ports list as described in [Creating Port Objects During Discovery Rule Configuration](#), on page 2686.
  - Step 5** Exclude specific source ports from monitoring, using either of the following methods:
    - Choose a port or ports from the **Available Ports** list and click **Add to Source**.
    - To exclude traffic from a specific source port without adding a port object, under the **Selected Source Ports** list, choose a **Protocol**, enter a **Port** number (a value from 1 to 65535), and click **Add**.
  - Step 6** Exclude specific destination ports from monitoring, using either of the following methods:
    - Choose a port or ports from the **Available Ports** list and click **Add to Destination**.
    - To exclude traffic from a specific destination port without adding a port object, under the **Selected Destination Ports** list, choose a **Protocol**, enter a **Port** number, and click **Add**.
  - Step 7** Click **Save** to save the changes you made.
- 

### What to do next

- Deploy configuration changes.

## Creating Port Objects During Discovery Rule Configuration

You can add new port objects to the list of available ports that appears in a discovery rule by adding them to the list of reusable port objects and groups that can be used anywhere in the system.

### Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
  - Step 2** In Networks, click **Add Rule**.
  - Step 3** Click **Port Exclusions**.
  - Step 4** To add a port to the Available Ports list, click **Add (+)**.
  - Step 5** Enter **Name**.

- Step 6** In the **Protocol** field, specify the protocol of the traffic you want to exclude.
- Step 7** In the **Port** field, enter the ports you want to exclude from monitoring.
- You can specify a single port, a range of ports using the dash (-), or a comma-separated list of ports and port ranges. Allowed port values are from 1 to 65535.
- Step 8** Click **Save**.
- Step 9** If the port does not immediately appear on the list, click **Refresh**.
- 

#### What to do next

- Deploy configuration changes.

## Zones in Network Discovery Rules

To improve performance, discovery rules can be configured so that the zones in the rule include the sensing interfaces on your managed devices that are physically connected to the networks-to-monitor in the rule.

Unfortunately, you may not always be kept informed of network configuration changes. A network administrator may modify a network configuration through routing or host changes without informing you, which may make it challenging to stay on top of proper network discovery policy configurations. If you do not know how the sensing interfaces on your managed devices are physically connected to your network, leave the zone configuration as the default. This default causes the system to deploy the discovery rule to all zones in your deployment. (If no zones are excluded, the system deploy the discovery policy to all zones.)

### Configuring Zones in Network Discovery Rules

#### Procedure

---

- Step 1** Choose **Policies > Network Discovery**.
- Step 2** Click **Add Rule**.
- Step 3** Click **Zones**.
- Step 4** Choose a zone or zones from the **Available Zones** list.
- Step 5** Click **Save** to save the changes you made.
- 

#### What to do next

- Deploy configuration changes.

## The Traffic-Based Detection Identity Source

Traffic-based detection is the only non-authoritative identity source supported by the system. When configured, managed devices detect LDAP, AIM, POP3, IMAP, Oracle, SIP (VoIP), FTP, HTTP, MDNS, and SMTP logins on the networks you specify. The data gained from traffic-based detection can be used only for user awareness. Unlike authoritative identity sources, you configure traffic-based detection in your network discovery policy as described in [Configuring Traffic-Based User Detection, on page 2689](#).

Note the following limitations:

- Traffic-based detection interprets only Kerberos logins for LDAP connections as LDAP authentications. Managed devices cannot detect encrypted LDAP authentications using protocols such as SSL or TLS.
- Traffic-based detection detects AIM logins using the OSCAR protocol only. They cannot detect AIM logins using TOC2.
- Traffic-based detection cannot restrict SMTP logging. This is because users are not added to the database based on SMTP logins; although the system detects SMTP logins, the logins are not recorded unless there is already a user with a matching email address in the database.

Traffic-based detection also records failed login attempts. A failed login attempt does not add a new user to the list of users in the database. The user activity type for detected failed login activity detected by traffic-based detection is **Failed User Login**.

---

**Note** The system cannot distinguish between failed and successful HTTP logins. To see HTTP user information, you must enable **Capture Failed Login Attempts** in the traffic-based detection configuration.

---

---

**Caution** Enabling or disabling non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

---

### Traffic-Based Detection Data

When a device detects a login using traffic-based detection, it sends the following information to the management center to be logged as user activity:

- The user name identified in the login.
- The time of the login.
- The IP address involved in the login, which can be the IP address of the user's host (for LDAP, POP3, IMAP, and AIM logins), the server (for HTTP, MDNS, FTP, SMTP and Oracle logins), or the session originator (for SIP logins).
- The user's email address (for POP3, IMAP, and SMTP logins).
- The name of the device that detected the login.

If the user was previously detected, the management center updates that user's login history. Note that the management center can use the email addresses in POP3 and IMAP logins to correlate with LDAP users. This means that, for example, if the management center detects a new IMAP login, and the email address in the IMAP login matches that for an existing LDAP user, the IMAP login does not create a new user; rather, it updates the LDAP user's history.

If the user was previously undetected, the management center adds the user to the users database. Unique AIM, SIP, and Oracle logins always create new user records, because there is no data in those login events that the management center can correlate with other login types.

The management center does **not** log user activity or user identities in the following cases:

- If you configured the network discovery policy to ignore that login type
- If a managed device detects an SMTP login, but the users database does not contain a previously detected LDAP, POP3, or IMAP user with a matching email address

The user data is added to the users table.

### Traffic-Based Detection Strategies

You can restrict the protocols where user activity is discovered to reduce the total number of detected users so you can focus on users likely to provide the most complete user information. Limiting protocol detection helps minimize user name clutter and preserve storage space on your management center.

Consider the following when selecting traffic-based detection protocols:

- Obtaining user names through protocols such as AIM, POP3, and IMAP may introduce user names not relevant to your organization due to network access from contractors, visitors, and other guests.
- AIM, Oracle, and SIP logins may create extraneous user records. This occurs because these login types are not associated with any of the user metadata that the system obtains from an LDAP server, nor are they associated with any of the information contained in the other types of login that your managed devices detect. Therefore, the management center cannot correlate these users with other types of users.

## Configuring Traffic-Based User Detection

When you enable traffic-based user detection in a network discovery rule, host discovery is automatically enabled. For more information about traffic-based detection, see [The Traffic-Based Detection Identity Source, on page 2687](#).

### Procedure

- 
- Step 1** Choose **Policies** > **Network Discovery**.
  - Step 2** Click **Users**.
  - Step 3** Click **Edit** (✎).
  - Step 4** Check the check boxes for protocols where you want to detect logins or clear check boxes for protocols where you do not want to detect logins, and choose whether you want to **Capture Failed Login Attempts**.
  - Step 5** Click **Save**.
- 

### What to do next

**Caution** Enabling or disabling non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 234](#) for more information.

---

- Configure network discovery rules to discover users as described in [Configuring Network Discovery Rules, on page 2682](#).
- Deploy configuration changes.

## Configuring Advanced Network Discovery Options

The Advanced of the network discovery policy allows you to configure policy-wide settings for what events are detected, how long discovery data is retained and how often it is updated, what vulnerability mappings are used for impact correlation, and how operating system and server identity conflicts are resolved. In addition, you can add host input sources and NetFlow exporters to allow import of data from other sources.

---

**Note** Database event limits for discovery and user activity events are set in system configuration.

---

### Procedure

- 
- Step 1** Choose **Policies** > **Network Discovery**.
  - Step 2** Click **Advanced**.
  - Step 3** Click **Edit** (✎) or **Add** (+) next to the setting you want to modify:
    - Data Storage Settings — Update the settings as described in [Configuring Network Discovery Data Storage, on page 2696](#).
    - Event Logging Settings — Update the settings as described in [Configuring Network Discovery Event Logging, on page 2697](#).
    - General Settings — Update the settings as described in [Configuring Network Discovery General Settings, on page 2691](#).
    - Identity Conflict Settings — Update the settings as described in [Configuring Network Discovery Identity Conflict Resolution, on page 2692](#).
    - Indications of Compromise Settings — Update the settings as described in [Enabling Indications of Compromise Rules, on page 2694](#).
    - NetFlow Exporters — Update the settings as described in [Adding NetFlow Exporters to a Network Discovery Policy, on page 2694](#).
    - OS and Server Identity Sources — Update the settings as described in [Adding Network Discovery OS and Server Identity Sources, on page 2697](#).
    - Vulnerabilities to use for Impact Assessment — Update the settings as described in [Enabling Network Discovery Vulnerability Impact Assessment, on page 2693](#).
  - Step 4** Click **Save**.
- 

### What to do next

- Deploy configuration changes.

## Network Discovery General Settings

The general settings control how often the system updates network maps and whether server banners are captured during discovery.

### Capture Banners

Select this check box if you want the system to store header information from network traffic that advertises server vendors and versions (“banners”). This information can provide additional context to the information gathered. You can access server banners collected for hosts by accessing server details.

### Update Interval

The interval at which the system updates information (such as when any of a host’s IP addresses was last seen, when an application was used, or the number of hits for an application). The default setting is 3600 seconds (1 hour).

Note that setting a lower interval for update timeouts provides more accurate information in the host display, but generates more network events.

## Configuring Network Discovery General Settings

### Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
  - Step 2** Click **Advanced**.
  - Step 3** Click **Edit** (✎) next to **General Settings**.
  - Step 4** Update the settings as described in [Network Discovery General Settings, on page 2691](#).
  - Step 5** Click **Save** to save the general settings.
- 

### What to do next

- Deploy configuration changes.

## Network Discovery Identity Conflict Settings

The system determines which operating system and applications are running on a host by matching fingerprints for operating systems and servers against patterns in traffic. To provide the most reliable operating system and server identity information, the system collates fingerprint information from several sources.

The system uses all passive data to derive operating system identities and assign a confidence value.

By default, unless there is an identity conflict, identity data added by a scanner or third-party application overrides identity data detected by the system. You can use the Identity Sources settings to rank scanner and third-party application fingerprint sources by priority. The system retains one identity for each source, but only data from the highest priority third-party application or scanner source is used as the current identity. Note, however, that user input data overrides scanner and third-party application data regardless of priority.

An identity conflict occurs when the system detects an identity that conflicts with an existing identity that came from either the active scanner or third-party application sources listed in the Identity Sources settings or from a system user. By default, identity conflicts are not automatically resolved and you must resolve them through the host profile or by rescanning the host or re-adding new identity data to override the passive identity. However, you can set your system to automatically resolve the conflict by keeping either the passive identity or the active identity.

### Generate Identity Conflict Event

Specifies whether the system generates an event when an identity conflict occurs.

### Automatically Resolve Conflicts

From the **Automatically Resolve Conflicts** drop-down list, choose one of the following:

- **Disabled** if you want to force manual conflict resolution of identity conflicts
- **Identity** if you want the system to use the passive fingerprint when an identity conflict occurs
- **Keep Active** if you want the system to use the current identity from the highest priority active source when an identity conflict occurs

## Configuring Network Discovery Identity Conflict Resolution

### Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
  - Step 2** Click **Advanced**.
  - Step 3** Click **Edit** (✎) next to **Identity Conflict Settings**.
  - Step 4** Update the settings in the Edit Identity Conflict Settings pop-up window as described in [Network Discovery Identity Conflict Settings, on page 2691](#).
  - Step 5** Click **Save** to save the identity conflict settings.
- 

### What to do next

- Deploy configuration changes.

## Network Discovery Vulnerability Impact Assessment Options

You can configure how the system performs impact correlation with intrusion events. Your choices are as follows:

- Check the **Use Network Discovery Vulnerability Mappings** check box if you want to use system-based vulnerability information to perform impact correlation.
- Check the **Use Third-Party Vulnerability Mappings** check box if you want to use third-party vulnerability references to perform impact correlation. For more information, see the *Firepower System Host Input API Guide*.

You can check either or both of the check boxes. If the system generates an intrusion event and the host involved in the event has servers or an operating system with vulnerabilities in the selected vulnerability mapping sets, the intrusion event is marked with the Vulnerable (level 1: red) impact icon. For any servers which do not have vendor or version information, note that you need to enable vulnerability mapping in the management center configuration.

If you clear both check boxes, intrusion events will **never** be marked with the Vulnerable (level 1: red) impact icon.

#### What to do next

- Deploy configuration changes.

## Indications of Compromise

The system uses IOC rules in the network discovery policy to identify a host as likely to be compromised by malicious means. When a host meets the conditions specified in these system-provided rules, the system tags it with an *indication of compromise* (IOC). The related rules are known as *IOC rules*. Each IOC rule corresponds to one type of IOC tag. The *IOC tags* specify the nature of the likely compromise.

The management center can tag the host and user involved when one of the following things occurs:

- The system correlates data gathered about your monitored network and its traffic, using intrusion, connection, Security Intelligence, and file or malware events, and determines that a potential IOC has occurred.
- The management center can import IOC data from your AMP for Endpoints deployments via the AMP cloud. Because this data examines activity on a host itself—such as actions taken by or on individual programs—it can provide insights into possible threats that network-only data cannot. For your convenience, the management center automatically obtains any new IOC tags that Cisco develops from the AMP cloud.

To configure this feature, see [Enabling Indications of Compromise Rules](#), on page 2694.

You can also write correlation rules against host IOC data and compliance allow lists that account for IOC-tagged hosts.

To investigate and work with tagged IOCs, see *Indications of Compromise Data* and its subtopics in [Cisco Secure Firewall Management Center Administration Guide](#).

## Enabling Indications of Compromise Rules

For your system to detect and tag indications of compromise (IOC), you must first activate at least one IOC rule in your network discovery policy. Each IOC rule corresponds to one type of IOC tag, and all IOC rules are predefined by Cisco; you cannot create original rules. You can enable any or all rules, depending on the needs of your network and organization. For example, if hosts using software such as Microsoft Excel never appear on your monitored network, you may decide not to enable the IOC tags that pertain to Excel-based threats.

### Before you begin

Because IOC rules trigger based on data provided by other components of the system and by AMP for Endpoints, those components must be correctly licensed and configured for IOC rules to set IOC tags. Enable the system features associated with the IOC rules you will enable, such as intrusion detection and prevention (IPS) and Advanced Malware Protection (AMP). If an IOC rule's associated feature is not enabled, no relevant data is collected and the rule cannot trigger.

### Procedure

- 
- Step 1** Choose **Policies > Network Discovery**.
  - Step 2** Click **Advanced**.
  - Step 3** Click **Edit** (✎) next to **Indications of Compromise Settings**.
  - Step 4** To toggle the entire IOC feature off or on, click the slider next to **Enable IOC**.
  - Step 5** To globally enable or disable individual IOC rules, click the slider in the rule's **Enabled** column.
  - Step 6** Click **Save** to save your IOC rule settings.
- 

### What to do next

- Deploy configuration changes.

## Adding NetFlow Exporters to a Network Discovery Policy

Use this procedure to add NetFlow exporters. Note that you cannot delete an exporter if it is currently in use in a discovery rule.

### Before you begin

- Review prerequisites: [Requirements for Using NetFlow Data, on page 2638](#)
- Configure NetFlow exporters: [NetFlow Data, on page 2637](#)

## Procedure

- 
- Step 1** Choose **Policies** > **Network Discovery**.
- Step 2** Click **Advanced**.
- Step 3** Click **Add (+)** next to **NetFlow Devices**.
- Step 4** Enter the **IP Address** of the exporter.
- Step 5** Click **Save**.
- 

### What to do next

- Configure a network discovery rule to monitor NetFlow traffic: [Configuring Network Discovery Rules, on page 2682](#)
- Deploy configuration changes.

## Network Discovery Data Storage Settings

Discovery data storage settings include the host limit and timeout settings.

### When Host Limit Reached

The number of hosts a Secure Firewall Management Center can monitor, and therefore store in the network map, depends on its model. The **When Host Limit Reached** option controls what happens when you detect a new host after you reach the host limit. You can:

#### Drop hosts

The system drops the host that has remained inactive for the longest time, then adds the new host. This is the default setting.

#### Don't insert new hosts

The system does not track any newly discovered hosts. The system only tracks new hosts after the host count drops below the limit, such as after an administrator increases the domain's host limit or manually deletes hosts from the network map, or if the system identifies hosts as timed-out due to inactivity.

Table 230: Reaching the Host Limit with Multitenancy

Setting	Domain Host Limit Set?	Domain Host Limit Reached	Ancestor Domain Host Limit Reached
Drop hosts	yes	Drops oldest host in the constrained domain.	Drops the oldest host among all descendant leaf domains configured to drop hosts.  If no host can be dropped, does not add the host.
	no	n/a	Drops the oldest host among all descendant leaf domains configured to drop hosts and that share the general pool.
Don't insert new hosts	yes or no	Does not add the host.	Does not add the host.

### Host Timeout

The amount of time that passes, in minutes, before the system drops a host from the network map due to inactivity. The default setting is 10080 minutes (one week). Individual host IP and MAC addresses can time out individually, but a host does not disappear from the network map unless all its associated addresses time out.

To avoid premature timeout of hosts, make sure that the host timeout value is longer than the update interval in the network discovery policy general settings.

### Server Timeout

The amount of time that passes, in minutes, before the system drops a server from the network map due to inactivity. The default setting is 10080 minutes (one week).

To avoid premature timeout of servers, make sure that the service timeout value is longer than the update interval in the network discovery policy general settings.

### Client Application Timeout

The amount of time that passes, in minutes, before the system drops a client from the network map due to inactivity. The default setting is 10080 minutes (one week).

Make sure that the client timeout value is longer than the update interval in the network discovery policy general settings.

### Related Topics

[Host Limit](#)

## Configuring Network Discovery Data Storage

### Procedure

---

**Step 1** Choose **Policies** > **Network Discovery**.

- Step 2** Click **Advanced**.
  - Step 3** Click **Edit** (✎) next to **Network Discovery Data Storage Settings**.
  - Step 4** Update the settings in the Data Storage Settings dialog as described in [Network Discovery Data Storage Settings, on page 2695](#).
  - Step 5** Click **Save** to save the data storage settings.
- 

#### What to do next

- Deploy configuration changes.

## Configuring Network Discovery Event Logging

The Event Logging Settings control whether discovery and host input events are logged. If you do not log an event, you cannot retrieve it in event views or use it to trigger correlation rules.

### Procedure

---

- Step 1** Choose **Policies > Network Discovery**.
  - Step 2** Click **Advanced**.
  - Step 3** Click **Edit** (✎) next to **Event Logging Settings**.
  - Step 4** Check or clear the check boxes next to the discovery and host input event types you want to log in the database.
  - Step 5** Click **Save** to save the event logging settings.
- 

#### What to do next

- Deploy configuration changes.

## Adding Network Discovery OS and Server Identity Sources

In Advanced of the network discovery policy, you can add new active sources or change the priority or timeout settings for existing sources.

Adding a scanner to this page does not add the full integration capabilities that exist for the Nmap scanners, but does allow integration of imported third-party application or scan results.

If you import data from a third-party application or scanner, make sure that you map vulnerabilities from the source to the vulnerabilities detected in your network.

### Procedure

---

- Step 1** Choose **Policies > Network Discovery**.

- Step 2** Click **Advanced**.
- Step 3** Click **Edit** (✎) next to **OS and Server Identity Sources**.
- Step 4** To add a new source, click **Add Source**.
- Step 5** Enter a **Name**.
- Step 6** Choose the input source **Type** from the drop-down list:
- Choose **Scanner** if you plan to import scan results using the AddScanResult function.
  - Choose **Application** if you do not plan to import scan results.
- Step 7** To indicate the duration of time that should elapse between the addition of an identity to the network map by this source and the deletion of that identity, choose **Hours**, **Days**, or **Weeks** from the **Timeout** drop-down list and enter the appropriate duration.
- Step 8** Optionally:
- To promote a source and cause the operating system and application identities to be used in favor of sources below it in the list, choose the source and click the up arrow.
  - To demote a source and cause the operating system and application identities to be used only if there are no identities provided by sources above it in the list, choose the source and click the down arrow.
  - To delete a source, click **Delete** (🗑) next to the source.
- Step 9** Click **Save** to save the identity source settings.
- 

#### What to do next

- Deploy configuration changes.

## Troubleshooting Your Network Discovery Strategy

Before you make any changes to the system's default detection capabilities, you should analyze what hosts are not being identified correctly and why, so you can decide what solution to implement.

### Are Your Managed Devices Correctly Placed?

If network devices such as load balancers, proxy servers, or NAT devices reside between the managed device and the unidentified or misidentified host, place a managed device closer to the misidentified host rather than using custom fingerprinting. Cisco does not recommend using custom fingerprinting in this scenario.

### Do Unidentified Operating Systems Have a Unique TCP Stack?

If the system misidentifies a host, you should investigate why the host is misidentified to help you decide between creating and activating a custom fingerprint or substituting Nmap or host input data for discovery data.

---

**Caution** If you encounter misidentified hosts, contact your support representative before creating custom fingerprints.

---

If a host is running an operating system that is not detected by the system by default and does not share identifying TCP stack characteristics with existing detected operating systems, you should create a custom fingerprint.

For example, if you have a customized version of Linux with a unique TCP stack that the system cannot identify, you would benefit from creating a custom fingerprint, which allows the system to identify the host and continuing monitoring it, rather than using scan results or third-party data, which require you to actively update the data yourself on an ongoing basis.

Note that many open source Linux distributions use the same kernel, and as such, the system identifies them using the Linux kernel name. If you create a custom fingerprint for a Red Hat Linux system, you may see other operating systems (such as Debian Linux, Mandrake Linux, Knoppix, and so on) identified as Red Hat Linux, because the same fingerprint matches multiple Linux distributions.

You should not use a fingerprint in every situation. For example, a modification may have been made to a host's TCP stack so that it resembles or is identical to another operating system. For example, an Apple Mac OS X host is altered, making its fingerprint identical to a Linux 2.4 host, causing the system to identify it as Linux 2.4 instead of Mac OS X. If you create a custom fingerprint for the Mac OS X host, it may cause all legitimate Linux 2.4 hosts to be erroneously identified as Mac OS X hosts. In this case, if Nmap correctly identifies the host, you could schedule regular Nmap scans for that host.

If you import data from a third-party system using host input, you must map the vendor, product, and version strings that the third party uses to describe servers and application protocols to the Cisco definitions for those products. Note that even if you map application data to system vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

The system may reconcile data from multiple sources to determine the current identity for an operating system or application.

For Nmap data, you can schedule regular Nmap scans. For host input data, you can regularly run the Perl script for the import or the command line utility. However, note that active scan data and host input data may not be updated with the frequency of discovery data.

### **Can the System Identify All Applications?**

If a host is correctly identified by the system but has unidentified applications, you can create a user-defined detector to provide the system with port and pattern matching information to help identify the application.

### **Have You Applied Patches that Fix Vulnerabilities?**

If the system correctly identifies a host but does not reflect applied fixes, you can use the host input feature to import patch information. When you import patch information, you must map the fix name to a fix in the database.

### **Do You Want to Track Third-Party Vulnerabilities?**

If you have vulnerability information from a third-party system that you want to use for impact correlation, you can map the third-party vulnerability identifiers for servers and application protocols to vulnerability identifiers in the Cisco database and then import the vulnerabilities using the host input feature. For more information on using the host input feature, see the *Firepower System Host Input API Guide*. Note that even

if you map application data to system vendor and version definitions, imported third-party vulnerabilities are not used for impact assessment for clients or web applications.

## PART **XXII**

# FlexConfig Policies

- [FlexConfig Policies, on page 2703](#)

## CHAPTER 102

# FlexConfig Policies

---

The following topics describe how to configure and deploy FlexConfig policies.

- [FlexConfig Policy Overview, on page 2703](#)
- [Requirements and Prerequisites for FlexConfig Policies, on page 2723](#)
- [Guidelines and Limitations for FlexConfig, on page 2723](#)
- [Customizing Device Configuration with FlexConfig Policies, on page 2724](#)
- [Examples for FlexConfig, on page 2737](#)
- [Migrating FlexConfig Policies, on page 2744](#)

## FlexConfig Policy Overview

A FlexConfig policy is a container of an ordered list of FlexConfig objects. Each object includes a series of Apache Velocity scripting language commands, ASA software configuration commands, and variables that you define. The contents of each FlexConfig object is essentially a program that generates a sequence of ASA commands that will then be deployed to the assigned devices. This command sequence then configures the related feature on the threat defense device.

Threat Defense uses ASA configuration commands to implement some features, but not all features. There is no unique set of threat defense configuration commands. Instead, the point of FlexConfig is to allow you to configure features that are not yet directly supported through management center policies and settings.

---

**Caution**

Cisco **strongly** recommends using FlexConfig policies only if you are an advanced user with a strong ASA background and at your own risk. You may configure any commands that are not prohibited. Enabling features through FlexConfig policies may cause unintended results with other configured features.

You may contact the Cisco Technical Assistance Center for support concerning FlexConfig policies that you have configured. The Cisco Technical Assistance Center does not design or write custom configurations on any customer's behalf. Cisco expresses no guarantees for correct operation or interoperability with other Firepower System features. FlexConfig features may become deprecated at any time. For fully guaranteed feature support, you must wait for the management center support. When in doubt, do not use FlexConfig policies.

---

## Recommended Usage for FlexConfig Policies

There are two main recommended uses for FlexConfig:

- You are converting from ASA to threat defense, and there are compatible features you are using (and need to continue using) that management center does not directly support. In this case, use the **show running-config** command on the ASA to see the configuration for the feature and create your FlexConfig objects to implement it. Experiment with the object's deployment settings (once/every time and append/prepend) to get the right setting. Verify by comparing **show running-config** output on the two devices.
- You are using threat defense but there is a setting or feature that you need to configure, e.g. the Cisco Technical Assistance Center tells you that a particular setting should resolve a specific problem you are encountering. For complicated features, use a lab device to test the FlexConfig and verify that you are getting the expected behavior.

The system includes a set of predefined FlexConfig objects that represent tested configurations. If the feature you need is not represented by these objects, first determine if you can configure an equivalent feature in standard policies. For example, the access control policy includes intrusion detection and prevention, HTTP and other types of protocol inspection, URL filtering, application filtering, and access control, which the ASA implements using separate features. Because many features are not configured using CLI commands, you will not see every policy represented within the output of **show running-config**.

---

**Note** At all times, keep in mind that there is not a one-to-one overlap between ASA and threat defense. Do not attempt to completely recreate an ASA configuration on a threat defense device. You must carefully test any feature that you configure using FlexConfig.

---

## CLI Commands in FlexConfig Objects

The threat defense uses ASA configuration commands to configure some features. Although not all ASA features are compatible with the threat defense, there are some features that can work on the threat defense but that you cannot configure in the management center policies. You can use FlexConfig objects to specify the CLI required to configure these features.

If you decide to use FlexConfig to manually configure a feature, you are responsible for knowing and implementing the commands according to the proper syntax. FlexConfig policies do not validate CLI command syntax. For more information about proper syntax and configuring CLI commands, use the ASA documentation as a reference:

- ASA CLI configuration guides explain how to configure a feature. Find the guides at <https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-installation-and-configuration-guides-list.html>
- ASA command references provide additional information sorted by command name. Find the references at <https://www.cisco.com/c/en/us/support/security/adaptive-security-appliance-asa-software/products-command-reference-list.html>

The following topics explain more about configuration commands.

## Determine the ASA Software Version and Current CLI Configuration

Because the system uses ASA software commands to configure some features, you need to determine the current ASA version used in software running on the threat defense device. This version number indicates which ASA CLI configuration guides to use for instructions on configuring a feature. You also should examine the current CLI-based configuration and compare it to the ASA configuration you want to implement.

Keep in mind that any ASA configuration will be very different from a threat defense configuration. Many threat defense policies are configured outside of the CLI, so you cannot see the configuration by looking at the commands. Do not try to create a one-to-one correspondence between an ASA and threat defense configuration.

To view this information, make an SSH connection to the device's management interface and issue the following commands:

- **show version system** and look for the Cisco Adaptive Security Appliance Software Version number. (If you issue the command through the Secure Firewall Management Center CLI tool, omit the **system** keyword.)
- **show running-config** to view the current CLI configuration.
- **show running-config all** to include all the default commands in the current CLI configuration.

You can also issue these commands from within management center using the following procedure.

### Procedure

- 
- Step 1** Choose **System > Health > Monitor**.
  - Step 2** Click the name of the device targeted by the FlexConfig policy.  
You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.
  - Step 3** Click **View System and Troubleshoot Details**.
  - Step 4** Click **Advanced Troubleshooting**.
  - Step 5** Click **Threat Defense CLI**.
  - Step 6** Choose the **Device**, then choose **show** as the command, and type **version** or one of the other commands as the parameter.
  - Step 7** Click **Execute**.

For version, search the output for the Cisco Adaptive Security Appliance Software Version number.

You can select the output and press Ctrl+C, then paste it into a text file for later analysis.

---

## Prohibited CLI Commands

The purpose of FlexConfig is to configure features that are available on ASA devices that you cannot configure on threat defense devices using management center.

Thus, you are prevented from configuring ASA features that have equivalents in management center. The following table lists some of these prohibited command areas.

In addition, some **clear** commands are prohibited because they overlap with managed policies, and can delete part of the configuration for a managed policy.

The FlexConfig object editor prevents you from including prohibited commands in the object.

Prohibited CLI Command	Description
AAA	Configuration blocked.
AAA-Server	Configuration blocked.
Access-list	Advanced ACL, Extended ACL, and Standard ACL are blocked. Ethertype ACL is allowed.  You can use standard and extended ACL objects defined in the object manager inside the template as variables.
ARP Inspection	Configuration blocked.
As-path Object	Configuration blocked.
Banner	Configuration blocked.
BGP	Configuration blocked.
Clock	Configuration blocked.
Community-list Object	Configuration blocked.
Copy	Configuration blocked.
Delete	Configuration blocked.
DHCP	Configuration blocked.
Enable Password	Configuration blocked.
Erase	Configuration blocked.
Fragment Setting	Blocked, except for <b>fragment reassembly</b> .
Fsck	Configuration blocked.
HTTP	Configuration blocked.
ICMP	Configuration blocked.
Interface	Only <b>nameif</b> , <b>mode</b> , <b>shutdown</b> , <b>ip address</b> and <b>mac-address</b> commands are blocked.
Multicast Routing	Configuration blocked.
NAT	Configuration blocked.
Network Object/Object-group	Network object creation in the FlexConfig object is blocked, but you can use network objects and groups defined in the object manager inside the template as variables.

Prohibited CLI Command	Description
NTP	Configuration blocked.
OSPF/OSPFv3	Configuration blocked.
pager	Configuration blocked.
Password Encryption	Configuration blocked.
Policy-list Object	Configuration blocked.
Prefix-list Object	Configuration blocked.
Reload	You cannot schedule reloads. The system does not use the <b>reload</b> command to restart the system, it uses the <b>reboot</b> command.
RIP	Configuration blocked.
Route-Map Object	Route-map object creation in the FlexConfig object is blocked, but you can use route map objects defined in the object manager inside the template as variables.
Service Object/Object-group	Service object creation in the FlexConfig object is blocked, but you can use port objects defined in the object manager inside the template as variables.
SNMP	Configuration blocked.
SSH	Configuration blocked.
Static Route	Configuration blocked.
Syslog	Configuration blocked.
Time Synchronization	Configuration blocked.
Timeout	Configuration blocked.
VPN	Configuration blocked.

## Template Scripts

You can use scripting language to control processing within a FlexConfig object. Scripting language instructions are a subset of commands supported in the Apache Velocity 1.3.1 template engine, a Java-based scripting language that supports looping, if/else statements, and variables.

To learn how to use the scripting language, see the *Velocity Developer Guide* at <http://velocity.apache.org/engine/devel/developer-guide.html>.

## FlexConfig Variables

You can use variables in a FlexConfig object in cases where part of a command or processing instruction depends on runtime information rather than static information. During deployment, the variables are replaced with strings obtained from other configurations for the device based on the type of variable:

- Policy object variables are replaced with strings obtained from objects defined in management center.
- System variables are replaced with information obtained from the device itself or from policies configured for it.
- Processing variables are loaded with the contents of policy object or system variables as scripting commands are processed. For example, in a loop, you iteratively load one value from a policy object or system variable into a processing variable, then use the processing variable to form a command string or perform some other action. These processing variables do not show up in the Variables list within a FlexConfig object. Also, you do not add them using the **Insert** menu in the FlexConfig object editor.
- Secret key variables are replaced with the single string defined for the variable within the FlexConfig object.

Variables start with the \$ character, except for secret keys, which start with the @ character. For example, \$ifname is a policy object variable in the following command, whereas @keyname is a secret key.

```
interface $ifname
key @keyname
```

---

**Note** The first time you insert a policy object or system variable, you must do so through the **Insert** menu in the FlexConfig object editor. This action adds the variable to the **Variables** list at the bottom of the FlexConfig object editor. But you must type in the variable string on subsequent uses, even when using system variables. If you are adding a processing variable, which does not have an object or system variable assignment, do not use the **Insert** menu. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

---

Whether a variable is resolved as a single string, a list of strings, or a table of values depends on the type of policy object or system variable you assign to the variable. (Secret keys always resolve to a single string.) You must understand what will be returned in order to process the variables correctly.

The following topics explain the various types of variable and how to process them.

### How to Process Variables

At runtime, a variable can resolve to a single string, a list of strings of the same type, a list of strings of different types, or a table of named values. In addition, variables that resolve to multiple values can be of determinate or indeterminate length. You must understand what will be returned in order to process the values correctly.

Following are the main possibilities.

#### Single Value Variables

If a variable always resolves to a single string, use the variable directly without modification in the FlexConfig script.

For example, the predefined text variable `tcpMssBytes` always resolves to a single value (which must be numeric). The **Sysopt\_basic** FlexConfig then uses an if/then/else structure to set the maximum segment size based on the value of another single-value text variable, `tcpMssMinimum`:

```
#if($tcpMssMinimum == "true")
  sysopt connection tcpmss minimum $tcpMssBytes
#else
  sysopt connection tcpmss $tcpMssBytes
#end
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of `$tcpMssBytes`, but you would type in the variable directly on the `#else` line.

Secret key variables are a special type of single value variable. For secret keys, you always use the **Insert** menu to add the variable, even for second and subsequent uses. These variables do not show up in the Variables list within the FlexConfig object.

**Note** Policy object variables for network objects also equate to a single IP address specification, either a host address, network address, or address range. However, in this case, you must know what type of address to expect, because the ASA commands require specific address types. For example, if a command requires a host address, using a network object variable that points to an object that contains a network address will result in an error during deployment.

## Multiple Value Variables, All Values Are the Same Type

Several policy object and system variables resolve to multiple values of the same type. For example, an object variable that points to a network object group resolves to a list of the IP addresses within the group. Similarly, the system variable `$$SYS_FW_INTERFACE_NAME_LIST` resolves to a list of interface names.

You can also create text objects for multiple values of the same type. For example, the predefined text object `enableInspectProtocolList` can contain more than one protocol name.

Multiple value variables that resolve to a list of items of the same type are frequently of indeterminate length. For example, you cannot know beforehand how many interfaces on a device are named, as users can configure or unconfigure interfaces at any time.

Thus, you would typically use a loop to process multiple value variables of the same type. For example, the predefined FlexConfig **Default\_Inspection\_Protocol\_Enable** uses a `#foreach` loop to go through the `enableInspectProtocolList` object and process each value.

```
policy-map global_policy
  class inspection_default
    #foreach ( $protocol in $enableInspectProtocolList)
      inspect $protocol
    #end
```

In this example, the script assigns each value in turn to the `$protocol` variable, which is then used in an ASA **inspect** command to enable the inspection engine for that protocol. In this case, you simply type in `$protocol` as a variable name. You do not use the **Insert** menu to add it, because you are not assigning an object or system value to the variable. However, you must use the **Insert** menu to add `$enableInspectProtocolList`.

The system loops through the code between `#foreach` and `#end` until there are no values remaining in `$enableInspectProtocolList`.

## Multiple Value Variables, Values Are Different Types

You can create multiple value text objects, but have each value serve a different purpose. For example, the predefined **netflow\_Destination** text object should have 3 values, in order, interface name, destination IP address, and UDP port number.

Objects defined in this way should have a determinate number of values. Otherwise, they would be hard to process.

Use the get method to process these objects. Type **.get(*n*)** at the end of the object name, replacing *n* with an index into the object. Start counting at 0, even though the text object lists its values starting at 1.

For example, the Netflow\_Add\_Destination object uses the following line to add the 3 values from netflow\_Destination to the ASA **flow-export** command.

```
flow-export destination $netflow_Destination.get(0) $netflow_Destination.get(1)
$netflow_Destination.get(2)
```

In this example, you would use the **Insert** menu in the FlexConfig object editor to add the first use of \$netflow\_Destination, and then add **.get(0)**. But you would type in the variable directly for the **\$netflow\_Destination.get(1)** and **\$netflow\_Destination.get(2)** specifications.

## Multiple Value Variables that Resolve to a Table of Values

Some system variables return a table of values. These variables include MAP in their name, for example, \$SYS\_FTD\_ROUTED\_INTF\_MAP\_LIST. The routed interface map returns data that looks like the following (line returns added for clarity):

```
[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]
```

In the above example, information is returned for 4 interfaces. Each interface includes a table of named values. For example, **intf\_hardwarare\_id** is the name of the interface hardware name property, and returns strings such as GigabitEthernet0/0.

This type of variable is typically of indeterminate length, so you need to use looping to process the values. But you also need to add the property name to the variable name to indicate which value to retrieve.

For example, IS-IS configuration requires that you add the ASA **isis** command to an interface that has a logical name in interface configuration mode. However, you enter that mode using the interface's hardware name. Thus, you need to identify which interfaces have logical names, then configure just those interfaces using their hardware names. The **ISIS\_Interface\_Configuration** predefined FlexConfig does this using an if/then

structure nested in a loop. In the following code, you can see that the `#foreach` scripting command loads each interface map into the `$intf` variable, then the `#if` statement keys off the `intf_logical_name` value in the map (`$intf.intf_logical_name`), and if the value is in the list defined in the `isisIntfList` predefined text variable, enters the interface command using the `intf_hardwarare_id` value (`$intf.intf_hardwarare_id`). You would need to edit the `isisIntfList` variable to add the names of the interfaces on which to configure IS-IS.

```
#foreach ($intf in $SYS_FTD_ROUTED_INTF_MAP_LIST)
  #if ($isisIntfList.contains($intf.intf_logical_name))
    interface $intf.intf_hardwarare_id
      isis
      #if ($isisAddressFamily.contains("ipv6"))
        ipv6 router isis
      #end
    #end
  #end
#end
```

## How to See What a Variable Will Return for a Device

An easy way to evaluate what a variable will return is to create a simple FlexConfig object that does nothing more than process an annotated list of variables. Then, you can assign it to a FlexConfig policy, assign the policy to a device, save the policy, then preview the configuration for that device. The preview will show the resolved values. You can select the preview text, press `Ctrl+C`, then paste the output into a text file for analysis.

---

**Note** Do not deploy this FlexConfig to the device, however, because it will not contain any valid configuration commands. You would get deployment errors. After obtaining the preview, delete the FlexConfig object from the FlexConfig policy and save the policy.

---

For example, you could construct the following FlexConfig object:

Following is a network object group variable for the IPv4-Private-All-RFC1918 object:

```
$IPv4_Private_addresses
```

Following is the system variable `SYS_FW_MANAGEMENT_IP`:

```
$SYS_FW_MANAGEMENT_IP
```

Following is the system variable `SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST`:

```
$SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST
```

Following is the system variable `SYS_FTD_ROUTED_INTF_MAP_LIST`:

```
$SYS_FTD_ROUTED_INTF_MAP_LIST
```

Following is the system variable `SYS_FW_INTERFACE_NAME_LIST`:

```
$SYS_FW_INTERFACE_NAME_LIST
```

The preview of this object might look like the following (line returns added for clarity):

```
###Flex-config Prepended CLI ###
```

```

###CLI generated from managed features ###

###Flex-config Appended CLI ###
Following is a network object group variable for the
IPv4-Private-All-RFC1918 object:

[10.0.0.0, 172.16.0.0, 192.168.0.0]

Following is the system variable SYS_FW_MANAGEMENT_IP:

192.168.0.171

Following is the system variable SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST:

[dns, ftp, h323 h225, h323 ras, rsh, rtsp, sqlnet, skinny, sunrpc,
xdmcp, sip, netbios, tftp, icmp, icmp error, ip-options]

Following is the system variable SYS_FTD_ROUTED_INTF_MAP_LIST:

[{intf_hardwarare_id=GigabitEthernet0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.10.1, intf_ipv6_link_local_address=,
intf_logical_name=outside},

{intf_hardwarare_id=GigabitEthernet0/1, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=255.255.255.0,
intf_ip_addr_v4=10.100.11.1, intf_ipv6_link_local_address=,
intf_logical_name=inside},

{intf_hardwarare_id=GigabitEthernet0/2, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=},

{intf_hardwarare_id=Management0/0, intf_ipv6_eui64_addresses=[],
intf_ipv6_prefix_addresses=[], intf_subnet_mask_v4=, intf_ip_addr_v4=,
intf_ipv6_link_local_address=, intf_logical_name=management}]

Following is the system variable SYS_FW_INTERFACE_NAME_LIST:

[outside, inside, management]

```

## FlexConfig Policy Object Variables

A policy object variable is associated with a specific policy object configured in the Object Manager. When you insert a policy object variable in a FlexConfig object, you give the variable a name and select the object associated with it.

Although you can give the variable the exact same name as the associated object, the variable itself is not the same thing as the associated object. You must use the **Insert > Insert Policy Object > Object Type** menu in the FlexConfig object editor to add the variable for the first time to the script in the FlexConfig to establish the association with the object. Simply typing in the name of the object preceded by a \$ sign does not create a policy object variable.

You can create variables to point to the following types of object. Ensure that you create the right type of object for each variable. To create objects, go to the **Objects > Object Management** page.

- **Text Objects**—For text strings, which can include IP addresses, numbers, and other free-form text such as interface or zone names. Select **FlexConfig > Text Object** from the table of contents, then click **Add Text Object**. You can configure these objects to contain a single value or multiple values. These objects

are highly flexible and built specifically for use within FlexConfig objects. For detailed information, see [Configure FlexConfig Text Objects, on page 2730](#).

- **Network**—For IP addresses. You can use network objects or groups. Select **Network** from the table of contents, then select **Add Network > Add Object** or **Add Group**. If you use a group object, the variable returns a list of each IP address specification within the group. Addresses can be host, network, or address ranges, depending on the object contents. See [Network, on page 1497](#).
- **Security Zones**—For interfaces within a security zone or interface group. Select **Interface** from the table of contents, then select **Add > Security Zone** or **Interface Group**. A security zone variable returns a list of the interfaces within that zone or group for the device being configured. See [Interface, on page 1494](#).
- **Standard ACL Object**—For standard access control lists. A standard ACL variable returns the name of the standard ACL object. Select **Access List > Standard** from the table of contents, then click **Add Standard Access List Object**. See [Access List, on page 1468](#).
- **Extended ACL Object**—For extended access control lists. An extended ACL variable returns the name of the extended ACL object. Select **Access List > Extended** from the table of contents, then click **Add Extended Access List Object**. See [Access List, on page 1468](#).
- **Route Map**—For route map objects. A route map variable returns the name of the route map object. Select **Route Map** from the table of contents, then click **Add Route Map**. See [Route Map, on page 1522](#).

## FlexConfig System Variables

System variables are replaced with information obtained from the device itself or from policies configured for it.

You must use the **Insert > Insert System Variable > Variable Name** menu in the FlexConfig object editor to add the variable for the first time to the script in the FlexConfig to establish the association with the system variable. Simply typing in the name of the system variable preceded by a \$ sign does not create a system variable within the context of the FlexConfig object.

The following table explains the available system variables. Before using a variable, examine what is typically returned for the variable; see [How to See What a Variable Will Return for a Device, on page 2711](#).

Name	Description
SYS_FW_OS_MODE	The operating system mode of the device. Possible values are ROUTED or TRANSPARENT.
SYS_FW_OS_MULTPLICITY	Whether the device is running in single or multiple context mode. Possible values are SINGLE, MULTI, or NOT_APPLICABLE.
SYS_FW_MANAGEMENT_IP	The management IP address of the device
SYS_FW_HOST_NAME	The device hostname
SYS_FTD_INTF_POLICY_MAP	A map with interface name as key and policy-map as value. This variable returns nothing if there are no interface-based service policies defined on the device.
SYS_FW_ENABLED_INSPECT_PROTOCOL_LIST	The list of protocols for which inspection is enabled.

Name	Description
SYS_FTD_ROUTED_INTF_MAP_LIST	A list of routed interface maps on the device. Each map includes a set of named values related to routed interface configuration.
SYS_FTD_SWITCHED_INTF_MAP_LIST	A list of switched interface maps on the device. Each map includes a set of named values related to switched interface configuration.
SYS_FTD_INLINE_INTF_MAP_LIST	A list of inline interface maps on the device. Each map includes a set of named values related to inline set interface configuration.
SYS_FTD_PASSIVE_INTF_MAP_LIST	A list of passive interface maps on the device. Each map includes a set of named values related to passive interface configuration.
SYS_FTD_INTF_BVI_MAP_LIST	A list of Bridge Virtual Interface maps on the device. Each map includes a set of named values related to BVI configuration.
SYS_FW_INTERFACE_HARDWARE_ID_LIST	A list of the hardware names for interfaces on the device, such as GigabitEthernet0/0.
SYS_FW_INTERFACE_NAME_LIST	A list of logical names for interfaces on the device, such as inside.
SYS_FW_INLINE_INTERFACE_NAME_LIST	A list of logical names for interfaces configured as passive or ERSPAN passive.
SYS_FW_NON_INLINE_INTERFACE_NAME_LIST	A list of logical names for interfaces that are not part of inline sets, such as all routed interfaces.

## Predefined FlexConfig Objects

The predefined FlexConfig objects provide tested configurations for select features. Use these objects if you need to configure these features, which otherwise cannot be configured using the management center.

The following table lists the available objects. Make note of the associated text objects. You must edit these text objects to customize the behavior of the predefined FlexConfig object. The text objects make it possible for you to customize the configuration using the IP addresses and other attributes required by your network and device.

If you need to modify a predefined FlexConfig object, copy the object, make changes to the copy, and save it with a new name. You cannot directly edit a predefined FlexConfig object.

Although you might be able to configure other ASA-based features using FlexConfig, the configuration of those features has not been tested. If an ASA feature overlaps with something that you can configure in management center policies, do not attempt to configure it through FlexConfig.

For example, Snort inspection includes the HTTP protocol, so do not enable ASA-style HTTP inspection. (In fact, you cannot add **http** to the `enableInspectProtocolList` object. In this case, you are prevented from misconfiguring your device.) Instead, configure the access control policy to perform application or URL filtering, as needed, to implement your HTTP inspection requirements.

Table 231: Predefined FlexConfig Objects

FlexConfig Object Name	Description	Associated Text Objects
Default_Inspection_Protocol_Disable	Disables protocols in the global_policy default policy map.	disableInspectProtocolList
Default_Inspection_Protocol_Enable	Enables protocols in the global_policy default policy map.	enableInspectProtocolList
Inspect_IPv6_Configure	Configures IPv6 inspection in the global_policy policy map, logging and dropping traffic based on IPv6 header contents.	IPv6RoutingHeaderDropLogList, IPv6RoutingHeaderLogList, IPv6RoutingHeaderDropList.
Inspect_IPv6_UnConfigure	Clears and disables IPv6 inspection.	—
ISIS_Configure	Configures global parameters for IS-IS routing.	isIsNet, isIsAddressFamily, isISType
ISIS_Interface_Configuration	Interface level IS-IS configuration.	isIsAddressFamily, IsIsIntfList Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST
ISIS_Unconfigure	Clears the IS-IS router configuration on the device.	—
ISIS_Unconfigure_All	Clears the IS-IS router configuration from the device, including the router assignment from the device interface.	—
NGFW_TCP_NORMALIZATION	Modifies the default TCP normalization configuration.	—
Policy_Based_Routing	To use this example configuration, copy it, modify the interface name, and use the r-map-object text object to identify a route map object in the object manager.	—
Policy_Based_Routing_Clear	Clears Policy Based Routing configurations from the device.	—
Sysopt_AAA_radius	Ignores the authentication key in RADIUS accounting responses.	—
Sysopt_AAA_radius_negate	Negates the Sysopt_AAA_radius configuration.	—
Sysopt_basic	Configures sysopt wait time , maximum segment size for TCP packets, and detailed traffic statistics.	tcpMssMinimum, tcpMssBytes

FlexConfig Object Name	Description	Associated Text Objects
Sysopt_basic_negate	Clears sysopt_basic detailed traffic statistics, wait time, and TCP maximum segment size.	—
Sysopt_clear_all	Clears all sysopt configurations from the device.	—
Sysopt_noproxyarp	Configures noproxy-arp CLIs.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_noproxyarp_negate	Clears Sysopt_noproxyarp configurations.	Uses system variable SYS_FW_NON_INLINE_INTF_NAME_LIST
Sysopt_Preserve_Vpn_Flow	Configures syopt preserve VPN flow.	—
Sysopt_Preserve_Vpn_Flow_negate	Clears the Sysopt_Preserve_Vpn_Flow configuration.	—
Sysopt_Reclassify_Vpn	Configures sysopt reclassify vpn.	—
Sysopt_Reclassify_Vpn_Negate	Negates sysopt reclassify vpn.	—
Threat_Detection_Clear	Clear the threat detection TCP Intercept configuration.	—
Threat_Detection_Configure	Configure threat detection statistics for attacks intercepted by TCP Intercept.	threat_detection_statistics
Wccp_Configure	This template provides an example for configuring WCCP.	isServiceIdentifier, serviceIdentifier, wccpPassword
Wccp_Configure_Clear	Clears WCCP configurations.	—

### Deprecated FlexConfig Objects

The following table lists objects that configure features you can now configure natively in the GUI. Discontinue using these objects at the earliest convenience.

Table 232: Deprecated Predefined FlexConfig Objects

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.3	DHCPv6_Prefix_Delegation_Configure	Configure one outside (Prefix Delegation client) and one inside interface (recipient of delegated prefix) for IPv6 prefix delegation. To use this template, copy it and modify the variables.  Associated text objects: pdoutside, pdinside  Also uses the system variable SYS_FTD_ROUTED_INF_MAP_LIST	Interface IPv6 Settings.
7.3	DHCPv6_Prefix_Delegation_UnConfigure	Removes the DHCPv6 prefix delegation configuration.	Interface IPv6 Settings.
6.3	Default_DNS_Configure	Configure the Default DNS group, which defines the DNS servers that can be used when resolving fully-qualified domain names on the data interfaces.  Associated text objects: defaultDNSNameServerList, defaultDNSParameters	Platform settings.
6.3	DNS_Configure	Configure DNS servers in a non-default DNS server group. Copy the object to change the name of the group.	<b>DNS Server Group</b> in the object manager.
6.3	DNS_UnConfigure	Removes the DNS server configuration performed by Default_DNS_Configure and DNS_Configure. Copy the object to change the DNS server group names if you altered DNS_Configure.	<b>DNS Server Group</b> in the object manager.
7.2	Eigrp_Configure	Configures EIGRP routing next-hop, auto-summary, router-id, eigrp-stub.  Associated text objects: eigrpAS, eigrpNetworks, eigrpDisableAutoSummary, eigrpRouterId, eigrpStubReceiveOnly, eigrpStubRedistributed, eigrpStubConnected, eigrpStubStatic, eigrpStubSummary	For all EIGRP objects, see <a href="#">EIGRP, on page 1377</a> .  The system does allow you to deploy post-upgrade, but also warns you to redo your EIGRP configurations. To help you with this process, we provide a command-line migration tool.

Deprecated Version	FlexConfig Object	Description	Now Configure In
7.2	Eigrp_Interface_Configure	Configures EIGRP interface authentication mode, authentication key, hello interval, hold time, split horizon.  Associated text objects: eigrpIntfList, eigrpAS, eigrpAuthKey, eigrpAuthKeyId, eigrpHelloInterval, eigrpHoldTime, eigrpDisableSplitHorizon  Also uses the system variable SYS_FTD_ROUTED_INTF_MAP_LIST	
7.2	Eigrp_Unconfigure	Clears EIGRP configuration for an autonomous system from the device.	
7.2	Eigrp_Unconfigure_all	Clears all EIGRP configurations.	
7.4	Netflow_Add_Destination	Creates and configures a Netflow export destination.  Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Clear_Parameters	Restores Netflow export global default settings.	Platform settings.
7.4	Netflow_Delete_Destination	Deletes a Netflow export destination.  Associated text objects: Netflow_Destinations, netflow_Event_Types	Platform settings.
7.4	Netflow_Set_Parameters	Sets global parameters for Netflow export.  Associated text objects: netflow_Parameters	Platform settings.
6.3	TCP_Embryonic_Conn_Limit	Configures embryonic connection limits to protect against SYN Flood Denial of Service (DoS) attacks.  Associated text objects: tcp_conn_misc, tcp_conn_limit	Service policy.

Deprecated Version	FlexConfig Object	Description	Now Configure In
6.3	TCP_Embryonic_Conn_Timeout	Configures embryonic connection timeouts to protect against SYN Flood Denial of Service (DoS) attacks.  Associated text objects: tcp_conn_misc, tcp_conn_timeout	Service policy.
7.2	VxLAN_Clear_Nve	Removes the NVE 1 configured when VxLAN_Configure_Port_And_Nve is used from the device.	For all VxLAN objects, see <a href="#">Configure VXLAN Interfaces, on page 969</a> .  If you configured VXLAN interfaces with FlexConfig in a previous version, they continue to work. In fact, FlexConfig takes precedence in this case—if you redo your VXLAN configurations in the web interface, remove the FlexConfig settings.
7.2	VxLAN_Clear_Nve_Only	Clears the NVE configured on the interface when deployed.	
7.2	VxLAN_Configure_Port_And_Nve	Configures VLAN port and NVE 1.  Associated text objects: vxlan_Port_And_Nve	
7.2	VxLAN_Make_Nve_Only	Sets an interface for NVE only.  Associated text objects: vxlan_Nve_Only  Also uses system variables SYS_FTD_ROUTED_MAP_LIST and SYS_FTD_SWICHD_INIF_MAP_LIST	
7.2	VxLAN_Make_Vni	Creates a VNI interface. After deploying this you have to unregister and re-register the device to properly discover the VNI interface.  Associated text objects: vxlan_Vni	

## Predefined Text Objects

There are several predefined text objects. These objects are associated with variables used in the predefined FlexConfig objects. In most cases, you must edit these objects to add values if you use the associated FlexConfig object, or you will see errors during deployment. Although some of these objects contain default values, others are empty.

For information on editing text objects, see [Configure FlexConfig Text Objects, on page 2730](#).

Name	Description	Associated FlexConfig Object
defaultDNSNameServerList (Deprecated.)	The DNS server IP address to configure in the Default DNS group.  Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
defaultDNSParameters (Deprecated.)	The parameters to control DNS behavior for the default DNS server group. The object contains separate entries, in order, for retries, timeout, expire-entry-timer, poll-timer, domain-name.  Starting with version 6.3, configure DNS for the data interfaces in the Threat Defense Platform Settings policy.	Default_DNS_Configure
disableInspectProtocolList	Disables protocols in the default policy map (global_policy).	Disable_Default_Inspection_Protocol
dnsNameServerList	The DNS server IP address to configure in a user-defined DNS group.	DNS_Configure
dnsParameters	The parameters to control DNS behavior for a non-default DNS server group. The object contains separate entries, in order, for retries, timeout, domain-name, name-server-interface.	DNS_Configure
enableInspectProtocolList	Enables protocols in the default policy map (global_policy). You are prevented from adding protocols whose inspection conflicts with Snort inspection.	Enable_Default_Inspection_Protocol
IPv6RoutingHeaderDropList	The list of IPv6 routing header types that you want to disallow. IPv6 inspection drops packets that contain these headers without logging the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderDropLogList	The list of IPv6 routing header types that you want to disallow and log. IPv6 inspection drops packets that contain these headers and sends a syslog message about the drop.	Inspect_IPv6_Configure
IPv6RoutingHeaderLogList	The list of IPv6 routing header types that you want to allow but log. IPv6 inspection allows packets that contain these headers, but sends a syslog message about the existence of the header.	Inspect_IPv6_Configure

Name	Description	Associated FlexConfig Object
isIsAddressFamily	The IPv4 or IPv6 address family.	ISIS_Configure ISIS_Interface_Configuration
IsIsIntfList	List of logical interface names.	ISIS_Interface_Configuration
isIsSType	IS Type (level-1, level-2-only or level-1-2).	ISIS_Configure
isIsNet	Network entity.	ISIS_Configure
isServiceIdentifier	When false, uses the standard <b>web-cache</b> service identifier.	Wccp_Configure
netflow_Destination	Defines a single NetFlow export destination's interface, destination, and UDP port number.	Netflow_Add_Destination
netflow_Event_Types	Defines the types of events to be exported for a destination as any subset of: <b>all</b> , <b>flow-create</b> , <b>flow-defined</b> , <b>flow-teardown</b> , <b>flow-update</b> .	Netflow_Add_Destination
netflow_Parameters	Provides the NetFlow export global settings: active refresh interval (number of minutes between flow update events), delay (flow create delay in seconds; default 0 = command will not appear), and template time-out rate in minutes.	Netflow_Set_Parameters
PrefixDelegationInside	Configures the inside interface for DHCPv6 prefix delegation. The object includes multiple entries, in order, interface name, IPv6 suffix with prefix length, and prefix pool name.	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
PrefixDelegationOutside	Configure the outside DHCPv6 prefix delegation client. The object includes multiple entries, in order, interface name and IPv6 prefix length	None, but could be used with a copy of DHCPv6_Prefix_Delegation_Configure.
serviceIdentifier	Dynamic WCCP service identifier number.	Wccp_Configure
tcp_conn_limit (Deprecated.)	Parameters used for configuring the TCP embryonic connection limits.  Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit

Name	Description	Associated FlexConfig Object
tcp_conn_misc (Deprecated.)	Parameters used for configuring the TCP embryonic connection settings.  Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Limit, TCP_Embryonic_Conn_Timeout
tcp_conn_timeout (Deprecated.)	Parameters used for configuring the TCP embryonic connection timeouts.  Starting with version 6.3, configure these features in the Threat Defense Service Policy, which you can find on the Advanced tab of the access control policy assigned to the device.	TCP_Embryonic_Conn_Timeout
tcpMssBytes	Maximum segment size in bytes.	Sysopt_basic
tcpMssMinimum	Checks whether to set maximum segment size (MSS), which is set only if this flag is true.	Sysopt_basic
threat_detection_statistics	Parameters used for threat detection statistics for TCP Intercept.	Threat_Detection_Configure
vxlan_Nve_Only	Parameters for configuring NVE-only on interface: <ul style="list-style-type: none"> <li>• logical name of interface</li> <li>• IPv4 address (optional for routed interface)</li> <li>• IPv4 netmask (optional for routed interface)</li> </ul>	VxLAN_Make_Nve_Only
vxlan_Port_And_Nve	Parameters used for configuring ports and NVE for VXLAN: <ul style="list-style-type: none"> <li>• vxlan port</li> <li>• source interface (logical name)</li> <li>• type (peer or mcast)</li> <li>• Peer IP Address or default-mcast-group</li> </ul>	VxLAN_Configure_Port_And_Nve

Name	Description	Associated FlexConfig Object
vxlan_Vni	Parameters used for creating VNI: <ul style="list-style-type: none"> <li>• Interface number (1-10000)</li> <li>• segment-id (1-16777215)</li> <li>• nameif (Logical Name of the interface)</li> <li>• type (routed or transparent)</li> <li>• IP address (used in case of routed mode device) or bridge-group number (used in case of transparent mode device)</li> <li>• netmask (If device is in routed mode) or unused</li> </ul>	VxLAN_Make_Vni
wccpPassword	WCCP password.	Wccp_Configure

## Requirements and Prerequisites for FlexConfig Policies

### Model Support

Threat Defense

### Supported Domains

Any

### User Roles

Admin

## Guidelines and Limitations for FlexConfig

- If you make a mistake in the FlexConfig policy, the system will roll back all changes included in the deployment attempt that includes the failed FlexConfig. Because rollback due to a failed deployment includes clearing the configuration, this can be disruptive to your network. Consider timing deployments that include FlexConfig changes to non-business hours. Also, consider isolation the deployment so it includes just FlexConfig changes, and no other policy updates.
- When you use the VxLAN\_Make\_VNI object, you must deploy the same FlexConfig to all units in a cluster or high availability pair before you form the cluster or high availability pair. The Management Center requires the VXLAN interfaces to match on all devices before forming the cluster or high availability pair.

- If you configure any service that applies to connections, such as SIP inspection, go to the device CLI and enter the **clear conn** command to clear connections. When the connections are rebuilt, the new configuration is applied to the sessions.

## Customizing Device Configuration with FlexConfig Policies

Use FlexConfig policies to customize the configuration of a threat defense device.

Before using FlexConfig, try to configure all the policies and settings you need using the other features in management center. FlexConfig is a method of last resort to configure ASA-based features that are compatible with threat defense but which are not otherwise configurable in management center.

Following is the end-to-end procedure for configuring and deploying a FlexConfig policy.

### Procedure

#### Step 1

Determine the CLI command sequence that you want to configure.

If you have a functioning configuration on an ASA device, use **show running-config** to get the sequence of commands that you need. Make adjustments to items such as interface names and IP addresses as needed.

If this is for a new feature, it is best to try to implement it on an ASA device in a lab setting to verify that you have the correct command sequence.

For more information, see the following topics:

- [Recommended Usage for FlexConfig Policies, on page 2704](#)
- [CLI Commands in FlexConfig Objects, on page 2704](#)

#### Step 2

Choose **Objects > Object Management**, then select **FlexConfig > FlexConfig Objects** from the table of contents.

Examine the predefined FlexConfig objects to determine if any will be able to generate the commands you need. Click **View** (🔍) to see the object contents. If an existing object is close to what you want, start by making a copy of the object, and then edit the copy. See [Predefined FlexConfig Objects, on page 2714](#).

Examining the objects will also give you an idea of the structure, command syntax, and expected sequencing for a FlexConfig object.

**Note** If you find any objects that you will use, either directly or as copies, examine the Variables list at the bottom of the object. Make note of the variable names, except those in all capitals that start with SYS, which are system variables. These variables are text objects that you will probably need to edit and define overrides for, especially if the default value column shows the object has no value.

#### Step 3

If you need to create your own FlexConfig objects, determine what variables you will need and create the associated objects.

The CLI you need to deploy might contain IP addresses, interface names, port numbers, and other parameters that you might want to adjust over time. These are best isolated into variables, which point to objects that contain the necessary values. You might also need variables for strings that are part of the configuration but which might change over time.

Also, determine if you need different values for each device to which you will assign the policy. For example, you might want to configure the feature on three devices, but you might need to specify a different interface name or IP address on a given command for each of these devices. If you need to customize the object for each device, ensure that you enable overrides when creating the object, and then define the override values per device.

See the following topics for an explanation of the various types of variables and how to configure the related objects when necessary.

- [FlexConfig Variables, on page 2708](#)
- [FlexConfig Policy Object Variables, on page 2712](#)
- [FlexConfig System Variables, on page 2713](#)
- [Configure FlexConfig Text Objects, on page 2730](#)

**Step 4** If you are using the predefined FlexConfig objects, edit the text objects used as variables.  
See [Configure FlexConfig Text Objects, on page 2730](#).

**Step 5** (If necessary.) [Configure FlexConfig Objects, on page 2726](#).

You need to create objects only if the predefined objects cannot do the job.

**Step 6** [Configure the FlexConfig Policy, on page 2731](#).

**Step 7** [Set Target Devices for a FlexConfig Policy, on page 2732](#).

You can also assign the policy to devices when you create the policy. The policy must have at least one assigned device before you can preview it.

**Step 8** [Preview the FlexConfig Policy, on page 2733](#).

You must save changes before you can preview the policy.

Verify that the generated commands are the ones intended, and that all variables are resolving correctly.

**Step 9** Choose **Deploy > Deployment** in the menu bar.

**Step 10** Select the devices assigned to the policy, and click **Deploy**.

Wait for deployment to complete.

**Step 11** [Verify the Deployed Configuration, on page 2734](#).

**Step 12** (If necessary.) [Remove Features Configured Using FlexConfig, on page 2735](#).

Unlike other types of policy, simply unassigning a FlexConfig from a device might not remove the related configuration. If you want to remove a FlexConfig-generated configuration, you follow the cited procedure.

If you are removing a Feature because it is now directly supported by the product, see also [Convert from FlexConfig to Managed Feature, on page 2737](#).

## Configure FlexConfig Objects

Use FlexConfig objects to define a configuration to be deployed to a device. Each FlexConfig policy is composed of a list of FlexConfig objects, so the objects are essentially code modules composed of Apache Velocity scripting commands, ASA software configuration commands, and variables.

There are several predefined FlexConfig objects that you can use directly, or you can make copies if you need to edit them. You can also create your own objects from scratch. A FlexConfig object's content can range from a single simple command string to elaborate CLI command structures that use variables and scripting commands to deploy commands whose content can differ from device to device or deployment to deployment.

You can also create FlexConfig policy objects when defining FlexConfig policies.

### Before you begin

Keep the following in mind:

- FlexConfig objects translate into commands that are then deployed to the device. These commands are already issued in global configuration mode. Therefore, do not include the **enable** and **configure terminal** commands as part of the FlexConfig object.
- Determine what types of variables you will need, and create any policy objects that you will require. You cannot create objects for variables while editing a FlexConfig object.
- Ensure that your commands do not conflict in any way with the VPN or access control configuration on the devices.
- If there is more than one set of commands for an interface, only the last set of commands is deployed. Therefore, we recommend you not use beginning and ending commands to configure interfaces. For an example of configuring interfaces, see the `ISIS_Interface_Configuration` predefined FlexConfig object.

### Procedure

---

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose **FlexConfig > FlexConfig Object** from the list of object types.

**Step 3** Do one of the following:

- Click **Add FlexConfig Object** to create a new object.
- Click **Edit** (✎) to edit an existing object.
- Click **View** (👁) to see the contents of a predefined object.
- If you want to edit a predefined object, click **Copy** (📄) to create a new object with the same contents.

**Step 4** Enter a **Name** and optionally, a description for the object.

**Step 5** In the object body area, enter the commands and instructions to produce the required configuration.

The object content is a sequence of scripting commands and configuration commands that generate a valid ASA software command sequence. The threat defense device uses ASA software commands to configure some features. For more information on scripting and configuration commands, see:

- [Template Scripts, on page 2707](#)
- [CLI Commands in FlexConfig Objects, on page 2704](#)

You can use variables to supply information that can be known only at runtime, or which can differ from device to device. You simply type in processing variables, but you must use the **Insert** menu to add variables that are associated with policy objects or system variables, or which are secret keys. For a complete discussion of variables, see [FlexConfig Variables, on page 2708](#).

- To insert system variables, choose **Insert > Insert System Variable > Variable Name**. For a detailed explanation of these variables, see [FlexConfig System Variables, on page 2713](#).
- To insert policy object variables, choose **Insert > Insert Policy Object > Object Type**, selecting the appropriate type of object. Then, give the variable a name (which can be the same name as the associated policy object), select the object to associate with the variable, and click **Save**. For a detailed explanation of these types, see [FlexConfig Policy Object Variables, on page 2712](#). For more detail on the procedure, see [Add a Policy Object Variable to a FlexConfig Object, on page 2728](#).
- To insert secret key variables, choose **Insert > Secret Key** and define the variable name and value. For more detail on the procedure, see [Configure Secret Keys, on page 2729](#).

**Note** You must use the **Insert** menu to create a new policy object or system variable. However, for subsequent uses of that variable, you must type it in, \$ included. This is also true for system variables: the first time you use it, add it from the **Insert** menu. Then, type it out for subsequent uses. If you use the **Insert** menu more than once for a system variable, the system variable is added to the Variables list multiple times, and the FlexConfig will not validate, meaning you cannot save your changes. For processing variables (those not associated with a policy object or system variable), simply type in the variable. If you are adding a secret key, always use the **Insert** menu. Secret key variables do not show up in the Variables list.

**Step 6** Choose the deployment frequency and type.

- **Deployment**—Whether to deploy the commands in the object **Once** or **Everytime**. The only way to choose the right option is to test the results of deployment.

Start by selecting **Everytime**. Then, after you attach the object to a FlexConfig policy, deploy the configuration. After a successful deployment, come back to the FlexConfig policy and preview the configuration for one of the assigned devices as described in [Preview the FlexConfig Policy, on page 2733](#). If the section labeled `###CLI generated from managed features ###` contains commands that clear or negate the commands in the object, and the `###Flex-config Appended CLI ###` section contains the commands to reconfigure the feature, you know that **Everytime** is the right option.

Even if you do not see negate commands, make some minor change to the device configuration, then run another deployment. If the deployment completes successfully, you can check the deployment transcript (see [Verify the Deployed Configuration, on page 2734](#)). If you see that the commands were issued again (even when they were already configured) without error, then you can keep **Everytime**.

Change to **Once** only if the system does not first negate the commands in the object before issuing them again, or if the deployment results in errors that are specific to the command. In some cases, the system does not allow you to issue a command that is already configured, but this is the exception.

Some additional tips:

- If the FlexConfig object points to system-managed objects such as network or ACL objects, choose **Everytime**. Otherwise, updates to the objects might not get deployed.

- Use **Once** if the only thing you do in the object is to clear a configuration. Then, remove the object from the FlexConfig policy after the next deployment.

- **Type**—Select one of the following:

- **Append**—(The default.) Commands in the object are put at the end of the configurations generated from the management center policies. You must use Append if you use policy object variables, which point to objects generated from managed objects. If commands generated for other policies overlap with those specified in the object, you should select this option so your commands are not overwritten. This is the safest option.
- **Prepend**—Commands in the object are put at the beginning of the configurations generated from the management center policies. You would typically use prepend for commands that clear or negate a configuration.

**Step 7** (Optional.) Click **Validate** (🔍) above the object body to check the integrity of the script.

The object is always validated when you click **Save**. You cannot save an invalid object.

**Step 8** Click **Save**.

#### What to do next

- If an active policy references your object, deploy configuration changes.

## Add a Policy Object Variable to a FlexConfig Object

You can insert variables into a FlexConfig policy object that are associated with other types of policy object. When the FlexConfig is deployed to a device, these variables resolve to the names or content of the associated object.

Use the following procedure for the first use of a policy object variable in a FlexConfig object. If you need to refer to the object again, type in the variable (including the \$ sign). To understand how to use these variables, see [How to Process Variables, on page 2708](#).

#### Before you begin

For information on editing a FlexConfig Object, see [Configure FlexConfig Objects, on page 2726](#).

#### Procedure

**Step 1** While editing a FlexConfig Policy Object, choose **Insert > Insert Policy Object > Object Type**, selecting the appropriate type of object.

**Step 2** Enter a name for the variable, and optionally, a description.

The name must be unique within the context of the FlexConfig object. It cannot include spaces. You are allowed to use the exact same name as the object associated with the variable.

**Step 3** Select the object to associate with the variable and click **Add** to move it to the **Selected Object** list.

You can associate a variable with a single object only.

**Note** For text objects, you can select any of the predefined objects as needed. However, many of these objects have no default values. You must update the objects to add the required values either directly or as overrides for the device to which you will deploy the FlexConfig object. Trying to deploy a FlexConfig without updating these objects typically results in deployment errors.

**Step 4** Click **Save**.

The variable appears in the Variables list at the bottom of the FlexConfig object editor.

---

## Configure Secret Keys

A secret key is any single-string variable whose content you want to mask, such as passwords. The system provides special treatment for these variables to help you prevent the dissemination of sensitive information.

Secret key variables do not show up in the Variables list in the FlexConfig object.

Use the following procedure to create, insert, and otherwise manage secret key variables in a FlexConfig object. Unlike other types of variables, you can use the **Insert** command every time you need to insert a given secret key variable. With respect to processing, these variables behave like single-value text object variables; see [Single Value Variables, on page 2708](#).

---

**Note** Any data defined in a secret key variable is masked from users except when previewing a FlexConfig policy. In addition, if you export a FlexConfig policy, the content of any secret key variable is erased. When you import the policy, you will need to manually edit each secret key variable to enter the data.

---

### Before you begin

For information on editing a FlexConfig Object, see [Configure FlexConfig Objects, on page 2726](#).

## Procedure

---

**Step 1** While editing a FlexConfig Policy Object, choose **Insert > Secret Key**.

**Step 2** In the **Insert Secret Key** dialog box, do any of the following:

- To create a new key, click **Add Secret Key**, then fill in the following information and click **Add**.
  - **Secret Key Name**—The name of the variable. This name appears in the FlexConfig object prefixed with @.
  - **Password, Confirm Password**—The secret string, which is masked with asterisks as you type.
- To insert a secret key variable in the FlexConfig object, select the check box for the variable.
- To edit the value of a secret key variable, click **Edit** (✎) for the variable. Make your changes and click **Add**.

- To delete a secret key variable, click **Delete** (  ) for the variable.

**Step 3** Click **Save**.

---

## Configure FlexConfig Text Objects

Use text objects in FlexConfig objects as the target of policy object variables. You can use variables to supply information that can be known only at runtime, or which can differ from device to device. During deployment, variables that point to text objects are replaced by the content of the text object.

Text objects contain free-form strings, which can be keywords, interface names, numbers, IP addresses, and so forth. The content depends on how you will use the information within a FlexConfig script.

Before creating or editing a text object, determine exactly what content you will need. This includes how you intend to process the object, which will help you decide between creating a single string or multiple string object. Read the following topics:

- [FlexConfig Variables, on page 2708](#)
- [How to Process Variables, on page 2708](#)

### Procedure

---

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose **FlexConfig > Text Object** from the list of object types.

**Step 3** Do one of the following:

- Click **Add Text Object** to create a new object.
- Click **Edit** (  ) to edit an existing object. You are allowed to edit the predefined text objects, which is required if you intended to use the predefined FlexConfig objects.

**Step 4** Enter a **Name** and optionally, a description for the object.

**Step 5** (New objects only.) Choose a **Variable Type** from the drop-down list:

- **Single**—If the object should contain a single text string.
- **Multiple**—If the object should contain a list of text strings.

You cannot change the variable type after you save the object.

**Step 6** If the variable type is **Multiple**, use the up and down arrows to specify a **Count**.

Rows are added or removed from the object as you change the number.

**Step 7** Add content to the object.

You can either click in the text box next to a variable number and type in a value, or you can set up device overrides for each device that will be assigned a FlexConfig object that uses the text object. You can also do both, in which case the values configured in the base object act as default values in cases where an override does not exist for a given device.

When editing predefined objects, it is a good practice to use device overrides, so that the system defaults remain in place for other users who might need to use the object in different FlexConfig policies. The approach you take depends on the requirements of your organization.

**Tip** Some predefined objects require multiple values where each value serves a specific purpose. Read the description text carefully to determine the expected values in the object. In some cases, the instructions specify that you must use overrides instead of changing the base values. In the case of `enableInspectProtocolList`, you are prevented from entering protocols whose inspection is incompatible with Snort inspection.

If you decide to use device overrides, do the following.

- a) Check the check box of **Allow Overrides**.
- b) Expand the Overrides area (if necessary) and click **Add**.

If an override already exists for the device, click edit for the override to change it.

- c) On **Targets** in the Add Object Override dialog box, select the device for which you are defining values and click **Add** to move it to the Selected Devices list.
- d) Click **Override**, adjust the **Count** as needed, then click in the variable fields and type in the values for the device.
- e) Click **Add**.

**Step 8** Click **Save**.

---

#### What to do next

- If an active policy references your object, deploy configuration changes.

## Configure the FlexConfig Policy

A FlexConfig policy contains two ordered lists of FlexConfig objects, one prepended list and one appended list. For an explanation of prepend/append, see [Configure FlexConfig Objects, on page 2726](#).

FlexConfig policies are shared policies that you can assign to multiple devices.

### Procedure

---

**Step 1** Choose **Devices > FlexConfig**.

**Step 2** Do one of the following:

- Click **New Policy** to create a new FlexConfig Policy. You are prompted to enter a name. Optionally, select devices in the Available Devices list and click **Add to Policy** to assign devices. Click **Save**.
- Click **Edit** (✎) to edit an existing Policy. You can change the name or description by clicking them in edit mode.
- Click **Copy** (📄) to create a new policy with the same contents. You are prompted for a name. Device assignments are not retained for the copy.

- Click delete to remove a policy you no longer need.

**Step 3** Select the FlexConfig objects required for the policy from the **Available FlexConfig** list and click > to add them to the policy.

Objects are automatically added to the prepended or appended list based on the deployment type specified in the FlexConfig object.

To remove a selected object, click **Delete** (  ) next to an object.

**Step 4** For each selected object, click **View** (  ) next to the object to identify the variables used in the object.

Except for system variables, which start with SYS, you need to ensure that the objects associated with the variables are not empty. A blank or brackets with nothing between them, [ ], indicate an empty object. You will need to edit these objects before deploying the policy.

**Note** If you use object overrides, those values will not show up in this view. Thus, an empty default value does not necessarily mean that you have not updated the object with the required values. Previewing the configuration will show whether the variables resolve correctly for a given device. See [Preview the FlexConfig Policy, on page 2733](#).

**Step 5** Click **Save**.

---

#### What to do next

- Set target devices for the policy; see [Set Target Devices for a FlexConfig Policy, on page 2732](#).
- Deploy configuration changes.

## Set Target Devices for a FlexConfig Policy

When you create a FlexConfig policy, you can select the devices that use the policy. You can subsequently change device assignments for the policy as described below.

---

**Note** Normally, when you unassign a policy from a device, the system automatically removes the associated configuration upon the next deployment. However, because FlexConfig objects are scripts for deploying customized commands, simply unassigning a FlexConfig policy from a device does not remove the commands that were configuring by the FlexConfig objects. If your intention is to remove FlexConfig-generated commands from a device's configuration, see [Remove Features Configured Using FlexConfig, on page 2735](#).

---

### Procedure

---

**Step 1** Choose **Devices > FlexConfig** and edit a FlexConfig policy.

**Step 2** Click **Policy Assignments**.

**Step 3** On **Targeted Devices**, build your target list:

- Add—Choose one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**. You can assign the policy to devices, high availability pairs, and clustered devices.
- Delete—Click **Delete** (  ) next to a single device, or select multiple devices, right-click, then choose **Delete Selection**.

- Step 4** Click **OK** to save your selection.
- Step 5** Click **Save** to save the FlexConfig policy.
- 

#### What to do next

- Deploy configuration changes.

## Preview the FlexConfig Policy

Preview a FlexConfig policy to see how the FlexConfig objects get translated into CLI commands. The preview shows the commands that will be generated for a selected device from the scripts and variables used in the FlexConfig objects. The variables are resolved based on the configuration for the device, so you get a clear idea of what will be deployed.

Use the preview to look for potential problems in the FlexConfig objects. Correct the objects until the preview shows the expected results.

You must preview the configuration separately for each device, because the variables can resolve differently based on the device configuration.

### Procedure

---

**Step 1** Choose **Devices > FlexConfig** and edit a FlexConfig policy.

**Step 2** If there are any pending changes, click **Save**.

The preview shows results only for those FlexConfig objects that were in the most recently saved version of the policy. You must save the policy to see a preview of newly-added objects.

**Step 3** Click **Preview Config**.

**Step 4** Choose a device from the **Select Device** drop-down list.

The system retrieves information from the device and configured policies, and determines what CLI commands will be generated on the next deployment to the device. You can select the output and use Ctrl+C to copy it to the clipboard, where you can paste it into a text file for further analysis.

The preview includes the following sections:

- Flex-config Prepended CLI—These are the commands generated by FlexConfigs that are prepended to the configuration.
- CLI generated from managed features—These are commands generated for policies configured in the management center. Commands are generated for new or changed policies since the last successful deployment to the device. These commands do not represent all commands needed to implement the assigned policies. No commands in this section are generated from FlexConfig objects.

- Flex-config Appended CLI—These are the commands generated by FlexConfigs that are appended to the configuration.

**Step 5** Click **Close** to close the preview dialog.

---

## Verify the Deployed Configuration

After you deploy a FlexConfig policy to a device, verify that the deployment was successful and that the resulting configuration is what you expected. Also, verify that the device is performing as expected.

### Procedure

---

**Step 1** To verify that deployment was successful:

- Click **Notifications** in the menu bar, which is unnamed between **Deploy** and **System**.

The icon looks like one of the following, and it might include a number if there are errors:

- **Indicates No Warnings** — Indicates no warnings or errors are present on the system.
- Indicates **One or More Warnings** — Indicates one or more warnings and no errors are present on the system.
- **Indicates One or More Errors** — Indicates one or more errors and any number of warnings are present on the system.

- On **Deployments**, verify that the deployment was successful.
- To see more detailed information, especially for failed deployments, click **Show History**.
- Select the deployment job in the list of jobs in the left column.

Jobs are listed in reverse chronological order, with the most recent job at the top of the list.

- Click download in the **Transcript** column for the device in the right column.

The deployment transcript includes commands sent to the device, and any responses returned from the device. These response can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands that you sent through FlexConfig. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

**Note** There is no distinction made in the transcript between commands sent for managed features and those generated from FlexConfig policies.

For example, the following sequence shows that management center sent commands to configure GigabitEthernet0/0 with the logical name outside. The device responded that it automatically set the security level to 0. Threat Defense does not use the security level for anything. Messages relevant to FlexConfig are in the CLI Apply section of the transcript.

```
===== CLI APPLY =====
FMC >> interface GigabitEthernet0/0
FMC >> nameif outside
```

```
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

**Step 2** Verify that the deployed configuration includes the expected commands.

You can do this by making an SSH connection to the device's management IP address. Use the **show running-config** command to view the configuration.

Alternatively, use the CLI tool within Secure Firewall Management Center.

a) Choose **> Health > Monitor** and click the name of the device.

You might need to click the open/close arrow in the **Count** column in the Status table to see any devices.

b) Click **Advanced Troubleshooting**.

c) Click **Threat Defense CLI**.

d) Select **show** as the command, and type **running-config** as the parameter.

e) Click **Execute**.

The running configuration appears in the text box. You can select the configuration and press Ctrl+C, then paste it into a text file for later analysis.

**Step 3** Verify that the device is performing as expected.

Use the **show** commands related to the feature to see detailed information and statistics. For example, if you enabled additional protocol inspections, the **show service-policy** command provides this information. The exact commands to use are feature-dependent and should be mentioned in the ASA configuration guide and command reference you used to learn how to configure the feature.

If commands that show statistics indicate that numbers are not changing (for example, hit counts, connection counts, and so forth), the configuration might be valid but not meaningful. If you know that traffic is going through the device that should show up in statistics, look for what is missing in your configuration. For example, NAT or access rules might be dropping or changing traffic before a feature can act on it.

You can use the **show** commands from an SSH session or through the management center CLI tool.

However, if the **show** command that you need to use is not available directly within the threat defense CLI, you will need make an SSH connection to the device to use the commands. From the CLI, enter the following command sequence to enter Privileged EXEC mode within the diagnostic CLI. From there, you should be able to enter these otherwise unsupported **show** commands.

```
> system support diagnostic-cli
Attaching to Diagnostic CLI ... Press 'Ctrl+a then d' to detach.
Type help or '?' for a list of available commands.
firepower> enable
Password: <press enter, do not enter a password>
firepower#
```

---

## Remove Features Configured Using FlexConfig

If you decide you need to remove a set of configuration commands you configured using FlexConfig, you might need to manually remove that configuration. Unassigning the FlexConfig policy from a device might not remove all of the configuration.

To manually remove the configuration, you create new FlexConfig objects to clear or negate the configuration commands.

### Before you begin

To determine if you need to manually remove some or all of the configuration generated by an object:

1. Examine the configuration preview, as described in [Preview the FlexConfig Policy, on page 2733](#). If the `###CLI generated from managed features ###` section contains the clear or negate commands to remove all of the commands in the FlexConfig object, then you can simply remove the object from the FlexConfig policy, save, and redeploy.
2. Remove the object from the FlexConfig policy, save the change, then preview the configuration again. If the `###CLI generated from managed features ###` section still does not include the required clear or negate commands, you must follow this procedure to manually remove the configuration.

## Procedure

- 
- Step 1** Choose **Objects > Object Management** and create the FlexConfig Objects to clear or negate the configuration commands.

If a feature has a **clear** command that can remove all configuration settings, then use that command. For example, the predefined `ISIS_Unconfigure_All` object contains a single command that removes all ISIS-related configuration commands:

```
clear configure router isis
```

If there is not a **clear** command for the feature, you need to use the **no** form of each command you want to remove. For example, the predefined `Sysopt_basic_negate` object removes the commands configured through the predefined `Sysopt_basic` object.

```
no sysopt traffic detailed-statistics
no sysopt connection timewait
```

You would typically configure a FlexConfig object that removes configurations as a prepended, deploy once object.

- Step 2** Choose **Devices > FlexConfig** and create a new FlexConfig policy or edit the existing policy.

If you want to preserve the FlexConfig policy that deploys the configuration commands, create a new policy specifically for negating the commands, and assign the devices to the policy. Then, add the new FlexConfig objects to the policy.

If you want to completely remove the FlexConfig configuration objects from all devices, you can simply delete those commands from the existing FlexConfig policy and replace them with the objects that negate the configuration.

- Step 3** Click **Save** to save the FlexConfig policy.

- Step 4** Click **Preview Config** and verify that the clear and negation commands are generating correctly.

- Step 5** Choose **Deploy > Deployment** in the menu bar, select the device, and click **Deploy**.

Wait for deployment to complete.

**Step 6** Verify that the commands were removed.

View the running configuration on the device to confirm that the commands are removed. For more detailed information, see [Verify the Deployed Configuration, on page 2734](#).

**Step 7** While editing the FlexConfig policy, click **Policy Assignments** and remove the device. Optionally, remove the FlexConfig Objects from the policy.

Assuming that the FlexConfig policy simply removes the unwanted configuration commands, there is no need to keep the policy assigned to the device after the removal is complete.

However, if the FlexConfig policy retains options that you still want configured on the device, remove the negation objects from the policy. They are no longer needed.

---

## Convert from FlexConfig to Managed Feature

Each software release adds managed features to the product, that is, features that you configure directly through policies that are controlled outside of FlexConfig. This can deprecate FlexConfig commands that you are currently using; your configurations are not automatically converted. After the upgrade, you cannot assign or create FlexConfig objects using the newly deprecated commands. After upgrading software, examine your FlexConfig policies and objects.

When a feature you configured using FlexConfig starts to be supported as a managed feature, you must convert from using FlexConfig to using the managed feature. In most cases, your existing FlexConfig configurations continue to work post-upgrade and you can still deploy. However, in some cases, using deprecated commands can cause deployment issues. Configuring a feature in both the GUI and FlexConfig is not supported.

---

**Note** Use the migration tool instead of this procedure if the tool supports the feature configuration you are migrating.

---

### Procedure

---

**Step 1** Remove the FlexConfig, as explained in [Remove Features Configured Using FlexConfig, on page 2735](#).

**Step 2** Configure the settings in the newly supported managed feature.

The release notes have a list of new features for the release.

---

## Examples for FlexConfig

Following are some examples of using FlexConfig.

## How to Configure Precision Time Protocol (ISA 3000)

The Precision Time Protocol (PTP) is a time-synchronization protocol developed to synchronize the clocks of various devices in a packet-based network. These device clocks are generally of varying precision and stability. The protocol is designed specifically for industrial, networked measurement and control systems, and is optimal for use in distributed systems because it requires minimal bandwidth and little processing overhead.

A PTP system is a distributed, networked system consisting of a combination of PTP and non-PTP devices. PTP devices include ordinary clocks, boundary clocks and transparent clocks. Non-PTP devices include network switches, routers and other infrastructure devices.

You can configure the threat defense device to be a transparent clock. The threat defense device does not synchronize its clock with the PTP clocks. The threat defense device will use the PTP default profile, as defined on the PTP clocks.

When you configure the PTP devices, you define a domain number for the devices that are meant to function together. Thus, you can configure multiple PTP domains, and then configure each non-PTP device to use the PTP clocks for one specific domain.

### Before you begin

Determine the domain number configured on the PTP clocks that the device should use. This example assumes the PTP domain number is 10. Also, determine the interfaces through which the system can reach the PTP clocks in the domain.

Following are guidelines for configuring PTP:

- This feature is only available on the Cisco ISA 3000 appliance.
- Cisco PTP supports multicast PTP messages only.
- PTP is available only for IPv4 networks, not for IPv6 networks.
- PTP configuration is supported on physical Ethernet data interfaces, whether stand-alone or bridge group members. It is not supported on the management interface, subinterfaces, EtherChannels, Bridge Virtual Interfaces (BVI), or any other virtual interfaces.
- PTP flows on VLAN subinterfaces are supported, assuming the appropriate PTP configuration is present on the parent interface.
- You must ensure that PTP packets are allowed to flow through the device. PTP traffic is identified by UDP destination ports 319 and 320, and destination IP address 224.0.1.129, so any access control rule that allows this traffic should work.
- In Routed firewall mode, you must enable Multicast routing for PTP multicast groups. In addition, if an interface on which you enable PTP is **not** in a bridge group, you must configure the interface to join the IGMP multicast group 224.0.1.129. If the physical interface is a bridge group member, you do not configure it to join the IGMP multicast group.

### Procedure

- 
- Step 1** (Routed mode only.) Enable Multicast routing, and configure the IGMP group for the interfaces.

In Routed mode, you must enable Multicast routing. In addition, for stand-alone physical interfaces, that is, those that are not bridge group members, you must also configure the interface to join the 224.0.1.129 IGMP group. You cannot configure bridge group members to join an IGMP group, but PTP configuration on bridge group members will work without the IGMP join.

Perform this procedure for each device on which you will configure PTP.

**Note** Write down the hardware names of each PTP-clock-facing interface on each device, for example, GigabitEthernet1/1.

- a) Choose **Devices > Device Management**, and edit the device.
- b) Click **Routing**.
- c) Choose **Multicast Routing > IGMP**.
- d) Check the **Enable Multicast Routing** check box.
- e) Click **Join Group**.
- f) Click **Add**, and in the **Add IGMP Join Group Parameters** dialog box, configure the following options and click **OK**.
  - **Interface**—Select the PTP-clock-facing stand-alone interface.
  - **Join Group**—Click + to add a new network object. Create a Host object with the address 224.0.1.129. When configuring additional interfaces, simply select this object. (See [Creating Network Objects, on page 1499](#).)

Repeat this step for each PTP-clock-facing stand-alone interface on the device.

- g) Click **Save** on the Routing page.

**Step 2** Create the FlexConfig object to enable PTP globally and on the interface.

The following procedure assumes that the PTP-clock-facing interface is the same on every device you are configuring. If you have used different interfaces on different devices, you need to create separate objects for each distinct combination. For example, if you use GigabitEthernet1/1 on devices A and B, GigabitEthernet1/2 on devices C and D, and both GigabitEthernet1/1 and 1/2 on devices E and F, you need 3 separate FlexConfig objects, and subsequently, 3 separate FlexConfig policies (explained in the next step).

- a) Choose **Objects > Object Management**.
- b) Choose **FlexConfig > FlexConfig Object** from the table of contents.
- c) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.
  - **Name**—The object name. For example, Enable\_PTP.
  - **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
  - **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features. This ensures that any other changes you make to interface configuration are configured before these commands.
  - **Object body**—In the object body, type the commands needed to configure PTP globally and on each PTP-clock-facing interface. For example, the commands needed for the global configuration for PTP domain 10 and the interface configuration on GigabitEthernet1/1 are:

```
ptp mode e2transparent
ptp domain 10
```

```
interface gigabitethernet1/1
  ptp enable
```

The object body should look similar to the following:

Insert |  Deployment:  Type:

```
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
  ptp enable
```

### Step 3 Create the FlexConfig policy and assign it to the devices.

If you created multiple FlexConfig objects for different combinations of PTP-clock-facing interfaces, you need to create separate FlexConfig policies for each object, and assign those policies to the correct devices based on the interfaces you need to configure. Repeat the following procedure for each group of devices.

- Choose **Devices > FlexConfig**.
- Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

- Select the PTP FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

Selected Append FlexConfigs		
#	Name	Description
1	Enable_PTP	

- Click **Save**.
- If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.
- Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the PTP FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the PTP commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
ptp mode e2etransparent
ptp domain 10
interface gigabitethernet1/1
  ptp enable
```

### Step 4 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See [Verify the Deployed Configuration, on page 2734](#).

**Step 5** Verify the PTP configuration on each device.

From an SSH or Console session into each device, verify the PTP settings:

```
> show ptp clock
PTP CLOCK INFO
  PTP Device Type: End to End Transparent Clock
  Operation mode: One Step
  Clock Identity: 34:62:88:FF:FE:1:73:81
  Clock Domain: 10
  Number of PTP ports: 4
> show ptp port
PTP PORT DATASET: GigabitEthernet1/1
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 1
  PTP version: 2
  Port state: Enabled

PTP PORT DATASET: GigabitEthernet1/2
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 2
  PTP version: 2
  Port state: Disabled

PTP PORT DATASET: GigabitEthernet1/3
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 3
  PTP version: 2
  Port state: Disabled

PTP PORT DATASET: GigabitEthernet1/4
  Port identity: Clock Identity: 34:62:88:FF:FE:1:73:81
  Port identity: Port Number: 4
  PTP version: 2
  Port state: Disabled
```

---

## How to Configure Automatic Hardware Bypass for Power Failure (ISA 3000)

You can enable hardware bypass so that traffic continues to flow between an interface pair during a power outage. Supported interface pairs are copper interfaces GigabitEthernet 1/1 and 1/2; and GigabitEthernet 1/3 and 1/4. If you have a fiber Ethernet model, only the copper Ethernet pair (GigabitEthernet 1/1 and 1/2) supports hardware bypass.

When hardware bypass is active, traffic passes between these interface pairs at layer 1. The threat defense CLI will see the interfaces as being down. No firewall functions are in place, so make sure you understand the risks of allowing traffic to pass through the device.

In CLI Console or an SSH session, use the **show hardware-bypass** command to monitor the operational status.

### Before you begin

For hardware bypass to work:

- You must place the interface pairs in the same bridge group.
- You must attach the interfaces to access ports on the switch. Do not attach them to trunk ports.

We recommend that you disable TCP sequence number randomization globally using the Threat Defense Service Policy attached to the access control policy assigned to the device. By default, the ISA 3000 rewrites the initial sequence number (ISN) of TCP connections passing through it to a random number. When hardware bypass is activated, the ISA 3000 is no longer in the data path and does not translate the sequence numbers. The receiving client receives an unexpected sequence number and drops the connection, so the TCP session needs to be re-established. Even with TCP sequence number randomization disabled, some TCP connections will have to be re-established because of the link that is temporarily down during the switchover.

## Procedure

### Step 1

Create the FlexConfig object to enable automatic bypass.

- Choose **Objects > Object Management**.
- Choose **FlexConfig > FlexConfig Object** from the table of contents.
- Click **Add FlexConfig Object**, configure the following properties, and click **Save**.
  - **Name**—The object name. For example, Enable\_HW-Bypass.
  - **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
  - **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
  - **Object body**—In the object body, type the commands needed to enable automatic hardware bypass. For example, the commands needed for both possible interface pairs:

```
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

The object body should look similar to the following:

### Step 2

Create the FlexConfig policy and assign it to the devices.

- Choose **Devices > FlexConfig**.
- Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

- c) Select the hardware bypass FlexConfig object in the **User Defined** folder in the table of contents and click **>** to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

Selected Append FlexConfigs	
#	Name
1	Enable_HW-Bypass

- d) Click **Save**.
- e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.
- f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the hardware bypass FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the hardware bypass commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
hardware-bypass GigabitEthernet 1/1-1/2
hardware-bypass GigabitEthernet 1/3-1/4
```

### Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See [Verify the Deployed Configuration, on page 2734](#).

### What to do next

If you want to manually invoke hardware bypass or manually turn it off, you need to create two FlexConfig objects:

- One that manually starts bypass, which would contain one or both of the following commands, depending on whether you want to invoke bypass for both pairs:

```
hardware-bypass manual GigabitEthernet 1/1-1/2
hardware-bypass manual GigabitEthernet 1/3-1/4
```

- One that manually turns off bypass, which would contain one or both of the following commands:

```
no hardware-bypass manual GigabitEthernet 1/1-1/2
no hardware-bypass manual GigabitEthernet 1/3-1/4
```

You would then need to add one or the other object to the FlexConfig policy, and deploy changes, to either turn bypass on or off. You would also need to immediately remove the object from the FlexConfig policy after deployment. If you manually invoke bypass, you would then need to repeat the process to turn it off again. Thus, using this manual method requires frequent and careful editing of the FlexConfig policy and additional deployments.

## Migrating FlexConfig Policies

**Attention** This section on migrating FlexConfig policies is applicable only for migrating ECMP, VXLAN, and EIGRP policies.

The ECMP, VXLAN, and EIGRP policies were configured using the FlexConfig objects and policies in earlier versions of the management center. You can now directly configure these policies in the management center UI. When you are upgrading the management center from earlier versions, the FlexConfig configuration is retained. However, to manage the policies from the UI, you must redo the configuration in the corresponding **Device (Edit) > Routing** page and remove the configuration from FlexConfig. To automate creation of the policies in the UI, management center provides an option to migrate the policies from FlexConfig to the UI. However, it does not remove the migrated policies from the FlexConfig. For post-migration procedure, refer to [Step 7, on page 2745](#).

### Before you begin

- Ensure that the deployed FlexConfig policy is up-to-date and not out-of-date. The migration option will be available only if the policy is up-to-date on at least 1 device. Migration does not take place for those devices that have out-of-date policies.
- If the policy is configured in both FlexConfig and the management center:
  - Migration will not be initiated if the policy is already configured at **Device (Edit) > Routing**.
  - During deployment, the management center displays an error message. Example EIGRP migration error message—*EIGRP is configured through FlexConfig object and also under Device Listing ->Routing EIGRP for the device. Maintain the EIGRP configuration in either Routing EIGRP or FlexConfig.*
- If the network objects used in the policy exist in the management center, during migration, they are reused. During migration, when a network object that is matching the IP configuration is not available, a new network object is created as *bb* appended with a timestamp and integer, like ***bb\_<timestamp>\_<integer>***. For more than one such network object, the integer variable in the name would be incremented by one.

### Procedure

- 
- Step 1** Choose **Devices > FlexConfig**, click **Edit** (✎) against the FlexConfig policy that you want to migrate.
  - Step 2** Click **Migrate Config**.

**Note** Once migration starts, both **Migrate Config** and FlexConfig **Edit** options are not available.

The **Migrate Config** option is not available, when:

- There are no applicable FlexConfig CLIs to be migrated.
- The FlexConfig policy is not associated with any FlexConfig objects.
- There are no devices that are associated with the FlexConfig policy.

**Step 3** In the **Migrate Flex Configuration** dialog box, select the device to which you wish to migrate the configuration, and then click **Ok**.

The migration progress is displayed as task notification. When the migration is complete, click the *View Details* link and download the migration report (PDF format).

**Step 4** To view the policy changes, choose **System > Monitoring > Audit** and click on the *Flex Config Migration* message.

**Step 5** To view the FlexConfig migration report, choose **System > Monitoring > Audit** and click on the *Flex Config Migration* message. To view the complete migration report, click the **Report** icon.

**Step 6** Verify the migrated configuration settings in the corresponding **Device (Edit) > Routing** page.

**Step 7** To remove the specific policy config from FlexConfig for the device, in the management center, do the following:

- a) Identify the migrated FlexConfig policy for the device.
- b) Use the copy option and create duplicate of the FlexConfig policy.
- c) Remove the corresponding CLI objects from the duplicated FlexConfig policy.
- d) Associate the device to the duplicated FlexConfig policy.

**Step 8** Save and deploy the configuration.

---

## CHAPTER 103

# Advanced Access Control Settings for Network Analysis and Intrusion Policies

---

The following topics describe how to configure advanced settings for network analysis and intrusion policies:

- [About Advanced Access Control Settings for Network Analysis and Intrusion Policies, on page 2749](#)
- [Requirements and Prerequisites for Advanced Access Control Settings for Network Analysis and Intrusion Policies, on page 2749](#)
- [Inspection of Packets That Pass Before Traffic Is Identified, on page 2750](#)
- [Advanced Settings for Network Analysis Policies, on page 2751](#)

## About Advanced Access Control Settings for Network Analysis and Intrusion Policies

Many of the advanced settings in an access control policy govern intrusion detection and prevention configurations that require specific expertise to configure. Advanced settings typically require little or no modification and are not common to every deployment.

## Requirements and Prerequisites for Advanced Access Control Settings for Network Analysis and Intrusion Policies

### Model Support

Any.

### Supported Domains

Any

### User Roles

- Admin
- Access Admin

- Network Admin

## Inspection of Packets That Pass Before Traffic Is Identified

For some features, including URL filtering, application detection, rate limiting, and Intelligent Application Bypass, a few packets must pass in order for the connection to be established, and to enable the system to identify the traffic and determine which access control rule (if any) will handle that traffic.

You must explicitly configure your access control policy to inspect these packets, prevent them from reaching their destination, and generate any events. See [Specify a Policy to Handle Packets That Pass Before Traffic Identification, on page 2750](#).

As soon as the system identifies the access control rule or default action that should handle the connection, the remaining packets in the connection are handled and inspected accordingly.

## Best Practices for Handling Packets That Pass Before Traffic Identification

- The default action specified for an access control policy is NOT applied to these packets.
- Instead, use the following guidelines to choose a value for the **Intrusion Policy used before Access Control rule is determined** setting in the Advanced settings of the access control policy.
  - You can choose a system-created or custom intrusion policy. For example, you can choose **Balanced Security and Connectivity**.
  - For performance reasons, unless you have good reason to do otherwise, this setting should match the default action set for your access control policy.
  - If your system does not perform intrusion inspection (for example, in a discovery-only deployment), select **No Rules Active**. The system will not inspect these initial packets, and they will be allowed to pass.
  - By default, this setting uses the default variable set. Ensure that this is suitable for your purposes. For information, see [Variable Set, on page 1541](#).
  - The network analysis policy associated with the first matching network analysis rule preprocesses traffic for the policy you select. If there are no network analysis rules, or none match, the default network analysis policy is used.

## Specify a Policy to Handle Packets That Pass Before Traffic Identification

---

**Note** This setting is sometimes referred to as the *default intrusion policy*. (This is distinct from the default action for an access control policy.)

---

### Before you begin

Review best practices for these settings. See [Best Practices for Handling Packets That Pass Before Traffic Identification, on page 2750](#).

## Procedure

- 
- Step 1** In the access control policy editor, click **Advanced**, then click **Edit** (✎) next to the **Network Analysis and Intrusion Policies** section.
- If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 2** Select an intrusion policy from the **Intrusion Policy used before Access Control rule is determined** drop-down list.
- If you choose a user-created policy, you can click **Edit** (✎) to edit the policy in a new window. You cannot edit system-provided policies.
- Step 3** Optionally, select a different variable set from the **Intrusion Policy Variable Set** drop-down list. You can also select **Edit** (✎) next to the variable set to create and edit variable sets. If you do not change the variable set, the system uses a default set.
- Step 4** Click **OK**.
- Step 5** Click **Save** to save the policy.
- 

### What to do next

- Deploy configuration changes.

### Related Topics

[Variable Set](#), on page 1541

# Advanced Settings for Network Analysis Policies

*Network analysis policies* govern how traffic is decoded and preprocessed so that it can be further evaluated, especially for anomalous traffic that might signal an intrusion attempt. This traffic preprocessing occurs after Security Intelligence matching and traffic decryption, but before intrusion policies inspect packets in detail. By default, the system-provided Balanced Security and Connectivity network analysis policy is the default network analysis policy.

**Tip** The system-provided Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules.

---

A simple way to tune preprocessing is to create and use a custom network analysis policy as the default. For advanced users with complex deployments, you can create multiple network analysis policies, each tailored to preprocess traffic differently. Then, you can configure the system to use those policies to govern the preprocessing of traffic using different security zones, networks, or VLANs.

To accomplish this, you add custom *network analysis rules* to your access control policy. A network analysis rule is simply a set of configurations and conditions that specifies how you preprocess traffic that matches those qualifications. You create and edit network analysis rules in the advanced options in an existing access control policy. Each rule belongs to only one policy.

Each rule has:

- a set of rule conditions that identifies the specific traffic you want to preprocess
- an associated network analysis policy that you want to use to preprocess traffic that meets all the rules' conditions

When it is time for the system to preprocess traffic, it matches packets to network analysis rules in top-down order by rule number. Traffic that does not match any network analysis rules is preprocessed by the default network analysis policy.

## Setting the Default Network Analysis Policy

You can choose a system- or user-created policy.

**Note** If you disable a preprocessor but the system needs to evaluate preprocessed packets against an enabled intrusion or preprocessor rule, the system automatically enables and uses the preprocessor although it remains disabled in the network analysis policy web interface. Tailoring preprocessing, especially using multiple custom network analysis policies, is an **advanced** task. Because preprocessing and intrusion inspection are so closely related, you **must** be careful that you allow the network analysis and intrusion policies examining a single packet to complement each other.

### Procedure

- 
- Step 1** In the access control policy editor, click **Advanced**, then click **Edit** (✎) next to the Network Analysis and Intrusion Policies section.
- If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 2** From the **Default Network Analysis Policy** drop-down list, select a default network analysis policy.
- If you choose a user-created policy, you can click **Edit** (✎) to edit the policy in a new window. You cannot edit system-provided policies.
- Step 3** Click **OK**.
- Step 4** Click **Save** to save the policy.
- 

### What to do next

- Deploy configuration changes.

### Related Topics

[Limitations of Custom Policies](#), on page 2055

## Network Analysis Rules

Within your access control policy's advanced settings, you can use network analysis rules to tailor preprocessing configurations to network traffic.

Network analysis rules are numbered, starting at 1. When it is time for the system to preprocess traffic, it matches packets to network analysis rules in top-down order by ascending rule number, and preprocesses traffic according to the first rule where all the rule's conditions match.

You can add zone, network, and VLAN tag conditions to a rule. If you do not configure a particular condition for a rule, the system does not match traffic based on that criterion. For example, a rule with a network condition but no zone condition evaluates traffic based on its source or destination IP address, regardless of its ingress or egress interface. Traffic that does not match any network analysis rules is preprocessed by the default network analysis policy.

### Network Analysis Policy Rule Conditions

Rule conditions enable you to fine-tune your network analysis policy to target the users and networks you want to control. See one of the following sections for more information.

#### Related Topics

[Security Zone Rule Conditions](#), on page 1965

[Network Rule Conditions](#), on page 1065

[VLAN Tags Rule Conditions](#), on page 1867

### Security Zone Rule Conditions

Security zones segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices.

Zone rule conditions control traffic by its source and destination security zones. If you add both source and destination zones to a zone condition, matching traffic must originate from an interface in one of the source zones and leave through an interface in one of the destination zones.

Just as all interfaces in a zone must be of the same type (all inline, passive, switched, or routed), all zones used in a zone condition must be of the same type. Because devices deployed passively do not transmit traffic, you cannot use a zone with passive interfaces as a destination zone.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

---

**Tip** Constraining rules by zone is one of the best ways to improve system performance. If a rule does not apply to traffic through any of device's interfaces, that rule does not affect that device's performance.

---

### Network Rule Conditions

Network rule conditions control traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

---

**Note** You *cannot* use FDQN network objects in identity rules.

---

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

## VLAN Tags Rule Conditions

---

**Note** VLAN tags in access rules only apply to inline sets. Access rules with VLAN tags do not match traffic on firewall interfaces.

---

VLAN rule conditions control VLAN-tagged traffic, including Q-in-Q (stacked VLAN) traffic. The system uses the innermost VLAN tag to filter VLAN traffic, with the exception of the prefilter policy, which uses the outermost VLAN tag in its rules.

Note the following Q-in-Q support:

- Threat Defense on Firepower 4100/9300—Does not support Q-in-Q (supports only one VLAN tag).
- Threat Defense on all other models:
  - Inline sets and passive interfaces—Supports Q-in-Q, up to 2 VLAN tags.
  - Firewall interfaces—Does not support Q-in-Q (supports only one VLAN tag).

You can use predefined objects to build VLAN conditions, or manually enter any VLAN tag from 1 to 4094. Use a hyphen to specify a range of VLAN tags.

In a cluster, if you encounter problems with VLAN matching, edit the access control policy advanced options, Transport/Network Preprocessor Settings, and select the **Ignore the VLAN header when tracking connections** option.

## Configuring Network Analysis Rules

### Procedure

---

**Step 1** In the access control policy editor, click **Advanced**, then click **Edit** (✎) next to the Network Analysis and Intrusion Policies section.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

**Tip** Click **Network Analysis Policy List** to view and edit existing custom network analysis policies.

**Step 2** Next to **Network Analysis Rules**, click the statement that indicates how many custom rules you have.

- Step 3** Click **Add Rule**.
- Step 4** Configure the rule's conditions by clicking the conditions you want to add.
- Step 5** Click **Network Analysis** and choose the **Network Analysis Policy** you want to use to preprocess the traffic matching this rule.
- Click **Edit** (✎) to edit a custom policy in a new window. You cannot edit system-provided policies.
- Step 6** Click **Add**.
- 

#### What to do next

- Deploy configuration changes.

## Managing Network Analysis Rules

A network analysis rule is simply a set of configurations and conditions that specifies how you preprocess traffic that matches those qualifications. You create and edit network analysis rules in the advanced options in an existing access control policy. Each rule belongs to only one policy.

### Procedure

---

- Step 1** In the access control policy editor, click **Advanced**, then click **Edit** (✎) next to the Intrusion and Network Analysis Policies section.
- If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.
- Step 2** Next to **Network Analysis Rules**, click the statement that indicates how many custom rules you have.
- Step 3** Edit your custom rules. You have the following options:
- To edit a rule's conditions, or change the network analysis policy invoked by the rule, click **Edit** (✎) next to the rule.
  - To change a rule's order of evaluation, click and drag the rule to the correct location. To select multiple rules, use the Shift and Ctrl keys.
  - To delete a rule, click **Delete** (🗑) next to the rule.
- Tip** Right-clicking a rule displays a context menu that allows you to cut, copy, paste, edit, delete, and add new network analysis rules.
- Step 4** Click **OK**.
- Step 5** Click **Save** to save the policy.
- 

#### What to do next

- Deploy configuration changes.

## CHAPTER 104

# Get Started with Snort 3 Network Analysis Policies

---

This chapter provides an insight into network analysis policy basics, prerequisites, and how to manage network analysis policies. It also provides information on custom network analysis policy creation and network analysis policy settings.

## Overview of Network Analysis Policies

*Network analysis policies* govern many traffic preprocessing options, and are invoked by advanced settings in your access control policy. Network analysis-related preprocessing occurs after Security Intelligence matching and SSL decryption, but before intrusion or file inspection begins.

By default, the system uses the *Balanced Security and Connectivity* network analysis policy to preprocess all traffic handled by an access control policy. However, you can choose a different default network analysis policy to perform this preprocessing. For your convenience, the system provides a choice of several non-modifiable network analysis policies, which are tuned for a specific balance of security and connectivity by the Cisco Talos Intelligence Group (Talos). You can also create a custom network analysis policy with custom preprocessing settings.

**Tip** System-provided intrusion and network analysis policies are similarly named but contain different configurations. For example, the Balanced Security and Connectivity network analysis policy and the Balanced Security and Connectivity intrusion policy work together and can both be updated in intrusion rule updates. However, the network analysis policy governs mostly preprocessing options, whereas the intrusion policy governs mostly intrusion rules. Network analysis and intrusion policies work together to examine your traffic.

You can also tailor traffic preprocessing options to specific security zones, networks, and VLANs by creating multiple custom network analysis policies, then assigning them to preprocess different traffic. (Note that ASA FirePOWER cannot restrict preprocessing by VLAN.)

## Manage Network Analysis Policies

Under your user name in the toolbar, the system displays a tree of available domains. To switch domains, choose the domain you want to access.

### Procedure

**Step 1** Choose one of the following paths to access the network analysis policy.

- **Policies > Access Control**, then click **Network Analysis Policy**
- **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**
- **Policies > Intrusion > Network Analysis Policies**

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

**Step 2** Manage your network analysis policy:

- Compare—Click **Compare Policies**; see *Comparing Policies* in the *Cisco Secure Firewall Management Center Configuration Guide*.

**Note** You can compare Snort 2 policies only.

- Create—If you want to create a new network analysis policy, click **Create Policy**.

Two versions of the network analysis policy are created, a **Snort 2 Version** and a **Snort 3 Version**.

- For the Snort 2 version, see *Custom Network Analysis Policy Creation for Snort 2* in the *Cisco Secure Firewall Management Center Configuration Guide*.
- For the Snort 3 version, see [Custom Network Analysis Policy Creation for Snort 3, on page 2761](#).
- Delete—If you want to delete a network analysis policy, click the **Delete** icon, then confirm that you want to delete the policy. You cannot delete a network analysis policy if an access control policy references it.

If the controls are dimmed, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- **Edit**—If you want to edit an existing network analysis policy, click the **Edit** icon.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- **Report**—Click the **Report** icon; see *Generating Current Policy Reports* in the *Cisco Secure Firewall Management Center Configuration Guide*.

## Snort 3 Definitions and Terminologies for Network Analysis Policy

The following table lists the Snort 3 concepts and terms used in the Network Analysis Policy.

**Table 233: Snort 3 Definitions and Terminologies for Network Analysis Policy**

Term	Description
Inspectors	Inspectors are plugins that process packets (similar to the Snort 2 preprocessor).
Binder inspector	<p>Binder inspector defines the flow when a particular inspector has to be accessed and taken into consideration.</p> <p>When the traffic matches the conditions defined in the binder inspector, only then do the values/configurations for that inspector come into effect.</p> <p>For more information, see <i>Binder Inspector</i> in <a href="#">Custom Network Analysis Policy Creation for Snort 3, on page 2761</a>.</p>
Singleton inspectors	<p>Singleton inspectors contain one instance. These inspectors do not support adding more instances like multiton inspectors. Settings of singleton inspector are applied to the entire traffic matching that inspector and not to a specific traffic segment.</p> <p>For more information, see <i>Singleton Inspectors</i> in <a href="#">Custom Network Analysis Policy Creation for Snort 3, on page 2761</a>.</p>

Term	Description
Multiton inspectors	<p>Multiton inspectors contain multiple instances which you can configure as needed. These inspectors support configuring settings based on specific conditions, such as network, port, and VLAN. One set of supported settings is called an instance.</p> <p>For more information, see <i>Multiton Inspectors</i> in <a href="#">Custom Network Analysis Policy Creation for Snort 3</a>, on page 2761.</p>
Schema	<p>The schema file is based on the OpenAPI JSON specification, and it validates the content that you upload or download. You can download the schema file and open it using any third-party JSON editor, such as Swagger editor. The schema file helps you to identify what parameters can be configured for inspectors with their corresponding allowed values, range, and accepted patterns to be used.</p> <p>For more information, see <a href="#">Customize the Network Analysis Policy</a>, on page 2769.</p>
Sample file	<p>It is a pre-existing template that contains example configurations to help you with configuring the inspectors.</p> <p>You can refer to the example configurations included in the sample file and make any changes that you may require.</p> <p>For more information, see <a href="#">Customize the Network Analysis Policy</a>, on page 2769.</p>
Full configuration	<p>You can download the entire inspector configurations in a single file.</p> <p>All information regarding the inspector configuration is available in this file.</p> <p>The full configuration is a merged configuration of the default configuration (rolled out as a part of the LSP updates by Cisco Talos) and the custom NAP inspector configurations.</p> <p>For more information, see <a href="#">Customize the Network Analysis Policy</a>, on page 2769.</p>

Term	Description
Overridden configuration	<p>In the <b>Snort 3 Version</b> of the network analysis policy page:</p> <ul style="list-style-type: none"> <li>• Under <b>Actions &gt; Upload</b>, you can click <b>Overridden Configuration</b> to upload the JSON file that contains the overridden configuration.</li> <li>• Under <b>Actions &gt; Download</b>, you can click <b>Overridden Configuration</b> to download the inspector configuration that has been overridden.</li> </ul> <p>If you have not overridden any inspector configuration, then this option is disabled. When you override the inspector configuration, then this option is enabled automatically to allow you to download.</p> <p>For more information, see <a href="#">Customize the Network Analysis Policy</a>, on page 2769.</p>

#### Related Topics

[Custom Network Analysis Policy Creation for Snort 3](#), on page 2761

[Customize the Network Analysis Policy](#), on page 2769

[Network Analysis Policy Mapping](#), on page 2766

## Prerequisites for Network Analysis and Intrusion Policies

To allow the Snort inspection engine to process traffic for intrusion and malware analysis, you must have the IPS license enabled for the Threat Defense device.

You must be an Admin user to manage network analysis, intrusion policies, and perform migration tasks.

## Custom Network Analysis Policy Creation for Snort 3

The default network analysis policy is tuned for typical network requirements and optimal performance. Usually, the default network analysis policy suffices most network requirements and you might not need to customize the policy. However, when you have a specific network requirement or when you are facing performance issues, the default network analysis policy can be customized. Note that customizing the network analysis policy is an advanced configuration that should be done only by advanced users or Cisco support.

Network analysis policy configuration for Snort 3 is a data-driven model, which is based on JSON and JSON Schema. Schema is based on the OpenAPI specification, and it helps you get a view of the supported inspectors, settings, settings type, and valid values. The Snort 3 inspectors are plugins that process packets (similar to the Snort 2 preprocessor). Network analysis policy configuration is available to download in the JSON format.

In Snort 3, the list of inspectors and settings are not in a one-to-one mapping with the Snort 2 list of preprocessors and settings. Also, the number of inspectors and settings available in management center is a subset of the inspectors and settings that Snort 3 supports. See <https://snort.org/snort3> for more information

on Snort 3. See <https://www.cisco.com/go/snort3-inspectors> for more information on the inspectors available in management center.

**Note**

- While upgrading the management center to the 7.0 release, the changes that were done in the Snort 2 version of the network analysis policy are not migrated to Snort 3 after the upgrade.
- Unlike the intrusion policy, there is no option to synchronize Snort 2 network analysis policy settings to Snort 3.

**Default Inspector Updates**

Lightweight Security Package (LSP) updates may contain new inspectors or modifications to integer ranges for existing inspector configurations. Following the installation of an LSP, new inspectors and/or updated ranges will be available under **Inspectors** in the **Snort 3 Version** of your network analysis policy.

**Binder Inspector**

Binder inspector defines the flow when a particular inspector has to be accessed and taken into consideration. When the traffic matches the conditions defined in the binder inspector, only then the values/configurations for that inspector come into effect. For example:

For the *imap* inspector, the binder defines the following condition when it has to be accessed. That is when:

- Service is equal to *imap*.
- Role is equal to *any*.

If these conditions are met, then use the type *imap*.

```
▼ binder
185 {
186   "when": {
187     "service": "imap",
188     "role": "any"
189   },
190   "use": {
191     "type": "imap"
192   }
193 },
```

### Singleton Inspectors

Singleton inspectors contain a single instance. These inspectors do not support adding more instances like multiton inspectors. Settings of singleton inspector are applied to the entire traffic and not to a specific traffic segment.

For example:

```
{
  "normalizer":{
    "enabled":true,
    "type":"singleton",
    "data":{
      "ip4":{
        "df":true
      }
    }
  }
}
```

### Multiton Inspectors

Multiton inspectors contain multiple instances which you can configure as needed. These inspectors support configuring settings based on specific conditions, such as network, port, and VLAN. One set of supported

settings is called an instance. There is a default instance, and you can also add additional instances based on specific conditions. If the traffic matches that condition, the settings from that instance are applied. Otherwise, the settings from the default instance are applied. Also, the name of the default instance is the same as the inspector's name.

For a multiton inspector, when you upload the overridden inspector configuration, you also need to include/define a matching binder condition (conditions under when the inspector has to be accessed or used) for each instance in the JSON file, otherwise, the upload will result in an error. You can also create new instances, but make sure that you include a binder condition for every new instance that you create to avoid errors.

For example:

- Multiton inspector where the default instance is modified.

```
{
  "http_inspect":{
    "enabled":true,
    "type":"multiton",
    "instances":[
      {
        "name":"http_inspect",
        "data":{
          "response_depth":5000
        }
      }
    ]
  }
}
```

- Multiton inspector where the default instance and default binder is modified.

```
{
  "http_inspect":{
    "enabled":true,
    "type":"multiton",
    "instances":[
      {
        "name":"http_inspect",
        "data":{
          "response_depth":5000
        }
      }
    ]
  },
  "binder":{
    "type":"binder",
    "enabled":true,
    "rules":[
      {
        "use":{
          "type":"http_inspect"
        },
        "when":{
          "role":"any",
          "ports":"8080",
          "proto":"tcp",
          "service":"http"
        }
      }
    ]
  }
}
```

- Multiton inspector where a custom instance and a custom binder is added.

```
{
  "http_inspect":{
    "enabled":true,
    "type":"multiton",
    "instances":[
      {
        "name":"http_inspect1",
        "data":{
          "response_depth":5000
        }
      }
    ]
  },
  "binder":{
    "type":"binder",
    "enabled":true,
    "rules":[
      {
        "use":{
          "type":"http_inspect",
          "name":"http_inspect1"
        },
        "when":{
          "role":"any",
          "ports":"8080",
          "proto":"tcp",
          "service":"http"
        }
      }
    ]
  }
}
```

## Common Industrial Protocol Safety

Common Industrial Protocol (CIP) Safety is a set of extensions to the CIP that enables the safe operation of devices. It also provides fail-safe communication between different nodes on a CIP network.

The CIP Safety protocol comprises two main components:

- CIP Safety segments—Used in Forward Open messages to exchange safety parameters for the subsequent safety session.
- CIP Safety messages—Used to exchange actual safety information.

The CIP inspector detects and identifies:

- CIP as a service and client
- Payloads, such as CIP Read, CIP Admin, CIP Infrastructure, and CIP Write

The CIP inspector can parse the CIP segments and detect the CIP Safety segments in the Forward Open requests.

To test the CIP Safety feature, you must enable the CIP inspector. See [Detect and Block Safety Segments in CIP Packets](#), on page 2766.

## Detect and Block Safety Segments in CIP Packets

Use case: To detect and block CIP safety segments while allowing other CIP packets:

- Create a custom network analysis policy called **cip\_safety**.
- Create access control rules in your access control policy to block CIP Safety and to allow all other packets.

To test the CIP Safety feature, enable the CIP inspector in the management center and assign it to an access control policy.

### Procedure

- 
- Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.
- Step 2** Click the **Snort 3 Version** of the network analysis policy **cip\_safety** that you created.
- Step 3** Under **Inspectors**, click **cip** to expand it.
- The default configuration appears in the left column and the overridden configuration appears in the right column under the inspector.
- Step 4** Under **Overridden Configuration** on the right column, click the **Edit Inspector** icon and change the "enabled" field in **cip** from false (default) to true.
- Step 5** Click **OK**.
- Step 6** Click **Save**.
- Step 7** To assign the **cip** inspector to the access control policy, choose **Policies > Access Control > Edit** and choose the **Advanced Settings** option from the **More** drop-down arrow at the end of the packet flow line.
- Step 8** Click **Edit** (✎) next to **Network Analysis and Intrusion Policies**.
- Step 9** In the **Network Analysis and Intrusion Policies** window, choose the access control policy **cip\_safety** that you created from the **Default Network Analysis Policy** drop-down list.
- The CIP inspector is now enabled in the management center and you can create the custom access control rules to block CIP Safety and to allow all other CIP packets.
- Step 10** After you send live traffic containing CIP Safety packet flows, go to **Connection Events** to verify that the payload is the expected payload that contains CIP Safety packet logs for the detection and block use case as mentioned in this procedure. **CIP** is detected as an application protocol and client (see the **Application Protocol** and **Client** fields), and **CIP Safety** is shown under the **Web Application** field.
- 

## Network Analysis Policy Mapping

For network analysis policies, Cisco Talos provides mapping information, which is used to find the corresponding Snort 2 version of the policies for the Snort 3 version.

This mapping ensures that the Snort 3 version of policies has its equivalent Snort 2 version.

## View Network Analysis Policy Mapping

### Procedure

- 
- Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.
  - Step 2** Click **NAP Mapping**.
  - Step 3** Expand the arrow for **View Mappings**.  
The Snort 3 network analysis policies that are automatically mapped to a Snort 2 equivalent policy are displayed.
  - Step 4** Click **OK**.
- 

## Create a Network Analysis Policy

All the existing network analysis policies are available in management center with their corresponding Snort 2 and Snort 3 versions. When you create a new network analysis policy, it is created with both the Snort 2 version and the Snort 3 version.

### Procedure

- 
- Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.
  - Step 2** Click **Create Policy**.
  - Step 3** Enter the **Name** and **Description**.
  - Step 4** Select a **Base Policy** and click **Save**.
- 

The new network analysis policy is created with its corresponding **Snort 2 Version** and **Snort 3 Version**.

## Modify the Network Analysis Policy

You can modify the network analysis policy to change its name, description, or the base policy.

### Procedure

- 
- Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.
  - Step 2** Click **Edit** to change the name, description, inspection mode, or the base policy.

**Note** If you edit the network analysis policy name, description, base policy, and inspection mode, the edits are applied to both the Snort 2 and Snort 3 versions. If you want to change the inspection mode for a specific version, then you can do that from within the network analysis policy page for that respective version.

**Step 3** Click **Save**.

---

## Search for an Inspector on the Network Analysis Policy Page

On the Snort 3 version of the network analysis policy page, you may need to search for an inspector by entering any relevant text in the search bar.

### Procedure

---

**Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.

**Step 2** Go to the **Snort 3 Version** of the network analysis policy.

**Step 3** Enter an inspector's name or any relevant text to search for in the **Search** bar.

All the inspectors matching the text you search for are displayed.

For example, if you enter **pop**, then the pop inspector and the binder inspector are shown as matching results on the screen.

---

[Customize the Network Analysis Policy](#), on page 2769

[Make Inline Edit for an Inspector to Override Configuration](#), on page 2772

## Copy the Inspector Configuration

You can copy the inspector configuration for the Snort 3 version of the network analysis policy according to your requirements.

### Procedure

---

**Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.

**Step 2** Go to the **Snort 3 Version** of the network analysis policy.

**Step 3** Under **Inspectors**, expand the required inspector for which you want to copy the configuration.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

**Step 4** Click the **Copy to clipboard** icon to copy the inspector configuration to the clipboard for one or both of the following.

- **Default Configuration** in the left column
- **Overridden Configuration** in the right column

**Step 5** Paste the copied inspector configuration to a JSON editor to make any edits you may require.

### Related Topics

[Customize the Network Analysis Policy](#), on page 2769

## Customize the Network Analysis Policy

You can customize the Snort 3 version of the network analysis policy according to your requirements.

### Procedure

**Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.

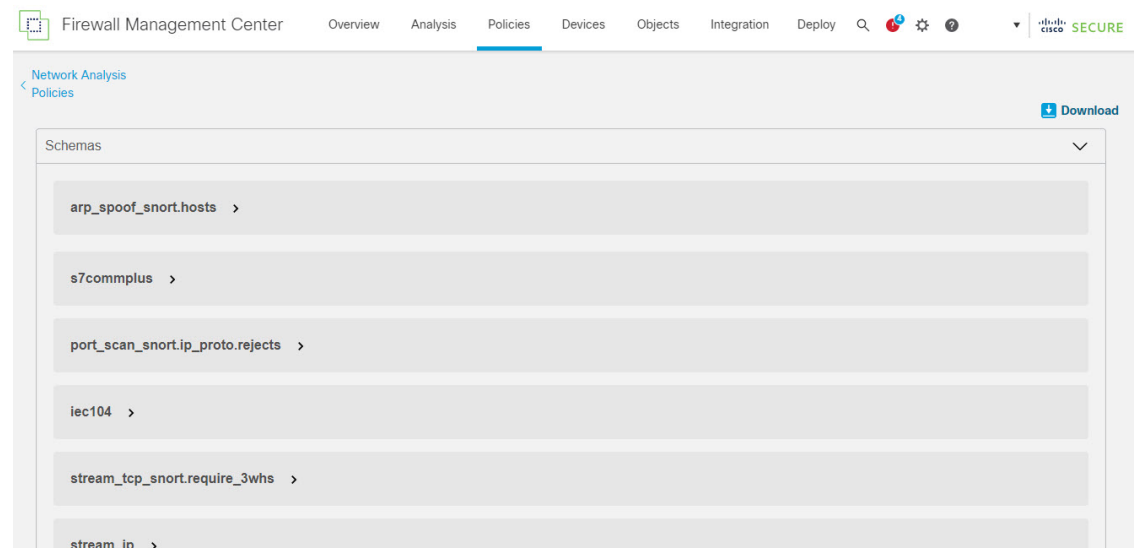

**Step 2** Go to the **Snort 3 Version** of the network analysis policy.

**Step 3** Click the **Actions** drop-down menu.

The following options are displayed:

- View Schema
- Download Schema / Download Sample File / Template
- Download Full Configuration
- Download Overridden Configuration
- Upload Overridden Configuration

**Step 4** Click **View Schema** to open the schema file directly in a browser.

**Step 5** You can download the schema file, sample file / template, full configuration, or overridden configuration as needed.

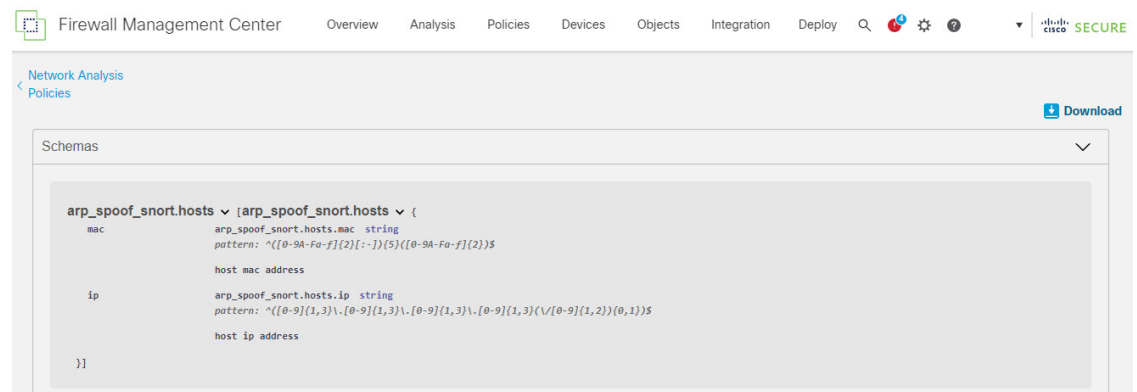

These options provide you an insight about the allowed values, range, and patterns, existing and default inspector configurations, and overridden inspector configurations.

- a) Click **Download Schema** to download the schema file.

The schema file validates the content that you upload or download. You can download the schema file and open it using any third-party JSON editor. The schema file helps you to identify what parameters can be configured for inspectors with their corresponding allowed values, range, and accepted patterns to be used.

For example, for the *arp\_spoof\_snort* inspector, you can configure the hosts. The hosts include the *mac* and *ip* address values. The schema file shows the following accepted pattern for these values.

- **mac – pattern:** `^([0-9A-Fa-f]{2}[:-]){5}([0-9A-Fa-f]{2})$`
- **ip – pattern:** `^([0-9]{1,3}\. [0-9]{1,3}\. [0-9]{1,3}\. [0-9]{1,3}(/ [0-9]{1,2}){0,1})$`

You must provide the values, range, patterns according to the accepted ones in the schema file to be able to successfully override the inspector configuration, otherwise, you get an error message.

- b) Click **Download Sample File / Template** to use a pre-existing template that contains example configurations to help you with configuring the inspectors.

You can refer to the example configurations included in the sample file and make any changes that you may require.

- c) Click **Download Full Configuration** to download the entire inspector configurations in a single JSON file.

Instead of expanding the inspectors separately, you can download the full configuration to look out for the information you need. All information regarding the inspector configuration is available in this file.

- d) Click **Download Overridden Configuration** to download the inspector configuration that has been overridden.

**Step 6** To override the existing configuration, follow the steps.

You can choose to override an inspector configuration using the following ways.

- Make inline edits for an inspector directly on the management center. See the topic **Make Inline Edit for an Inspector to Override Configuration** in the **Getting Started with Network Analysis Policies** chapter of the *Cisco Secure Firewall Management Center Snort 3 Configuration Guide*.

- Continue to follow the current procedure of using the **Actions** drop-down menu to upload the overridden configuration file.

If you chose to make inline edits directly in the management center, then you don't need to follow the current procedure further. Otherwise, you must follow this procedure completely.

- a) Under **Inspectors**, expand the required inspector for which you want to override the default configuration.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

You may need to search for an inspector by entering any relevant text in in the search bar.

- b) Click the **Copy to clipboard** icon to copy the default inspector configuration to the clipboard.

- c) Create a JSON file and paste the default configuration in it.

- d) Keep the inspector configuration that you want to override, and remove all the other configuration and instances from the JSON file.

You can also use the **Sample File / Template** to understand how to override the default configuration.

This is a sample file that includes JSON snippets explaining how you can customize the network analysis policy for Snort 3.

- e) Make changes to the inspector configuration as needed.

Validate the changes and make sure they conform to the schema file. For multiton inspectors, make sure that the binder conditions for all instances are included in the JSON file. See *Multiton Inspectors* in the topic **Custom Network Analysis Policy Creation for Snort 3** in the *Cisco Secure Firewall Management Center Snort 3 Configuration Guide* for more information.

- f) If you are copying any further default inspector configurations, append that inspector configuration to the existing file that contains the overridden configuration.

**Note** The copied inspector configuration must comply with the JSON standards.

- g) Save the overridden configuration file to your system.

### Step 7

From the **Actions** drop-down menu, choose Upload Overridden Configuration to upload the JSON file that contains the overridden configuration.

**Caution** Upload only the changes that you require. You should not upload the entire configuration as it makes the overrides sticky in nature and therefore, any subsequent changes to the default configuration as part of the LSP updates would not be applied.

You can drag and drop a file or click to browse to the JSON file saved in your system that contains the overridden inspector configuration.

- **Merge inspector overrides** – Content in the uploaded file is merged with the existing configuration if there is no common inspector. If there are common inspectors, then the content in the uploaded file (for common inspectors) takes precedence over the previous content, and it replaces the previous configuration for those inspectors.
- **Replace inspector overrides** – Removes all previous overrides and replaces them with the new content in the uploaded file.

**Attention** Choosing this option deletes all the previous overrides. Make an informed decision before you override the configuration using this option.

If any error occurs while uploading the overridden inspectors, you see the error in the **Upload Overridden Configuration File** pop-up window. You can also download the file with the error, fix the error, and reupload the file.

**Step 8** In the **Upload Overridden Configuration File** pop-up window, click **Import** to upload the overridden inspector configuration.

After you upload the overridden inspector configuration, you will see an orange icon next to the inspector that signifies that it is an overridden inspector.

Also, the **Overridden Configuration** column under the inspector shows the overridden value.

You can also view all the overridden inspectors using the **Show Overrides Only** checkbox adjacent to the Search bar.

**Note** Make sure that you always download the overridden configuration, open the JSON file, and append any new changes/overrides to the inspector configurations to this file. This action is needed so that you do not lose the old overridden configurations.

**Step 9** (Optional) Take a backup of the overridden configuration file on your system before making any new inspector configuration changes.

**Tip** We recommend that you take the backup from time to time as you override the inspector configuration.

---

#### Related Topics

[Revert Overridden Configuration to Default Configuration](#), on page 2774

## Make Inline Edit for an Inspector to Override Configuration

For the Snort 3 version of the network analysis policy, you can make an inline edit for the inspector configuration to override the configuration according to your requirements.

Alternatively, you can also use the **Actions** drop-down menu to upload the overridden configuration file. See [Customize the Network Analysis Policy, on page 2769](#) for more information.

### Procedure

---

**Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.

**Step 2** Go to the **Snort 3 Version** of the network analysis policy.

**Step 3** Under **Inspectors**, expand the required inspector for which you want to override the default setting.

The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.

**Step 4** Under the **Overridden Configuration** in the right column, click **Edit Inspector** (Pencil) icon to make changes to the inspector configuration.

The Override Configuration pop-up appears where you can make the required edits.

- Note**
- Make sure that you keep only those settings that you want to override. If you leave a setting with the same value, that field becomes sticky. This means if that setting is changed in the future by Talos, the current value will be retained.
  - If you are adding or deleting any custom instance, make sure that you add or delete a binder rule for that instance in the binder inspector as well.

**Step 5** Click **OK**.

If there are any errors according to the JSON standards, it shows you an error message.

**Step 6** Click **Save** to save the changes.

If the changes conform to the OpenAPI schema specification, the management center allows you to save the configuration, otherwise, the **Error saving overridden configuration** pop-up appears that shows the errors. You can also download the file with the errors.

---

## Revert Unsaved Changes during Inline Edits

While making inline edits to override the configuration for an inspector, you can revert any unsaved changes. Note that this action reverts all unsaved changes to the most recently saved value, but does not revert the configuration to the default configuration for an inspector.

### Procedure

---

**Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.

**Step 2** Go to the **Snort 3 Version** of the network analysis policy.

**Step 3** Under **Inspectors**, expand the required inspector for which you want to revert the unsaved changes.

The default configuration is displayed in the left column and the overridden configuration is displayed in the right column under the inspector.

**Step 4** Under the **Overridden Configuration** on the right column, click the **Cross (X)** icon to revert any unsaved changes for the inspector.

Alternatively, you can click **Cancel** to cancel the changes.

If you do not have any unsaved changes to the inspector configuration, then this option is not visible.

---

## Revert Overridden Configuration to Default Configuration

You can revert any changes that you made to override the default configuration for an inspector. This action reverts the overridden configuration to the default configuration for an inspector.

### Procedure

- 
- Step 1** Go to **Policies > Intrusion > Network Analysis Policies**.
  - Step 2** Go to the **Snort 3 Version** of the network analysis policy.
  - Step 3** Under **Inspectors**, expand the required inspector for which you want to revert the overridden configuration.  
The overridden inspectors are shown with the orange icon next to their name.  
The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector. Under the **Overridden Configuration** on the right column, click **Revert to default configuration** (back arrow) icon to revert the overridden configuration for the inspector to the default configuration.  
If you did not make any changes to the default configuration for the inspector, then this option is disabled.
  - Step 4** Click **Revert** to confirm the decision.
  - Step 5** Click **Save** to save the changes.  
If you do not want to save the changes, you can click **Cancel** or the **Cross (X)** icon.
-

## Validate Snort 3 Policies

To validate the Snort 3 policies, here is a list of basic information that user can make note of:

- Current version of the management center can manage multiple threat defense versions.
- Current version of management center supports NAP configurations which are not applicable to previous version of threat defense devices.
- Current NAP Policy and validations will work based on the current version support.
- Changes may include content which is not valid for previous versions of threat defenses.
- Policy configuration changes are accepted if they are valid configuration for the current version and which is performed using current Snort 3 binary and NAP schema.
- For previous version threat defenses, validation is performed during deployment using NAP schema and Snort 3 binary for that specific version. If there is any configuration which is not applicable for the given version, user is provided information or warning that we will not deploy the configuration which is not supported on the given version and remaining configuration will get deployed.

In this procedure, when we associate the NAP policy to an Access Control Policy and deploy it on a device, for example any inspector like rate filter configuration is applied to validate the Snort 3 policies.

### Procedure

- 
- Step 1** **Steps to Override NAP Policy Configuration:** Under **Inspectors** in the **Snort 3 Version** of the network analysis policy, expand the required inspector for which you want to override the default setting. The default configuration is displayed on the left column and the overridden configuration is displayed on the right column under the inspector.
- Step 2** Under the **Overridden Configuration** on the right column, click **Edit Inspector** (Pencil) icon to make changes to any inspector like `rate_filter`. The Override Configuration pop-up appears where you can make the required edits to the `rate_filter` inspector.
- Step 3** Click **OK**.
- Step 4** Click **Save** to save the changes. Alternatively, you can also use the **Actions** drop-down menu to upload the overridden configuration file.
- Step 5** Click the **Actions** drop-down menu in the **Snort 3 Version** of the network analysis policy.
- Step 6** Under **Upload** you can click **Overridden Configuration** to upload the JSON file that contains the overridden configuration.

**Caution** Upload only the changes that you require. You should not upload the entire configuration as it makes the overrides sticky in nature and therefore, any subsequent changes to the default configuration as part of the LSP updates will not be applied.

You can drag and drop a file or click to browse to the JSON file saved in your system that contains the overridden inspector configuration.

- **Merge inspector overrides** – Content in the uploaded file is merged with the existing configuration if there is no common inspector. If there are common inspectors, then the content in the uploaded file (for common inspectors) takes precedence over the previous content, and it replaces the previous configuration for those inspectors.
- **Replace inspector overrides** – Removes all previous overrides and replaces them with the new content in the uploaded file.

**Attention** As choosing this option deletes all the previous overrides, make an informed decision before you override the configuration using this option.

If any error occurs while uploading the overridden inspectors, you see the error on the **Upload Overridden Configuration File** pop-up window. You can also download the file with the error, then fix the error and reupload the file.

- Step 7** **Steps to Associate NAP Policy to Access Control Policy:** In the access control policy editor, click **Advanced**, then click **Edit** next to the Network Analysis and Intrusion Policies section.
- Step 8** From the **Default Network Analysis Policy** drop-down list, select a default network analysis policy.
- If you choose a user-created policy, you can click **Edit** to edit the policy in a new window. You cannot edit system-provided policies.
- Step 9** Click **OK**.
- Step 10** Click **Save** to save the policy.
- Step 11** Alternatively, in the access control policy editor, click **Advanced**, then click **Edit** next to the Network Analysis and Intrusion Policies section.
- Step 12** Click **Add Rule**.
- Step 13** Configure the rule's conditions by clicking the conditions you want to add.
- Step 14** Click **Network Analysis** and choose the **Network Analysis Policy** you want to use to preprocess the traffic matching this rule.
- Step 15** Click **Add**.
- Step 16** **Deployment:** On the management center menu bar, click **Deploy** and then select **Deployment**.
- Step 17** Identify and choose the devices on which you want to deploy configuration changes.
- Search—Search for the device name, type, domain, group, or status in the search box.
  - Expand—Click **Expand Arrow** to view device-specific configuration changes to be deployed.
- By selecting the device check box, all the changes for the device, which are listed under the device, are pushed for deployment. However, you can use the **Policy Selection** to select individual policies or configurations to deploy while withholding the remaining changes without deploying them.
- Optionally, use **Show or Hide Policy** to selectively view or hide the associated unmodified policies.
- Step 18** Click **Deploy**.

**Step 19** If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

**Note** It shows a warning that Snort 3 Network analysis policy contains inspectors or attributes that are not valid for this threat defense version, following the invalid settings will be skipped in deployment: Invalid inspectors are : [“rate\_filter”] only for devices lower than 7.1 version.

---

## Examples of Custom Network Analysis Policy Configuration

This is a sample file that includes JSON snippets explaining how you can customize the network analysis policy for Snort 3. You can choose to override an inspector configuration using the following ways:

- Make inline edits for an inspector directly on the management center. See [Make Inline Edit for an Inspector to Override Configuration, on page 2772](#).
- Use the **Actions** drop-down menu to upload the overridden configuration file. See [Customize the Network Analysis Policy, on page 2769](#).

Before you choose any of these options, review all the following details and examples that will help you in defining the network analysis policy overrides successfully. You must read and understand the examples for various scenarios explained here to avoid any risks and errors.

If you choose to override an inspector configuration from the **Actions** drop-down menu, you need to construct a JSON file for the network analysis policy overrides and upload the file.

For overriding an inspector configuration in the network analysis policy, you must upload only the changes that you require. You should not upload the entire configuration because it makes the overrides sticky in nature and therefore, any subsequent changes to the default values or configuration as part of the LSP updates would not be applied.

Here are the examples for various scenarios:

### Enabling a Singleton Inspector when the Default State in the Base Policy is Disabled

```
{
  "rate_filter": {
    "enabled": true,
    "type": "singleton",
    "data": []
  }
}
```

### Disabling a Singleton Inspector when the Default State in the Base Policy is Enabled

```
{
  "rate_filter": {
    "enabled": false,
    "type": "singleton",
    "data": []
  }
}
```

**Enabling a Multiton Inspector when the Default State in the Base Policy is Disabled**

```
{
  "ssh": {
    "enabled": true,
    "type": "multiton",
    "instances": []
  }
}
```

**Disabling a Multiton Inspector when the Default State in the Base Policy is Enabled**

```
{
  "ssh": {
    "enabled": false,
    "type": "multiton",
    "instances": []
  },
  "iecl04": {
    "type": "multiton",
    "enabled": false,
    "instances": []
  }
}
```

**Overriding the Default Value of Specific Setting(s) for Singleton Inspector**

```
{
  "normalizer": {
    "enabled": true,
    "type": "singleton",
    "data": {
      "tcp": {
        "block": true
      },
      "ip6": true
    }
  }
}
```

**Overriding Specific Setting(s) of a Default Instance (where Instance Name Matches with Inspector Type) in Multiton Inspector**

```
{
  "http_inspect": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "data": {
          "unzip": false
        },
        "name": "http_inspect"
      }
    ]
  }
}
```

### Adding Binder Rule for a Default Instance with Required Changes

**Note** Default binder rules can't be edited, they are always appended at the end.

```
{
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "use": {
          "type": "http_inspect"
        },
        "when": {
          "role": "server",
          "service": "http",
          "dst_nets": "10.1.1.0/24"
        }
      }
    ]
  }
}
```

### Adding a New Custom Instance

**Note** Corresponding binder rule entry must be defined in the binder inspector.

```
{
  "telnet": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "name": "telnet_my_instance",
        "data": {
          "encrypted_traffic": true
        }
      }
    ]
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_my_instance"
        }
      }
    ]
  }
}
```

## Overriding a Singleton Instance, Multiton Default Instance, and Creating a New Multiton Instance in a Single JSON Override

Example to show the following in a single JSON override:

- Overriding a Singleton instance (**normalizer** inspector)
- Overriding a Multiton default instance (**http\_inspect** inspector)
- Creating a new Multiton instance (**telnet** inspector)

```
{
  "normalizer": {
    "enabled": true,
    "type": "singleton",
    "data": {
      "tcp": {
        "block": true
      },
      "ip6": true
    }
  },
  "http_inspect": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "data": {
          "unzip": false,
          "xff_headers": "x-forwarded-for true-client-ip x-another-forwarding-header"
        },
        "name": "http_inspect"
      }
    ]
  },
  "telnet": {
    "enabled": true,
    "type": "multiton",
    "instances": [
      {
        "name": "telnet_my_instance",
        "data": {
          "encrypted_traffic": true
        }
      }
    ]
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_my_instance"
        }
      },
      {
        "use": {
          "type": "http_inspect"
        }
      }
    ]
  }
}
```

```

    },
    "when": {
      "role": "server",
      "service": "http",
      "dst_nets": "10.1.1.0/24"
    }
  ]
}

```

**Note** You don't need to give the **name** attribute for the default instance in binder rules.

### Configuring arp\_spoof

Example for configuring **arp\_spoof**:

The **arp\_spoof** inspector does not have any default configurations for any attributes. This demonstrates the case where you can provide the overrides.

```

{
  "arp_spoof": {
    "type": "singleton",
    "data": {
      "hosts": [
        {
          "ip": "1.1.1.1",
          "mac": "ff:0f:f1:0f:0f:ff"
        },
        {
          "ip": "2.2.2.2",
          "mac": "ff:0f:f2:0f:0f:ff"
        }
      ]
    },
    "enabled": true
  }
}

```

### Configuring rate\_filter

```

{
  "rate_filter": {
    "data": [
      {
        "apply_to": "[10.1.2.100, 10.1.2.101]",
        "count": 5,
        "gid": 135,
        "new_action": "alert",
        "seconds": 1,
        "sid": 1,
        "timeout": 5,
        "track": "by_src"
      }
    ],
    "enabled": true,
    "type": "singleton"
  }
}

```

### Configuring Binder Rules when Multi-Hierarchy Network Analysis Policy is Used

This example illustrates adding a new custom instance in child policy and the way binder rules should be written. Binder rules are defined as a list and therefore, it is important to pick up the rules defined in the parent policy and build the new rules on top of it as rules will not be merged automatically. The binder rules available in child policy are a source of truth in totality.

On the threat defense, the default Cisco Talos policy rules are appended on these user-defined overrides.

#### Parent Policy:

We have defined a custom instance by the name **telnet\_parent\_instance** and the corresponding binder rule.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": true
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

#### Child Policy:

This network analysis policy has the aforementioned policy as its base policy. We have defined a custom instance by the name **telnet\_child\_instance** and have also defined the binder rules for this instance. The binder rules from parent policy need to be copied here, and then child policy binder rules can be prepended or appended on top of it based on the nature of the rule.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": false
        },
        "name": "telnet_child_instance"
      }
    ]
  }
}
```

```

    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet",
          "nets": "10.2.2.0/24"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_child_instance"
        }
      },
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}

```

### Configuring List Inspector Attribute in General

While changing overrides for any attribute of type list, it is important to pass the full contents rather than partial override. This means if a base policy attributes are defined as:

```

{
  "list-attribute": [
    {
      "entry1": {
        "key1": "value1"
      }
    },
    {
      "entry2": {
        "key2": "value2"
      }
    }
  ]
}

```

If you want to modify **value1** to **value1-new**, the override payload must look like the following:

#### Correct Way:

```

{
  "list-attribute": [
    {
      "entry1": {
        "key1": "value1-new"
      }
    },
    {

```

```

    "entry2": {
      "key2": "value2"
    }
  ]
}

```

**Incorrect Way:**

```

{
  "list-attribute": [
    {
      "entry1": {
        "key1": "value1-new"
      }
    }
  ]
}

```

You can understand this configuration by taking the trimmed values of the `alt_max_command_line_len` attribute in the `smtp` inspector. Suppose the default (base) policy configuration for `smtp` inspector is as follows:

```

{
  "smtp": {
    "type": "multiton",
    "instances": [
      {
        "name": "smtp",
        "data": {
          "decompress_zip": false,
          "normalize_cmds": "ATRN AUTH BDAT CHUNKING DATA DEBUG EHLO
EMAL ESAM ESND ESOM ETRN EVFY EXPN HELO HELP IDENT MAIL
NOOP ONEX QUEU QUIT RCPT RSET SAML SEND SOML STARTTLS TICK
TIME TURN TURNME VERB VRFY X-ADAT XADR XAUTH XCIR X-DRCP X-
ERCP XEXCH50 X-EXCH50 X-EXPS XGEN XLICENSE X-LINK2STATE XQUE
XSTA XTRN XUSR",
          "ignore_data": false,
          "max_command_line_len": 512,
          "max_header_line_len": 1000,
          "log_rcptto": false,
          "decompress_swf": false,
          "max_response_line_len": 512,
          "b64_decode_depth": -1,
          "max_auth_command_line_len": 1000,
          "log_email_hdrs": false,
          "xlink2state": "alert",
          "binary_data_cmds": "BDAT XEXCH50",
          "auth_cmds": "AUTH XAUTH X-EXPS",
          "log_filename": false,
          "uu_decode_depth": -1,
          "ignore_tls_data": false,
          "data_cmds": "DATA",
          "bitenc_decode_depth": -1,
          "alt_max_command_line_len": [
            {
              "length": 255,
              "command": "ATRN"
            },
            {
              "command": "AUTH",
              "length": 246
            },
            {
              "length": 255,

```

```

        "command": "BDAT"
      },
      {
        "length": 246,
        "command": "DATA"
      }
    ],
    "log_mailfrom": false,
    "decompress_pdf": false,
    "normalize": "none",
    "email_hdrs_log_depth": 1464,
    "valid_cmds": "ATRN AUTH BDAT CHUNKING DATA DEBUG EHLO
EMAL ESAM ESND ESOM ETRN EVFY EXPN HELO HELP IDENT MAIL
NOOP ONEX QUEU QUIT RCPT RSET SAML SEND SOML STARTTLS TICK
TIME TURN TURNME VERB VRFY X-ADAT XADR XAUTH XCIR X-DRCP X-
ERCP XEXCH50 X-EXCH50 X-EXPS XGEN XLICENSE X-LINK2STATE XQUE
XSTA XTRN XUSR",
    "qp_decode_depth": -1
  }
}
],
"enabled": true
}
}

```

Now, if you want to add two more objects to the `alt_max_command_line_len` list:

```

{
  "length": 246,
  "command": "XEXCH50"
},
{
  "length": 246,
  "command": "X-EXPS"
}

```

Then the custom network analysis policy override JSON would look like the following:

```

{
  "smtp": {
    "type": "multiton",
    "instances": [
      {
        "name": "smtp",
        "data": {
          "alt_max_command_line_len": [
            {
              "length": 255,
              "command": "ATRN"
            },
            {
              "command": "AUTH",
              "length": 246
            },
            {
              "length": 255,
              "command": "BDAT"
            },
            {
              "length": 246,
              "command": "DATA"
            },
            {
              "length": 246,
              "command": "XEXCH50"
            }
          ]
        }
      }
    ]
  }
}

```

```

        },
        {
          "length": 246,
          "command": "X-EXPS"
        }
      ]
    }
  },
  "enabled": true
}
}

```

### Configuring Overrides when Multi-Hierarchy Network Analysis Policy is used in Multiton Inspector

This example illustrates overriding attributes in child policy and how the merged configuration will be used in the child policy for any instance. Any overrides defined in the child policy will be merged with the parent policy. Thus, if attribute1 and attribute2 are overridden in parent policy and attribute2 and attribute3 are overridden in the child policy, the merged configurations are for child policy. This means that attribute1 (defined in parent policy), attribute2 (defined in child policy), and attribute3 (defined in child policy) will be configured on the device.

#### Parent Policy:

Here we have defined a custom instance by the name **telnet\_parent\_instance** and overridden 2 attributes namely, **normalize** and **encrypted\_traffic** in the custom instance.

```

{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": false
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}

```

#### Child Policy:

This network analysis policy has the aforementioned policy as its base policy. We have overridden attribute **encrypted\_traffic** from parent policy and also overridden new attribute **ayt\_attack\_thresh**.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "encrypted_traffic": true,
          "ayt_attack_thresh": 1
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  }
}
```

With the above policy JSON, when you deploy the network analysis policy the following merged JSON will be configured on the device.

```
{
  "telnet": {
    "type": "multiton",
    "instances": [
      {
        "data": {
          "normalize": true,
          "encrypted_traffic": true,
          "ayt_attack_thresh": 1
        },
        "name": "telnet_parent_instance"
      }
    ],
    "enabled": true
  },
  "binder": {
    "enabled": true,
    "type": "binder",
    "rules": [
      {
        "when": {
          "role": "any",
          "service": "telnet"
        },
        "use": {
          "type": "telnet",
          "name": "telnet_parent_instance"
        }
      }
    ]
  }
}
```

This example illustrates details for the custom network analysis policy. The same behavior is also exhibited in the default instance. Also, a similar merging would be done for Singleton inspectors.

### Removing all the Inspector Overrides for the Network Analysis Policy:

Whenever you want to remove all the overrides for a specific network analysis policy, you can upload an empty JSON. While uploading the overrides, choose the option **Replace inspector overrides**.

```
{
}
```

## Network Analysis Policy Settings and Cached Changes

When you create a new network analysis policy, it has the same settings as its base policy.

When tailoring a network analysis policy, especially when disabling inspectors, keep in mind that some inspectors and intrusion rules require that traffic first be decoded or preprocessed in a certain way. If you disable a required inspector, the system automatically uses it with its current settings, although the inspector remains disabled in the network analysis policy web interface.

---

**Note** Because preprocessing and intrusion inspection are so closely related, the network analysis and intrusion policies examining a single packet **must** complement each other. Tailoring preprocessing, especially using multiple custom network analysis policies, is an **advanced** task.

---

The system caches one network analysis policy per user. While editing a network analysis policy, if you select any menu or other path to another page, your changes stay in the system cache even if you leave the page.

## Custom Rules in Snort 3

You can create a custom intrusion rule by importing a local rule file. The rule file can either have a `.txt` or `.rules` extension. The system saves the custom rule in the local rule category, regardless of the method you used to create it. A custom rule must belong to a rule group. However, a custom rule can be a part of two or more groups as well.

When you create a custom intrusion rule, the system assigns it a unique rule number, which has the format `GID:SID:Rev`. The elements of this number are:

- **GID**—Generator ID. For custom rules, it is not necessary to specify the GID. The system automatically generates the GID based on whether you are in the Global domain or a sub-domain while uploading the rules. For all standard text rules, this value is 2000 for a Global domain.
- **SID**—Snort ID. Indicates whether the rule is a local rule or a system rule. When you create a new rule, assign a unique SID to the rule.  
SID numbers for local rules start at 1000000, and the SID for each new local rule is incremented by one.
- **Rev**—The revision number. For a new rule, the revision number is one. Each time you modify a custom rule the revision number should be incremented by one.

In a custom standard text rule, you set the rule header settings and the rule keywords and arguments. You can use the rule header settings to focus the rule to only match traffic using a specific protocol and traveling to or from specific IP addresses or ports.

- Note**
- Snort 3 custom rules cannot be edited. Ensure that custom rules have a valid classification message for `classtype` within the rule text. If you import a rule without a classification or wrong classification, then delete and recreate the rule.
  - You can create custom intrusion rules using Snort 3. However, support for tuning and troubleshooting these rules is not available currently.

### Sensitive Data Detection in Snort 3

Sensitive data such as social security numbers, credit card numbers, emails, and so on may be leaked onto the internet, intentionally or accidentally. Sensitive data detection is used to detect and generate events on possible sensitive data leakage. Events are generated only if there is a transfer of significant amount of Personally Identifiable Information (PII) data. Sensitive data detection can mask PII in the output of events.

#### sd\_pattern Option

Use the `sd_pattern` IPS option to detect and filter PII. This information includes credit card numbers, U.S. Social Security numbers, phone numbers, and email addresses. A regular expression (regex) syntax is available for defining your own PII.

The `sd_pattern` option has the following settings:

- **Pattern**—An implicit, required setting that specifies the regular expression to look for in the PDU. The regex must be written in PCRE syntax.
- **Threshold**—An explicit, optional setting that specifies the number of matches in the PDU required to generate an event.

The `sd_pattern` as IPS rule option is available in Snort with no requirements for additional inspectors. The rule option's syntax is:

```
sd_pattern: "<pattern>"[, threshold <count>];
```

For example:

```
sd_pattern:"credit_card", threshold 2;
```

#### Built-in Patterns

There are five built-in patterns for sensitive data. To use the built-in patterns in the "pattern" setting, you must specify the name of the PII type that needs to be matched and the necessary regex is substituted for it. The PII name and regex mappings or patterns are described as follows:

- `credit_card`—  
`\d{4}\D?\d{4}\D?\d{2}\D?\d{2}\D?\d{3,4}`
- `us_social`—  
`[0-8]\d{2}-\d{2}-\d{4}`
- `us_social_nodashes`—

```
[0-8]\d{8}
```

- Email—

```
[a-zA-Z0-9!#$%&'*\+\/=?^_`{|}~-]+(?:\. [a-zA-Z0-9!#$%&'*\+\/=?^_`{|}~-]+)*@(?: [a-zA-Z0-9]
(?: [a-zA-Z0-9-]* [a-zA-Z0-9])?\.)+[a-zA-Z0-9] (?: [a-zA-Z0-9-]* [a-zA-Z0-9])? ?
```

- us\_phone—

```
(?:\+?1[-.\s]?)?(?([2-9][0-8]\d)\)?[-.\s]([2-9]\d{2})[-.\s](\d{4})
```

PII Name	Pattern
credit_card	\d{4}\D?\d{4}\D?\d{2}\D?\d{2}\D?\d{3,4}
us_social	[0-8]\d{2}-\d{2}-\d{4}
us_social_nodashes	[0-8]\d{8}
Email	[a-zA-Z0-9!#\$%&'*\+\/=?^_`{ }~-]+(?:\. [a-zA-Z0-9!#\$%&'*\+\/=?^_`{ }~-]+)*@(?: [a-zA-Z0-9] (?: [a-zA-Z0-9-]* [a-zA-Z0-9])?\.)+[a-zA-Z0-9] (?: [a-zA-Z0-9-]* [a-zA-Z0-9])? ?
us_phone	(?:\+?1[-.\s]?)?(?([2-9][0-8]\d)\)?[-.\s]([2-9]\d{2})[-.\s](\d{4})

Masking for data matching these patterns only work with system-provided rules or built-in patterns for Credit Cards, U.S. Social Security numbers, emails, and U.S. phone numbers. Masking does not work for custom rules or user-defined PII patterns. Rules are available in the Lightweight Security Package (LSP) for sensitive data, gid:13. By default, they are not enabled in any system-provided policy.

The sensitive data rules in LSP cover all built-in patterns and have the following threshold values:

- credit\_card: 2
- us\_social: 2
- us\_social\_nodashes: 20
- email: 20
- us\_phone: 20

You can use the `sd_pattern` option to create custom rules and modify existing rules. To do this, use the Snort 3 intrusion policy interface.

An example of a rule with `sd_pattern` with a custom pattern and threshold:

```
alert tcp (sid: 1000000001; sd_pattern:"[lw-]+@[lw-]+\.[lw-]{2,4}",threshold 4; msg: "email, threshold 4")
```

## Examples

An example of custom rules using sensitive data detection:

Rule with built-in pattern:

```
alert tcp (
  msg:"SENSITIVE-DATA Email";
  flow:only_stream;
  pkt_data;
  sd_pattern:"email", threshold 5;
  service:http, smtp, ftp-data, imap, pop3;
```

```

        gid:2000;
        sid:1000001;
    )

```

#### Rule with custom pattern

```

alert tcp (
    msg:"SENSITIVE-DATA US phone numbers";
    flow:only_stream;
    file_data;
    sd_pattern:"+?3?8?(0[\s\.-]\d{2}[\s\.-]\d{3}[\s\.-]\d{2}[\s\.-]\d{2})", threshold
2;

    service:http, smtp, ftp-data, imap, pop3;
    gid:2000;
    sid:1000002;
)

```

Here are some more examples of complete Snort IPS rules with built-in sensitive data patterns:

- alert tcp ( sid:1; msg:"Credit Card"; sd\_pattern:"credit\_card", threshold 2; )
- alert tcp ( sid:2; msg:"US Social Number"; sd\_pattern:"us\_social", threshold 2; )
- alert tcp ( sid:3; msg:"US Social Number No Dashes"; sd\_pattern:"us\_social\_nodashes", threshold 2; )
- alert tcp ( sid:4; msg:"US Phone Number"; sd\_pattern:"us\_phone", threshold 2; )
- alert tcp ( sid:5; msg:"Email"; sd\_pattern:"email", threshold 2; )

Disabling data masking is not supported in the Secure Firewall Management Center and Secure Firewall Device Manager.

## Overview of Encrypted Visibility Engine

The encrypted visibility engine (EVE) is used to provide more visibility into the encrypted sessions without the need to decrypt them. These insights into encrypted sessions are obtained by Cisco's open-source library that is packaged in Cisco's vulnerability database (VDB). The library fingerprints and analyzes incoming encrypted sessions and matches it against a set of known fingerprints. This database of known fingerprints is also available in the Cisco VDB.

---

**Note** The encrypted visibility engine feature is supported only on management center-managed devices running Snort 3. This feature is not supported on Snort 2 devices, device manager-managed devices, or Security Cloud Control.

---

Some of the important features of EVE are the following:

- You can take access control policy actions on the traffic using information derived from EVE.
- The VDB included in Cisco Secure Firewall has the ability to assign applications to some processes detected by EVE with a high confidence value. Alternatively, you can create custom application detectors to:
  - Map EVE-detected processes to new user-defined applications.
  - Override the built-in value of process confidence that is used to assign applications to EVE-detected processes.

See the **Configuring Custom Application Detectors** and **Specifying EVE Process Assignments** sections in the **Application Detection** chapter of the [Cisco Secure Firewall Management Center Device Configuration Guide](#).

- EVE can detect the operating system type and version of the client that created a Client Hello packet in the encrypted traffic.
- EVE supports fingerprinting and analysis of Quick UDP Internet Connections (QUIC) traffic too. The server name from the Client Hello packet is displayed in the URL field of the **Connection Events** page.

---

**Attention**

To use EVE on management center, you must have a valid IPS license on your device. In the absence of a IPS license, the policy displays a warning and deployment is not allowed.

---

---

**Note**

EVE can detect the operating system type and version of SSL sessions. Normal usage of the operating system, such as running applications and package management software, can trigger OS detection. To view client OS detection, in addition to enabling the EVE toggle button, you must enable **Hosts** under **Policies > Network Discovery**. To view a list of possible operating systems on the host IP address, click **Analysis > Hosts > Network Map**, and then choose the required host.

---

**Related Links**

[Configure EVE, on page 2793](#)

## How EVE Works

The Encrypted Visibility Engine (EVE) inspects the Client Hello portion of the TLS handshake to identify client processes. The Client Hello is the initial data packet that is sent to the server. This gives a good indication of the client process on the host. This fingerprint, combined with other data such as destination IP address, provides the basis for EVE's application identification. By identifying specific application fingerprints in the TLS session establishment, the system can identify the client process and take appropriate action (allow/block).

EVE can identify over 5,000 client processes. The system maps a number of these processes to client applications for use as criteria in access control rules. This gives the system the ability to identify and control these applications without enabling TLS decryption. By using fingerprints of known malicious processes, EVE technology can also be used to identify and block encrypted malicious traffic without outbound decryption.

Through machine learning (ML) technology, Cisco processes over one billion TLS fingerprints and over 10000 malware samples daily to create and update EVE fingerprints. These updates are then delivered to customers using Cisco Vulnerability Database (VDB) package.

If EVE does not recognize a fingerprint, it identifies client application and estimates the threat score of the first flow using the destination details, such as IP address, port, and server name. At this point, the status of the fingerprints are randomized and the status can be viewed in the debug logs. For subsequent flows with the same fingerprint, EVE skips reanalysis and marks the fingerprint status as unlabeled. If you intend to block traffic based on EVE's Low or Very Low score thresholds, the initial flow is blocked. However, future flows will be allowed once the application's fingerprint is cached.

# Indications of Compromise Events

The host's Indications of Compromise (IoC) events for encrypted visibility engine detection allows you to check connection events with a very high malware confidence level, as reported by EVE. IoC events are triggered for encrypted sessions generated from a host using a malicious client. You can view information, such as IP address, MAC address, and OS information of the malicious host, and the timestamp of the suspicious activity.

A session with Encrypted Visibility Threat Confidence score 'Very High' as seen in connection events generates an IoC event. You must enable **Hosts** from **Policies > Network Discovery**. In the management center, you can view the IoC event existence from:

- **Analysis > Indications of Compromise.**
- **Analysis > Network Map > Indications of Compromise >** Choose the host that must be checked.

You can view the process information of the session that generated the IoC from:

**Analysis > Connection Events > Table View of Connection Events > IoC** column. Note that you must manually select the Encrypted Visibility fields and IoC field.

# QUIC Fingerprinting in EVE

Snort can identify client applications in Quick UDP Internet Connections (QUIC sessions) based on EVE. QUIC fingerprinting can:

- Detect applications over QUIC without enabling decryption.
- Identify malware without enabling decryption.
- Detect service applications. You can assign access control rules based on the service detected over the QUIC protocol.

# Configure EVE

## Procedure

- 
- Step 1** Choose **Policies > Access Control**.
  - Step 2** Click **Edit** (✎) next to the access control policy you want to edit.
  - Step 3** Choose **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.
  - Step 4** Click **Edit** (✎) next to **Encrypted Visibility Engine**.
  - Step 5** In the **Encrypted Visibility Engine** page, enable the **Encrypted Visibility Engine (EVE)** toggle button.
  - Step 6** **Use EVE for Application Detection**—This toggle button is enabled by default, which means that EVE is allowed to assign client applications to processes.

EVE's fingerprint information is added in the **Encrypted Visibility Fingerprint** column header of the connection events or unified events. For further analysis of the EVE data collected, you can right-click the fingerprint information to open a dropdown menu. In the menu, click **View Encrypted Visibility Engine Process Analysis** to go to [appid.cisco.com](http://appid.cisco.com) and view details, such as the fingerprint, VDB version, and so on. Different rows with the same fingerprint string and potential process names associated with them and their prevalence are displayed. Prevalence indicates the frequency of a process associated with a particular fingerprint in the data collection system. You can choose the process names and click **Submit Request** to give feedback about any discrepancy in EVE's process detection. For example, you can submit requests if the process name that is detected does not match with the traffic that is being sent or if the process name is not detected at all for a particular fingerprint.

If you disable the **Use EVE for Application Detection** toggle button:

- AppID-identified clients are assigned to processes and you can see the EVE process and score, but there is no mapping of EVE-detected processes to applications and no action is taken. You can see the details of the events under **Connection Events** or **Unified Events**. To see the difference in connection events (with and without application assignment), see the **Client Application** column header.
- The **Encrypted Visibility Fingerprint** field in the connection events or unified events is empty.

**Step 7** Enable the **Block Traffic Based on EVE Score** toggle button to block traffic based on EVE's threat confidence score. Any incoming traffic that is a potential threat is blocked by default.

The default block threshold is 99 percent, which means:

- If EVE detects the traffic to be malware with 99 percent confidence or more, the traffic is blocked.
- If EVE detects the traffic to be malware with less than 99 percent confidence, EVE takes no action.

**Note** If EVE has blocked the traffic, in the **Connection Events** page, the **Reason** column header displays **Encrypted Visibility Block**.

**Step 8** Use the slider to adjust the threshold for blocking based on EVE's threat confidence, which ranges from **Very Low** to **Very High**.

**Step 9** For further granular control, enable the **Advanced Mode** toggle button. Now, you can assign a specific EVE Threat Confidence Score for blocking traffic. The default block threshold is 99 percent.

**Caution** We recommend that you do not set a threshold below 50 percent to ensure optimal performance.

**Step 10** Click **OK**.

**Step 11** Click **Save**.

---

### What to do next

Deploy configuration changes.

## View EVE Events

After enabling the **Encrypted Visibility Engine** and deploying your access control policy, you can start sending live traffic through your system. You can view the logged connection events on the **Connection Events** page. To access the connection events, in the management center:

### Procedure

---

**Step 1** Click **Analysis > Connections > Events**.

**Step 2** Click the **Table View of Connection Events** tab.

You can also view the connection event fields in the **Unified Events** viewer, which is under the **Analysis** menu.

Encrypted Visibility Engine can identify the client process that initiated a connection, the OS on the client, and if the process contains malware or not.

---

On the **Connection Events** page, you must explicitly enable the following columns that are added for Encrypted Visibility Engine.

- Encrypted Visibility Process Name
- Encrypted Visibility Process Confidence Score
- Encrypted Visibility Threat Confidence
- Encrypted Visibility Threat Confidence Score
- Detection Type

For information about these fields, see the section **Connection and Security Intelligence Event Fields** in the **Connection and Security-Related Connection Events** chapter of the [Cisco Secure Firewall Management Center Administration Guide](#).

---

**Note** On the **Connection Events** page, if processes are assigned applications, the **Detection Type** column displays **Encrypted Visibility Engine** indicating that the client application was identified by EVE. Without application assignments to process names, the **Detection Type** column displays **AppID** indicating that the engine that identified the client application was AppID.

---

## View EVE Dashboard

You can view the EVE analysis information in the following dashboards:

### Before you begin

To view the Encrypted Visibility Engine (EVE) widgets:

- In an access control policy, the **Encrypted Visibility Engine (EVE)** must be enabled under the **Advanced Settings**.

## Procedure

- 
- Step 1** Go to **Overview > Dashboards**, and click **Dashboard**.
- Step 2** In the **Summary Dashboard** window, click the **switch dashboard** link and choose **Application Statistics** from the dropdown box.
- Step 3** Choose the **Encrypted Visibility Engine** tab to view the following two dashboards:
- **Top Encrypted Visibility Engine Discovered Processes**—Displays top client processes used in your network and the connection count. You can click the process name in the table to see the filtered view of the **Connection Events** page, which is filtered by the process name.
  - **Connections by Encrypted Visibility Engine Threat Confidence**—Displays connections by the confidence levels (Very High, Very Low, and so on). You can click the Threat confidence level in the table to see the filtered view of the **Connection Events** page, which is filtered by the confidence level.
- 

## About Elephant Flow Detection and Remediation

You can use the elephant flow detection feature to detect and remediate elephant flows. The following remediation actions can be applied:

- **Bypass elephant flow**—You can configure elephant flow to bypass Snort inspection. If this is configured, Snort does not receive any packet from that flow.
- **Throttle elephant flow**—You can apply rate-limit to the flow and continue to inspect flows. The flow rate is calculated dynamically and 10% of the flow rate is reduced. Snort sends the verdict (QoS flow with 10% less flow rate) to the firewall engine. If you choose to bypass all applications including unidentified applications, you cannot configure the throttle action (rate-limit) for any flow.

---

**Note** For the elephant flow detection to work, Snort 3 must be the detection engine.

---

## Elephant Flow Upgrade from Intelligent Application Bypass

Intelligent Application Bypass (IAB) is deprecated from version 7.2.0 onwards for Snort 3 devices.

For devices running 7.2.0 or later, you must configure elephant flow settings under the **Elephant Flow Settings** section in the AC policy (Advanced settings tab).

Post-upgrade to 7.2.0 (or later), if you are using a Snort 3 device, the elephant flow configuration settings will be picked and deployed from the **Elephant Flow Settings** section and not from the **Intelligent Application**

**Bypass Settings** section, so if you have not migrated to Elephant Flow configuration settings, your device will lose the elephant flow configuration upon the next deployment.

The following table shows the IAB or elephant flow configurations that can be applied to version 7.2.0 or later and to version 7.1.0 or earlier that are running Snort 3 or Snort 2 engines.

Management Center	Threat Defense	Elephant Flow or IAB Configuration
Management Center 7.0 or 7.1	Snort 2 device	Configuration from IAB is applicable.
	Snort 3 device	Configuration from IAB is applicable.
Management Center 7.2.0	Snort 2 device	Configuration from IAB is applicable.
	Snort 3 device (7.1.0 and earlier)	Configuration from IAB is applicable.
	Snort 3 device (7.2.0 and later)	Configuration from Elephant Flow is applicable.

## Configure Elephant Flow

You can configure elephant flow to take actions on elephant flows, which helps resolve issues, such as system duress, high CPU utilization, packet drops, and so on.

---

**Attention** Elephant flow detection is not applicable for prefiltered, trusted, or fast-forwarded flows, which do not process through Snort. As elephant flows are detected by Snort, elephant flow detection is not applicable for encrypted traffic.

---

### Procedure

---

**Step 1** In the access control policy editor, click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line. Then, click **Edit** (✎) next to **Elephant Flow Settings**.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

Figure 380: Configure Elephant Flow Detection

**Step 2** The **Elephant Flow Detection** toggle button is enabled by default. You can configure the values for flow bytes and flow duration. When they exceed your configured values, elephant flow events are generated.

**Step 3** To remediate elephant flows, enable the **Elephant Flow Remediation** toggle button.

**Step 4** To set the criteria for remediation of the elephant flow, configure the values for CPU utilization %, duration of fixed time windows, and packet drop %.

CPU utilization is calculated per elephant flow and is derived from the flow latency. If the CPU utilization crosses the configured threshold and other configurations, such as fixed time windows and packet drops, are also matched, the elephant flow remediation actions are applied. Similarly, packet drop calculation is based on the packets dropped per CPU. After the packet drop percentage exceeds the configured value on a specific CPU, the remediation actions are applied. For example, consider that configurations are set to the default, that is, CPU utilization of 40%, fixed time window of 30 seconds, and packet drop of 5%. On a specific CPU, if more than 5% of packet drops are detected and the CPU utilization per flow exceeds 40% in the fixed time frame of 30 seconds, then the flows are either bypassed or throttled.

**Step 5** You can perform the following actions for elephant flow remediation when it meets the configured criteria:

- a. **Bypass the flow**—Enable this button to bypass Snort inspection for selected applications or filters. Choose from:
  - **All applications including unidentified applications**—Select this option to bypass all the application traffic. If you configure this option, you cannot configure the throttle action (rate-limit) for any flow.
  - **Select Applications/Filters**—Select this option to select the applications or filters whose traffic you want to bypass; see the topic **Configuring Application Conditions and Filters** in the **Access Control Rules** chapter in the [Cisco Secure Firewall Management Center Device Configuration Guide](#).
- b. **Throttle the flow**—Enable this button to apply rate-limit to the flow and continue to inspect flows. Note that you can select the applications or filters to bypass Snort inspection and throttle the remaining flows.

**Note** Automatic removal of throttle from a throttled elephant flow occurs when the system is out of duress, that is, the percentage of Snort packet drops is lesser than your configured threshold. Consequently, rate limiting is also removed.

You can also manually remove throttling from a throttled elephant flow, using the following threat defense commands:

- **clear efd-throttle <5-tuple/all> bypass**—This command removes throttling from the throttled elephant flow and bypasses Snort inspection.
- **clear efd-throttle <5-tuple/all>**—This command removes throttling from the throttled elephant flow and Snort inspection continues. Elephant flow remediation is skipped after using this command.

For more information about these commands, see the [Cisco Secure Firewall Threat Defense Command Reference](#).

**Step 6** In the **Remediation Exemption Rule** section, click **Add Rule** to configure L4 access control list (ACL) rules for flows that must be exempted from remediation.

**Step 7** In the **Add Rule** window, use the **Networks** tab to add the network details, that is the source network and the destination network. Use the **Ports** tab to add the source port and the destination port.

If an elephant flow is detected and it matches the rules that are defined, an event is generated with the reason as **Elephant Flow Exempted** in the **Reason** column header of **Connection Events**.

**Step 8** In the **Remediation Exemption Rule** section, you can view the flows that are exempt from the remediation action.

**Step 9** Click **OK** to save the elephant flow settings.

**Step 10** Click **Save** to save the policy.

---

### What to do next

Deploy configuration changes.

After configuring your elephant flow settings, monitor your connection events to see if any flows are detected, bypassed, or throttled. You can view this in the **Reason** field of your connection event. The three reasons for elephant flow connections are:

- Elephant Flow
- Elephant Flow Throttled
- Elephant Flow Trusted

---

**Attention** Enabling elephant flow detection alone does not cause generation of connection events for elephant flows. If a connection event is already logged for another reason and the flow is also an elephant flow, then the **Reason** field contains this information. However, to ensure that you are logging all elephant flows, you must enable connection logging in the applicable access control rules.

---

Refer to [Cisco Secure Firewall Elephant Flow Detection](#) for more information.

## CHAPTER 105

# Application Layer Preprocessors

---

The following topics explain application layer preprocessors and how to configure them:

- [Introduction to Application Layer Preprocessors, on page 2801](#)
- [License Requirements for Application Layer Preprocessors, on page 2802](#)
- [Requirements and Prerequisites for Application Layer Preprocessors, on page 2802](#)
- [The DCE/RPC Preprocessor, on page 2802](#)
- [The DNS Preprocessor, on page 2813](#)
- [The FTP/Telnet Decoder, on page 2816](#)
- [The HTTP Inspect Preprocessor, on page 2824](#)
- [The Sun RPC Preprocessor, on page 2839](#)
- [The SIP Preprocessor, on page 2841](#)

- [The POP Preprocessor, on page 2850](#)
- [The SMTP Preprocessor, on page 2853](#)
- [The SSH Preprocessor, on page 2859](#)
- [The SSL Preprocessor, on page 2863](#)

## Introduction to Application Layer Preprocessors

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

Application layer protocols can represent the same data in a variety of ways. The system provides application layer protocol decoders that normalize specific types of packet data into formats that the intrusion rules engine can analyze. Normalizing application-layer protocol encodings allows the rules engine to effectively apply the same content-related rules to packets whose data is represented differently and obtain meaningful results.

When an intrusion rule or rule argument requires a disabled preprocessor, the system automatically uses it with its current configuration even though it remains disabled in the network analysis policy's web interface.

Note that preprocessors do not generate events in most cases unless you enable the accompanying preprocessor rules in an intrusion policy.

# The DCE/RPC Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The DCE/RPC protocol allows processes on separate network hosts to communicate as if the processes were on the same host. These inter-process communications are commonly transported between hosts over TCP and UDP. Within the TCP transport, DCE/RPC might also be further encapsulated in the Windows Server Message Block (SMB) protocol or in Samba, an open-source SMB implementation used for inter-process communication in a mixed environment comprised of Windows and UNIX- or Linux-like operating systems. In addition, Windows IIS web servers on your network might use IIS RPC over HTTP, which provides distributed communication through a firewall, to proxy TCP-transported DCE/RPC traffic.

Note that descriptions of DCE/RPC preprocessor options and functionality include the Microsoft implementation of DCE/RPC known as MSRPC; descriptions of SMB options and functionality refer to both SMB and Samba.

Although most DCE/RPC exploits occur in DCE/RPC client requests targeted for DCE/RPC servers, which could be practically any host on your network that is running Windows or Samba, exploits can also occur in server responses. The DCE/RPC preprocessor detects DCE/RPC requests and responses encapsulated in TCP, UDP, and SMB transports, including TCP-transported DCE/RPC using version 1 RPC over HTTP. The preprocessor analyzes DCE/RPC data streams and detects anomalous behavior and evasion techniques in DCE/RPC traffic. It also analyzes SMB data streams and detects anomalous SMB behavior and evasion techniques.

The DCE/RPC preprocessor also desegments SMB and defragments DCE/RPC in addition to the IP defragmentation provided by the IP defragmentation preprocessor and the TCP stream reassembly provided by the TCP stream preprocessor.

Finally, the DCE/RPC preprocessor normalizes DCE/RPC traffic for processing by the rules engine.

## Connectionless and Connection-Oriented DCE/RPC Traffic

DCE/RPC messages comply with one of two distinct DCE/RPC Protocol Data Unit (PDU) protocols:

### connection-oriented DCE/RPC PDU protocol

The DCE/RPC preprocessor detects connection-oriented DCE/RPC in the TCP, SMB, and RPC over HTTP transports.

### connectionless DCE/RPC PDU protocol

The DCE/RPC preprocessor detects connectionless DCE/RPC in the UDP transport.

The two DCE/RPC PDU protocols have their own unique headers and data characteristics. For example, the connection-oriented DCE/RPC header length is typically 24 bytes and the connectionless DCE/RPC header length is fixed at 80 bytes. Also, correct fragment order of fragmented connectionless DCE/RPC cannot be handled by a connectionless transport and, instead, must be ensured by connectionless DCE/RPC header values; in contrast, the transport protocol ensures correct fragment order for connection-oriented DCE/RPC. The DCE/RPC preprocessor uses these and other protocol-specific characteristics to monitor both protocols for anomalies and other evasion techniques, and to decode and defragment traffic before passing it to the rules engine.

The following diagram illustrates the point at which the DCE/RPC preprocessor begins processing DCE/RPC traffic for the different transports.

Note the following in the figure:

- The well-known TCP or UDP port 135 identifies DCE/RPC traffic in the TCP and UDP transports.

- The figure does not include RPC over HTTP.

For RPC over HTTP, connection-oriented DCE/RPC is transported directly over TCP as shown in the figure after an initial setup sequence over HTTP.

- The DCE/RPC preprocessor typically receives SMB traffic on the well-known TCP port 139 for the NetBIOS Session Service or the similarly implemented well-known Windows port 445.

Because SMB has many functions other than transporting DCE/RPC, the preprocessor first tests whether the SMB traffic is carrying DCE/RPC traffic and stops processing if it is not or continues processing if it is.

- IP encapsulates all DCE/RPC transports.
- TCP transports all connection-oriented DCE/RPC.
- UDP transports connectionless DCE/RPC.

## DCE/RPC Target-Based Policies

Windows and Samba DCE/RPC implementations differ significantly. For example, all versions of Windows use the DCE/RPC context ID in the first fragment when defragmenting DCE/RPC traffic, and all versions of Samba use the context ID in the last fragment. As another example, Windows Vista uses the *opnum* (operation number) header field in the first fragment to identify a specific function call, and Samba and all other Windows versions use the *opnum* field in the last fragment.

There are also significant differences in Windows and Samba SMB implementations. For example, Windows recognizes the SMB OPEN and READ commands when working with named pipes, but Samba does not recognize these commands.

When you enable the DCE/RPC preprocessor, you automatically enable a default target-based policy. Optionally, you can add target-based policies that target other hosts running different Windows or Samba versions. The default target-based policy applies to any host not included in another target-based policy.

In each target-based policy, you can:

- enable one or more transports and specify *detection ports* for each
- enable and specify *auto-detection ports*
- set the preprocessor to detect when there is an attempt to connect to one or more shared SMB resources that you identify
- configure the preprocessor to detect files in SMB traffic and to inspect a specified number of bytes in a detected file
- modify an advanced option that should be modified only by a user with SMB protocol expertise; this option lets you set the preprocessor to detect when a number of chained SMB AndX commands exceed a specified maximum number

In addition to enabling SMB traffic file detection in the DCE/RPC preprocessor, you can configure a file policy to optionally capture and block these files, or submit them to the Cisco AMP cloud for dynamic analysis. Within that policy, you must create a file rule with an **Action** of **Detect Files** or **Block Files** and a selected **Application Protocol** of **Any** or **NetBIOS-ssn (SMB)**.

## RPC over HTTP Transport

Microsoft RPC over HTTP allows you to tunnel DCE/RPC traffic through a firewall as shown in the following diagram. The DCE/RPC preprocessor detects version 1 of Microsoft RPC over HTTP.

The Microsoft IIS proxy server and the DCE/RPC server can be on the same host or on different hosts. Separate proxy and server options provide for both cases. Note the following in the figure:

- The DCE/RPC server monitors port 593 for DCE/RPC client traffic, but the firewall blocks port 593. Firewalls typically block port 593 by default.
- RPC over HTTP transports DCE/RPC over HTTP using well-known HTTP port 80, which firewalls are likely to permit.
- Example 1 shows that you would choose the **RPC over HTTP proxy** option to monitor traffic between the DCE/RPC client and the Microsoft IIS RPC proxy server.
- Example 2 shows that you would choose the **RPC over HTTP server** option when the Microsoft IIS RPC proxy server and the DCE/RPC server are located on different hosts and the device monitors traffic between the two servers.
- Traffic is comprised solely of connection-oriented DCE/RPC over TCP after RPC over HTTP completes the proxied setup between the DCE/RPC client and server.

## DCE/RPC Global Options

Global DCE/RPC preprocessor options control how the preprocessor functions. Note that, except for the **Memory Cap Reached** and **Auto-Detect Policy on SMB Session** options, modifying these options could have a negative impact on performance or detection capability. You should not modify them unless you have a thorough understanding of the preprocessor and the interaction between the preprocessor and enabled DCE/RPC rules.

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Maximum Fragment Size

When **Enable Defragmentation** is selected, specifies the maximum DCE/RPC fragment length allowed. The preprocessor truncates larger fragments for processing purposes to the specified size before defragmenting but does not alter the actual packet. A blank field disables this option.

Make sure that the **Maximum Fragment Size** option is greater than or equal to the depth to which the rules need to detect.

### Reassembly Threshold

When **Enable Defragmentation** is selected, 0 disables this option, or specifies a minimum number of fragmented DCE/RPC bytes and, if applicable, segmented SMB bytes to queue before sending a reassembled packet to the rules engine. A low value increases the likelihood of early detection but could have a negative impact on performance. You should test for performance impact if you enable this option.

Make sure that the **Reassembly Threshold** option is greater than or equal to the depth to which the rules need to detect.

### Enable Defragmentation

Specifies whether to defragment fragmented DCE/RPC traffic. When disabled, the preprocessor still detects anomalies and sends DCE/RPC data to the rules engine, but at the risk of missing exploits in fragmented DCE/RPC data.

Although this option provides the flexibility of not defragmenting DCE/RPC traffic, most DCE/RPC exploits attempt to take advantage of fragmentation to hide the exploit. Disabling this option would bypass most known exploits, resulting in a large number of false negatives.

### Memory Cap Reached

Detects when the maximum memory limit allocated to the preprocessor is reached or exceeded. When the maximum memory cap is reached or exceeded, the preprocessor frees all pending data associated with the session that caused the memory cap event and ignores the rest of that session.

You can enable rule 133:1 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Auto-Detect Policy on SMB Session

Detects the Windows or Samba version that is identified in SMB `Session Setup AndX` requests and responses. When the detected version is different from the Windows or Samba version configured for the **Policy** configuration option, the detected version overrides the configured version for that session only.

For example, if you set **Policy** to Windows XP and the preprocessor detects Windows Vista, the preprocessor uses a Windows Vista policy for that session. Other settings remain in effect.

When the DCE/RPC transport is not SMB (that is, when the transport is TCP or UDP), the version cannot be detected and the policy cannot be automatically configured.

To enable this option, choose one of the following from the drop-down list:

- Choose **Client** to inspect server-to-client traffic for the policy type.
- Choose **Server** to inspect client-to-server traffic for the policy type.
- Choose **Both** to inspect server-to-client and client-to-server traffic for the policy type.

### Legacy SMB Inspection Mode

When **Legacy SMB Inspection Mode** is enabled, the system applies SMB intrusion rules only to SMB Version 1 traffic, and applies DCE/RPC intrusion rules to DCE/RPC traffic using SMB Version 1 as a transport. When this option is disabled, the system applies SMB intrusion rules to traffic using SMB Versions 1, 2, and 3, but applies DCE/RPC intrusion rules to DCE/RPC traffic using SMB as a transport only for SMB Version 1.

### Related Topics

[Basic content and protected\\_content Keyword Arguments](#), on page 2120

[Overview: The byte\\_jump and byte\\_test Keywords](#)

## DCE/RPC Target-Based Policy Options

In each target-based policy, you can enable one or more of the TCP, UDP, SMB, and RPC over HTTP transports. When you enable a transport, you must also specify one or more *detection ports*, that is, ports that are known to carry DCE/RPC traffic.

Cisco recommends that you use the default detection ports, which are either well-known ports or otherwise commonly-used ports for each protocol. You would add detection ports only if you detected DCE/RPC traffic on a non-default port.

You can specify ports for one or more transports in any combination in a Windows target-based policy to match the traffic on your network, but you can only specify ports for the SMB transport in a Samba target-based policy.

---

**Note** You must enable at least one DCE/RPC transport in the default target-based policy except when you have added a DCE/RPC target-based policy that has at least one transport enabled. For example, you might want to specify the hosts for all DCE/RPC implementations and not have the default target-based policy deploy to unspecified hosts, in which case you would not enable a transport for the default target-based policy.

---

Optionally, you can also enable and specify *auto-detection ports*, that is, ports that the preprocessor tests first to determine if they carry DCE/RPC traffic and continues processing only when it detects DCE/RPC traffic.

When you enable auto-detection ports, ensure that they are set to the port range from 1024 to 65535 to cover the entire ephemeral port range.

Note that auto-detection occurs only for ports not already identified by transport detection ports.

It is unlikely that you would enable or specify auto-detection ports for the RPC over HTTP Proxy Auto-Detect Ports option or the SMB Auto-Detect Ports option because there is little likelihood that traffic for either would occur or even be possible except on the specified default detection ports.

Each target-based policy allows you to specify the various options below. If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Networks

The host IP addresses where you want to deploy the DCE/RPC target-based server policy. Also named the **Server Address** field in the Add Target pop-up window when you add a target-based policy.

You can specify a single IP address or address block, or a comma-separated list of either or both. You can configure up to 255 total profiles including the default policy.

Note that the `default` setting in the default policy specifies all IP addresses on your monitored network segment that are not covered by another target-based policy. Therefore, you cannot and do not need to specify an IP address or CIDR block/prefix length for the default policy, and you cannot leave this setting blank in another policy or use address notation to represent `any` (for example, `0.0.0.0/0` or `::/0`).

### Policy

The Windows or Samba DCE/RPC implementation used by the targeted host or hosts on your monitored network segment.

Note that you can enable the **Auto-Detect Policy on SMB Session** global option to automatically override the setting for this option on a per session basis when SMB is the DCE/RPC transport.

### SMB Invalid Shares

Identifies one or more SMB shared resources the preprocessor will detect when there is an attempt to connect to a shared resource that you specify. You can specify multiple shares in a comma-separated list and, optionally, you can enclose shares in quotes, which was required in previous software versions but is no longer required; for example:

```
"C$", D$, "admin", private
```

The preprocessor detects invalid shares in SMB traffic when you have enabled **SMB Ports**.

Note that in most cases you should append a dollar sign to a drive named by Windows that you identify as an invalid share. For example, identify drive C as `C$` or `"C$"`.

Note also that to detect SMB invalid shares, you must also enable **SMB Ports** or **SMB Auto-Detect Ports**.

You can enable rule 133:26 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### SMB Maximum AndX Chain

The maximum number of chained SMB AndX commands to permit. Typically, more than a few chained AndX commands represent anomalous behavior and could indicate an evasion attempt. Specify 1 to permit no chained commands or 0 to disable detecting the number of chained commands.

Note that the preprocessor first counts the number of chained commands and generates an event if accompanying SMB preprocessor rules are enabled and the number of chained commands equals or exceeds the configured value. It then continues processing.

---

**Caution** Only someone who is expert in the SMB protocol should modify the setting for the **SMB Maximum AndX Chains** option.

---

You can enable rule 133:20 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### RPC proxy traffic only

Enabling **RPC over HTTP Proxy Ports** indicates whether detected client-side RPC over HTTP traffic is proxy traffic only or might include other web server traffic. For example, port 80 could carry both proxy and other web server traffic.

When this option is disabled, both proxy and other web server traffic are expected. Enable this option, for example, if the server is a dedicated proxy server. When enabled, the preprocessor tests traffic to determine if it carries DCE/RPC, ignores the traffic if it does not, and continues processing if it does. Note that enabling this option adds functionality only if the **RPC over HTTP Proxy Ports** check box is also enabled.

### RPC over HTTP Proxy Ports

Enables detection of DCE/RPC traffic tunneled by RPC over HTTP over each specified port when your managed device is positioned between the DCE/RPC client and the Microsoft IIS RPC proxy server.

When enabled, you can add any ports where you see DCE/RPC traffic, although this is unlikely to be necessary because web servers typically use the default port for both DCE/RPC and other traffic. When enabled, you would not enable **RPC over HTTP Proxy Auto-Detect Ports**, but you would enable the **RPC Proxy Traffic Only** when detected client-side RPC over HTTP traffic is proxy traffic only and does not include other web server traffic.

---

**Note** You would rarely, if ever, select this option.

---

### RPC over HTTP Server Ports

Enables detection of DCE/RPC traffic tunneled by RPC over HTTP on each specified port when the Microsoft IIS RPC proxy server and the DCE/RPC server are located on different hosts and the device monitors traffic between the two servers.

Typically, when you enable this option you should also enable **RPC over HTTP Server Auto-Detect Ports** with a port range from 1025 to 65535 for that option even if you are not aware of any proxy web servers on your network. Note that the RPC over HTTP server port is sometimes reconfigured, in which case you should add the reconfigured server port to port list for this option.

### TCP Ports

Enables detection of DCE/RPC traffic in TCP on each specified port.

Legitimate DCE/RPC traffic and exploits might use a wide variety of ports, and other ports above port 1024 are common. Typically, when this option is enabled you should also enable **TCP Auto-Detect Ports** with a port range from 1025 to 65535 for that option.

### UDP Ports

Enables detection of DCE/RPC traffic in UDP on each specified port.

Legitimate DCE/RPC traffic and exploits might use a wide variety of ports, and other ports above port 1024 are common. Typically, when this option is enabled you should also enable **UDP Auto-Detect Ports** with a port range from 1025 to 65535 for that option.

### SMB Ports

Enables detection of DCE/RPC traffic in SMB on each specified port.

You could encounter SMB traffic using the default detection ports. Other ports are rare. Typically, use the default settings.

Note that you can enable the **Auto-Detect Policy on SMB Session** global option to automatically override the policy type configured for a targeted policy on a per session basis when SMB is the DCE/RPC transport.

#### RPC over HTTP Proxy Auto-Detect Ports

Enables auto-detection of DCE/RPC traffic tunneled by RPC over HTTP on the specified ports when your managed device is positioned between the DCE/RPC client and the Microsoft IIS RPC proxy server.

When enabled, you would typically specify a port range from 1025 to 65535 to cover the entire range of ephemeral ports.

#### RPC over HTTP Server Auto-Detect Ports

Enables auto-detection of DCE/RPC traffic tunneled by RPC over HTTP on the specified ports when the Microsoft IIS RPC proxy server and the DCE/RPC server are located on different hosts and the device monitors traffic between the two servers.

#### TCP Auto-Detect Ports

Enables auto-detection of DCE/RPC traffic in TCP on the specified ports.

#### UDP Auto-Detect Ports

Enables auto-detection of DCE/RPC traffic in UDP on each specified port.

#### SMB Auto-Detect Ports

Enables auto-detection of DCE/RPC traffic in SMB.

---

**Note** You would rarely, if ever, select this option.

---

#### SMB File Inspection

Enables inspection of SMB traffic for file detection. You have the following options:

- Select **Off** to disable file inspection.
- Select **Only** to inspect file data without inspecting the DCE/RPC traffic in SMB. Selecting this option can improve performance over inspecting both files and DCE/RPC traffic.
- Select **On** to inspect both files and the DCE/RPC traffic in SMB. Selecting this option can impact performance.

Inspection of SMB traffic for the following is not supported:

- files transferred concurrently in a single TCP or SMB session
- files transferred across multiple TCP or SMB sessions
- files transferred with non-contiguous data, such as when message signing is negotiated
- files transferred with different data at the same offset, overlapping the data
- files opened on a remote client for editing that the client saves to the file server

### SMB File Inspection Depth

If **SMB File Inspection** is set to **Only** or **On**, the number of bytes inspected when a file is detected in SMB traffic. Specify one of the following:

- a positive value
- 0 to inspect the entire file
- -1 to disable file inspection

Enter a value in this field equal to or smaller than the one defined in the File and Malware Settings section of the Advanced tab in your access control policy. If you set a value for this option larger than the one defined for **Limit the number of bytes inspected when doing file type detection**, the system uses the access control policy setting as the functional maximum.

If **SMB File Inspection** is set to **Off**, this field is disabled.

## Traffic-Associated DCE/RPC Rules

Most DCE/RPC preprocessor rules trigger against anomalies and evasion techniques detected in SMB, connection-oriented DCE/RPC, or connectionless DCE/RPC traffic. The following table identifies the rules that you can enable for each type of traffic.

*Table 234: Traffic-Associated DCE/RPC Rules*

Traffic	Preprocessor Rule GID:SID
SMB	133:2 through 133:26, and 133:48 through 133:59
Connection-Oriented DCE/RPC	133:27 through 133:39
Detect Connectionless DCE/RPC	133:40 through 133:43

## Configuring the DCE/RPC Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

You configure the DCE/RPC preprocessor by modifying any of the global options that control how the preprocessor functions, and by specifying one or more target-based server policies that identify the DCE/RPC servers on your network by IP address and by either the Windows or Samba version running on them. Target-based policy configuration also includes enabling transport protocols, specifying the ports carrying DCE/RPC traffic to those hosts, and setting other server-specific options.

### Before you begin

- Confirm that networks you want to identify in a custom target-based policy match or are a subset of the networks, zones, and VLANs handled by its parent network analysis policy. See [Advanced Settings for Network Analysis Policies, on page 2751](#) for more information.

## Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.  
If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel on the left.
- Step 5** If **DCE/RPC Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **DCE/RPC Configuration**.
- Step 7** Modify the options in the **Global Settings** section; see [DCE/RPC Global Options, on page 2805](#).
- Step 8** You have the following choices:
- Add a server profile — Click **Add** (+) next to **Servers**. Specify one or more IP addresses in the **Server Address** field, then click **OK**.
  - Delete a server profile — Click **Delete** (🗑) next to the policy.
  - Edit a server profile — Click the configured address for the profile under **Servers**, or click **default**. You can modify any of the settings in the **Configuration** section; see [DCE/RPC Target-Based Policy Options, on page 2807](#).
- Step 9** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.
- 

### What to do next

- If you want to generate intrusion events, enable DCE/RPC preprocessor rules (GID 132 or 133). For more information, see [Setting Intrusion Rule States, on page 2086](#), [DCE/RPC Global Options, on page 2805](#), [DCE/RPC Target-Based Policy Options, on page 2807](#), and [Traffic-Associated DCE/RPC Rules, on page 2811](#).
- Deploy configuration changes.

### Related Topics

# The DNS Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

The DNS preprocessor inspects DNS name server responses for the following specific exploits:

- Overflow attempts on RData text fields
- Obsolete DNS resource record types
- Experimental DNS resource record types

The most common type of DNS name server response provides one or more IP addresses that correspond to domain names in the query that prompted the response. Other types of server responses provide, for example, the destination of an email message or the location of a name server that can provide information not available from the server originally queried.

A DNS response is comprised of:

- a message header
- a Question section that contains one or more requests
- three sections that respond to requests in the Question section
  - Answer
  - Authority
  - Additional Information.

Responses in these three sections reflect the information in *resource records* (RR) maintained on the name server. The following table describes these three sections.

**Table 235: DNS Name Server RR Responses**

This section...	Includes...	For example...
Answer	Optionally, one or more resource records that provide a specific answer to a query	The IP address corresponding to a domain name
Authority	Optionally, one or more resource records that point to an authoritative name server	The name of an authoritative name server for the response
Additional Information	Optionally, one or more resource records that provided additional information related to the Answer sections	The IP address of another server to query

There are many types of resource records, all adhering to the following structure:

Theoretically, any type of resource record can be used in the Answer, Authority, or Additional Information section of a name server response message. The DNS preprocessor inspects any resource record in each of the three response sections for the exploits it detects.

The Type and RData resource record fields are of particular importance to the DNS preprocessor. The Type field identifies the type of resource record. The RData (resource data) field provides the response content. The size and content of the RData field differ depending on the type of resource record.

DNS messages typically use the UDP transport protocol but also use TCP when the message type requires reliable delivery or the message size exceeds UDP capabilities. The DNS preprocessor inspects DNS server responses in both UDP and TCP traffic.

The DNS preprocessor does not inspect TCP sessions picked up in midstream, and ceases inspection if a session loses state because of dropped packets.

## DNS Preprocessor Options

### Ports

This field specifies the source port or ports the DNS preprocessor should monitor for DNS server responses. Separate multiple ports with commas.

The typical port to configure for the DNS preprocessor is well-known port 53, which DNS name servers use for DNS messages in both UDP and TCP.

### Detect Overflow attempts on RData Text fields

When the resource record type is TXT (text), the RData field is a variable-length ASCII text field.

When selected, this option detects a specific vulnerability identified by entry CVE-2006-3441 in MITRE's Current Vulnerabilities and Exposures database. This is a known vulnerability in Microsoft Windows 2000 Service Pack 4, Windows XP Service Pack 1 and Service Pack 2, and Windows Server 2003 Service Pack 1. An attacker can exploit this vulnerability and take complete control of a host by sending or otherwise causing the host to receive a maliciously crafted name server response that causes a miscalculation in the length of an RData text field, resulting in a buffer overflow.

You should enable this option when your network might include hosts running operating systems that have not been upgraded to correct this vulnerability.

You can enable rule 131:3 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Detect Obsolete DNS RR Types

RFC 1035 identifies several resource record types as obsolete. Because these are obsolete record types, some systems do not account for them and may be open to exploits. You would not expect to encounter these record types in normal DNS responses unless you have purposely configured your network to include them.

You can configure the system to detect known obsolete resource record types. The following table lists and describes these record types.

**Table 236: Obsolete DNS Resource Record Types**

RR Type	Code	Description
3	MD	a mail destination
4	MF	a mail forwarder

You can enable rule 131:1 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Detecting Experimental DNS RR Types

RFC 1035 identifies several resource record types as experimental. Because these are experimental record types, some systems do not account for them and may be open to exploits. You would not expect to encounter these record types in normal DNS responses unless you have purposely configured your network to include them.

You can configure the system to detect known experimental resource record types. The following table lists and describes these record types.

**Table 237: Experimental DNS Resource Record Types**

RR Type	Code	Description
7	MB	a mailbox domain name
8	MG	a mail group member
9	MR	a mail rename domain name
10	NUL	a null resource record

You can enable rule 131:2 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

## Configuring the DNS Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

## Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **DNS Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **DNS Configuration**.
- Step 7** Modify the settings as described in [DNS Preprocessor Options, on page 2814](#).
- Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.
- 

### What to do next

- If you want to generate intrusion events, enable DNS preprocessor rules (GID 131). For more information, see [Setting Intrusion Rule States, on page 2086](#) and [DNS Preprocessor Options, on page 2814](#).
- Deploy configuration changes.

## The FTP/Telnet Decoder

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The FTP/Telnet decoder analyzes FTP and telnet data streams, normalizing FTP and telnet commands before processing by the rules engine.

## Global FTP and Telnet Options

You can set global options to determine whether the FTP/Telnet decoder performs stateful or stateless inspection of packets, whether the decoder detects encrypted FTP or telnet sessions, and whether the decoder continues to check a data stream after it encounters encrypted data.

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Stateful Inspection

When selected, causes the FTP/Telnet decoder to save state and provide session context for individual packets and only inspect reassembled sessions. When cleared, analyzes each individual packet without session context.

To check for FTP data transfers, this option must be selected.

### Detect Encrypted Traffic

Detects encrypted telnet and FTP sessions.

You can enable rules 125:7 and 126:2 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Continue to Inspect Encrypted Data

Instructs the preprocessor to continue checking a data stream after it is encrypted, looking for eventual decrypted data that can be processed.

## Telnet Options

You can enable or disable normalization of telnet commands by the FTP/Telnet decoder, enable or disable a specific anomaly case, and set the threshold number of Are You There (AYT) attacks to permit.

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Ports

Indicates the ports whose telnet traffic you want to normalize. Telnet typically connects to TCP port 23. In the interface, list multiple ports separated by commas.

---

**Caution** Because encrypted traffic (SSL) cannot be decoded, adding port 22 (SSH) could yield unexpected results.

---

### Normalize

Normalizes telnet traffic to the specified ports.

### Detect Anomalies

Enables detection of Telnet SB (subnegotiation begin) without the corresponding SE (subnegotiation end).

Telnet supports subnegotiation, which begins with SB (subnegotiation begin) and must end with an SE (subnegotiation end). However, certain implementations of Telnet servers will ignore the SB without a corresponding SE. This is anomalous behavior that could be an evasion case. Because FTP uses the Telnet protocol on the control connection, it is also susceptible to this behavior.

You can enable rule 126:3 to generate an event and, in an inline deployment, drop offending packets when this anomaly is detected in Telnet traffic, and rule 125:9 when it is detected on the FTP command channel. See [Setting Intrusion Rule States, on page 2086](#).

### Are You There Attack Threshold Number

Detects when the number of consecutive AYT commands exceeds the specified threshold. Cisco recommends that you set the AYT threshold to a value no higher than the default value.

You can enable rule 126:1 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

## Server-Level FTP Options

You can set options for decoding on multiple FTP servers. Each server profile you create contains the server IP address and the ports on the server where traffic should be monitored. You can specify which FTP commands to validate and which to ignore for a particular server, and set maximum parameter lengths for commands. You can also set the specific command syntax the decoder should validate against for particular commands and set alternate maximum command parameter lengths.

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Networks

Use this option to specify one or more IP addresses of FTP servers.

You can specify a single IP address or address block, or a comma-separated list comprised of either or both. You can configure up to 1024 characters, and you can specify up to 255 profiles including the default profile.

Note that the `default` setting in the default policy specifies all IP addresses on your monitored network segment that are not covered by another target-based policy. Therefore, you cannot and do not need to specify an IP address or address block for the default policy, and you cannot leave this setting blank in another policy or use address notation to represent `any` (for example, `0.0.0.0/0` or `::/0`).

### Ports

Use this option to specify the ports on the FTP server where the managed device should monitor traffic. In the interface, list multiple ports separated by commas. Port 21 is the well-known port for FTP traffic.

### File Get Commands

Use this option to define the FTP commands used to transfer files from server to client. Do not change these values unless directed to do so by Support.

---

**Caution** Do not modify the **File Get Commands** field unless directed to by Support.

---

### File Put Commands

Use this option to define the FTP commands used to transfer files from client to server. Do not change these values unless directed to do so by Support.

---

**Caution** Do not modify the **File Put Commands** field unless directed to by Support.

---

### Additional FTP Commands

Use this line to specify the additional commands that the decoder should detect. Separate additional commands by spaces.

Additional commands you may want to add include `xPWD`, `xCWD`, `xCUP`, `xMKD`, and `xRMD`. For more information on these commands, see RFC 775, the Directory oriented FTP commands specification by the Network Working Group.

### Default Max Parameter Length

Use this option to detect the maximum parameter length for commands where an alternate maximum parameter length has not been set. You can add as many alternative maximum parameter lengths as needed.

You can enable rule 125:3 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Alternate Max Parameter Length

Use this option to specify commands where you want to detect a different maximum parameter length, and to specify the maximum parameter length for those commands. Click **Add** to add lines where you can specify a different maximum parameter length to detect for particular commands.

### Check Commands for String Format Attacks

Use this option to check the specified commands for string format attacks.

You can enable rule 125:5 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Command Validity

Use this option to enter a valid format for a specific command. Click **Add** to add a command validation line.

You can enable rules 125:2 and 125:4 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Ignore FTP Transfers

Use this option to improve performance on FTP data transfers by disabling all inspection other than state inspection on the data transfer channel.

---

**Note** To inspect data transfers, the global FTP/Telnet **Stateful Inspection** option must be selected.

---

### Detect Telnet Escape Codes within FTP Commands

Use this option to detect when telnet commands are used over the FTP command channel.

You can enable rule 125:1 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Ignore Erase Commands during Normalization

When **Detect Telnet Escape Codes within FTP Commands** is selected, use this option to ignore telnet character and line erase commands when normalizing FTP traffic. The setting should match how the FTP server handles telnet erase commands. Note that newer FTP servers typically ignore telnet erase commands, while older servers typically process them.

### Troubleshooting Option: Log FTP Command Validation Configuration

Support might ask you during a troubleshooting call to configure your system to print the configuration information for each FTP command listed for the server.

---

**Caution** Do not enable **Log FTP Command Validation Configuration** unless instructed to do so by Support.

---

## FTP Command Validation Statements

When setting up a validation statement for an FTP command, you can specify a group of alternative parameters by separating the parameters with spaces. You can also create a binary OR relationship between two parameters by separating them with a pipe character (|) in the validation statement. Surrounding parameters by square brackets ([]) indicates that those parameters are optional. Surrounding parameters with curly brackets ({} ) indicates that those parameters are required.

You can create FTP command parameter validation statements to validate the syntax of a parameter received as part of an FTP communication.

Any of the parameters listed in the following table can be used in FTP command parameter validation statements.

**Table 238: FTP Command Parameters**

If you use...	The following validation occurs...
int	The represented parameter must be an integer.
number	The represented parameter must be an integer between 1 and 255.
char _chars	The represented parameter must be a single character and a member of the characters specified in the _chars argument.  For example, defining the command validity for <code>MODE</code> with the validation statement <code>char SBC</code> checks that the parameter for the <code>MODE</code> command comprises the character <code>s</code> (representing Stream mode), the character <code>B</code> (representing Block mode), or the character <code>C</code> (representing Compressed mode).

If you use...	The following validation occurs...
<code>date _datefmt</code>	If <code>_datefmt</code> contains #, the represented parameter must be a number. If <code>_datefmt</code> contains c, the represented parameter must be a character. If <code>_datefmt</code> contains literal strings, the represented parameter must match the literal string.
<code>string</code>	The represented parameter must be a string.
<code>host_port</code>	The represented parameter must be a valid host port specifier as defined by RFC 959, the File Transfer Protocol specification by the Network Working Group.

You can combine the syntax in the table above as needed to create parameter validation statements that correctly validate each FTP command where you need to validate traffic.

**Note** When you include a complex expression in a TYPE command, surround it by spaces. Also, surround each operand within the expression by spaces. For example, type `char A | B`, not `char A|B`.

[FTP Command Validation Statements](#), on page 2820

## Client-Level FTP Options

Use these options to configure custom FTP client profiles. If an option description does not include a preprocessor rule, the option is not associated with a preprocessor rule.

### Networks

Use this option to specify one or more IP addresses of FTP clients.

You can specify a single IP address or address block, or a comma-separated list comprised of either or both. You can specify up to 1024 characters, and you can specify up to 255 profiles including the default profile.

Note that the `default` setting in the default policy specifies all IP addresses on your monitored network segment that are not covered by another target-based policy. Therefore, you cannot and do not need to specify an IP address or address block for the default policy, and you cannot leave this setting blank in another policy or use address notation to represent `any` (for example, `0.0.0.0/0` or `::/0`).

### Max Response Length

Use this option to specify the maximum allowed response length to an FTP command accepted by the client. This can detect basic buffer overflows.

You can enable rule 125:6 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States](#), on page 2086.

### Detect FTP Bounce Attempts

Use this option to detect FTP bounce attacks.

You can enable rule 125:8 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

#### Allow FTP Bounce to

Use this option to configure a list of additional hosts and ports on those hosts on which FTP PORT commands should not be treated as FTP bounce attacks.

#### Detect Telnet Escape Codes within FTP Commands

Use this option to detect when telnet commands are used over the FTP command channel.

You can enable rule 125:1 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

#### Ignore Erase Commands During Normalization

When **Detect Telnet Escape Codes within FTP Commands** is selected, use this option to ignore telnet character and line erase commands when normalizing FTP traffic. The setting should match how the FTP client handles telnet erase commands. Note that newer FTP clients typically ignore telnet erase commands, while older clients typically process them.

## Configuring the FTP/Telnet Decoder

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

You can configure client profiles for FTP clients to monitor FTP traffic from clients.

#### Before you begin

- Confirm that any networks you want to identify in a custom target-based policy match or are a subset of the networks, zones, and VLANs handled by its parent network analysis policy. See [Advanced Settings for Network Analysis Policies, on page 2751](#) for more information.

### Procedure

---

**Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

**Step 3** Click **Edit** (✎) next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **FTP and Telnet Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **FTP and Telnet Configuration**.
- Step 7** Set options in the **Global Settings** section as described in [Global FTP and Telnet Options, on page 2817](#).
- Step 8** Set options in the **Telnet Settings** section as described in [Telnet Options, on page 2817](#).
- Step 9** Manage FTP server profiles:
- Add a server profile — Click **Add** (+) next to **FTP Server**. Specify one or more IP addresses for the client in the **Server Address** field and click **OK**. You can specify a single IP address or address block, or a comma-separated list of either or both. You can specify up to 1024 characters, and you can configure up to 255 policies, including the default policy.
  - Edit a server profile — Click the configured address for a custom profile under **FTP Server**, or click **default**. You can modify the settings in the **Configuration** section; see [Server-Level FTP Options, on page 2818](#).
  - Delete a server profile — Click **Delete** (🗑) next to the profile.
- Step 10** Manage FTP client profiles:
- Add a client profile — Click **Add** (+) next to **FTP Client**. Specify one or more IP addresses for the client in the **Client Address** field and click **OK**. You can specify a single IP address or address block, or a comma-separated list of either or both. You can specify up to 1024 characters, and you can configure up to 255 policies, including the default policy.
  - Edit a client profile — Click the configured address for a profile you have added under **FTP Client**, or click **default**. You can modify the settings in the Configuration page area; see [Client-Level FTP Options, on page 2821](#).
  - Delete a client profile — Click **Delete** (🗑) next to a custom profile.
- Step 11** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- If you want to generate intrusion events, enable FTP and telnet preprocessor rules (GID 125 and 126). For more information, see [Setting Intrusion Rule States, on page 2086](#).
- Deploy configuration changes.

# The HTTP Inspect Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The HTTP Inspect preprocessor is responsible for:

- decoding and normalizing HTTP requests sent to and HTTP responses received from web servers on your network
- separating messages sent to web servers into URI, non-cookie header, cookie header, method, and message body components to improve performance of HTTP-related intrusion rules
- separating messages received from web servers into status code, status message, non-set-cookie header, cookie header, and response body components to improve performance of HTTP-related intrusion rules
- detecting possible URI-encoding attacks
- making the normalized data available for additional rule processing
- detecting and preventing attacks through malicious scripts such as JavaScript.

HTTP traffic can be encoded in a variety of formats, making it difficult for rules to appropriately inspect. HTTP Inspect decodes 14 types of encoding, ensuring that your HTTP traffic gets the best inspection possible.

You can configure HTTP Inspect options globally, on a single server, or for a list of servers.

Note that the preprocessor engine performs HTTP normalization *statelessly*. That is, it normalizes HTTP strings on a packet-by-packet basis, and can only process HTTP strings that have been reassembled by the TCP stream preprocessor.

## **fast\_blocking**

Among the global configuration options for the HTTP Inspect preprocessor, the `fast_blocking` option was introduced starting Snort version 2.9.16.0. This option enables inspecting HTTP data before the data is cleared. This enables early IPS rule evaluation so that the block rules are applied and the connection is blocked at the earliest instead of blocking it after clearing the data. This configuration is effective only when inline normalization is enabled.

To enable the `fast_blocking` option, you must use a network analysis policy with Maximum Detection as the base policy.

## Global HTTP Normalization Options

The global HTTP options provided for the HTTP Inspect preprocessor control how the preprocessor functions. Use these options to enable or disable HTTP normalization when ports not specified as web server ports receive HTTP traffic.

Note the following:

- If you enable **Unlimited Decompression**, the **Maximum Compressed Data Depth** and **Maximum Decompressed Data Depth** options are automatically set to 65535 when you commit your changes.

- The highest value is used when the values for **Maximum Compressed Data Depth** or **Maximum Decompressed Data Depth** are different in:
  - the default network analysis policy
  - any other custom network analysis policy invoked by network analysis rules in the same access control policy

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Detect Anomalous HTTP Servers

Detects HTTP traffic sent to or received by ports not specified as web server ports.

---

**Note** If you turn this option on, be sure to list all ports that do receive HTTP traffic in a server profile on the HTTP Configuration page. If you do not, and you enable this option and the accompanying preprocessor rule, normal traffic to and from the server will generate events. The default server profile contains all ports normally used for HTTP traffic, but if you modified that profile, you may need to add those ports to another profile to prevent events from being generated.

---

You can enable rule 120:1 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Detect HTTP Proxy Servers

Detects HTTP traffic using proxy servers not defined by the **Allow HTTP Proxy Use** option.

You can enable rule 119:17 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Maximum Compressed Data Depth

Sets the maximum size of compressed data to decompress when **Inspect Compressed Data** (and, optionally, **Decompress SWF File (LZMA)**, **Decompress SWF File (Deflate)**, or **Decompress PDF File (Deflate)**) is enabled.

### Maximum Decompressed Data Depth

Sets the maximum size of the normalized decompressed data when **Inspect Compressed Data** (and, optionally, **Decompress SWF File (LZMA)**, **Decompress SWF File (Deflate)**, or **Decompress PDF File (Deflate)**) is enabled.

## Server-Level HTTP Normalization Options

You can set server-level options for each server you monitor, globally for all servers, or for a list of servers. Additionally, you can use a predefined server profile to set these options, or you can set them individually to meet the needs of your environment. Use these options, or one of the default profiles that set these options, to specify the HTTP server ports whose traffic you want to normalize, the amount of server response payload you want to normalize, and the types of encoding you want to normalize.

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Networks

Use this option to specify the IP address of one or more servers. You can specify a single IP address or address block, or a comma-separated list comprised of either or both.

In addition to a limit of up to 255 total profiles, including the default profile, you can include up to 496 characters, or approximately 26 entries, in an HTTP server list, and specify a total of 256 address entries for all server profiles.

Note that the `default` setting in the default policy specifies all IP addresses on your monitored network segment that are not covered by another target-based policy. Therefore, you cannot and do not need to specify an IP address or CIDR block/prefix length for the default policy, and you cannot leave this setting blank in another policy or use address notation to represent `any` (for example, `0.0.0.0/0` or `::/0`).

### Ports

The ports whose HTTP traffic the preprocessor engine normalizes. Separate multiple port numbers with commas.

### Oversize Dir Length

Detects URL directories longer than the specified value.

You can enable rule 119:15 to generate events and, in an inline deployment, drop offending packets when the preprocessor detects a request for a URL that is longer than the specified length.

### Client Flow Depth

Specifies the number of bytes for rules to inspect in raw HTTP packets, including header and payload data, in client-side HTTP traffic defined in **Ports**. Client flow depth does not apply when HTTP content rule options within a rule inspect specific parts of a request message.

Specify any of the following:

- A positive value inspects the specified number of bytes in the first packet. If the first packet contains fewer bytes than specified, inspect the entire packet. Note that the specified value applies to both segmented and reassembled packets.

Note also that a value of 300 typically eliminates inspection of large HTTP Cookies that appear at the end of many client request headers.

- 0 inspects all client-side traffic, including multiple packets in a session and exceeding the upper byte limit if necessary. Note that this value is likely to affect performance.
- -1 ignores all client-side traffic.

### Server Flow Depth

Specifies the number of bytes for rules to inspect in raw HTTP packets in server-side HTTP traffic specified by **Ports**. Inspection includes the raw header and payload when **Inspect HTTP Responses** disabled and only the raw response body when **Inspect HTTP Response** is enabled.

Server flow depth specifies the number of bytes of raw server response data in a session for rules to inspect in server-side HTTP traffic defined in **Ports**. You can use this option to balance performance and the level of inspection of HTTP server response data. Server flow depth does not apply when HTTP content options within a rule inspect specific parts of a response message.

Unlike client flow depth, server flow depth specifies the number of bytes per HTTP response, not per HTTP request packet, for rules to inspect.

You can specify any of the following:

- A positive value:

When **Inspect HTTP Responses** is **enabled**, inspects only the raw HTTP response body, and not raw HTTP headers; also inspects decompressed data when **Inspect Compressed Data** is enabled.

When **Inspect HTTP Responses** is **disabled**, inspects the raw packet header and payload.

If the session includes fewer response bytes than specified, rules fully inspect all response packets in a given session, across multiple packets as needed. If the session includes more response bytes than specified, rules inspect only the specified number of bytes for that session, across multiple packets as needed.

Note that a small flow depth value may cause false negatives from rules that target server-side traffic defined in **Ports**. Most of these rules target either the HTTP header or content that is likely to be in the first hundred or so bytes of non-header data. Headers are usually under 300 bytes long, but header size may vary.

Note also that the specified value applies to both segmented and reassembled packets.

- 0 inspects the entire packet for all HTTP server-side traffic defined in **Ports**, including response data in a session that exceeds 65535 bytes.

Note that this value is likely to affect performance.

- -1:

When **Inspect HTTP Responses** is **enabled**, inspects only raw HTTP headers and not the raw HTTP response body.

When **Inspect HTTP Responses** is **disabled**, ignores all server-side traffic defined in **Ports**.

### Maximum Header Length

Detects a header field longer than the specified maximum number of bytes in an HTTP request; also in HTTP responses when **Inspect HTTP Responses** is enabled. A value of 0 disables this option. Specify a positive value to enable it.

You can enable rule 119:19 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Maximum Number of Headers

Detects when the number of headers exceeds this setting in an HTTP request. A value of 0 disables this option. Specify a positive value to enable it.

You can enable rule 119:20 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Maximum Number of Spaces

Detects when the number of white spaces in a folded line equals or exceeds this setting in an HTTP request. A value of 0 disables this option. Specify a positive value to enable it.

You can enable rule 119:26 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### HTTP Client Body Extraction Depth

Specifies the number of bytes to extract from the message body of an HTTP client request. You can use an intrusion rule to inspect the extracted data by selecting the `content` or `protected_content` keyword **HTTP Client Body** option.

Specify -1 to ignore the client body. Specify 0 to extract the entire client body. Note that identifying specific bytes to extract can improve system performance. Note also that you must specify a value greater than or equal to 0 for the **HTTP Client Body** option to function in an intrusion rule.

### Small Chunk Size

Specifies the maximum number of bytes at which a chunk is considered small. Specify a positive value. A value of 0 disables detection of anomalous consecutive small segments. See the **Consecutive Small Chunks** option for more information.

### Consecutive Small Chunks

Specifies how many consecutive small chunks represent an abnormally large number in client or server traffic that uses chunked transfer encoding. The **Small Chunk Size** option specifies the maximum size of a small chunk.

For example, set **Small Chunk Size** to 10 and **Consecutive Small Chunks** to 5 to detect 5 consecutive chunks of 10 bytes or less.

You can enable preprocessor rule 119:27 to generate events and, in an inline deployment, drop offending packets on excessive small chunks in client traffic, and rule 120:7 in server traffic. When **Small Chunk Size** is enabled and this option is set to 0 or 1, enabling these rules would trigger an event on every chunk of the specified size or less.

### HTTP Methods

Specifies HTTP request methods in addition to GET and POST that you expect the system to encounter in traffic. Use a comma to separate multiple values.

Intrusion rules use the `content` or `protected_content` keyword with the **HTTP Method** argument to search for content in HTTP methods. You can enable rule 119:31 to generate events and, in an inline deployment, drop offending packets when a method other than GET, POST, or a method configured for this option is encountered in traffic. See [Setting Intrusion Rule States, on page 2086](#).

### No Alerts

Disables intrusion events when accompanying preprocessor rules are enabled.

---

**Note** This option does **not** disable HTTP standard text rules and shared object rules.

---

### Normalize HTTP Headers

When **Inspect HTTP Responses** is enabled, enables normalization of non-cookie data in request and response headers. When **Inspect HTTP Responses** is **not** enabled, enables normalization of the entire HTTP header, including cookies, in request and response headers.

### Inspect HTTP Cookies

Enables extraction of cookies from HTTP request headers. Also enables extraction of set-cookie data from response headers when **Inspect HTTP Responses** is enabled. Disabling this option when cookie extraction is not required can improve performance.

Note that the `Cookie:` and `Set-Cookie:` header names, leading spaces on the header line, and the `CRLF` that terminates the header line are inspected as part of the header and not as part of the cookie.

### Normalize Cookies in HTTP headers

Enables normalization of cookies in HTTP request headers. When **Inspect HTTP Responses** is enabled, also enables normalization of set-cookie data in response headers. You must select **Inspect HTTP Cookies** before selecting this options.

### Allow HTTP Proxy Use

Allows the monitored web server to be used as an HTTP proxy. This option is used only in the inspection of HTTP requests.

### Inspect URI Only

Inspects only the URI portion of the normalized HTTP request packet.

### Inspect HTTP Responses

Enables extended inspection of HTTP responses so, in addition to decoding and normalizing HTTP request messages, the preprocessor extracts response fields for inspection by the rules engine. Enabling this option causes the system to extract the response header, body, status code, and so on, and also extracts set-cookie data when **Inspect HTTP Cookies** is enabled.

You can enable rules 120:2 and 120:3 to generate events and, in an inline deployment, drop offending packets, as follows:

**Table 239: Inspect HTTP Response Rules**

This rule...	Triggers when...
120:2	an invalid HTTP response status code occurs.
120:3	an HTTP response does not include Content-Length or Transfer-Encoding.

### Normalize UTF Encodings to UTF-8

When **Inspect HTTP Responses** is enabled, detects UTF-16LE, UTF-16BE, UTF-32LE, and UTF32-BE encodings in HTTP responses and normalizes them to UTF-8.

You can enable rule 120:4 to generate events and, in an inline deployment, drop offending packets when UTF normalization fails.

### Inspect Compressed Data

When **Inspect HTTP Responses** is enabled, enables decompression of gzip and deflate-compatible compressed data in the HTTP response body, and inspection of the normalized decompressed data. The system inspects chunked and non-chunked HTTP response data. The system inspects decompressed data packet by packet across multiple packets as needed; that is, the system does not combine the decompressed data from different packets for inspection. Decompression ends when **Maximum Compressed Data Depth**, **Maximum Decompressed Data Depth**, or the end of the compressed data is reached. Inspection of decompressed data ends when **Server Flow Depth** is reached unless you also select **Unlimited Decompression**. You can use the `file_data` rule keyword to inspect decompressed data.

You can enable rules 120:6 and 120:24 to generate events and, in an inline deployment, drop offending packets, as follows:

**Table 240: Inspect Compressed HTTP Response Rules**

This rule...	Triggers when...
120:6	decompression of a compressed HTTP response fails.
120:24	partial decompression of a compressed HTTP response fails.

### Unlimited Decompression

When **Inspect Compressed Data** (and, optionally, **Decompress SWF File (LZMA)**, **Decompress SWF File (Deflate)**, or **Decompress PDF File (Deflate)**) is enabled, overrides **Maximum Decompressed Data Depth** across multiple packets; that is, this option enables unlimited decompression across multiple packets. Note that enabling this option does not affect **Maximum Compressed Data Depth** or **Maximum Decompressed Data Depth** within a single packet. Note also that enabling this option sets **Maximum Compressed Data Depth** and **Maximum Decompressed Data Depth** to 65535 when you commit your changes.

### Normalize Javascript

When **Inspect HTTP Responses** is enabled, enables detection and normalization of Javascript within the HTTP response body. The preprocessor normalizes obfuscated Javascript data such as the `unescape` and `decodeURI` functions and the `String.fromCharCode` method. The preprocessor normalizes the following encodings within the `unescape`, `decodeURI`, and `decodeURIComponent` functions:

- %XX
- %uXXXX
- 0xXX
- \xXX
- \uXXXX

The preprocessor detects consecutive white spaces and normalizes them into a single space. When this option is enabled, a configuration field allows you to specify the maximum number of consecutive white spaces to

permit in obfuscated Javascript data. You can enter a value from 1 to 65535. The value 0 disables event generation, regardless of whether the preprocessor rule (120:10) associated with this field is enabled.

The preprocessor also normalizes the Javascript plus (+) operator and concatenates strings using the operator.

You can use the `file_data` intrusion rule keyword to point intrusion rules to the normalized Javascript data.

You can enable rules 120:9, 120:10, and 120:11 to generate events and, in an inline deployment, drop offending packets, as follows:

**Table 241: Normalize Javascript Option Rules**

This rule...	Triggers when...
120:9	the obfuscation level within the preprocessor is greater than or equal to 2.
120:10	the number of consecutive white spaces in the Javascript obfuscated data is greater than or equal to the value configured for the maximum number of consecutive white spaces allowed.
120:11	escaped or encoded data includes more than one type of encoding.

### Decompress SWF File (LZMA) and Decompress SWF File (Deflate)

When **HTTP Inspect Responses** is enabled, these options decompress the compressed portions of files located within the HTTP response body of HTTP requests.

**Note** You can **only** decompress the compressed portions of files found in HTTP GET responses.

- **Decompress SWF File (LZMA)** decompresses the LZMA-compatible compressed portions of Adobe ShockWave Flash (.swf) files
- **Decompress SWF File (Deflate)** decompresses the deflate-compatible compressed portions of Adobe ShockWave Flash (.swf) files

Decompression ends when **Maximum Compressed Data Depth**, **Maximum Decompressed Data Depth**, or the end of the compressed data is reached. Inspection of decompressed data ends when **Server Flow Depth** is reached unless you also select **Unlimited Decompression**. You can use the `file_data` intrusion rule keyword to inspect decompressed data.

You can enable rules 120:12 and 120:13 to generate events and, in an inline deployment, drop offending packets, as follows:

**Table 242: Decompress SWF File Option Rules**

This rule...	Triggers when...
120:12	deflate file decompression fails.
120:13	LZMA file decompression fails.

### Decompress PDF File (Deflate)

When **HTTP Inspect Responses** is enabled, **Decompress PDF File (Deflate)** decompresses the deflate-compatible compressed portions of Portable Document Format (.pdf) files located within the HTTP response body of HTTP requests. The system can only decompress PDF files with the `/FlateDecode` stream filter. Other stream filters (including `/FlateDecode /FlateDecode`) are unsupported.

**Note** You can **only** decompress the compressed portions of files found in HTTP GET responses.

Decompression ends when **Maximum Compressed Data Depth**, **Maximum Decompressed Data Depth**, or the end of the compressed data is reached. Inspection of decompressed data ends when **Server Flow Depth** is reached unless you also select **Unlimited Decompression**. You can use the `file_data` intrusion rule keyword to inspect decompressed data.

You can enable rules 120:14, 120:15, 120:16, and 120:17 to generate events and, in an inline deployment, drop offending packets, as follows:

**Table 243: Decompress PDF File (Deflate) Option Rules**

This rule...	Triggers when...
120:14	file decompression fails.
120:15	file decompression fails due to an unsupported compression type.
120:16	file decompression fails due to an unsupported PDF stream filter.
120:17	file parsing fails.

### Extract Original Client IP Address

Enables the examination of original client IP addresses during intrusion inspection. The system extracts the original client IP address from the X-Forwarded-For (XFF), True-Client-IP, or custom HTTP headers you define in the **XFF Header Priority** option. You can view the extracted original client IP address in the intrusion events table.

You can enable rules 119:23, 119:29, and 119:30 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### XFF Header Priority

Specifies the order in which the system processes original client IP headers when multiple headers are present in an HTTP request. By default, the system examines X-Forwarded-For (XFF) headers, then True-Client-IP headers. Use the up and down arrow icons beside each header type to adjust its priority.

This option also allows you to specify original client IP headers other than XFF or True-Client-IP for extraction and evaluation. Click **Add** to add custom header names to the priority list. The system only supports custom headers that use the same syntax as an XFF or True-Client-IP header.

Keep in mind the following when configuring this option:

- The system uses this priority order when evaluating original client IP address headers for both access control and intrusion inspection.

- If multiple original client IP headers are present, the system processes only the header with the highest priority.
- The XFF header contains a list of IP addresses, which represent the proxy servers through which the request has passed. To prevent spoofing, the system uses the last IP address in the list (that is, the address appended by the trusted proxy) as the original client IP address.

### Log URI

Enables extraction of the raw URI, if present, from HTTP request packets and associates the URI with all intrusion events generated for the session.

When this option is enabled, you can display the first fifty characters of the extracted URI in the HTTP URI column of the intrusion events table view. You can display the complete URI, up to 2048 bytes, in the packet view.

### Log Hostname

Enables extraction of the host name, if present, from the HTTP request Host header and associates the host name with all intrusion events generated for the session. When multiple Host headers are present, extracts the host name from the first header.

When this option is enabled, you can display the first fifty characters of the extracted host name in the HTTP Hostname column of the intrusion events table view. You can display the complete host name, up to 256 bytes, in the packet view.

You can enable rule 119:25 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

Note that, when enabled, rule 119:24 triggers if it detects multiple Host headers in an HTTP request, regardless of the setting for this option.

### Profile

Specifies the types of encoding that are normalized for HTTP traffic. The system provides a default profile appropriate for most servers, default profiles for Apache servers and IIS servers, and custom default settings that you can tailor to meet the needs of your monitored traffic:

- Select **All** to use the standard default profile, appropriate for all servers.
- Select **IIS** to use the system-provided IIS profile.
- Select **Apache** to use the system-provided Apache profile.
- Select **Custom** to create your own server profile.

## Server-Level HTTP Normalization Encoding Options

When you set the HTTP server-level **Profile** option to `Custom`, you can specify the types of encoding that are normalized for HTTP traffic, and enable HTTP preprocessor rules to generate events against traffic containing the different encoding types.

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

**ASCII Encoding**

Decodes encoded ASCII characters and specifies whether the rules engine generates an event on ASCII-encoded URIs.

You can enable rule 119:1 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

**UTF-8 Encoding**

Decodes standard UTF-8 Unicode sequences in the URI.

You can enable rule 119:6 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

**Microsoft %U Encoding**

Decodes the IIS %u encoding scheme that uses %u followed by four characters where the 4 characters are a hex encoded value that correlates to an IIS Unicode codepoint.

---

**Tip** Legitimate clients rarely use %u encodings, so Cisco recommends decoding HTTP traffic encoded with %u encodings.

---

You can enable rule 119:3 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

**Bare Byte UTF-8 Encoding**

Decodes bare byte encoding, which uses non-ASCII characters as valid values in decoding UTF-8 values.

---

**Tip** Bare byte encoding allows the user to emulate an IIS server and interpret non-standard encodings correctly. Cisco recommends enabling this option because no legitimate clients encode UTF-8 this way.

---

You can enable rule 119:4 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

**Microsoft IIS Encoding**

Decodes using Unicode codepoint mapping.

---

**Tip** Cisco recommends enabling this option, because it is seen mainly in attacks and evasion attempts.

---

You can enable rule 119:7 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

**Double Encoding**

Decodes IIS double encoded traffic by making two passes through the request URI performing decodes in each one. Cisco recommends enabling this option because it is usually found only in attack scenarios.

You can enable rule 119:2 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Multi-Slash Obfuscation

Normalizes multiple slashes in a row into a single slash.

You can enable rule 119:8 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### IIS Backslash Obfuscation

Normalizes backslashes to forward slashes.

You can enable rule 119:9 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Directory Traversal

Normalizes directory traversals and self-referential directories. If you enable the accompanying preprocessor rules to generate events against this type of traffic, it may generate false positives because some web sites refer to files using directory traversals.

You can enable rules 119:10 and 119:11 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Tab Obfuscation

Normalizes the non-RFC standard of using a tab for a space delimiter. Apache and other non-IIS web servers use the tab character (0x09) as a delimiter in URLs.

---

**Note** Regardless of the configuration for this option, the HTTP Inspect preprocessor treats a tab as white space if a space character (0x20) precedes it.

---

You can enable rule 119:12 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Invalid RFC Delimiter

Normalizes line breaks (\n) in URI data.

You can enable rule 119:13 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Webroot Directory Traversal

Detects directory traversals that traverse past the initial directory in the URL.

You can enable rule 119:18 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Tab URI Delimiter

Turns on the use of the tab character (0x09) as a delimiter for a URI. Apache, newer versions of IIS, and some other web servers use the tab character as a delimiter in URLs.

---

**Note** Regardless of the configuration for this option, the HTTP Inspect preprocessor treats a tab as white space if a space character (0x20) precedes it.

---

### Non-RFC characters

Detects the non-RFC character list you add in the corresponding field when it appears within incoming or outgoing URI data. When modifying this field, use the hexadecimal format that represents the byte character. If and when you configure this option, set the value with care. Using a character that is very common may overwhelm you with events.

You can enable rule 119:14 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Max Chunk Encoding Size

Detects abnormally large chunk sizes in URI data.

You can enable rules 119:16 and 119:22 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Disable Pipeline Decoding

Disables HTTP decoding for pipelined requests. When this option is disabled, performance is enhanced because HTTP requests waiting in the pipeline are not decoded or analyzed, and are only inspected using generic pattern matching.

### Non-Strict URI Parsing

Enables non-strict URI parsing. Use this option only on servers that will accept non-standard URIs in the format "GET /index.html abc xo qr \n". Using this option, the decoder assumes that the URI is between the first and second space, even if there is no valid HTTP identifier after the second space.

### Extended ASCII Encoding

Enables parsing of extended ASCII characters in an HTTP request URI. Note that this option is available in custom server profiles only, and not in the default profiles provided for Apache, IIS, or all servers.

## Configuring The HTTP Inspect Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

### Before you begin

- Confirm that any networks you want to identify in a custom target-based policy match or are a subset of the networks, zones, and VLANs handled by its parent network analysis policy. See [Advanced Settings for Network Analysis Policies, on page 2751](#) for more information.

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **HTTP Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **HTTP Configuration**.
- Step 7** Modify the options in the Global Settings page area; see [Global HTTP Normalization Options, on page 2824](#).
- Step 8** You have three choices:
- Add a server profile — Click **Add** (+) in the **Servers** section. Specify one or more IP addresses for the client in the **Server Address** field, and click **OK**. You can specify a single IP address or address block, or a comma-separated list of either or both. You can include up to 496 characters in a list, specify a total of 256 address entries for all server profiles, and create a total of 255 profiles including the default profile.
  - Edit a server profile — Click the configured address for a profile you have added under **Servers**, or click **default**. You can modify any of the settings in the **Configuration** section; see [Server-Level HTTP Normalization Options, on page 2825](#). If you choose **Custom** for the **Profile** value, you can also modify the encoding options described in [Server-Level HTTP Normalization Encoding Options, on page 2833](#).
  - Delete a server profile — Click **Delete** (🗑) next to a custom profile.
- Step 9** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.
- 

### What to do next

- If you want generate events and, in an inline deployment, drop offending packets, enable HTTP preprocessor rules (GID 119). For more information, see [Setting Intrusion Rule States, on page 2086](#).

- Deploy configuration changes.

## Additional HTTP Inspect Preprocessor Rules

You can enable the rules in the **Preprocessor Rule GID:SID** column of the following table to generate events for HTTP Inspect preprocessor rules that are not associated with specific configuration options.

*Table 244: Additional HTTP Inspect Preprocessor Rules*

Preprocessor Rule GID:SID	Triggers when...
119:21	an HTTP request header has more than one <code>content-length</code> field.
119:24	an HTTP request has more than one Host header.
119:28	an HTTP POST method has neither a <code>content-length</code> header nor chunked <code>transfer-encoding</code> .
119:32	HTTP version 0.9 is encountered in traffic. Note that the TCP stream configuration must also be enabled.
119:33	an HTTP URI includes an unescaped space.
119:34	a TCP connection contains 24 or more pipelined HTTP requests.
120:5	UTF-7 encoding is encountered in HTTP response traffic; UTF-7 should only appear where 7-bit parity is required, such as in SMTP traffic.
120:8	the <code>content-length</code> or chunk size is invalid.
120:18	an HTTP server response occurs before the client request.
120:19	an HTTP response includes multiple content lengths.
120:20	an HTTP response includes multiple content encodings.
120:25	an HTTP response includes invalid header folding.
120:26	a junk line occurs before an HTTP response header.
120:27	an HTTP response does not include an end of header.
120:28	an invalid chunk size occurs, or chunk size is followed by junk characters.

# The Sun RPC Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

Remote Procedure Call (RPC) normalization takes fragmented RPC records and normalizes them to a single record so the rules engine can inspect the complete record. For example, an attacker may attempt to discover the port where RPC `admind` runs. Some UNIX hosts use RPC `admind` to perform remote distributed system tasks. If the host performs weak authentication, a malicious user could take control of remote administration. The standard text rule (GID: 1) with the Snort ID (SID) 575 detects this attack by searching for content in specific locations to identify inappropriate `portmap GETPORT` requests.

## Sun RPC Preprocessor Options

### Ports

Specify the ports whose traffic you want to normalize. In the interface, list multiple ports separated by commas. Typical RPC ports are 111 and 32771. If your network sends RPC traffic to other ports, consider adding them.

### Detect fragmented RPC records

Detects RPC fragmented records.

You can enable rules 106:1 and 106:5 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Detect multiple records in one packet

Detects more than one RPC request per packet (or reassembled packet).

You can enable rule 106:2 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Detect fragmented record sums which exceed one fragment

Detects reassembled fragment record lengths that exceed the current packet length.

You can enable rule 106:3 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### Detect single fragment records which exceed the size of one packet

Detects partial records

You can enable rule 106:4 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

## Configuring the Sun RPC Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **Sun RPC Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **Sun RPC Configuration**.
- Step 7** Modify the settings described in [Sun RPC Preprocessor Options, on page 2839](#).
- Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

### What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable Sun RPC preprocessor rules (GID 106). For more information, see [Setting Intrusion Rule States, on page 2086](#).
- Deploy configuration changes.

# The SIP Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

The Session Initiation Protocol (SIP) provides call setup, modification, and teardown of one or more sessions for one or more users of client applications such as Internet telephony, multimedia conferencing, instant messaging, online gaming, and file transfer. A *method* field in each SIP request identifies the purpose of the request, and a Request-URI specifies where to send the request. A status code in each SIP response indicates the outcome of the requested action.

After calls are set up using SIP, the Real-time Transport Protocol (RTP) is responsible for subsequent audio and video communication; this part of the session is sometimes referred to as the call channel, the data channel, or the audio/video data channel. RTP uses the Session Description Protocol (SDP) within the SIP message body for data-channel parameter negotiation, session announcement, and session invitation.

The SIP preprocessor is responsible for:

- decoding and analyzing SIP 2.0 traffic
- extracting the SIP header and message body, including SDP data when present, and passing the extracted data to the rules engine for further inspection
- generating events when the following conditions are detected and the corresponding preprocessor rules are enabled:
  - anomalies and known vulnerabilities in SIP packets
  - out-of-order and invalid call sequences
- optionally, ignoring the call channel

The preprocessor identifies the RTP channel based on the port identified in the SDP message, which is embedded in the SIP message body, but the preprocessor does not provide RTP protocol inspection.

Note the following when using the SIP preprocessor:

- UDP typically carries media sessions supported by SIP. UDP stream preprocessing provides SIP session tracking for the SIP preprocessor.
- SIP rule keywords allow you to point to the SIP packet header or message body and to limit detection to packets for specific SIP methods or status codes.

## SIP Preprocessor Options

For the following options, you can specify a positive value from 1 to 65535 bytes, or 0 to disable event generation for the option regardless of whether the associated rule is enabled.

- **Maximum Request URI Length**
- **Maximum Call ID Length**

- **Maximum Request Name Length**
- **Maximum From Length**
- **Maximum To Length**
- **Maximum Via Length**
- **Maximum Contact Length**
- **Maximum Content Length**

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### **Ports**

Specifies the ports to inspect for SIP traffic. You can specify an integer from 0 to 65535. Separate multiple port numbers with commas.

### **Methods to Check**

Specifies SIP methods to detect. You can specify any of the following currently defined SIP methods:

```
ack, benotify, bye, cancel, do, info, invite, join, message,  
notify, options, prack, publish, quath, refer, register,  
service, sprack, subscribe, unsubscribe, update
```

Methods are case-insensitive. The method name can include alphabetic characters, numbers, and the underscore character. No other special characters are permitted. Separate multiple methods with commas.

Because new SIP methods might be defined in the future, your configuration can include an alphabetic string that is not currently defined. The system supports up to 32 methods, including the 21 currently defined methods and an additional 11 methods. The system ignores any undefined methods that you might configure.

Note that, in addition to any methods you specify for this option, the 32 total methods includes methods specified using the `sip_method` keyword in intrusion rules.

### **Maximum Dialogs within a Session**

Specifies the maximum number of dialogs allowed within a stream session. If more dialogs than this number are created, the oldest dialogs are dropped until the number of dialogs does not exceed the maximum number specified. You can specify an integer from 1 to 4194303.

You can enable rule 140:27 to generate events and, in an inline deployment, drop offending packets for this option. See [Setting Intrusion Rule States, on page 2086](#).

### **Maximum Request URI Length**

Specifies the maximum number of bytes to allow in the Request-URI header field. A Longer URI generates an event and, in an inline deployment, drops offending packets when rule 140:3 is enabled. The request URI field indicates the destination path or page for the request.

**Maximum Call ID Length**

Specifies the maximum number of bytes to allow in the request or response Call-ID header field. A longer Call-ID generates an event and, in an inline deployment, drops offending packets when rule 140:5 is enabled. The Call-ID field uniquely identifies the SIP session in requests and responses.

**Maximum Request Name Length**

Specifies the maximum number of bytes to allow in the request name, which is the name of the method specified in the CSeq transaction identifier. A longer request name generates an event and, in an inline deployment, drops offending packets when rule 140:7 is enabled.

**Maximum From Length**

Specifies the maximum number of bytes to allow in the request or response From header field. A longer From generates an event and, in an inline deployment, drops offending packets when rule 140:9 is enabled. The From field identifies the message initiator.

**Maximum To Length**

Specifies the maximum number of bytes to allow in the request or response To header field. A longer To generates an event and, in an inline deployment, drops offending packets when rule 140:11 is enabled. The To field identifies the message recipient.

**Maximum Via Length**

Specifies the maximum number of bytes to allow in the request or response Via header field. A longer Via generates an event and, in an inline deployment, drops offending packets when rule 140:13 is enabled. The Via field provides the path followed by the request and, in a response, receipt information.

**Maximum Contact Length**

Specifies the maximum number of bytes to allow in the request or response Contact header field. A longer Contact generates an event and, in an inline deployment, drops offending packets when rule 140:15 is enabled. The Contact field provides a URI that specifies the location to contact with subsequent messages.

**Maximum Content Length**

Specifies the maximum number of bytes to allow in the content of the request or response message body. Longer content generates an event and, in an inline deployment, drops offending packets when rule 140:16 is enabled.

**Ignore Audio/Video Data Channel**

Enables and disables inspection of data channel traffic. Note that the preprocessor continues inspection of other non-data-channel SIP traffic when you enable this option.

**Related Topics**

[SIP Keywords](#), on page 2170

## Configuring the SIP Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **SIP Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **SIP Configuration**.
- Step 7** Modify the options described in [SIP Preprocessor Options, on page 2841](#).
- Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

### What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable SIP preprocessor rules (GID 140). For more information, see [Setting Intrusion Rule States, on page 2086](#).
- Deploy configuration changes.

### Related Topics

[Managing Layers, on page 2216](#)

[Conflicts and Changes: Network Analysis and Intrusion Policies, on page 2059](#)

## Additional SIP Preprocessor Rules

The SIP preprocessor rules in the following table are not associated with specific configuration options. As with other SIP preprocessor rules, you must enable these rules if you want them to generate events and, in an inline deployment, drop offending packets.

**Table 245: Additional SIP Preprocessor Rules**

Preprocessor Rule GID:SID	Triggers when...
140:1	the preprocessor is monitoring the maximum number of SIP sessions allowed by the system.
140:2	the required Request_URI field is empty in a SIP request.
140:4	the Call-ID header field is empty in a SIP request or response.
140:6	the value for the sequence number in the SIP request or response CSeq field is not a 32-bit unsigned integer less than 231.
140:8	the From header field is empty in a SIP request or response.
140:10	the To header field is empty in a SIP request or response.
140:12	the Via header field is empty in a SIP request or response
140:14	the required Contact header field is empty in a SIP request or response.
140:17	a single SIP request or response packet in UDP traffic contains multiple messages. Note that older SIP versions supported multiple messages, but SIP 2.0 supports only one message per packet.
140:18	the actual length of the message body in a SIP request or response in UDP traffic does not match the value specified in the Content-Length header field in a SIP request or response.
140:19	the preprocessor does not recognize a method name in the CSeq field of a SIP response.
140:20	the SIP server does not challenge an authenticated invite message. Note that this occurs in the case of the InviteReplay billing attack.
140:21	session information changes before the call is set up. Note that this occurs in the case of the FakeBusy billing attack.
140:22	the response status code is not a three-digit number.
140:23	the Content-Type header field does not specify a content type and the message body contains data.
140:24	the SIP version is not 1, 1.1, or 2.0.
140:25	the method specified in the CSeq header and the method field do not match in a SIP request.

Preprocessor Rule GID:SID	Triggers when...
140:26	the preprocessor does not recognize the method named in the SIP request method field.

## The GTP Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

The General Service Packet Radio (GPRS) Tunneling Protocol (GTP) provides communication over a GTP core network. The GTP preprocessor detects anomalies in GTP traffic and forwards command channel signaling messages to the rules engine for inspection. You can use the `gtp_version`, `gtp_type`, and `gtp_info` rule keywords to inspect GTP command channel traffic for exploits.

A single configuration option allows you to modify the default setting for the ports that the preprocessor inspects for GTP command channel messages.

## GTP Preprocessor Rules

You must enable the GTP preprocessor rules in the following table if you want them to generate events and, in an inline deployment, drop offending packets.

*Table 246: GTP Preprocessor Rules*

Preprocessor Rule GID:SID	Description
143:1	Generates an event when the preprocessor detects an invalid message length.
143:2	Generates an event when the preprocessor detects an invalid information element length.
143:3	Generates an event when the preprocessor detects information elements that are out of order.

## Configuring the GTP Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

You can use this procedure to modify the ports the GTP preprocessor monitors for GTP command messages.

## Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel on the left.
- Step 5** If **GTP Command Channel Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **GTP Command Channel Configuration**.
- Step 7** Enter a **Ports** value.
- Separate multiple ports with commas.
- Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.
- 

### What to do next

- If you want to enable intrusion events, enable GTP preprocessor rules (GID 143). For more information, see [Setting Intrusion Rule States, on page 2086](#).
- Deploy configuration changes.

## The IMAP Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The Internet Message Application Protocol (IMAP) is used to retrieve email from a remote IMAP server. The IMAP preprocessor inspects server-to-client IMAP4 traffic and, when associated preprocessor rules are enabled, generates events on anomalous traffic. The preprocessor can also extract and decode email attachments

in client-to-server IMAP4 traffic and send the attachment data to the rules engine. You can use the `file_data` keyword in an intrusion rule to point to the attachment data.

Extraction and decoding include multiple attachments, when present, and large attachments that span multiple packets.

## IMAP Preprocessor Options

Note that decoding, or extraction when the MIME email attachment does not require decoding, includes multiple attachments when present, and large attachments that span multiple packets.

Note also that the highest value is used when the values for the **Base64 Decoding Depth**, **7-Bit/8-Bit/Binary Decoding Depth**, **Quoted-Printable Decoding Depth**, or **Unix-to-Unix Decoding Depth** options are different in:

- the default network analysis policy
- any other custom network analysis policy invoked by network analysis rules in the same access control policy

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Ports

Specifies the ports to inspect for IMAP traffic. You can specify an integer from 0 to 65535. Separate multiple port numbers with commas.

### Base64 Decoding Depth

Specifies the maximum number of bytes to extract and decode from each Base64 encoded MIME email attachment. You can specify a positive value, or specify 0 to decode all the Base64 data. Specify -1 to ignore Base64 data.

Note that positive values not divisible by 4 are rounded up to the next multiple of 4 except for the values 65533, 65534, and 65535, which are rounded down to 65532.

When this option is enabled, you can enable rule 141:4 generate events and, in an inline deployment, drop offending packets when decoding fails; decoding could fail, for example, because of incorrect encoding or corrupted data.

### 7-Bit/8-Bit/Binary Decoding Depth

Specifies the maximum bytes of data to extract from each MIME email attachment that does not require decoding. These attachment types include 7-bit, 8-bit, binary, and various multipart content types such as plain text, jpeg images, mp3 files, and so on. You can specify a positive value, or specify 0 to extract all data in the packet. Specify -1 to ignore non-decoded data.

When this option is enabled, you can enable rule 141:6 to generate events and, in an inline deployment, drop offending packets when extraction fails; extraction could fail, for example, because of corrupted data.

### Quoted-Printable Decoding Depth

Specifies the maximum number of bytes to extract and decode from each quoted-printable (QP) encoded MIME email attachment. You can specify a positive value, or specify 0 to decode all QP encoded data in the packet. Specify -1 to ignore QP encoded data.

When this option is enabled, you can enable rule 141:5 to generate events and, in an inline deployment, drop offending packets when decoding fails; decoding could fail, for example, because of incorrect encoding or corrupted data.

### Unix-to-Unix Decoding Depth

Specifies the maximum number of bytes to extract and decode from each Unix-to-Unix encoded (uuencoded) email attachment. You can specify a positive value, or specify 0 to decode all uuencoded data in the packet. Specify -1 to ignore uuencoded data.

When this option is enabled, you can enable rule 141:7 to generate events and, in an inline deployment, drop offending packets when decoding fails; decoding could fail, for example, because of incorrect encoding or corrupted data.

## Configuring the IMAP Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.  
**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
  - Step 2** Click **Snort 2 Version** next to the policy you want to edit.
  - Step 3** Click **Edit** (✎) next to the policy you want to edit.  
If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
  - Step 4** Click **Settings** in the navigation panel.
  - Step 5** If **IMAP Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.
  - Step 6** Click **Edit** (✎) next to **IMAP Configuration**.
  - Step 7** Modify the settings described in [IMAP Preprocessor Options](#), on page 2848.

**Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

#### What to do next

- If you want to enable intrusion events, enable IMAP preprocessor rules (GID 141); see [Setting Intrusion Rule States](#), on page 2086.
- Deploy configuration changes.

#### Related Topics

[Layers in Intrusion and Network Analysis Policies](#), on page 2209

## Additional IMAP Preprocessor Rules

The IMAP preprocessor rules in the following table are not associated with specific configuration options. As with other IMAP preprocessor rules, you must enable these rules if you want them to generate events and, in an inline deployment, drop offending packets.

Table 247: Additional IMAP Preprocessor Rules

Preprocessor Rule GID:SID	Description
141:1	Generates an event when the preprocessor detects a client command that is not defined in RFC 3501.
141:2	Generates an event when the preprocessor detects a server response that is not defined in RFC 3501.
141:3	Generates an event when the preprocessor is using the maximum amount of memory allowed by the system. At this point, the preprocessor stops decoding until memory becomes available.

## The POP Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

The Post Office Protocol (POP) is used to retrieve email from a remote POP mail server. The POP preprocessor inspects server-to-client POP3 traffic and, when associated preprocessor rules are enabled, generates events on anomalous traffic. The preprocessor can also extract and decode email attachments in client-to-server POP3

traffic and send the attachment data to the rules engine. You can use the `file_data` keyword in an intrusion rule to point to attachment data.

Extraction and decoding include multiple attachments, when present, and large attachments that span multiple packets.

## POP Preprocessor Options

Note that decoding, or extraction when the MIME email attachment does not require decoding, includes multiple attachments when present, and large attachments that span multiple packets.

Note also that the highest value is used when the values for the **Base64 Decoding Depth**, **7-Bit/8-Bit/Binary Decoding Depth**, **Quoted-Printable Decoding Depth**, or **Unix-to-Unix Decoding Depth** options are different in:

- the default network analysis policy
- any other custom network analysis policy invoked by network analysis rules in the same access control policy

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Ports

Specifies the ports to inspect for POP traffic. You can specify an integer from 0 to 65535. Separate multiple port numbers with commas.

### Base64 Decoding Depth

Specifies the maximum number of bytes to extract and decode from each Base64 encoded MIME email attachment. You can specify a positive value, or specify 0 to decode all the Base64 data. Specify -1 to ignore Base64 data.

Note that positive values not divisible by 4 are rounded up to the next multiple of 4 except for the values 65533, 65534, and 65535, which are rounded down to 65532.

When this option is enabled, you can enable rule 142:4 to generate an event and, in an inline deployment, drop offending packets when decoding fails; decoding could fail, for example, because of incorrect encoding or corrupted data.

### 7-Bit/8-Bit/Binary Decoding Depth

Specifies the maximum bytes of data to extract from each MIME email attachment that does not require decoding. These attachment types include 7-bit, 8-bit, binary, and various multipart content types such as plain text, jpeg images, mp3 files, and so on. You can specify a positive value, or specify 0 to extract all data in the packet. Specify -1 to ignore non-decoded data.

When this option is enabled, you can enable rule 142:6 to generate an event and, in an inline deployment, drop offending packets when extraction fails; extraction could fail, for example, because of corrupted data.

**Quoted-Printable Decoding Depth**

Specifies the maximum number of bytes to extract and decode from each quoted-printable (QP) encoded MIME email attachment. You can specify a positive value, or specify 0 to decode all QP encoded data in the packet. Specify -1 to ignore QP encoded data.

When this option is enabled, you can enable rule 142:5 to generate an event and, in an inline deployment, drop offending packets when decoding fails; decoding could fail, for example, because of incorrect encoding or corrupted data.

**Unix-to-Unix Decoding Depth**

Specifies the maximum number of bytes to extract and decode from each Unix-to-Unix encoded (uuencoded) email attachment. You can specify a positive value, or specify 0 to decode all uuencoded data in the packet. Specify -1 to ignore uuencoded data.

When this option is enabled, you can enable rule 142:7 to generate an event and, in an inline deployment, drop offending packets when decoding fails; decoding could fail, for example, because of incorrect encoding or corrupted data.

## Additional POP Preprocessor Rules

The POP preprocessor rules in the following table are not associated with specific configuration options. As with other POP preprocessor rules, you must enable these rules if you want them to generate events and, in an inline deployment, drop offending packets.

*Table 248: Additional POP Preprocessor Rules*

Preprocessor Rule GID:SID	Description
142:1	Generates an event when the preprocessor detects a client command that is not defined in RFC 1939.
142:2	Generates an event when the preprocessor detects a server response that is not defined in RFC 1939.
142:3	Generates an event when the preprocessor is using the maximum amount of memory allowed by the system. At this point, the preprocessor stops decoding until memory becomes available.

## The SMTP Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The SMTP preprocessor instructs the rules engine to normalize SMTP commands. The preprocessor can also extract and decode email attachments in client-to-server traffic and, depending on the software version, extract

email file names, addresses, and header data to provide context when displaying intrusion events triggered by SMTP traffic.

## SMTP Preprocessor Options

You can enable or disable normalization, and you can configure options to control the types of anomalous traffic the SMTP decoder detects.

Note that decoding, or extraction when the MIME email attachment does not require decoding, includes multiple attachments when present, and large attachments that span multiple packets.

Note also that the highest value is used when the values for the **Base64 Decoding Depth**, **7-Bit/8-Bit/Binary Decoding Depth**, **Quoted-Printable Decoding Depth**, or **Unix-to-Unix Decoding Depth** options are different in:

- the default network analysis policy
- any other custom network analysis policy invoked by network analysis rules in the same access control policy

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Ports

Specifies the ports whose SMTP traffic you want to normalize. You can specify a value greater than or equal to 0. Separate multiple ports with commas.

### Stateful Inspection

When selected, causes SMTP decoder to save state and provide session context for individual packets and only inspects reassembled sessions. When cleared, analyzes each individual packet without session context.

### Normalize

When set to `All`, normalizes all commands. Checks for more than one space character after a command.

When set to `None`, normalizes no commands.

When set to `Cmds`, normalizes the commands listed in **Custom Commands**.

### Custom Commands

When **Normalize** is set to `Cmds`, normalizes the listed commands.

Specify commands which should be normalized in the text box. Checks for more than one space character after a command.

The space (ASCII 0x20) and tab (ASCII 0x09) characters count as space characters for normalization purposes.

### Ignore Data

Does not process mail data; processes only MIME mail header data.

**Ignore TLS Data**

Does not process data encrypted under the Transport Layer Security protocol.

**No Alerts**

Disables intrusion events when accompanying preprocessor rules are enabled.

**Detect Unknown Commands**

Detects unknown commands in SMTP traffic.

You can enable rule 124:5 to generate events and, in an inline deployment, drop offending packets for this option.

**Max Command Line Len**

Detects when an SMTP command line is longer than this value. Specify 0 to never detect command line length.

RFC 2821, the Network Working Group specification on the Simple Mail Transfer Protocol, recommends 512 as a maximum command line length.

You can enable rule 124:1 to generate events and, in an inline deployment, drop offending packets for this option.

**Max Header Line Len**

Detects when an SMTP data header line is longer than this value. Specify 0 to never detect data header line length.

You can enable rules 124:2 and 124:7 to generate events and, in an inline deployment, drop offending packets for this option.

**Max Response Line Len**

Detects when an SMTP response line is longer than this value. Specify 0 to never detect response line length.

RFC 2821 recommends 512 as a maximum response line length.

You can enable rule 124:3 to generate events and, in an inline deployment, drop offending packets for this option and also for **Alt Mac Command Line Len**, when that option is enabled.

**Alt Max Command Line Len**

Detects when the SMTP command line for any of the specified commands is longer than this value. Specify 0 to never detect command line length for the specified commands. Different default line lengths are set for numerous commands.

This setting overrides the Max Command Line Len setting for the specified commands.

You can enable rule 124:3 to generate events and, in an inline deployment, drop offending packets for this option and also for **Max Response Line Len** when that option is enabled.

**Invalid Commands**

Detects if these commands are sent from the client side.

You can enable rule 124:6 to generate events and, in an inline deployment, drop offending packets for this option and also for **Invalid Commands**.

### Valid Commands

Permits commands in this list.

Even if this list is empty, the preprocessor permits the following valid commands: ATRN AUTH BDAT DATA DEBUG EHLO EMAL ESAM ESND ESOM ETRN EVFY EXPN HELO HELP IDENT MAIL NOOP ONEX QUEU QUIT RCPT RSET SAML SEND SIZE SOML STARTTLS TICK TIME TURN TURNME VERB VRFY XADR XAUTH XCIR XEXCH50 X-EXPS XGEN XLICENSE X-LINK2STATE XQUE XSTA XTRN XUSR

---

**Note** RCPT TO and MAIL FROM are SMTP commands. The preprocessor configuration uses command names of RCPT and MAIL, respectively. Within the code, the preprocessor maps RCPT and MAIL to the correct command name.

---

You can enable rule 124:4 to generate events and, in an inline deployment, drop offending packets for this option and also for **Invalid Commands** when that option is configured.

### Data Commands

Lists commands that initiate sending data in the same way the SMTP DATA command sends data per RFC 5321. Separate multiple commands with spaces.

### Binary Data Commands

Lists commands that initiate sending data in a way that is similar to how the BDAT command sends data per RFC 3030. Separate multiple commands with spaces.

### Authentication Commands

Lists commands that initiate an authentication exchange between client and server. Separate multiple commands with spaces.

### Detect xlink2state

Detects packets that are part of X-Link2State Microsoft Exchange buffer data overflow attacks. In inline deployments, the system can also drop those packets.

You can enable rule 124:8 to generate events and, in an inline deployment, drop offending packets for this option.

### Base64 Decoding Depth

When **Ignore Data** is disabled, specifies the maximum number of bytes to extract and decode from each Base64 encoded MIME email attachment. You can specify from a positive value, or specify 0 to decode all the Base64 data. Specify -1 to ignore Base64 data. The preprocessor will not decode data when **Ignore Data** is selected.

Note that positive values not divisible by 4 are rounded up to the next multiple of 4 except for the values 65533, 65534, and 65535, which are rounded down to 65532.

When this option is enabled, you can enable rule 124:10 to generate events and, in an inline deployment, drop offending packets when decoding fails; decoding could fail, for example, because of incorrect encoding or corrupted data.

Note that this option replaces the deprecated options **Enable MIME Decoding** and **Maximum MIME Decoding Depth**, which are still supported in existing intrusion policies for backward compatibility.

### 7-Bit/8-Bit/Binary Decoding Depth

When **Ignore Data** is disabled, specifies the maximum bytes of data to extract from each MIME email attachment that does not require decoding. These attachment types include 7-bit, 8-bit, binary, and various multipart content types such as plain text, jpeg images, mp3 files, and so on. You can specify a positive value, or specify 0 to extract all data in the packet. Specify -1 to ignore non-decoded data. The preprocessor will not extract data when **Ignore Data** is selected.

### Quoted-Printable Decoding Depth

When **Ignore Data** is disabled, specifies the maximum number of bytes to extract and decode from each quoted-printable (QP) encoded MIME email attachment.

You can specify from 1 to 65535 bytes, or specify 0 to decode all QP encoded data in the packet. Specify -1 to ignore QP encoded data. The preprocessor will not decode data when **Ignore Data** is selected.

When this option is enabled, you can enable rule 124:11 to generate events and, in an inline deployment, drop offending packets when decoding fails; decoding could fail, for example, because of incorrect encoding or corrupted data.

### Unix-to-Unix Decoding Depth

When **Ignore Data** is disabled, specifies the maximum number of bytes to extract and decode from each Unix-to-Unix encoded (uuencoded) email attachment. You can specify from 1 to 65535 bytes, or specify 0 to decode all uuencoded data in the packet. Specify -1 to ignore uuencoded data. The preprocessor will not decode data when **Ignore Data** is selected.

When this option is enabled, you can enable rule 124:13 to generate events and, in an inline deployment, drop offending packets when decoding fails; decoding could fail, for example, because of incorrect encoding or corrupted data.

### Log MIME Attachment Names

Enables extraction of MIME attachment file names from the MIME Content-Disposition header and associates the file names with all intrusion events generated for the session. Multiple file names are supported.

When this option is enabled, you can view file names associated with events in the Email Attachment column of the intrusion events table view.

### Log To Addresses

Enables extraction of recipient email addresses from the SMTP RCPT TO command and associates the recipient addresses with all intrusion events generated for the session. Multiple recipients are supported.

When this option is enabled, you can view recipients associated with events in the Email Recipient column of the intrusion events table view.

**Log From Addresses**

Enables extraction of sender email addresses from the SMTP MAIL FROM command and associates the sender addresses with all intrusion events generated for the session. Multiple sender addresses are supported.

When this option is enabled, you can view senders associated with events in the Email Sender column of the intrusion events table view.

**Log Headers**

Enables extraction of email headers. The number of bytes to extract is determined by the value specified for **Header Log Depth**.

You can use the `content` or `protected_content` keyword to write intrusion rules that use email header data as a pattern. You can also view the extracted email header in the intrusion event packet view.

**Header Log Depth**

Specifies the number of bytes of the email header to extract when **Log Headers** is enabled. You can specify 0 to 20480 bytes. A value of 0 disables **Log Headers**.

**Related Topics**

## The SSH Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The SSH preprocessor detects:

- The Challenge-Response Buffer Overflow exploit
- The CRC-32 exploit
- The SecureCRT SSH Client Buffer Overflow exploit
- Protocol mismatches
- Incorrect SSH message direction
- Any version string other than version 1 or 2

Challenge-Response Buffer Overflow and CRC-32 attacks occur after the key exchange and are, therefore, encrypted. Both attacks send an uncharacteristically large payload of more than 20 KBytes to the server immediately after the authentication challenge. CRC-32 attacks apply only to SSH Version 1; Challenge-Response Buffer Overflow exploits apply only to SSH Version 2. The version string is read at the beginning of the session. Except for the difference in the version string, both attacks are handled in the same way.

The SecureCRT SSH exploit and protocol mismatch attacks occur when attempting to secure a connection, before the key exchange. The SecureCRT exploit sends an overly long protocol identifier string to the client that causes a buffer overflow. A protocol mismatch occurs when either a non-SSH client application attempts to connect to a secure SSH server or the server and client version numbers do not match.

You can configure the SSH preprocessor to inspect traffic on a specified port or list of ports, or to automatically detect SSH traffic. It will continue to inspect SSH traffic until either a specified number of encrypted packets

has passed within a specified number of bytes, or until a specified maximum number of bytes is exceeded within the specified number of packets. If the maximum number of bytes is exceeded, it is assumed that a CRC-32 (SSH Version 1) or a Challenge-Response Buffer Overflow (SSH Version 2) attack has occurred. Note that without configuration the preprocessor detects any version string value other than version 1 or 2.

Also note that the SSH preprocessor does not handle brute force attacks.

## SSH Preprocessor Options

The preprocessor stops inspecting traffic for a session when either of the following occurs:

- a valid exchange between the server and the client has occurred for this number of encrypted packets; the connection continues.
- the **Number of Bytes Sent Without Server Response** is reached before the number of encrypted packets to inspect is reached; the assumption is made that there is an attack.

Each valid server response during **Number of Encrypted Packets to Inspect** resets the **Number of Bytes Sent Without Server Response** and the packet count continues.

Consider the following example SSH preprocessor configuration:

- **Server Ports:** 22
- **Autodetect Ports:** off
- **Maximum Length of Protocol Version String:** 80
- **Number of Encrypted Packets to Inspect:** 25
- **Number of Bytes Sent Without Server Response:** 19,600
- All detect options are enabled.

In the example, the preprocessor inspects traffic only on port 22. That is, auto-detection is disabled, so it inspects only on the specified port.

Additionally, the preprocessor in the example stops inspecting traffic when either of the following occurs:

- The client sends 25 encrypted packets which contain no more than 19,600 bytes, cumulative. The assumption is there is no attack.
- The client sends more than 19,600 bytes within 25 encrypted packets. In this case, the preprocessor considers the attack to be the Challenge-Response Buffer Overflow exploit because the session in the example is an SSH Version 2 session.

The preprocessor in the example will also detect any of the following that occur while it is processing traffic:

- a server overflow, triggered by a version string greater than 80 bytes and indicating a SecureCRT exploit
- a protocol mismatch
- a packet flowing in the wrong direction

Finally, the preprocessor will automatically detect any version string other than version 1 or version 2.

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

**Server Ports**

Specifies on which ports the SSH preprocessor should inspect traffic.

You can configure a single port or a comma-separated list of ports.

**Autodetect Ports**

Sets the preprocessor to automatically detect SSH traffic.

When this option is selected, the preprocessor inspects all traffic for an SSH version number. It stops processing when neither the client nor the server packet contains a version number. When disabled, the preprocessor inspects only the traffic identified by the **Server Ports** option.

**Number of Encrypted Packets to Inspect**

Specifies the number of stream reassembled encrypted packets to examine per session.

Setting this option to zero will allow all traffic to pass.

Reducing the number of encrypted packets to inspect may result in some attacks escaping detection. Raising the number of encrypted packets to inspect may negatively affect performance.

**Number of Bytes Sent Without Server Response**

Specifies the maximum number of bytes an SSH client may send to a server without getting a response before assuming there is a Challenge-Response Buffer Overflow or CRC-32 attack.

Increase the value for this option if the preprocessor generates false positives on the Challenge-Response Buffer Overflow or CRC-32 exploit.

**Maximum Length of Protocol Version String**

Specifies the maximum number of bytes allowed in the server's version string before considering it to be a SecureCRT exploit.

**Detect Challenge-Response Buffer Overflow Attack**

Enables or disables detecting the Challenge-Response Buffer Overflow exploit.

You can enable rule 128:1 to generate events and, in an inline deployment, drop offending packets for this option. Note that an SFTP session can occasionally trigger rule 128:1.

**Detect SSH1 CRC-32 Attack**

Enables or disables detecting the CRC-32 exploit.

You can enable rule 128:2 to generate events and, in an inline deployment, drop offending packets for this option.

**Detect Server Overflow**

Enables or disables detecting the SecureCRT SSH Client Buffer Overflow exploit.

You can enable rule 128:3 to generate events and, in an inline deployment, drop offending packets for this option.

**Detect Protocol Mismatch**

Enables or disables detecting protocol mismatches.

You can enable rule 128:4 to generate events and, in an inline deployment, drop offending packets for this option.

**Detect Bad Message Direction**

Enables or disables detecting when traffic flows in the wrong direction (that is, if the presumed server generates client traffic, or if a client generates server traffic).

You can enable rule 128:5 to generate events and, in an inline deployment, drop offending packets for this option.

**Detect Payload Size Incorrect for the Given Payload**

Enables or disables detecting packets with an incorrect payload size such as when the length specified in the SSH packet is not consistent with the total length specified in the IP header or the message is truncated, that is, there is not enough data for a full SSH header.

You can enable rule 128:6 to generate events and, in an inline deployment, drop offending packets for this option.

**Detect Bad Version String**

Note that, when enabled, the preprocessor detects without configuration any version string other than version 1 or 2.

You can enable rule 128:7 to generate events and, in an inline deployment, drop offending packets for this option.

## Configuring the SSH Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

### Procedure

---

**Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

**Step 3** Click **Edit** (✎) next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **SSH Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **SSH Configuration**.
- Step 7** Modify the options described in [SSH Preprocessor Options, on page 2860](#).
- Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- If you want to enable intrusion events, enable SSH preprocessor rules (GID 128). For more information, see [Setting Intrusion Rule States, on page 2086](#).
- Deploy configuration changes.

## The SSL Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The SSL preprocessor allows you to configure SSL inspection, which can block encrypted traffic, decrypt it, or inspect the traffic with access control. Whether or not you configure SSL inspection, the SSL preprocessor also analyzes SSL handshake messages when detected in traffic and determines when a session becomes encrypted. Identifying encrypted traffic allows the system to stop intrusion and file inspection of encrypted payloads, which helps reduce false positives and improve performance.

The SSL preprocessor can also examine encrypted traffic to detect attempts to exploit the Heartbleed bug, and generate events when it detects such exploits.

You can suspend inspecting traffic for intrusions and malware once the session is encrypted. If you configure SSL inspection, the SSL preprocessor also identifies encrypted traffic you can block, decrypt, or inspect with access control.

Using the SSL preprocessor to decrypt encrypted traffic does not require a license. All other SSL preprocessor functionality, including halting inspection of encrypted payloads for malware and intrusions, and detecting Heartbleed bug exploits, requires a Protection license.

## How SSL Preprocessing Works

The SSL preprocessor stops intrusion and file inspection of encrypted data, and inspects encrypted traffic with an SSL policy if you configure SSL inspection. This can help to eliminate false positives. The SSL preprocessor maintains state information as it inspects the SSL handshake, tracking both the state and SSL version for that session. When the preprocessor detects that a session state is encrypted, the system marks the traffic in that session as encrypted. You can configure the system to stop processing on all packets in an encrypted session when encryption is established, as well as generate an event when it detects an attempt to exploit the Heartbleed bug.

For each packet, the SSL preprocessor verifies that the traffic contains an IP header, a TCP header, and a TCP payload, and that it occurs on the ports specified for SSL preprocessing. For qualifying traffic, the following scenarios determine whether the traffic is encrypted:

- The system observes all packets in a session, **Server side data is trusted** is not enabled, and the session includes a Finished message from both the server and the client and at least one packet from each side with an Application record and without an Alert record.
- The system misses some of the traffic, **Server side data is trusted** is not enabled, and the session includes at least one packet from each side with an Application record that is not answered with an Alert record.
- The system observes all packets in a session, **Server side data is trusted** is enabled, and the session includes a Finished message from the client and at least one packet from the client with an Application record and without an Alert record.
- The system misses some of the traffic, **Server side data is trusted** is enabled, and the session includes at least one packet from the client with an Application record that is not answered with an Alert record.

If you choose to stop processing on encrypted traffic, the system ignores future packets in a session after it marks the session as encrypted.

In addition, during the SSL handshake, the preprocessor monitors heartbeat requests and responses. The preprocessor generates an event if it detects:

- a heartbeat request containing a payload length value greater than the payload itself
- a heartbeat response that is larger than the value stored in the Max Heartbeat Length field

---

**Note** You can add the `ssl_state` and `ssl_version` keywords to a rule to use SSL state or version information within the rule.

---

### Related Topics

[SSL Keywords](#), on page 2162

## SSL Preprocessor Options

---

**Note** The system-provided network analysis policies enable the SSL preprocessor by default. Cisco recommends that you do not disable the SSL preprocessor in custom deployments if you expect encrypted traffic to cross your network.

---

Without SSL inspection configured, the system attempts to inspect encrypted traffic for malware and intrusions without decrypting it. When you enable the SSL preprocessor, it detects when a session becomes encrypted. After the SSL preprocessor is enabled, the rules engine can invoke the preprocessor to obtain SSL state and version information. If you enable rules using the `ssl_state` and `ssl_version` keywords in an intrusion policy, you should also enable the SSL preprocessor in that policy.

### Ports

Specifies the ports, separated by commas, where the SSL preprocessor should monitor traffic for encrypted sessions. Only ports specified in this field will be checked for encrypted traffic.

---

**Note** If the SSL preprocessor detects non-SSL traffic over the ports specified for SSL monitoring, it tries to decode the traffic as SSL traffic, and then flags it as corrupt.

---

### Stop inspecting encrypted traffic

Enables or disables inspection of traffic in a session after the session is marked as encrypted.

Enable this option to disable inspection and reassembly for encrypted sessions. The SSL preprocessor maintains state for the session so it can disable inspection of all traffic in the session. When this option is enabled a few packets of a session are verified to ensure the flow is encrypted after which deep inspection is bypassed. Every bypassed session increases the fast-forwarded flows count shown in the response of the **show snort statistics** command. Moreover, since deep inspection is bypassed, the initiator and responder bytes in the connection event are not accurate. They are less than the value of the actual session, since it only includes the packets inspected by Snort and it does not include any packets after the deep inspection is bypassed. This behavior holds good for connection summary events and all traffic values shown in the widgets.

The system only stops inspecting traffic in encrypted sessions if both:

- SSL preprocessing is enabled
- this option is selected

If you clear this option, you cannot modify the **Server side data is trusted** option.

### Server side data is trusted

When Stop inspecting encrypted traffic is enabled, enables identification of encrypted traffic based only on the client-side traffic,

### Max Heartbeat Length

By specifying a number of bytes, enables inspection of heartbeat requests and responses within the SSL handshake for Heartbleed bug exploit attempts. You can specify an integer from 1 to 65535, or 0 to disable the option.

If the preprocessor detects a heartbeat request whose payload length is greater than the actual payload length and rule 137:3 is enabled, or a heartbeat response greater in size than the value configured for this option when rule 137:4 is enabled, the preprocessor generates an event and, in an inline deployment, drops offending packets.

## Configuring the SSL Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

### Procedure

**Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

**Step 3** Click **Edit** (✎) next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 4** Click **Settings** in the navigation panel.

**Step 5** If **SSL Configuration** under **Application Layer Preprocessors** is disabled, click **Enabled**.

**Step 6** Click **Edit** (✎) next to **SSL Configuration**.

**Step 7** Modify any of the settings described in [SSL Preprocessor Options, on page 2864](#).

- Enter a value in the **Ports** field. Separate multiple values with commas.
- Check or clear the **Stop inspecting encrypted traffic** check box.
- If you checked **Stop inspecting encrypted traffic**, check or clear **Server side data is trusted**.
- Enter a value in the **Max Heartbeat Length** field.

**Tip** A value of 0 disables this option.

**Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

### What to do next

- If you want to enable intrusion events, enable SSL preprocessor rules (GID 137). For more information, see [Setting Intrusion Rule States, on page 2086](#).
- Deploy configuration changes.

**Related Topics**

[Managing Layers](#), on page 2216

## SSL Preprocessor Rules

If you want to generate events and, in an inline deployment, drop offending packets, enable SSL preprocessor rules (GID 137).

The following table describes the SSL preprocessor rules you can enable.

**Table 249: SSL Preprocessor Rules**

Preprocessor Rule GID:SID	Description
137:1	Detects a ClientHello message after a ServerHello message, which is invalid and considered to be anomalous behavior.
137:2	Detects a ServerHello message without a ClientHello message when the SSL preprocessor option <b>Server side data is trusted</b> is disabled, which is invalid and considered to be anomalous behavior.
137:3	Detects a heartbeat request with a payload length greater than the payload itself when the SSL preprocessor option <b>Max Heartbeat Length</b> contains a non-zero value, which indicates an attempt to exploit the Heartbleed bug.
137:4	Detects a heartbeat response larger than a non-zero value specified in the SSL preprocessor option <b>Max Heartbeat Length</b> , which indicates an attempt to exploit the Heartbleed bug.

## CHAPTER 106

# SCADA Preprocessors

The following topics explain preprocessors for Supervisory Control and Data Acquisition (SCADA) protocols, and how to configure them:

- [Introduction to SCADA Preprocessors, on page 2869](#)
- [License Requirements for SCADA Preprocessors, on page 2869](#)
- [Requirements and Prerequisites for SCADA Preprocessors, on page 2870](#)
- [The Modbus Preprocessor, on page 2870](#)
- [The DNP3 Preprocessor, on page 2872](#)
- [The CIP Preprocessor, on page 2874](#)
- [The S7Commplus Preprocessor, on page 2878](#)

## Introduction to SCADA Preprocessors

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

Supervisory Control and Data Acquisition (SCADA) protocols monitor, control, and acquire data from industrial, infrastructure, and facility processes such as manufacturing, production, water treatment, electric power distribution, airport and shipping systems, and so on. The system provides preprocessors for the Modbus, Distributed Network Protocol (DNP3), Common Industrial Protocol (CIP), and S7Commplus SCADA protocols that you can configure as part of your network analysis policy.

If the Modbus, DNP3, CIP, or S7Commplus preprocessor is disabled, and you enable and deploy an intrusion rule that requires one of these preprocessors, the system automatically uses the required preprocessor, with its current settings, although the preprocessor remains disabled in the web interface for the corresponding network analysis policy.

## The Modbus Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The Modbus protocol, which was first published in 1979 by Modicon, is a widely used SCADA protocol. The Modbus preprocessor detects anomalies in Modbus traffic and decodes the Modbus protocol for processing by the rules engine, which uses Modbus keywords to access certain protocol fields.

A single configuration option allows you to modify the default setting for the port that the preprocessor inspects for Modbus traffic.

**Related Topics**

[SCADA Keywords](#), on page 2184

## Modbus Preprocessor Ports Option

**Ports**

Specifies the ports that the preprocessor inspects for Modbus traffic. Separate multiple ports with commas.

# Configuring the Modbus Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

You should not enable this preprocessor in a network analysis policy that you apply to traffic if your network does not contain any Modbus-enabled devices.

## Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **Modbus Configuration** under **SCADA Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **Modbus Configuration**.
- Step 7** Enter a value in the **Ports** field.
- Separate multiple values with commas.
- Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable Modbus preprocessor rules (GID 144). For more information, see [Setting Intrusion Rule States, on page 2086](#) and [Modbus Preprocessor Rules, on page 2872](#).
- Deploy configuration changes.

### Related Topics

[Managing Layers](#), on page 2216

## Modbus Preprocessor Rules

You must enable the Modbus preprocessor rules in the following table if you want these rules to generate events and, in an inline deployment, drop offending packets.

Table 250: Modbus Preprocessor Rules

Preprocessor Rule GID:SID	Description
144:1	Generates an event when the length in the Modbus header does not match the length required by the Modbus function code.  Each Modbus function has an expected format for requests and responses. If the length of the message does not match the expected format, this event is generated.
144:2	Generates an event when the Modbus protocol ID is non-zero. The protocol ID field is used for multiplexing other protocols with Modbus. Because the preprocessor does not process these other protocols, this event is generated instead.
144:3	Generates an event when the preprocessor detects a reserved Modbus function code.

## The DNP3 Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

The Distributed Network Protocol (DNP3) is a SCADA protocol that was originally developed to provide consistent communication between electrical stations. DNP3 has also become widely used in the water, waste, transportation, and many other industries.

The DNP3 preprocessor detects anomalies in DNP3 traffic and decodes the DNP3 protocol for processing by the rules engine, which uses DNP3 keywords to access certain protocol fields.

### Related Topics

[DNP3 Keywords](#), on page 2185

## DNP3 Preprocessor Options

### Ports

Enables inspection of DNP3 traffic on each specified port. You can specify a single port or a comma-separated list of ports.

### Log bad CRCs

Validates the checksums contained in DNP3 link layer frames. Frames with invalid checksums are ignored.

You can enable rule 145:1 to generate events and, in an inline deployment, drop offending packets when invalid checksums are detected.

## Configuring the DNP3 Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

You should not enable this preprocessor in a network analysis policy that you apply to traffic if your network does not contain any DNP3-enabled devices.

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **DNP3 Configuration** under **SCADA Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **DNP3 Configuration**.
- Step 7** Enter a value for **Ports**.
- Separate multiple values with commas.
- Step 8** Check or clear the **Log bad CRCs** check box.
- Step 9** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.
- 

### What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable DNP3 preprocessor rules (GID 145). For more information, see [Setting Intrusion Rule States, on page 2086](#), [DNP3 Preprocessor Options, on page 2872](#), and [DNP3 Preprocessor Rules, on page 2874](#).

- Deploy configuration changes.

#### Related Topics

[Managing Layers](#), on page 2216

## DNP3 Preprocessor Rules

You must enable the DNP3 preprocessor rules in the following table if you want these rules to generate events and, in an inline deployment, drop offending packets.

Table 251: DNP3 Preprocessor Rules

Preprocessor Rule GID:SID	Description
145:1	When <b>Log bad CRC</b> is enabled, generates an event when the preprocessor detects a link layer frame with an invalid checksum.
145:2	Generates an event and blocks the packet when the preprocessor detects a DNP3 link layer frame with an invalid length.
145:3	Generates an event and blocks the packet during reassembly when the preprocessor detects a transport layer segment with an invalid sequence number.
145:4	Generates an event when the DNP3 reassembly buffer is cleared before a complete fragment can be reassembled. This happens when a segment carrying the FIR flag appears after other segments have been queued.
145:5	Generates an event when the preprocessor detects a DNP3 link layer frame that uses a reserved address.
145:6	Generates an event when the preprocessor detects a DNP3 request or response that uses a reserved function code.

## The CIP Preprocessor

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

The Common Industrial Protocol (CIP) is a widely used application protocol that supports industrial automation applications. EtherNet/IP (ENIP) is an implementation of CIP that is used on Ethernet-based networks.

The CIP preprocessor detects CIP and ENIP traffic running on TCP or UDP and sends it to the intrusion rules engine. You can use CIP and ENIP keywords in custom intrusion rules to detect attacks in CIP and ENIP traffic. See [CIP and ENIP Keywords](#). Additionally, you can control traffic by specifying CIP and ENIP application conditions in access control rules. See [Configuring Application Conditions and Filters](#), on page 1869.

## CIP Preprocessor Options

### Ports

Specifies the ports to inspect for CIP and ENIP traffic. You can specify an integer from 0 to 65535. Separate multiple port numbers with commas.

**Note** You must add the default CIP detection port 44818 and any other ports you list to the TCP stream **Perform Stream Reassembly on Both Ports** list.

### Default Unconnected Timeout (seconds)

When a CIP request message does not contain a protocol-specific timeout value and **Maximum number of concurrent unconnected requests per TCP connection** is reached, the system times the message for the number of seconds specified by this option. When the timer expires, the message is removed to make room for future requests. You can specify an integer from 0 to 360. When you specify 0, all traffic that does not have a protocol-specific timeout times out first.

### Maximum number of concurrent unconnected requests per TCP connection

The number of concurrent requests that can go unanswered before the system closes the connection. You can specify an integer from 1 to 10000.

### Maximum number of CIP connections per TCP connection

The maximum number of simultaneous CIP connections allowed by the system per TCP connection. You can specify an integer from 1 to 10000.

## CIP Events

By design, application detectors detect and event viewers display the same application one time per session. A CIP session can include multiple applications in different packets, and a single CIP packet can contain multiple applications. The CIP preprocessor handles all CIP and ENIP traffic according to the corresponding intrusion rule.

The following table shows the CIP values displayed in event views.

*Table 252: CIP Event Field Values*

Event Field	Displayed Value
Application Protocol	CIP or ENIP
Client	CIP Client or ENIP Client

Event Field	Displayed Value
Web Application	<p>The specific application detected, which is:</p> <ul style="list-style-type: none"> <li>For access control rules that allow or monitor traffic, the last application protocol detected. Access control rules that you configure to log connections might not generate events for CIP applications, and access control rules that you do not configure to log connections do not generate events for CIP applications.</li> <li>For access control rules that block traffic, the application protocol that triggered the event. When an access control rule blocks a list of CIP applications, event viewers display the first application protocol that is detected.</li> </ul>

## CIP Preprocessor Rules

If you want the CIP preprocessor rules listed in the following table to generate events, you must enable them. See [Setting Intrusion Rule States, on page 2086](#) for information on enabling rules.

**Table 253: CIP Preprocessor Rules**

GID:SID	Rule Message
148:1	CIP_MALFORMED
148:2	CIP_NONCONFORMING
148:3	CIP_CONNECTION_LIMIT
148:4	CIP_REQUEST_LIMIT

## Guidelines for Configuring the CIP Preprocessor

Note the following when configuring the CIP preprocessor:

- You must add the default CIP detection port 44818 and any other CIP **Ports** you list to the TCP stream **Perform Stream Reassembly on Both Ports** list.
- Event viewers give special handling to CIP applications. See [CIP Events, on page 2875](#).
- We recommend that you use an intrusion prevention action as the default action of your access control policy.
- The CIP preprocessor does not support an access control policy default action of **Access Control: Trust All Traffic**, which may produce undesirable behavior, including not dropping traffic triggered by CIP applications specified in intrusion rules and access control rules.
- The CIP preprocessor does not support an access control policy default action of **Access Control: Block All Traffic**, which may produce undesirable behavior, including blocking CIP applications that you do not expect to be blocked.
- The CIP preprocessor does not support application visibility for CIP applications, including network discovery.

- To detect CIP and ENIP applications and use them in access control rules, intrusion rules and so on, you must manually enable the CIP preprocessor in the corresponding custom network analysis policy.
- To drop traffic that triggers CIP preprocessor rules and CIP intrusion rules, ensure that **Drop when Inline** is enabled in the corresponding intrusion policy. See [Setting Drop Behavior in an Inline Deployment](#).
- To block CIP or ENIP application traffic using access control rules, ensure that the inline normalization preprocessor and its **Inline Mode** option are enabled (the default setting) in the corresponding network analysis policy.

## Configuring the CIP Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

### Before you begin

- You must add the default CIP detection port 44818 and any other ports you list as CIP **Ports** to the TCP stream **Perform Stream Reassembly on Both Ports** list.
- Familiarize yourself with [Guidelines for Configuring the CIP Preprocessor, on page 2876](#).
- The CIP preprocessor is not supported for threat defense devices.

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **CIP Configuration** under **SCADA Preprocessors** is disabled, click **Enabled**.
- Step 6** You can modify any of the options described in [CIP Preprocessor Options, on page 2875](#).
- Step 7** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

---

#### What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable CIP intrusion rules and, optionally, CIP preprocessor rules (GID 148). For more information, see [Setting Intrusion Rule States, on page 2086](#), [CIP Preprocessor Rules, on page 2876](#), and [CIP Events, on page 2875](#).
- Deploy configuration changes.

## The S7Commplus Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The S7Commplus preprocessor detects S7Commplus traffic. You can use S7Commplus keywords in custom intrusion rules to detect attacks in S7Commplus traffic. See [S7Commplus Keywords, on page 2189](#).

## Configuring the S7Commplus Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The S7Commplus preprocessor is supported on all threat defense devices.

### Procedure

---

**Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

**Step 3** Click **Edit** (✎) next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 4** Click **Settings** in the navigation panel.

- Step 5** If **S7Commplus Configuration** under **SCADA Preprocessors** is disabled, click **Enabled**.
- Step 6** Optionally, click **Edit** (✎) next to **S7Commplus Configuration** and modify **s7commplus\_ports** to identify ports that the preprocessor inspects for S7Commplus traffic. Separate multiple ports with commas.
- Step 7** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- If you want to generate intrusion events, enable S7Commplus preprocessor rules (GID 149). For more information, see [Setting Intrusion Rule States, on page 2086](#)
- Deploy configuration changes.

## CHAPTER 107

# Transport and Network Layer Preprocessors

The following topics explain transport and network layer preprocessors and how to configure them:

- [Introduction to Transport and Network Layer Preprocessors, on page 2881](#)
- [License Requirements for Transport and Network Layer Preprocessors, on page 2881](#)
- [Requirements and Prerequisites for Transport and Network Layer Preprocessors, on page 2882](#)
- [Advanced Transport/Network Preprocessor Settings, on page 2882](#)
- [Checksum Verification, on page 2885](#)
- [The Inline Normalization Preprocessor, on page 2887](#)
- [The IP Defragmentation Preprocessor, on page 2893](#)
- [The Packet Decoder, on page 2898](#)
- [TCP Stream Preprocessing, on page 2903](#)
- [UDP Stream Preprocessing, on page 2913](#)

## Introduction to Transport and Network Layer Preprocessors

Transport and network layer preprocessors detect attacks that exploit IP fragmentation, checksum validation, and TCP and UDP session preprocessing. Before packets are sent to preprocessors, the packet decoder converts packet headers and payloads into a format that can be easily used by the preprocessors and the intrusion rules engine and detects various anomalous behaviors in packet headers. After packet decoding and before sending packets to other preprocessors, the inline normalization preprocessor normalizes traffic for inline deployments.

When an intrusion rule or rule argument requires a disabled preprocessor, the system automatically uses it with its current configuration even though it remains disabled in the network analysis policy's web interface.

- Intrusion Admin

## Advanced Transport/Network Preprocessor Settings

Advanced transport and network preprocessor settings apply globally to all networks, zones, and VLANs where you deploy your access control policy. You configure these advanced settings in an access control policy rather than in a network analysis policy.

## Ignored VLAN Headers

Different VLAN tags in traffic traveling in different directions for the same connection can affect traffic reassembly and rule processing. For example, in the following graphic traffic for the same connection could be transmitted over VLAN A and received over VLAN B.

You can configure the system to ignore the VLAN header so packets can be correctly processed for your deployment.

## Active Responses in Intrusion Drop Rules

A drop rule is an intrusion or preprocessor rule whose rule state is set to Drop and Generate Events. In an inline deployment, the system responds to TCP or UDP drop rules by dropping the triggering packet and blocking the session where the packet originated.

**Tip** Because UDP data streams are not typically thought of in terms of *sessions*, the stream preprocessor uses the source and destination IP address fields in the encapsulating IP datagram header and the port fields in the UDP header to determine the direction of flow and identify a UDP session.

You can configure the system to initiate one or more *active responses* to more precisely and specifically close a TCP connection or UDP session when an offending packet triggers a TCP or UDP drop rule. You can use active responses in inline, including routed and transparent, deployments. Active responses are not suited or supported for passive deployments.

To configure active responses:

- Create or modify a TCP or UDP (**resp** keyword only) intrusion rule. See [Intrusion Rule Header Protocol, on page 2100](#).
- Add the **react** or **resp** keyword to the intrusion rule; see [xActive Response Keywords, on page 2192](#).
- Optionally, for a TCP connection, specify the maximum number of additional active responses to send and the number of seconds to wait between active responses; see **Maximum Active Responses** and **Minimum Response Seconds** in [Advanced Transport/Network Preprocessor Options, on page 2883](#).

Active responses close the session when matching traffic triggers a drop rule, as follows:

- **TCP**—drops the triggering packet and inserts a TCP Reset (RST) packet in both the client and server traffic.
- **UDP**—sends an ICMP unreachable packet to each end of the session.

## Advanced Transport/Network Preprocessor Options

### Ignore the VLAN header when tracking connections

Specifies whether to ignore or include VLAN headers when identifying traffic, as follows:

- When this option is selected, the system ignores VLAN headers. Use this setting for deployed devices that might detect different VLAN tags for the same connection in traffic traveling in different directions
- When this option is disabled, the system includes VLAN headers. Use this setting for deployed devices that will not detect different VLAN tags for the same connection traffic traveling in different directions.

### Maximum Active Responses

Specifies a maximum number of active responses per TCP connection. When additional traffic occurs on a connection where an active response has been initiated, and the traffic occurs more than **Minimum Response Seconds** after a previous active response, the system sends another active response unless the specified maximum has been reached. A setting of 0 disables additional active responses triggered by **resp** or **react** rules. See [Active Responses in Intrusion Drop Rules, on page 2882](#) and [Active Response Keywords, on page 2192](#).

Note that a triggered **resp** or **react** rule initiates an active response regardless of the configuration of this option.

**Minimum Response Seconds**

Until **Maximum Active Responses** occur, specifies the number of seconds to wait before any additional traffic on a connection where the system has initiated an active response results in a subsequent active response.

**Troubleshooting Options: Session Termination Logging Threshold**

---

**Caution** Do not modify Session Termination Logging Threshold unless instructed to do so by Support.

---

Support might ask you during a troubleshooting call to configure your system to log a message when an individual connection exceeds the specified threshold. Changing the setting for this option will affect performance and should be done only with Support guidance.

This option specifies for the number of bytes that result in a logged message when the session terminates and the specified number was exceeded.

---

**Note** The upper limit of 1GB is also restricted by the amount of memory on the managed device allocated for stream processing.

---

**Related Topics**

[Active Response Keywords](#), on page 2192

## Configuring Advanced Transport/Network Preprocessor Settings

You must be an Admin, Access Admin, or Network Admin to perform this task.

**Procedure**

- 
- Step 1** In the access control policy editor, click **Edit** (✎) on the policy you want to modify.
- Step 2** Click **More > Advanced Settings**, and then click **Edit** (✎) next to the **Transport/Network Preprocessor Settings** section.
- Step 3** Except for the troubleshooting option **Session Termination Logging Threshold**, modify the options described in [Advanced Transport/Network Preprocessor Options, on page 2883](#).
- Caution** Do not modify **Session Termination Logging Threshold** unless instructed to do so by Support.
- Step 4** Click **OK**.
- 

**What to do next**

- Optionally, further configure the policy as described in [Editing an Access Control Policy, on page 1833](#).
- Deploy configuration changes.

# Checksum Verification

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The system can verify all protocol-level checksums to ensure that complete IP, TCP, UDP, and ICMP transmissions are received and that, at a basic level, packets have not been tampered with or accidentally altered in transit. A checksum uses an algorithm to verify the integrity of a protocol in the packet. The packet is considered to be unchanged if the system computes the same value that is written in the packet by the end host.

Disabling checksum verification may leave your network susceptible to insertion attacks. Note that the system does not generate checksum verification events. In an inline deployment, you can configure the system to drop packets with invalid checksums.

## Checksum Verification Options

You can set any of the following options to **Enabled** or **Disabled** in a passive or inline deployment, or to **Drop** in an inline deployment:

- **ICMP Checksums**
- **IP Checksums**
- **TCP Checksums**
- **UDP Checksums**

To drop offending packets, in addition to setting an option to **Drop** you must also enable **Inline Mode** in the associated network analysis policy and ensure that the device is deployed inline.

Setting these options to **Drop** in a passive deployment, or in an inline deployment in tap mode, is the same as setting them to **Enabled**.

---

**Attention** Under **TCP checksums**, the **Ignore** option (which is the default) bypasses or ignores any configured Snort rules.

---

The default for all checksum verification options is **Enabled**. However, threat defense routed and transparent interfaces always drop packets that fail IP checksum verification. Note that the threat defense routed and transparent interfaces fix UDP packets with a bad checksum before passing the packets to the Snort process.

## Verifying Checksums

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **Checksum Verification** under **Transport/Network Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **Checksum Verification**.
- Step 7** Modify the options described in [Checksum Verification, on page 2885](#).
- Note** Under **TCP checksums**, the **Ignore** option (which is the default) bypasses or ignores any configured Snort rules.
- Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.
- 

#### What to do next

- Deploy configuration changes.

# The Inline Normalization Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

The inline normalization preprocessor normalizes traffic to minimize the chances of attackers evading detection in inline deployments.

---

**Note** For the system to affect traffic, you must deploy relevant configurations to managed devices using routed, switched, or transparent interfaces, or inline interface pairs.

---

You can specify normalization of any combination of IPv4, IPv6, ICMPv4, ICMPv6, and TCP traffic. Most normalizations are on a per-packet basis and are conducted by the inline normalization preprocessor. However, the TCP stream preprocessor handles most state-related packet and stream normalizations, including TCP payload normalization.

Inline normalization takes place immediately after decoding by the packet decoder and before processing by other preprocessors. Normalization proceeds from the inner to outer packet layers.

The inline normalization preprocessor does not generate events; it prepares packets for use by other preprocessors and the rules engine in inline deployments. The preprocessor also helps ensure that the packets the system processes are the same as the packets received by the hosts on your network.

---

**Note** In an inline deployment, we recommend that you enable inline mode and configure the inline normalization preprocessor with the **Normalize TCP Payload** option enabled. In a passive deployment, we recommend that you use adaptive profile updates.

---

## Related Topics

[Preprocessor Traffic Modification in Inline Deployments](#)  
[About Adaptive Profiles](#), on page 2937

## Inline Normalization Options

### Minimum TTL

When **Reset TTL** is greater than or equal to the value set for this option, specifies the following:

- the minimum value the system will permit in the IPv4 Time to Live (TTL) field when **Normalize IPv4** is enabled; a lower value results in normalizing the packet value for TTL to the value set for **Reset TTL**
- the minimum value the system will permit in the IPv6 Hop Limit field when **Normalize IPv6** is enabled; a lower value results in normalizing the packet value for Hop Limit to the value set for **Reset TTL**

The system assumes a value of 1 when the field is empty.

**Note** For threat defense routed and transparent interfaces, the **Minimum TTL** and **Reset TTL** options are ignored. The maximum TTL for a connection is determined by the TTL in the initial packet. The TTL for subsequent packets can decrease, but it cannot increase. The system will reset the TTL to the lowest previously-seen TTL for that connection. This prevents TTL evasion attacks.

When the packet decoding **Detect Protocol Header Anomalies** option is enabled, you can enable the following rules in the decoder rule category to generate events and, in an inline deployment, drop offending packets for this option:

- You can enable rule 116:428 to trigger when the system detects an IPv4 packet with a TTL less than the specified minimum.
- You can enable rule 116:270 to trigger when the system detects an IPv6 packet with a hop limit that is less than the specified minimum.

### Reset TTL

When set to a value greater than or equal to **Minimum TTL**, normalizes the following:

- the IPv4 TTL field when **Normalize IPv4** is enabled
- the IPv6 Hop Limit field when **Normalize IPv6** is enabled

The system normalizes the packet by changing its TTL or Hop Limit value to the value set for this option when the packet value is less than **Minimum TTL**. Leaving this field blank, or setting it to 0, or to any value less than **Minimum TTL**, disables the option.

### Normalize IPv4

Enables normalization of IPv4 traffic. The system also normalizes the TTL field as needed when:

- this option is enabled, and
- the value set for **Reset TTL** enables TTL normalization.

You can also enable additional IPv4 options when this option is enabled.

When you enable this option, the system performs the following base IPv4 normalizations:

- truncates packets with excess payload to the datagram length specified in the IP header
- clears the Differentiated Services (DS) field, formerly known as the Type of Service (TOS) field
- sets all option octets to 1 (No Operation)

This option is ignored for threat defense routed and transparent interfaces. Threat Defense devices will drop any RSVP packet that contains IP options other than the router alert, end of options list (EOOL), and no operation (NOP) options on any routed or transparent interface.

### Normalize Don't Fragment Bit

Clears the single-bit Don't Fragment subfield of the IPv4 Flags header field. Enabling this option allows a downstream router to fragment packets if necessary instead of dropping them; enabling this option can also

prevent evasions based on crafting packets to be dropped. You must enable **Normalize IPv4** to select this option.

#### **Normalize Reserved Bit**

Clears the single-bit Reserved subfield of the IPv4 Flags header field. You would typically enable this option. You must enable **Normalize IPv4** to select this option.

#### **Normalize TOS Bit**

Clears the one byte Differentiated Services field, formerly known as Type of Service. You must enable **Normalize IPv4** to select this option.

#### **Normalize Excess Payload**

Truncates packets with excess payload to the datagram length specified in the IP header plus the Layer 2 (for example, Ethernet) header, but does not truncate below the minimum frame length. You must enable **Normalize IPv4** to select this option.

This option is ignored for threat defense routed and transparent interfaces. Packets with excess payload are always dropped on these interfaces.

#### **Normalize IPv6**

Sets all Option Type fields in the Hop-by-Hop Options and Destination Options extension headers to 00 (Skip and continue processing). The system also normalizes the Hop Limit field as needed when this option is enabled and the value set for **Reset TTL** enables hop limit normalization.

#### **Normalize ICMPv4**

Clears the 8-bit Code field in Echo (Request) and Echo Reply messages in ICMPv4 traffic.

#### **Normalize ICMPv6**

Clears the 8-bit Code field in Echo (Request) and Echo Reply messages in ICMPv6 traffic.

#### **Normalize/Clear Reserved Bits**

Clears the Reserved bits in the TCP header.

#### **Normalize/Clear Option Padding Bytes**

Clears any TCP option padding bytes.

#### **Clear Urgent Pointer if URG=0**

Clears the 16-bit TCP header Urgent Pointer field if the urgent (URG) control bit is not set.

#### **Clear Urgent Pointer/URG on Empty Payload**

Clears the TCP header Urgent Pointer field and the URG control bit if there is no payload.

#### **Clear URG if Urgent Pointer is Not Set**

Clears the TCP header URG control bit if the urgent pointer is not set.

**Normalize Urgent Pointer**

Sets the two-byte TCP header Urgent Pointer field to the payload length if the pointer is greater than the payload length.

**Normalize TCP Payload**

Enables normalization of the TCP Data field to ensure consistency in retransmitted data. Any segment that cannot be properly reassembled is dropped.

**Remove Data on SYN**

Removes data in synchronization (SYN) packets if your TCP operating system policy is **not** Mac OS.

This option also disables rule 129:2, which can otherwise trigger when the TCP stream preprocessor **Policy** option is not set to **Mac OS**.

**Remove Data on RST**

Removes any data from a TCP reset (RST) packet.

**Trim Data to Window**

Trims the TCP Data field to the size specified in the Window field.

**Trim Data to MSS**

Trims the TCP Data field to the Maximum Segment Size (MSS) if the payload is longer than MSS.

**Block Unresolvable TCP Header Anomalies**

When you enable this option, the system blocks anomalous TCP packets that, if normalized, would be invalid and likely would be blocked by the receiving host. For example, the system blocks any SYN packet transmitted subsequent to an established session.

The system also drops any packet that matches any of the following TCP stream preprocessor rules, regardless of whether the rules are enabled:

- 129:1
- 129:3
- 129:4
- 129:6
- 129:8
- 129:11
- 129:14 through 129:19

The Total Blocked Packets performance graph tracks the number of packets blocked in inline deployments and, in passive deployments and inline deployments in tap mode, the number that would have been blocked in an inline deployment.

### Explicit Congestion Notification

Enables per-packet or per-stream normalization of Explicit Congestion Notification (ECN) flags as follows:

- select **Packet** to clear ECN flags on a per-packet basis regardless of negotiation
- select **Stream** to clear ECN flags on a per-stream basis if ECN use was not negotiated

If you select **Stream**, you must also ensure that the TCP stream preprocessor **Require TCP 3-Way Handshake** option is enabled for this normalization to take place.

### Clear Existing TCP Options

Enables **Allow These TCP Options**.

### Allow These TCP Options

Disables normalization of specific TCP options you allow in traffic.

The system does not normalize options that you explicitly allow. It normalizes options that you do not explicitly allow by setting the options to No Operation (TCP Option 1).

The system always allows the following options regardless of the configuration of **Allow These TCP Options** because they are commonly used for optimal TCP performance:

- Maximum Segment Size (MSS)
- Window Scale
- Time Stamp TCP

The system does not automatically allow other less commonly used options.

You can allow specific options by configuring a comma-separated list of option keywords, option numbers, or both as shown in the following example:

```
sack, echo, 19
```

Specifying an option keyword is the same as specifying the number for one or more TCP options associated with the keyword. For example, specifying `sack` is the same as specifying TCP options 4 (Selective Acknowledgment Permitted) and 5 (Selective Acknowledgment). Option keywords are not case sensitive.

You can also specify `any`, which allows all TCP options and effectively disables normalization of all TCP options.

The following table summarizes how you can specify TCP options to allow. If you leave the field empty, the system allows only the MSS, Window Scale, and Time Stamp options.

Specify...	To allow...
sack	TCP options 4 (Selective Acknowledgment Permitted) and 5 (Selective Acknowledgment)
echo	TCP options 6 (Echo Request) and 7 (Echo Reply)
partial_order	TCP options 9 (Partial Order Connection Permitted) and 10 (Partial Order Service Profile)

Specify...	To allow...
conn_count	TCP Connection Count options 11 (CC), 12 (CC.New), and 13 (CC.Echo)
alt_checksum	TCP options 14 (Alternate Checksum Request) and 15 (Alternate Checksum)
md5	TCP option 19 (MD5 Signature)
the option number, 2 to 255	a specific option, including options for which there is no keyword
any	all TCP options; this setting effectively disables TCP option normalization

When you do not specify `any` for this option, normalizations include the following:

- except MSS, Window Scale, Time Stamp, and any explicitly allowed options, sets all option bytes to No Operation (TCP Option 1)
- sets the Time Stamp octets to No Operation if Time Stamp is present but invalid, or valid but not negotiated
- blocks the packet if Time Stamp is negotiated but not present
- clears the Time Stamp Echo Reply (TSecr) option field if the Acknowledgment (ACK) control bit is not set
- sets the MSS and Window Scale options to No Operation (TCP Option 1) if the SYN control bit is not set

## Configuring Inline Normalization

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

### Before you begin

- If you want to normalize or drop offending packets, enable **Inline Mode** as described in [Preprocessor Traffic Modification in Inline Deployments](#). The managed device must also be deployed inline.

### Procedure

---

**Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel (NOT the caret; click the word).
- Step 5** If **Inline Normalization** under **Transport/Network Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **Inline Normalization**.
- Step 7** Set the options described in [The Inline Normalization Preprocessor, on page 2887](#).
- Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- If you want the inline normalization Minimum TTL option to generate intrusion events, enable either or both packet decoder rules 116:429 (IPv4) and 116:270 (IPv6). For more information, see [Setting Intrusion Rule States, on page 2086](#), and [Inline Normalization Options, on page 2887](#).
- Deploy configuration changes.

## The IP Defragmentation Preprocessor

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

When an IP datagram is broken into two or more smaller IP datagrams because it is larger than the maximum transmission unit (MTU), it is *fragmented*. A single IP datagram fragment may not contain enough information to identify a hidden attack. Attackers may attempt to evade detection by transmitting attack data in fragmented packets. The IP defragmentation preprocessor reassembles fragmented IP datagrams before the rules engine executes rules against them so the rules can more appropriately identify attacks in those packets. If fragmented datagrams cannot be reassembled, rules do not execute against them.

## IP Fragmentation Exploits

Enabling IP defragmentation helps you detect attacks against hosts on your network, like the teardrop attack, and resource consumption attacks against the system itself, like the Jolt2 attack.

The Teardrop attack exploits a bug in certain operating systems that causes them to crash when trying to reassemble overlapping IP fragments. When enabled and configured to do so, the IP defragmentation preprocessor identifies the overlapping fragments. The IP defragmentation preprocessor detects the first packets in an overlapping fragment attack such as Teardrop, but does not detect subsequent packets for the same attack.

The Jolt2 attack sends a large number of copies of the same fragmented IP packet in an attempt to overuse IP defragmentors and cause a denial of service attack. A memory usage cap disrupts this and similar attacks in the IP defragmentation preprocessor, and places the system self-preservation above exhaustive inspection. The system is not overwhelmed by the attack, remains operational, and continues to inspect network traffic.

Different operating systems reassemble fragmented packets in different ways. Attackers who can determine which operating systems your hosts are running can also fragment malicious packets so that a target host reassembles them in a specific manner. Because the system does not know which operating systems the hosts on your monitored network are running, the preprocessor may reassemble and inspect the packets incorrectly, thus allowing an exploit to pass through undetected. To mitigate this kind of attack, you can configure the defragmentation preprocessor to use the appropriate method of defragmenting packets for each host on your network.

Note that you can also use adaptive profile updates in a passive deployment to dynamically select target-based policies for the IP defragmentation preprocessor using host operating system information for the target host in a packet.

## Target-Based Defragmentation Policies

A host's operating system uses three criteria to determine which packet fragments to favor when reassembling the packet:

- the order in which the fragment was received by the operating system
- its offset (the fragment's distance, in bytes, from the beginning of the packet)
- its beginning and ending position compared to overlap fragments.

Although every operating system uses these criteria, different operating systems favor different fragments when reassembling fragmented packets. Therefore, two hosts with different operating systems on your network could reassemble the same overlapping fragments in entirely different ways.

An attacker, aware of the operating system of one of your hosts, could attempt to evade detection and exploit that host by sending malicious content hidden in overlapping packet fragments. This packet, when reassembled and inspected, seems innocuous, but when reassembled by the target host, contains a malicious exploit. However, if you configure the IP defragmentation preprocessor to be aware of the operating systems running on your monitored network segment, it will reassemble the fragments the same way that the target host does, allowing it to identify the attack.

## IP Defragmentation Options

You can choose to simply enable or disable IP defragmentation; however, Cisco recommends that you specify the behavior of the enabled IP defragmentation preprocessor at a more granular level.

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

You can configure the following global option:

### Preallocated Fragments

The maximum number of individual fragments that the preprocessor can process at once. Specifying the number of fragment nodes to preallocate enables static memory allocation.

**Caution** Processing an individual fragment uses approximately 1550 bytes of memory. If the preprocessor requires more memory to process the individual fragments than the predetermined allowable memory limit for the managed device, the memory limit for the device takes precedence.

You can configure the following options for each IP defragmentation policy:

### Networks

The IP address of the host or hosts to which you want to apply the defragmentation policy.

You can specify a single IP address or address block, or a comma-separated list of either or both. You can specify up to 255 total profiles, including the default policy.

Note that the `default` setting in the default policy specifies all IP addresses on your monitored network segment that are not covered by another target-based policy. Therefore, you cannot and do not need to specify an IP address or CIDR block/prefix length for the default policy, and you cannot leave this setting blank in another policy or use address notation to represent `any` (for example, `0.0.0.0/0` or `::/0`).

### Policy

The defragmentation policy you want to use for a set of hosts on your monitored network segment.

You can select one of seven defragmentation policies, depending on the operating system of the target host. The following table lists the seven policies and the operating systems that use each one. The First and Last policy names reflect whether those policies favor original or subsequent overlapping packets.

This option is ignored for threat defense routed and transparent interfaces.

**Table 254: Target-Based Defragmentation Policies**

Policy	Operating Systems
BSD	AIX FreeBSD IRIX VAX/VMS
BSD-right	HP JetDirect
First	Mac OS HP-UX
Linux	Linux OpenBSD
Last	Cisco IOS

Policy	Operating Systems
Solaris	SunOS
Windows	Windows

### Timeout

Specifies the maximum amount of time, in seconds, that the preprocessor engine can use when reassembling a fragmented packet. If the packet cannot be reassembled within the specified time period, the preprocessor engine stops attempting to reassemble the packet and discards received fragments.

### Min TTL

Specifies the minimum acceptable TTL value a packet may have. This option detects TTL-based insertion attacks.

You can enable rule 123:11 to generate events and, in an inline deployment, drop offending packets for this option.

### Detect Anomalies

Identifies fragmentation problems such as overlapping fragments.

This option is ignored for threat defense routed and transparent interfaces.

You can enable the following rules to generate events and, in an inline deployment, drop offending packets for this option:

- 123:1 through 123:4
- 123:5 (BSD policy)
- 123:6 through 123:8

### Overlap Limit

Specifies that when the configured number of overlapping segments in a session has been detected, defragmentation stops for that session.

You must enable **Detect Anomalies** to configure this option. A blank value disables this option. A value of 0 specifies an unlimited number overlapping segments.

This option is ignored for threat defense routed and transparent interfaces. Overlapping fragments are always dropped on those interfaces.

You can enable rule 123:12 to generate events and, in an inline deployment, drop offending packets for this option.

### Minimum Fragment Size

Specifies that when a non-last fragment smaller than the configured number of bytes has been detected, the packet is considered malicious.

You must enable **Detect Anomalies** to configure this option. A blank value disables this option. A value of 0 specifies an unlimited number of bytes.

You can enable rule 123:13 to generate events and, in an inline deployment, drop offending packets for this option.

## Configuring IP Defragmentation

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

### Before you begin

- Confirm that any networks you want to identify in a custom target-based policy match or are a subset of the networks, zones, and VLANs handled by its parent network analysis policy. See [Advanced Settings for Network Analysis Policies, on page 2751](#) for more information.

### Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **IP Defragmentation** under **Transport/Network Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **IP Defragmentation**.
- Step 7** Optionally, enter a value in the **Preallocated Fragments** field.
- Step 8** You have the following choices:
- Add a server profile — Click **Add** (+) next to **Servers** on the left side of the page, then enter a value in the **Host Address** field and click **OK**. You can specify a single IP address or address block, or a comma-separated list of either or both. You can create a total of 255 target-based policies including the default policy.
  - Edit a server profile — Click the configured address for under **Servers** on the left side of the page, or click **default**.
  - Delete a profile — Click **Delete** (🗑) next to the policy.
- Step 9** Modify the options described in [IP Defragmentation Options, on page 2894](#).

**Step 10** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable IP defragmentation rules (GID 123). For more information, see [Setting Intrusion Rule States, on page 2086](#) and [IP Defragmentation Options, on page 2894](#).
- Deploy configuration changes.

### Related Topics

[Layer Basics](#), on page 2209

[Conflicts and Changes: Network Analysis and Intrusion Policies](#), on page 2059

## The Packet Decoder

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

Before sending captured packets to a preprocessor, the system first sends the packets to the packet decoder. The packet decoder converts packet headers and payloads into a format that preprocessors and the rules engine can easily use. Each stack layer is decoded in turn, beginning with the data link layer and continuing through the network and transport layers.

## Packet Decoder Options

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

### Decode GTP Data Channel

Decodes the encapsulated GTP (General Packet Radio Service [GPRS] Tunneling Protocol) data channel. By default, the decoder decodes version 0 data on port 3386 and version 1 data on port 2152. You can use the `GTP_PORTS` default variable to modify the ports that identify encapsulated GTP traffic.

You can enable rules 116:297 and 116:298 to generate events and, in an inline deployment, drop offending packets for this option.

### Detect Teredo on Non-Standard Ports

Inspects Teredo tunneling of IPv6 traffic that is identified on a UDP port other than port 3544.

The system always inspects IPv6 traffic when it is present. By default, IPv6 inspection includes the 4in6, 6in4, 6to4, and 6in6 tunneling schemes, and also includes Teredo tunneling when the UDP header specifies port 3544.

In an IPv4 network, IPv4 hosts can use the Teredo protocol to tunnel IPv6 traffic through an IPv4 Network Address Translation (NAT) device. Teredo encapsulates IPv6 packets within IPv4 UDP datagrams to permit IPv6 connectivity behind an IPv4 NAT device. The system normally uses UDP port 3544 to identify Teredo traffic. However, an attacker could use a non-standard port in an attempt to avoid detection. You can enable **Detect Teredo on Non-Standard Ports** to cause the system to inspect all UDP payloads for Teredo tunneling.

Teredo decoding occurs only on the first UDP header, and only when IPv4 is used for the outer network layer. When a second UDP layer is present after the Teredo IPv6 layer because of UDP data encapsulated in the IPv6 data, the rules engine uses UDP intrusion rules to analyze both the inner and outer UDP layers.

Note that intrusion rules 12065, 12066, 12067, and 12068 in the **policy-other** rule category detect, but do not decode, Teredo traffic. Optionally, you can use these rules to drop Teredo traffic in an inline deployment; however, you should ensure that these rules are disabled or set to generate events without dropping traffic when you enable **Detect Teredo on Non-Standard Ports**.

### Detect Excessive Length Value

Detects when the packet header specifies a packet length that is greater than the actual packet length.

This option is ignored for threat defense routed, transparent, and inline interfaces. Packets that have excessive header length are always dropped. However, this option does apply to threat defense inline tap and passive interfaces.

You can enable rules 116:6, 116:47, 116:97, and 116:275 to generate events and, in an inline deployment, drop offending packets for this option.

### Detect Invalid IP Options

Detects invalid IP header options to identify exploits that use invalid IP options. For example, there is a denial of service attack against a firewall which causes the system to freeze. The firewall attempts to parse invalid Timestamp and Security IP options and fails to check for a zero length, which causes an irrecoverable infinite loop. The rules engine identifies the zero length option, and provides information you can use to mitigate the attack at the firewall.

Threat Defense devices will drop any RSVP packet that contains IP options other than the router alert, end of options list (EOOL), and no operation (NOP) options on any routed or transparent interface. For inline, inline tap, or passive interfaces, IP options will be handled as described above.

You can enable rules 116:4 and 116:5 to generate events and, in an inline deployment, drop offending packets for this option.

### Detect Experimental TCP Options

Detects TCP headers with experimental TCP options. The following table describes these options.

TCP Option	Description
9	Partial Order Connection Permitted
10	Partial Order Service Profile
14	Alternate Checksum Request

TCP Option	Description
15	Alternate Checksum Data
18	Trailer Checksum
20	Space Communications Protocol Standards (SCPS)
21	Selective Negative Acknowledgements (SCPS)
22	Record Boundaries (SCPS)
23	Corruption (SPCS)
24	SNAP
26	TCP Compression Filter

Because these are experimental options, some systems do not account for them and may be open to exploits.

**Note** In addition to the experimental options listed in the above table, the system considers any TCP option with an option number greater than 26 to be experimental.

You can enable rule 116:58 to generate events and, in an inline deployment, drop offending packets for this option.

### Detect Obsolete TCP Options

Detects TCP headers with obsolete TCP options. Because these are obsolete options, some systems do not account for them and may be open to exploits. The following table describes these options.

TCP Option	Description
6	Echo
7	Echo Reply
16	Skeeter
17	Bubba
19	MD5 Signature
25	Unassigned

You can enable rule 116:57 to generate events and, in an inline deployment, drop offending packets for this option.

### Detect T/TCP

Detects TCP headers with the CC.ECHO option. The CC.ECHO option confirms that TCP for Transactions (T/TCP) is being used. Because T/TCP header options are not in widespread use, some systems do not account for them and may be open to exploits.

You can enable rule 116:56 to generate events and, in an inline deployment, drop offending packets for this option.

### Detect Other TCP Options

Detects TCP headers with invalid TCP options not detected by other TCP decoding event options. For example, this option detects TCP options with the incorrect length or with a length that places the option data outside the TCP header.

This option is ignored for threat defense routed and transparent interfaces. Packets that have invalid TCP options are always dropped.

You can enable rules 116:54, 116:55, and 116:59 to generate events and, in an inline deployment, drop offending packets for this option.

### Detect Protocol Header Anomalies

Detects other decoding errors not detected by the more specific IP and TCP decoder options. For example, the decoder might detect a malformed data-link protocol header.

This option is ignored for threat defense routed, transparent, and inline interfaces. Packets that have header anomalies are always dropped. However, this option does apply to Threat Defense inline tap and passive interfaces.

To generate events and, in an inline deployment, drop offending packets for this option, you can enable any of the following rules:

<b>GID:SID</b>	<b>Generates an event if:</b>
116:467	The packet is smaller than the minimum size of a packet encapsulated with a Cisco FabricPath header.
116:468	The Cisco Meta Data (CMD) field in the header contains a header length smaller than the minimum size of a valid CMD header. The CMD field is associated with the Cisco Trustsec protocol.
116:469	The CMD field in the header contains an invalid field length.
116:470	The CMD field in the header contains an invalid Security Group Tag (SGT) option type.
116:471	The CMD field in the header contains an SGT with a reserved value.

You can also enable any packet decoder rule not associated with other packet decoder options.

# Configuring Packet Decoding

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

## Procedure

**Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

**Step 3** Click **Edit** (✎) next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 4** Click **Settings** in the navigation panel.

**Step 5** If **Packet Decoding** under **Transport/Network Layer Preprocessors** is disabled, click **Enabled**.

**Step 6** Click **Edit** (✎) next to **Packet Decoding**.

**Step 7** Enable or disable the options described in [Packet Decoder Options, on page 2898](#).

**Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

### What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable packet decoder rules (GID 116). For more information, see [Setting Intrusion Rule States, on page 2086](#) and [Packet Decoder Options, on page 2898](#).
- Deploy configuration changes.

# TCP Stream Preprocessing

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

The TCP protocol defines various states in which connections can exist. Each TCP connection is identified by the source and destination IP addresses and source and destination ports. TCP permits only one connection with the same connection parameter values to exist at a time.

## State-Related TCP Exploits

If you add the `flow` keyword with the `established` argument to an intrusion rule, the intrusion rules engine inspects packets matching the rule and the flow directive in stateful mode. Stateful mode evaluates only the traffic that is part of a TCP session established with a legitimate three-way handshake between a client and server.

You can configure the system so that the preprocessor detects any TCP traffic that cannot be identified as part of an established TCP session, although this is not recommended for typical use because the events would quickly overload the system and not provide meaningful data.

Attacks like `stick` and `snot` use the system's extensive rule sets and packet inspection against itself. These tools generate packets based on the patterns in Snort-based intrusion rules, and send them across the network. If your rules do not include the `flow` or `flowbits` keyword to configure them for stateful inspection, each packet will trigger the rule, overwhelming the system. Stateful inspection allows you to ignore these packets because they are not part of an established TCP session and do not provide meaningful information. When performing stateful inspection, the rules engine detects only those attacks that are part of an established TCP session, allowing analysts to focus on these rather than the volume of events caused by `stick` or `snot`.

## Target-Based TCP Policies

Different operating systems implement TCP in different ways. For example, Windows and some other operating systems require a TCP reset segment to have a precise TCP sequence number to reset a session, while Linux and other operating systems permit a range of sequence numbers. In this example, the stream preprocessor must understand exactly how the destination host will respond to the reset based on the sequence number. The stream preprocessor stops tracking the session only when the destination host considers the reset to be valid, so an attack cannot evade detection by sending packets after the preprocessor stops inspecting the stream. Other variations in TCP implementations include such things as whether an operating system employs a TCP timestamp option and, if so, how it handles the timestamp, and whether an operating system accepts or ignores data in a SYN packet.

Different operating systems also reassemble overlapping TCP segments in different ways. Overlapping TCP segments could reflect normal retransmissions of unacknowledged TCP traffic. They could also represent an attempt by an attacker, aware of the operating system of one of your hosts, to evade detection and exploit that host by sending malicious content hidden in overlapping segments. However, you can configure the stream preprocessor to be aware of the operating systems running on your monitored network segment so it reassembles segments the same way the target host does, allowing it to identify the attack.

You can create one or more TCP policies to tailor TCP stream inspection and reassembly to the different operating systems on your monitored network segment. For each policy, you identify one of thirteen operating system policies. You bind each TCP policy to a specific IP address or address block using as many TCP policies as you need to identify any or all of the hosts using a different operating system. The default TCP policy applies to any hosts on the monitored network that you do not identify in any other TCP policy, so there is no need to specify an IP address or address block for the default TCP policy.

Note that you can also use adaptive profile updates in a passive deployment to dynamically select target-based policies for the TCP stream preprocessor using host operating system information for the target host in a packet.

## TCP Stream Reassembly

The stream preprocessor collects and reassembles all the packets that are part of a TCP session's server-to-client communication stream, client-to-server communication stream, or both. This allows the rules engine to inspect the stream as a single, reassembled entity rather than inspecting only the individual packets that are part of a given stream.

Stream reassembly allows the rules engine to identify stream-based attacks, which it may not detect when inspecting individual packets. You can specify which communication streams the rules engine reassembles based on your network needs. For example, when monitoring traffic on your web servers, you may only want to inspect client traffic because you are much less likely to receive malicious traffic from your own web server.

In each TCP policy, you can specify a comma-separated list of ports to identify the traffic for the stream preprocessor to reassemble. If adaptive profile updates are enabled, you can also list services that identify traffic to reassemble, either as an alternative to ports or in combination with ports.

You can specify ports, services, or both. You can specify separate lists of ports for any combination of client ports, server ports, and both. You can also specify separate lists of services for any combination of client services, server services, and both. For example, assume that you wanted to reassemble the following:

- SMTP (port 25) traffic from the client
- FTP server responses (port 21)
- telnet (port 23) traffic in both directions

You could configure the following:

- For client ports, specify `23, 25`
- For server ports, specify `21, 23`

Or, instead, you could configure the following:

- For client ports, specify `25`
- For server ports, specify `21`
- For both ports, specify `23`

Additionally, consider the following example which combines ports and services and would be valid when adaptive profile updates are enabled:

- For client ports, specify `23`
- For client services, specify `smtp`

- For server ports, specify `21`
- For server services, specify `telnet`

Negating a port (for example, `!80`) can improve performance by preventing the TCP stream preprocessor from processing traffic for that port.

Although you can also specify `all` as the argument to provide reassembly for all ports, Cisco does **not** recommend setting ports to `all` because it may increase the amount of traffic inspected by this preprocessor and slow performance unnecessarily.

TCP reassembly automatically and transparently includes ports that you add to other preprocessors. However, if you do explicitly add ports to TCP reassembly lists that you have added to other preprocessor configurations, these additional ports are handled normally. This includes port lists for the following preprocessors:

- FTP/Telnet (server-level FTP)
- DCE/RPC
- HTTP Inspect
- SMTP
- Session Initiation Protocol
- POP
- IMAP
- SSL

Note that reassembling additional traffic types (client, server, both) increases resource demands.

## TCP Stream Preprocessing Options

If no preprocessor rule is mentioned in the following descriptions, the option is not associated with a preprocessor rule.

You can configure the following global TCP option:

### Packet Type Performance Boost

Enables ignoring TCP traffic for all ports and application protocols that are not specified in enabled intrusion rules, except when a TCP rule with both the source and destination ports set to `any` has a `flow` or `flowbits` option. This performance improvement could result in missed attacks.

You can configure the following options for each TCP policy.

### Network

Specifies the host IP addresses to which you want to apply the TCP stream reassembly policy.

You can specify a single IP address or address block. You can specify up to 255 total profiles including the default policy.

Note that the `default` setting in the default policy specifies all IP addresses on your monitored network segment that are not covered by another target-based policy. Therefore, you cannot and do not need to specify

an IP address or CIDR block/prefix length for the default policy, and you cannot leave this setting blank in another policy or use address notation to represent `any` (for example, `0.0.0.0/0` or `::/0`).

### Policy

Identifies the TCP policy operating system of the target host or hosts. If you select a policy other than **Mac OS**, the system removes the data from the synchronization (SYN) packets and disables event generation for rule 129:2. Note that enabling the inline normalization preprocessor **Remove Data on SYN** option also disables rule 129:2.

The following table identifies the operating system policies and the host operating systems that use each.

**Table 255: TCP Operating System Policies**

Policy	Operating Systems
First	unknown OS
Last	Cisco IOS
BSD	AIX FreeBSD OpenBSD
Linux	Linux 2.4 kernel Linux 2.6 kernel
Old Linux	Linux 2.2 and earlier kernel
Windows	Windows 98 Windows NT Windows 2000 Windows XP
Windows 2003	Windows 2003
Windows Vista	Windows Vista
Solaris	Solaris OS SunOS
IRIX	SGI Irix
HPUX	HP-UX 11.0 and later
HPUX 10	HP-UX 10.2 and earlier
Mac OS	Mac OS 10 (Mac OS X)

---

**Tip** The First operating system policy could offer some protection when you do not know the host operating system. However, it may result in missed attacks. You should edit the policy to specify the correct operating system if you know it.

---

### Timeout

The number of seconds between 1 and 86400 the intrusion rules engine keeps an inactive stream in the state table. If the stream is not reassembled in the specified time, the intrusion rules engine deletes it from the state table.

---

**Note** If your managed device is deployed on a segment where the network traffic is likely to reach the device's bandwidth limits, you should consider setting this value higher (for example, to 600 seconds) to lower the amount of processing overhead.

---

threat defense devices ignore this option and, instead, use the settings in the advanced access control **Threat Defense Service Policy**. See [Configure a Service Policy Rule, on page 2000](#) for more information.

### Maximum TCP Window

Specifies the maximum TCP window size between 1 and 1073725440 bytes allowed as specified by a receiving host. Setting the value to 0 disables checking for the TCP window size.

---

**Caution** The upper limit is the maximum window size permitted by RFC, and is intended to prevent an attacker from evading detection, but setting a significantly large maximum window size could result in a self-imposed denial of service.

---

When **Stateful Inspection Anomalies** is enabled, you can enable rule 129:6 to generate events and, in an inline deployment, drop offending packets for this option.

### Overlap Limit

Specifies that when the configured number between 0 (unlimited) and 255 of overlapping segments in a session has been detected, segment reassembly stops for that session and, if **Stateful Inspection Anomalies** is enabled and the accompanying preprocessor rule is enabled, an event is generated.

You can enable rule 129:7 to generate events and, in an inline deployment, drop offending packets for this option.

### Flush Factor

In an inline deployment, specifies that when a segment of decreased size has been detected subsequent to the configured number between 1 and 2048 of segments of non-decreasing size, the system flushes segment data accumulated for detection. Setting the value to 0 disables detection of this segment pattern, which can indicate the end of a request or response. Note that the Inline Normalization **Normalize TCP Payload** option must be enabled for this option to be effective.

### Stateful Inspection Anomalies

Detects anomalous behavior in the TCP stack. When accompanying preprocessor rules are enabled, this may generate many events if TCP/IP stacks are poorly written.

This option is ignored for threat defense routed and transparent interfaces.

You can enable the following rules to generate events and, in an inline deployment, drop offending packets for this option:

- 129:1 through 129:5
- 129:6 (Mac OS only)
- 129:8 through 129:11
- 129:13 through 129:19

Note the following:

- for rule 129:6 to trigger you must also configure a value greater than 0 for **Maximum TCP Window**.
- for rules 129:9 and 129:10 to trigger you must also enable **TCP Session Hijacking**.

### TCP Session Hijacking

Detects TCP session hijacking by validating the hardware (MAC) addresses detected from both sides of a TCP connection during the 3-way handshake against subsequent packets received on the session. When the MAC address for one side or the other does not match, if **Stateful Inspection Anomalies** is enabled and one of the two corresponding preprocessor rules are enabled, the system generates events.

This option is ignored for threat defense routed and transparent interfaces.

You can enable rules 129:9 and 129:10 to generate events and, in an inline deployment, drop offending packets for this option. Note that for either of these rules to generate events you must also enable **Stateful Inspection Anomalies**.

### Consecutive Small Segments

When **Stateful Inspection Anomalies** is enabled, specifies a maximum number of 1 to 2048 consecutive small TCP segments allowed. Setting the value to 0 disables checking for consecutive small segments.

You must set this option together with the **Small Segment Size** option, either disabling both or setting a non-zero value for both. Note that receiving as many as 2000 consecutive segments, even if each segment was 1 byte in length, without an intervening ACK would be far more consecutive segments than you would normally expect.

This option is ignored for threat defense routed and transparent interfaces.

You can enable rule 129:12 to generate events and, in an inline deployment, drop offending packets for this option.

### Small Segment Size

When **Stateful Inspection Anomalies** is enabled, specifies the 1 to 2048 byte TCP segment size that is considered small. Setting the value to 0 disables specifying the size of a small segment.

This option is ignored for threat defense routed and transparent interfaces.

You must set this option together with the **Consecutive Small Segments** option, either disabling both or setting a non-zero value for both. Note that a 2048 byte TCP segment is larger than a normal 1500 byte Ethernet frame.

### Ports Ignoring Small Segments

When **Stateful Inspection Anomalies**, **Consecutive Small Segments**, and **Small Segment Size** are enabled, specifies a comma-separated list of one or more ports that ignore small TCP segment detection. Leaving this option blank specifies that no ports are ignored.

This option is ignored for threat defense routed and transparent interfaces.

You can add any port to the list, but the list only affects ports specified in one of the **Perform Stream Reassembly on** port lists in the TCP policy.

### Require TCP 3-Way Handshake

Specifies that sessions are treated as established only upon completion of a TCP three-way handshake. Disable this option to increase performance, protect from SYN flood attacks, and permit operation in a partially asynchronous environment. Enable it to avoid attacks that attempt to generate false positives by sending information that is not part of an established TCP session.

You can enable rule 129:20 to generate events and, in an inline deployment, drop offending packets for this option.

### 3-Way Handshake Timeout

Specifies the number of seconds between 0 (unlimited) and 86400 (twenty-four hours) by which a handshake must be completed when **Require TCP 3-Way Handshake** is enabled. You must enable **Require TCP 3-Way Handshake** to modify the value for this option.

For Firepower Software devices and threat defense inline, inline tap, and passive interfaces, the default is 0. For threat defense routed and transparent interfaces, the timeout is always 30 seconds; the value configured here is ignored.

### Packet Size Performance Boost

Sets the preprocessor to not queue large packets in the reassembly buffer. This performance improvement could result in missed attacks. Disable this option to protect against evasion attempts using small packets of one to twenty bytes. Enable it when you are assured of no such attacks because all traffic is comprised of very large packets.

### Legacy Reassembly

Sets the stream preprocessor to emulate the deprecated Stream 4 preprocessor when reassembling packets, which lets you compare events reassembled by the stream preprocessor to events based on the same data stream reassembled by the Stream 4 preprocessor.

### Asynchronous Network

Specifies whether the monitored network is an asynchronous network, that is, a network where the system sees only half the traffic. When this option is enabled, the system does not reassemble TCP streams to increase performance.

This option is ignored for threat defense routed and transparent interfaces.

### Perform Stream Reassembly on Client Ports

Enables stream reassembly based on ports for the client side of the connection. In other words, it reassembles streams destined for web servers, mail servers, or other IP addresses typically defined by the IP addresses specified in \$HOME\_NET. Use this option when you expect malicious traffic to originate from clients.

This option is ignored for threat defense routed and transparent interfaces.

### Perform Stream Reassembly on Client Services

Enables stream reassembly based on services for the client side of the connection. Use this option when you expect malicious traffic to originate from clients.

At least one client detector must be enabled for each client service you select. By default, all Cisco-provided detectors are activated. If no detector is enabled for an associated client application, the system automatically enables all Cisco-provided detectors for the application; if none exist, the system enables the most recently modified user-defined detector for the application.

This feature requires Protection and Control licenses.

This option is ignored for threat defense routed and transparent interfaces.

### Perform Stream Reassembly on Server Ports

Enables stream reassembly based on ports for the server side of the connection only. In other words, it reassembles streams originating from web servers, mail servers, or other IP addresses typically defined by the IP addresses specified in \$EXTERNAL\_NET. Use this option when you want to watch for server side attacks. You can disable this option by not specifying ports.

This option is ignored for threat defense routed and transparent interfaces.

---

**Note** For a thorough inspection of a service, add the service name in the Perform Stream Reassembly on Server Services field in addition to adding the port number in the Perform Stream Reassembly on Server Ports field. For example, add 'HTTP' service in the Perform Stream Reassembly on Server Services field to inspect HTTP service in addition to adding port number 80 in the Perform Stream Reassembly on Server Ports field.

---

### Perform Stream Reassembly on Server Services

Enables stream reassembly based on services for the server side of the connection only. Use this option when you want to watch for server side attacks. You can disable this option by not specifying services.

At least one detector must be enabled. By default, all Cisco-provided detectors are activated. If no detector is enabled for a service, the system automatically enables all Cisco-provided detectors for the associated application protocol; if none exist, the system enables the most recently modified user-defined detector for the application protocol.

This feature requires Protection and Control licenses.

This option is ignored for threat defense routed and transparent interfaces.

### Perform Stream Reassembly on Both Ports

Enables stream reassembly based on ports for both the client and server side of the connection. Use this option when you expect that malicious traffic for the same ports may travel in either direction between clients and servers. You can disable this option by not specifying ports.

This option is ignored for threat defense routed and transparent interfaces.

### Perform Stream Reassembly on Both Services

Enables stream reassembly based on services for both the client and server side of the connection. Use this option when you expect that malicious traffic for the same services may travel in either direction between clients and servers. You can disable this option by not specifying services.

At least one detector must be enabled. By default, all Cisco-provided detectors are activated. If no detector is enabled for an associated client application or application protocol, the system automatically enables all Cisco-provided detectors for the application or application protocol; if none exist, the system enables the most recently modified user-defined detector for the application or application protocol.

This feature requires Protection and Control licenses.

This option is ignored for threat defense routed and transparent interfaces.

### Troubleshooting Options: Maximum Queued Bytes

Support might ask you during a troubleshooting call to specify the amount of data that can be queued on one side of a TCP connection. A value of 0 specifies an unlimited number of bytes.

---

**Caution** Changing the setting for this troubleshooting option will affect performance and should be done only with Support guidance.

---

### Troubleshooting Options: Maximum Queued Segments

Support might ask you during a troubleshooting call to specify the maximum number of bytes of data segments that can be queued on one side of a TCP connection. A value of 0 specifies an unlimited number of data segment bytes.

---

**Caution** Changing the setting for this troubleshooting option will affect performance and should be done only with Support guidance.

---

# Configuring TCP Stream Preprocessing

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

## Before you begin

- Confirm that networks you want to identify in a custom target-based policy match or are a subset of the networks, zones, and VLANs handled by its parent network analysis policy. See [Advanced Settings for Network Analysis Policies, on page 2751](#) for more information.

## Procedure

**Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

**Step 3** Click **Edit** (✎) next to the policy you want to modify.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 4** Click **Settings** in the navigation panel on the left.

**Step 5** If the **TCP Stream Configuration** setting is disabled under **Transport/Network Layer Preprocessors**, enable it by clicking **Enabled**.

**Step 6** Click **Edit** (✎) next to **TCP Stream Configuration**.

**Step 7** Check or clear the **Packet Type Performance Boost** check box in the **Global Settings** section.

**Step 8** You can:

- Add a target-based policy — Click **Add** (+) next to **Hosts** in the Targets section. Specify one or more IP addresses in the **Host Address** field. You can specify a single IP address or address block. You can create a total of 255 target-based policies including the default policy. When done, click **OK**.
- Edit an exist target-based policy — Under **Hosts**, click on the address for the policy you want to edit, or click default to edit the **default** configuration values.
- Modify the TCP Stream Preprocessing options — See [TCP Stream Preprocessing Options, on page 2905](#).

**Caution** Do not modify **Maximum Queued Bytes** or **Maximum Queued Segments** unless instructed to do so by Support.

**Tip** To modify stream reassembly settings based on client, server, or both services, click inside the field you want to modify or click **Edit** next to the field. Use arrow to move services between the **Available** and **Enabled** lists in the pop-up window, then click **OK**.

- Delete an existing target-based policy — Click **Delete** (  ) next to the policy you want to remove.

**Step 9** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable TCP Stream preprocessor rules (GID 129). For more information, see [Setting Intrusion Rule States, on page 2086](#) and [TCP Stream Preprocessing Options, on page 2905](#).
- Deploy configuration changes.

# UDP Stream Preprocessing

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

UDP stream preprocessing occurs when the rules engine processes packets against a UDP rule that includes the `flow` keyword using any of the following arguments:

- `Established`
- `To Client`
- `From Client`
- `To Server`
- `From Server`

UDP data streams are not typically thought of in terms of *sessions*. UDP is a connectionless protocol that does not provide a means for two endpoints to establish a communication channel, exchange data, and close the channel. However, the stream preprocessor uses the source and destination IP address fields in the encapsulating IP datagram header and the port fields in the UDP header to determine the direction of flow and identify a session. A session ends when a configurable timer is exceeded, or when either endpoint receives an ICMP message that the other endpoint is unreachable or the requested service is unavailable.

Note that the system does not generate events related to UDP stream preprocessing; however, you can enable related packet decoder rules to detect UDP protocol header anomalies.

**Related Topics**

[TCP Header Values and Stream Size](#), on page 2158

## UDP Stream Preprocessing Options

**Timeout**

Specifies the number of seconds the preprocessor keeps an inactive stream in the state table. If additional datagrams are not seen in the specified time, the preprocessor deletes the stream from the state table.

Threat Defense devices ignore this option and, instead, use the settings in the advanced access control **Threat Defense Service Policy**. See [Configure a Service Policy Rule, on page 2000](#) for more information.

**Packet Type Performance Boost**

Sets to preprocessor to ignore UDP traffic for all ports and application protocols that are not specified in enabled rules, except when a UDP rule with both the source and destination ports set to `any` has a `flow` or `flowbits` option. This performance improvement could result in missed attacks.

## Configuring UDP Stream Preprocessing

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

**Procedure**

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **UDP Stream Configuration** under **Transport/Network Layer Preprocessors** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **UDP Stream Configuration**.
- Step 7** Set the options described in [UDP Stream Preprocessing Options, on page 2914](#).
- Step 8** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, cached changes since the last commit are discarded if you edit a different policy.

---

**What to do next**

- If you want to generate events and, in an inline deployment, drop offending packets, enable related packet decoder rules (GID 116). For more information, see [Setting Intrusion Rule States, on page 2086](#) and [The Packet Decoder, on page 2898](#).
- Deploy configuration changes.

## CHAPTER 108

# Specific Threat Detection

---

The following topics explain how to use preprocessors in a network analysis policy to detect specific threats:

- [Introduction to Specific Threat Detection, on page 2917](#)
- [License Requirements for Specific Threat Detection, on page 2917](#)
- [Requirements and Prerequisites for Specific Threat Detection, on page 2918](#)
- [Back Orifice Detection, on page 2918](#)
- [Portscan Detection, on page 2920](#)
- [Rate-Based Attack Prevention, on page 2927](#)

## Introduction to Specific Threat Detection

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

You can use several preprocessors in a network analysis policy to detect specific threats to your monitored network, such as Back Orifice attacks, several portscan types, and rate-based attacks that attempt to overwhelm your network with excessive traffic. When the GID Signatures specific to pre-processor is enabled, the Network Analysis Policy on Web will show disabled. However, the pre-processors will be turned on device using the available default settings.

You can also use sensitive data detection, which you configure in an intrusion policy, to detect unsecured transmission of sensitive numerical data.

## Back Orifice Detection

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

The system provides a preprocessor that detects the existence of the Back Orifice program. This program can be used to gain admin access to your Windows hosts.

## Back Orifice Detection Preprocessor

The Back Orifice preprocessor analyzes UDP traffic for the Back Orifice magic cookie, "`*!*QWTY?`", which is located in the first eight bytes of the packet and is XOR-encrypted.

The Back Orifice preprocessor has a configuration page, but no configuration options. When it is enabled, you must also enable preprocessor rules for the preprocessor to generate events and, in an inline deployment, drop offending packets.

**Table 256: Back Orifice GID:SDs**

Preprocessor rule GID:SID	Description
105:1	Back Orifice traffic detected
105:2	Back Orifice client traffic detected
105:3	Back Orifice server traffic detected
105:4	Back Orifice Snort buffer attack detected

# Detecting Back Orifice

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

## Procedure

- 
- Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.
- Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.
- Step 2** Click **Snort 2 Version** next to the policy you want to edit.
- Step 3** Click **Edit** (✎) next to the policy you want to edit.
- If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 4** Click **Settings** in the navigation panel.
- Step 5** If **Back Orifice Detection** under **Specific Threat Detection** is disabled, click **Enabled**.
- Note** There are no user-configurable options for Back Orifice.
- Step 6** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.
- 

### What to do next

- If you want to generate events and, in an inline deployment, drop offending packets, enable Back Orifice Detection rules 105:1, 105:2, 105:3, or 105:4. For more information, see [Intrusion Rule States, on page 2085](#) and [Back Orifice Detection Preprocessor, on page 2918](#).
- Deploy configuration changes.

# Portscan Detection

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

A portscan is a form of network reconnaissance that is often used by attackers as a prelude to an attack. In a portscan, an attacker sends specially crafted packets to a targeted host. By examining the packets that the host responds with, the attacker can often determine which ports are open on the host and, either directly or by inference, which application protocols are running on these ports.

By itself, a portscan is not evidence of an attack. In fact, some of the portscanning techniques used by attackers can also be employed by legitimate users on your network. Cisco's portscan detector is designed to help you determine which portscans might be malicious by detecting patterns of activity.

**Attention** Devices load-balance inspection across internal resources. If portscan detection is not working as expected, you may need to configure the sensitivity level as **High**.

We strongly recommend that you upgrade to Snort 3 and use the portscan feature introduced in version 7.2.0. For more details, see the [Cisco Secure Firewall Management Center Snort 3 Configuration Guide](#) and the [Snort 3 Inspector Reference](#).

## Portscan Types, Protocols, and Filtered Sensitivity Levels

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

Attackers are likely to use several methods to probe your network. Often they use different protocols to draw out different responses from a target host, hoping that if one type of protocol is blocked, another may be available.

**Table 257: Protocol Types**

Protocol	Description
TCP	Detects TCP probes such as SYN scans, ACK scans, TCP connect() scans, and scans with unusual flag combinations such as Xmas tree, FIN, and NULL
UDP	Detects UDP probes such as zero-byte UDP packets
ICMP	Detects ICMP echo requests (pings)
IP	Detects IP protocol scans. These scans differ from TCP and UDP scans because the attacker, instead of looking for open ports, is trying to discover which IP protocols are supported on a target host.

Portscans are generally divided into four types based on the number of targeted hosts, the number of scanning hosts, and the number of ports that are scanned.

**Table 258: Portscan Types**

Type	Description
Portscan Detection	<p>A one-to-one portscan in which an attacker uses one or a few hosts to scan multiple ports on a single target host.</p> <p>One-to-one portscans are characterized by:</p> <ul style="list-style-type: none"> <li>• a low number of scanning hosts</li> <li>• a single host that is scanned</li> <li>• a high number of ports scanned</li> </ul> <p>This option detects TCP, UDP, and IP portscans.</p>
Port Sweep	<p>A one-to-many portsweep in which an attacker uses one or a few hosts to scan a single port on multiple target hosts.</p> <p>Portsweeps are characterized by:</p> <ul style="list-style-type: none"> <li>• a low number of scanning hosts</li> <li>• a high number of scanned hosts</li> <li>• a low number of unique ports scanned</li> </ul> <p>This option detects TCP, UDP, ICMP, and IP portsweeps.</p>
Decoy Portscan	<p>A one-to-one portscan in which the attacker mixes spoofed source IP addresses with the actual scanning IP address.</p> <p>Decoy portscans are characterized by:</p> <ul style="list-style-type: none"> <li>• a high number of scanning hosts</li> <li>• a low number of ports that are scanned only once</li> <li>• a single (or a low number of) scanned hosts</li> </ul> <p>The decoy portscan option detects TCP, UDP, and IP protocol portscans.</p>
Distributed Portscan	<p>A many-to-one portscan in which multiple hosts query a single host for open ports.</p> <p>Distributed portscans are characterized by:</p> <ul style="list-style-type: none"> <li>• a high number of scanning hosts</li> <li>• a high number of ports that are scanned only once</li> <li>• a single (or a low number of) scanned hosts</li> </ul> <p>The distributed portscan option detects TCP, UDP, and IP protocol portscans.</p>

The information that the portscan detector learns about a probe is largely based on seeing negative responses from the probed hosts. For example, when a web client tries to connect to a web server, the client uses port 80/tcp and the server can be counted on to have that port open. However, when an attacker probes a server, the attacker does not know in advance if it offers web services. When the portscan detector sees a negative response (that is, an ICMP unreachable or TCP RST packet), it records the response as a potential portscan. The process is more difficult when the targeted host is on the other side of a device such as a firewall or router that filters negative responses. In this case, the portscan detector can generate *filtered* portscan events based on the sensitivity level that you select.

Table 259: Sensitivity Levels

Level	Description
Low	<p>Detects only negative responses from targeted hosts. Select this sensitivity level to suppress false positives, but keep in mind that some types of portscans (slow scans, filtered scans) might be missed.</p> <p>This level uses the shortest time window for portscan detection.</p>
Medium	<p>Detects portscans based on the number of connections to a host, which means that you can detect filtered portscans. However, very active hosts such as network address translators and proxies may generate false positives.</p> <p>Note that you can add the IP addresses of these active hosts to the <b>Ignore Scanned</b> field to mitigate this type of false positive.</p> <p>This level uses a longer time window for portscan detection.</p>
High	<p>Detects portscans based on a time window, which means that you can detect time-based portscans. However, if you use this option, you should be careful to tune the detector over time by specifying IP addresses in the <b>Ignore Scanned</b> and <b>Ignore Scanner</b> fields.</p> <p>This level uses a much longer time window for portscan detection.</p>

## Portscan Event Generation

When portscan detection is enabled, you must enable rules with Generator ID (GID) 122 and a Snort ID (SID) from among SIDs 1 through 27 to detect the various portscans and portsweeps.

**Note** For events generated by the portscan connection detector, the protocol number is set to 255. Because portscan does not have a specific protocol associated with it by default, the Internet Assigned Numbers Authority (IANA) does not have a protocol number assigned to it. IANA designates 255 as a reserved number, so that number is used in portscan events to indicate that there is not an associated protocol for the event.

Table 260: Portscan Detection SIDs (GID 122)

Portscan Type	Protocol	Sensitivity Level	Preprocessor Rule SID
Portscan Detection	TCP	Low	1
	UDP	Medium or High	5
	ICMP	Low	17
	IP	Medium or High	21
		Low	Does not generate events.
		Medium or High	Does not generate events.
		Low	9
		Medium or High	13
Port Sweep	TCP	Low	3, 27
	UDP	Medium or High	7
	ICMP	Low	19
	IP	Medium or High	23
		Low	25
		Medium or High	26
		Low	11
		Medium or High	15
Decoy Portscan	TCP	Low	2
	UDP	Medium or High	6
	ICMP	Low	18
	IP	Medium or High	22
		Low	Does not generate events.
		Medium or High	Does not generate events.
		Low	10
		Medium or High	14

Portscan Type	Protocol	Sensitivity Level	Preprocessor Rule SID
Distributed Portscan	TCP	Low	4
	UDP	Medium or High	8
	ICMP	Low	20
	IP	Medium or High	24
		Low	Does not generate events.
		Medium or High	Does not generate events.
		Low	12
		Medium or High	16

## Portscan Event Packet View

When you enable the accompanying preprocessor rules, the portscan detector generates intrusion events that you can view just as you would any other intrusion event. However, the information presented on the packet view is different from the other types of intrusion events.

Begin by using the intrusion event views to drill down to the packet view for a portscan event. Note that you cannot download a portscan packet because single portscan events are based on multiple packets; however, the portscan packet view provides all usable packet information.

For any IP address, you can click the address to view the context menu and select **whois** to perform a lookup on the IP address or **View Host Profile** to view the host profile for that host.

**Table 261: Portscan Packet View**

Information	Description
Device	The device that detected the event.
Time	The time when the event occurred.
Message	The event message generated by the preprocessor.
Source IP	The IP address of the scanning host.
Destination IP	The IP address of the scanned host.
Priority Count	The number of negative responses (for example, TCP RSTs and ICMP unreachables) from the scanned host. The higher the number of negative responses, the higher the priority count.
Connection Count	The number of active connections on the hosts. This value is more accurate for connection-based scans such as TCP and IP.

Information	Description
IP Count	The number of times that the IP addresses that contact the scanned host changes. For example, if the first IP address is 10.1.1.1, the second IP is 10.1.1.2, and the third IP is 10.1.1.1, then the IP count is 3.  This number is less accurate for active hosts such as proxies and DNS servers.
Scanner/Scanned IP Range	The range of IP addresses for the scanned hosts or the scanning hosts, depending on the type of scan. For portsweeps, this field shows the IP range of scanned hosts. For portscans, this shows the IP range of the scanning hosts.
Port/Proto Count	For TCP and UDP portscans, the number of times that the port being scanned changes. For example, if the first port scanned is 80, the second port scanned is 8080, and the third port scanned is again 80, then the port count is 3.  For IP protocol portscans, the number of times that the protocol being used to connect to the scanned host changes.
Port/Proto Range	For TCP and UDP portscans, the range of the ports that were scanned.  For IP protocol portscans, the range of IP protocol numbers that were used to attempt to connect to the scanned host.
Open Ports	The TCP ports that were open on the scanned host. This field appears only when the portscan detects one or more open ports.

## Configuring Portscan Detection

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

The portscan detection configuration options allow you to finely tune how the portscan detector reports scan activity.

### Procedure

**Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

**Step 3** Click **Edit** (✎) next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Step 4** Click **Settings**.
- Step 5** If **Portscan Detection** under **Specific Threat Detection** is disabled, click **Enabled**.
- Step 6** Click **Edit** (✎) next to **Portscan Detection**.
- Step 7** In the **Protocol** field, specify protocols to enable.
- Note** You must ensure TCP stream processing is enabled to detect scans over TCP, and that UDP stream processing is enabled to detect scans over UDP.
- Step 8** In the **Scan Type** field, specify portscan types you want to detect.
- Step 9** Choose a level from the **Sensitivity Level** list; see [Portscan Types, Protocols, and Filtered Sensitivity Levels, on page 2920](#).
- Step 10** If you want to monitor specific hosts for signs of portscan activity, enter the host IP address in the **Watch IP** field.
- You can specify a single IP address or address block, or a comma-separated lists of either or both. Leave the field blank to watch all network traffic.
- Step 11** If you want to ignore hosts as scanners, enter the host IP address in the **Ignore Scanners** field.
- You can specify a single IP address or address block, or a comma-separated lists of either or both.
- Step 12** If you want to ignore hosts as targets of a scan, enter the host IP address in the **Ignore Scanned** field.
- You can specify a single IP address or address block, or a comma-separated lists of either or both.
- Tip** Use the **Ignore Scanners** and **Ignore Scanned** fields to indicate hosts on your network that are especially active. You may need to modify this list of hosts over time.
- Step 13** If you want to discontinue monitoring of sessions picked up in mid-stream, clear the **Detect Ack Scans** check box.
- Note** Detection of mid-stream sessions helps to identify ACK scans, but may cause false events, particularly on networks with heavy traffic and dropped packets.
- Step 14** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.
- If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- If you want portscan detection to detect various portscans and portsweeps, enable rules 122:1 through 122:27. For more information, see [Intrusion Rule States, on page 2085](#) and [Portscan Event Generation, on page 2922](#).
- Deploy configuration changes.

# Rate-Based Attack Prevention

---

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

---

Rate-based attacks are attacks that depend on frequency of connection or repeated attempts to perpetrate the attack. You can use rate-based detection criteria to detect a rate-based attack as it occurs and respond to it when it happens, then return to normal detection settings after it stops.

You can configure your network analysis policy to include rate-based filters that detect excessive activity directed at hosts on your network. You can use this feature on managed devices deployed in inline mode to block rate-based attacks for a specified time, then revert to only generating events and not drop traffic.

The SYN attack prevention option helps you protect your network hosts against SYN floods. You can protect individual hosts or whole networks based on the number of packets seen over a period of time. If your device is deployed passively, you can generate events. If your device is placed inline, you can also drop the malicious packets. After the timeout period elapses, if the rate condition has stopped, the event generation and packet dropping stops.

For example, you could configure a setting to allow a maximum number of SYN packets from any one IP address, and block further connections from that IP address for 60 seconds.

You can also limit TCP/IP connections to or from hosts on your network to prevent denial of service (DoS) attacks or excessive activity by users. When the system detects the configured number of successful connections to or from a specified IP address or range of addresses, it generates events on additional connections. The rate-based event generation continues until the timeout period elapses without the rate condition occurring. In an inline deployment you can choose to drop packets until the rate condition times out.

For example, you could configure a setting to allow a maximum of 10 successful simultaneous connections from any one IP address, and block further connections from that IP address for 60 seconds.

---

**Note** Devices load-balance inspection across internal resources. When you configure rate-based attack prevention, you configure the triggering rate per resource, not per device. If rate-based attack prevention is not working as expected, you may need to lower the triggering rate. It triggers alert, if users send too many connection attempts within prescribed time intervals. Hence it is recommended to rate limit the rule. For help determining the correct rate, contact Support.

---

The following diagram shows an example where an attacker is attempting to access a host. Repeated attempts to find a password trigger a rule which has rate-based attack prevention configured. The rate-based settings change the rule attribute to Drop and Generate Events after rule matches occur five times in a 10-second span. The new rule attribute times out after 15 seconds.

After the timeout, note that packets are still dropped in the rate-based sampling period that follows. If the sampled rate is above the threshold in the current or previous sampling period, the new action continues. The new action reverts to generating events only after a sampling period completes where the sampled rate is below the threshold rate.

### Related Topics

[Dynamic Intrusion Rule States](#), on page 2092

## Rate-Based Attack Prevention Examples

The `detection_filter` keyword and the thresholding and suppression features provide other ways to filter either the traffic itself or the events that the system generates. You can use rate-based attack prevention alone or in any combination with thresholding, suppression, or the `detection_filter` keyword.

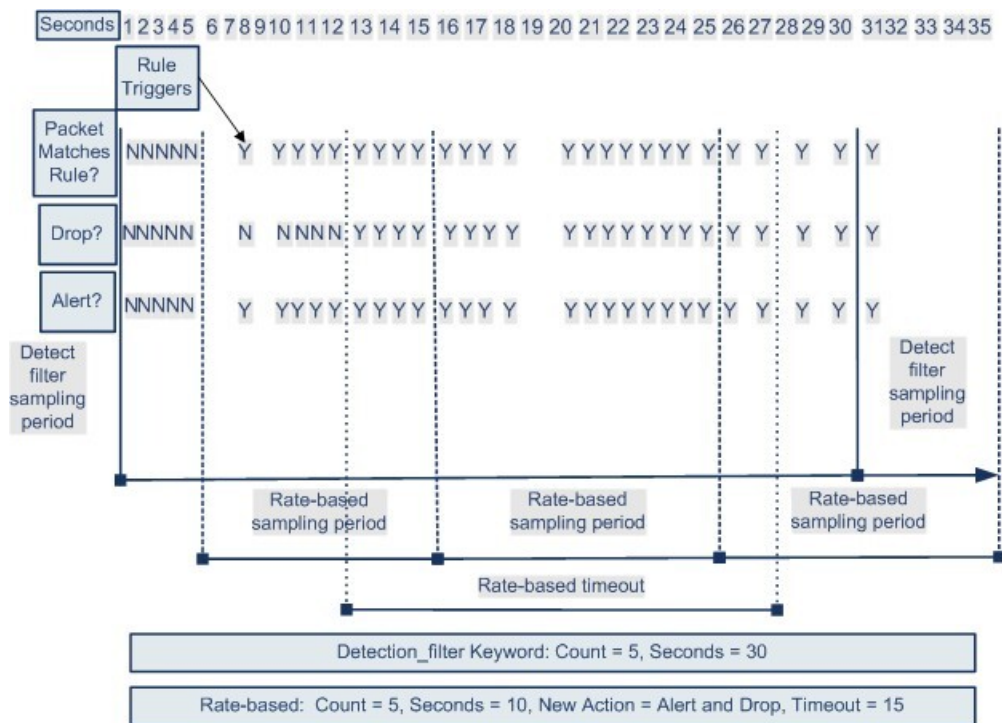

The `detection_filter` keyword, thresholding or suppression, and rate-based criteria may all apply to the same traffic. When you enable suppression for a rule, events are suppressed for the specified IP addresses even if a rate-based change occurs.

### `detection_filter` Keyword Example

The following example shows an attacker attempting a brute-force login. Repeated attempts to find a password trigger a rule that also includes the `detection_filter` keyword, with a count set to 5. This rule has rate-based attack prevention configured. The rate-based settings change the rule attribute to Drop and Generate Events for 20 seconds when there are five hits on the rule in a 10-second span.

As shown in the diagram, the first five packets matching the rule do not generate events because the rule does not trigger until the rate exceeds the rate indicated by the `detection_filter` keyword. After the rule triggers, event notification begins, but the rate-based criteria do not trigger the new action of Drop and Generate Events until five more packets pass.

After the rate-based criteria are met, events are generated and the packets are dropped until the rate-based timeout period expires and the rate falls below the threshold. After twenty seconds elapse, the rate-based action times out. After the timeout, note that packets are still dropped in the rate-based sampling period that follows. Because the sampled rate is above the threshold rate in the previous sampling period when the timeout happens, the rate-based action continues.

Note that although the example does not depict this, you can use the Drop and Generate Events rule state in combination with the `detection_filter` keyword to start dropping traffic when hits for the rule reach the specified rate. When deciding whether to configure rate-based settings for a rule, consider whether setting the rule to Drop and Generate Events and including the `detection_filter` keyword would achieve the same result, or whether you want to manage the rate and timeout settings in the intrusion policy.

**Related Topics**

[Intrusion Rule States](#), on page 2085

**Dynamic Rule State Thresholding or Suppression Example**

The following example shows an attacker attempting a brute-force login. Repeated attempts to find a password trigger a rule that has rate-based attack prevention configured. The rate-based settings change the rule attribute to Drop and Generate Events for 15 seconds when there are five hits on the rule in 10 seconds. In addition, a limit threshold limits the number of events the rule can generate to 10 events in 23 seconds.

As shown in the diagram, the rule generates events for the first five matching packets. After five packets, the rate-based criteria trigger the new action of Drop and Generate Events, and for the next five packets the rule generates events and the system drops the packet. After the tenth packet, the limit threshold has been reached, so for the remaining packets the system does not generate events but does drop the packets.

After the timeout, note that packets are still dropped in the rate-based sampling period that follows. If the sampled rate is above the threshold rate in the current or previous sampling period, the new action continues. The new action reverts to Generate Events only after a sampling period completes where the sampled rate is below the threshold rate.

372/03

Note that although it is not shown in this example, if a new action triggers because of rate-based criteria *after* a threshold has been reached, the system generates a single event to indicate the change in action. So, for example, when the limit threshold of 10 is reached and the system stops generating events and the action changes from Generate Events to Drop and Generate Events on the 14th packet, the system generates an eleventh event to indicate the change in action.

## Policy-Wide Rate-Based Detection and Thresholding or Suppression Example

The following example shows an attacker attempting denial of service (DoS) attacks on hosts in your network. Many simultaneous connections to hosts from the same sources trigger a policy-wide Control Simultaneous Connections setting. The setting generates events and drops malicious traffic when there are five connections from one source in 10 seconds. In addition, a global limit threshold limits the number of events any rule or setting can generate to 10 events in 20 seconds.

As shown in the diagram, the policy-wide setting generates events for the first ten matching packets and drops the traffic. After the tenth packet, the limit threshold is reached, so for the remaining packets no events are generated but the packets are dropped.

After the timeout, note that packets are still dropped in the rate-based sampling period that follows. If the sampled rate is above the threshold rate in the current or previous sampling period, the rate-based action of generating events and dropping traffic continues. The rate-based action stops only after a sampling period completes where the sampled rate is below the threshold rate.

372200

Note that although it is not shown in this example, if a new action triggers because of rate-based criteria *after* a threshold has been reached, the system generates a single event to indicate the change in action. So, for example, if the limit threshold of 10 has been reached and the system stops generating events and the action changes to Drop and Generate events on the 14th packet, the system generates an eleventh event to indicate the change in action.

### Rate-Based Detection with Multiple Filtering Methods Example

The following example shows an attacker attempting a brute force login, and describes a case where a `detection_filter` keyword, rate-based filtering, and thresholding interact. Repeated attempts to find a password trigger a rule which includes the `detection_filter` keyword, with a count set to 5. This rule also has rate-based attack prevention settings that change the rule attribute to Drop and Generate Events for 30 seconds when there are five rule hits in 15 seconds. In addition, a limit threshold limits the rule to 10 events in 30 seconds.

As shown in the diagram, the first five packets matching the rule do not cause event notification because the rule does not trigger until the rate indicated in the `detection_filter` keyword is exceeded. After the rule triggers, event notification begins, but the rate-based criteria do not trigger the new action of Drop and Generate Events until five more packets pass. After the rate-based criteria are met, the system generates events for packets 11-15 and drops the packets. After the fifteenth packet, the limit threshold has been reached, so for the remaining packets the system does not generate events but does drop the packets.

After the rate-based timeout, note that packets are still dropped in the rate-based sampling period that follows. Because the sampled rate is above the threshold rate in the previous sampling period, the new action continues.

## Rate-Based Attack Prevention Options and Configuration

Rate-based attack prevention identifies abnormal traffic patterns and attempts to minimize the impact of that traffic on legitimate requests. Rate-based attacks usually have one of the following characteristics:

- Any traffic containing excessive incomplete connections to hosts on the network, indicating a SYN flood attack
- Any traffic containing excessive complete connections to hosts on the network, indicating a TCP/IP connection flood attack
- Excessive rule matches in traffic going to a particular destination IP address or addresses or coming from a particular source IP address or addresses
- Excessive matches for a particular rule across all traffic

In a network analysis policy, you can either configure SYN flood or TCP/IP connection flood detection for the entire policy; in an intrusion policy, you can set rate-based filters for individual intrusion or preprocessor rules. Note that you cannot manually add a rate-based filter to GID 135 rules or modify their rule state. Rules with GID 135 use the client as the source value and the server as the destination value.

When **SYN Attack Prevention** is enabled, rule 135:1 triggers if a defined rate condition is exceeded.

When **Control Simultaneous Connections** is enabled, rule 135:2 triggers if a defined rate condition is exceeded, and rule 135:3 triggers if a session closes or times out.

---

**Note** Devices load-balance inspection across internal resources. When you configure rate-based attack prevention, you configure the triggering rate per resource, not per device. If rate-based attack prevention is not working as expected, you may need to lower the triggering rate. It triggers alert, if users send too many connection attempts within prescribed time intervals. Hence it is recommended to rate limit the rule. For help determining the correct rate, contact Support.

---

Each rate-based filter contains several components:

- For policy-wide or rule-based source or destination settings, the network address designation
- The rule matching rate, which you configure as a count of rule matches within a specific number of seconds
- A new action to be taken when the rate is exceeded

When you set a rate-based setting for the entire policy, the system generates events when it detects a rate-based attack, and can drop the traffic in an inline deployment. When setting rate-based actions for individual rules, you have three available actions: Generate Events, Drop and Generate Events, and Disable.

- The duration of the action, which you configure as a timeout value

Note that when started, the new action occurs until the timeout is reached, even if the rate falls below the configured rate during that time period. When the timeout period expires, if the rate has fallen below the threshold, the action for the rule reverts to the action initially configured for the rule. For policy-wide settings, the action reverts to the action of each rule the traffic matches or stops if it does not match any rules.

You can configure rate-based attack prevention in an inline deployment to block attacks, either temporarily or permanently. Without rate-based configuration, rules set to Generate Events create events, but the system does not drop packets for those rules. However, if the attack traffic matches rules that have rate-based criteria configured, the rate action may cause packet dropping to occur for the period of time that the rate action is active, even if those rules are not initially set to Drop and Generate Events.

---

**Note** Rate-based actions cannot enable disabled rules or drop traffic that matches disabled rules. However, if you set a rate-based filter at the policy level, you can generate events on or generate events on and drop traffic that contains an excessive number of SYN packets or SYN/ACK interactions within a designated time period.

---

You can define multiple rate-based filters on the same rule. The first filter listed in the intrusion policy has the highest priority. Note that when two rate-based filter actions conflict, the system implements the action of the first rate-based filter. Similarly, policy-wide rate-based filters override rate-based filters set on individual rules if the filters conflict.

#### Related Topics

[Setting a Dynamic Rule State from the Rules Page](#), on page 2094

## Rate-Based Attack Prevention, Detection Filtering, and Thresholding or Suppression

The `detection_filter` keyword prevents a rule from triggering until a threshold number of rule matches occur within a specified time. When a rule includes the `detection_filter` keyword, the system tracks the number of incoming packets matching the pattern in the rule per timeout period. The system can count hits

for that rule from particular source or destination IP addresses. After the rate exceeds the rate in the rule, event notification for that rule begins.

You can use thresholding and suppression to reduce excessive events by limiting the number of event notifications for a rule, a source, or destination, or by suppressing notifications altogether for that rule. You can also configure a global rule threshold that applies to each rule that does not have an overriding specific threshold.

If you apply suppression to a rule, the system suppresses event notifications for that rule for all applicable IP addresses even if a rate-based action change occurs because of a policy-wide or rule-specific rate-based setting.

## Configuring Rate-Based Attack Prevention

**Note** This section applies to Snort 2 preprocessors. For information on Snort 3 inspectors, see <https://www.cisco.com/go/snort3-inspectors>.

You can configure rate-based attack prevention at the policy level to stop SYN flood attacks. You can also stop excessive connections from a specific source or to a specific destination.

### Procedure

**Step 1** Choose **Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**.

**Note** If your custom user role limits access to the first path listed here, use the second path to access the policy.

**Step 2** Click **Snort 2 Version** next to the policy you want to edit.

**Step 3** Click **Edit** (✎) next to the policy you want to edit.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 4** Click **Settings**.

**Step 5** If **Rate-Based Attack Prevention** under **Specific Threat Detection** is disabled, click **Enabled**.

**Step 6** Click **Edit** (✎) next to **Rate-Based Attack Prevention**.

**Step 7** You have two choices:

- To prevent incomplete connections intended to flood a host, click **Add** under **SYN Attack Prevention**.
- To prevent excessive numbers of connections, click **Add** under **Control Simultaneous Connections**.

**Step 8** Specify how you want to track traffic:

- To track all traffic from a specific source or range of sources, choose **Source** from the **Track By** drop-down list, and enter a single IP address or address block in the **Network** field.
- To track all traffic to a specific destination or range of destinations, choose **Destination** from the **Track By** drop-down list, and enter an IP address or address block in the **Network** field.

- Note**
- Do not enter the IP address 0.0.0.0/0 in the Network field to monitor all subnets or IPs. The system does not support this IP address (which is usually used to identify all subnets or IPs) for Rate Based Attack Prevention.
  - The system tracks traffic separately for each IP address included in the **Network** field. Traffic from an IP address that exceeds the configured rate results in generated events only for that IP address. As an example, you might set a source CIDR block of 10.1.0.0/16 for the network setting and configure the system to generate events when there are ten simultaneous connections open. If eight connections are open from 10.1.4.21 and six from 10.1.5.10, the system does not generate events, because neither source has the triggering number of connections open. However, if eleven simultaneous connections are open from 10.1.4.21, the system generates events only for the connections from 10.1.4.21.

**Step 9** Specify the triggering rate for the rate tracking setting:

- For SYN attack configuration, enter the number of SYN packets per number of seconds in the **Rate** fields.
- For simultaneous connection configuration, enter the number of connections in the **Count** field.

Devices load-balance inspection across internal resources. When you configure rate-based attack prevention, you configure the triggering rate per resource, not per device. If rate-based attack prevention is not working as expected, you may need to lower the triggering rate. It triggers alert, if users send too many connection attempts within prescribed time intervals. Hence it is recommended to rate limit the rule. For help determining the correct rate, contact Support.

**Step 10** To drop packets matching the rate-based attack prevention settings, check the **Drop** check box.

**Step 11** In the **Timeout** field, enter the time period after which to stop generating events (and if applicable, dropping) for traffic with the matching pattern of SYNs or simultaneous connections.

**Caution** Setting a high timeout value may entirely block connection to a host in an inline deployment.

**Step 12** Click **OK**.

**Step 13** To save changes you made in this policy since the last policy commit, click **Policy Information**, then click **Commit Changes**.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

### What to do next

- Deploy configuration changes.

## CHAPTER 109

# Adaptive Profiles

---

The following topics describe how to configure adaptive profiles:

- [About Adaptive Profiles, on page 2937](#)
- [License Requirements for Adaptive Profiles, on page 2938](#)
- [Requirements and Prerequisites for Adaptive Profiles, on page 2938](#)
- [Adaptive Profile Updates, on page 2938](#)
- [Adaptive Profile Updates and Cisco Recommended Rules, on page 2939](#)
- [Adaptive Profile Options, on page 2939](#)
- [Configuring Adaptive Profiles, on page 2940](#)

## About Adaptive Profiles

Adaptive profiles must be enabled in order to:

- Perform application and file control, including malware protection (AMP), and to allow intrusion rules to use service metadata.

---

**Caution** Adaptive profiling **must** be enabled (its default state) as described in [Configuring Adaptive Profiles, on page 2940](#) for access control rules to perform application and file control, including malware protection (AMP), and for intrusion rules to use service metadata.

---

- For passive deployments, enable adaptive profile updates to defragment and reassemble IP traffic according to the destination hosts' operating systems.

---

**Note** For inline deployments Cisco recommends that, instead of enabling adaptive profile updates, you configure the inline normalization preprocessor with the **Normalize TCP Payload** option enabled.

---

# Adaptive Profile Updates

Typically, the system uses the static settings in your network analysis policy to preprocess and analyze traffic. With adaptive profile updates, the system can adapt processing behavior using host information either detected by network discovery or imported from a third party.

Profile updates, like the target-based profiles you can configure manually in a network analysis policy, help to defragment IP packets and reassemble streams in the same way as the operating system on the target host. The intrusion rules engine then analyzes the data in the same format as that used by the destination host.

Manually configured target-based profiles apply either the default operating system profile you select, or profiles you bind to specific hosts. Profile updates, however, switch to the appropriate operating system profile based on the operating system in the host profile for the target host.

Consider a scenario where you configure profile updates for the 10.6.0.0/16 subnet and set the default IP Defragmentation target-based policy to Linux. The management center where you configure the settings has a network map that includes the 10.6.0.0/16 subnet.

- When the system detects traffic from Host A, which is not in the 10.6.0.0/16 subnet, it uses the Linux target-based policy to reassemble IP fragments.

- When the system detects traffic from Host B, which is in the 10.6.0.0/16 subnet, it retrieves Host B's operating system data from the network map. The system uses a profile based on that operating system to defragment the traffic destined for Host B.

## Adaptive Profile Updates and Cisco Recommended Rules

The adaptive profile updates feature is an advanced setting in an access control policy that applies globally to all intrusion policies invoked by that access control policy. The Cisco recommended rules feature applies to the individual intrusion policy where you configure it.

Like Cisco recommended rules, profile updates compare metadata in a rule to host information to determine whether a rule should apply for a particular host. However, while Cisco recommended rules provide recommendations for enabling or disabling rules using that information, profile updates use the information to apply specific rules to specific traffic.

Cisco recommended rules require your interaction to implement suggested changes to rule states. Profile updates, on the other hand, do not modify intrusion policies. Treatment of rules based on profile updates happens on a packet-by-packet basis.

Additionally, Cisco recommended rules can result in enabling disabled rules. Profile updates, in contrast, only affect the application of rules that are already enabled in intrusion policies. Profile updates never change the rule state.

You can use profile updates and Cisco recommended rules in combination. Profile updates use the rule state for a rule when your intrusion policy is deployed to determine whether to include it as a candidate for applying, and your choices to accept or decline recommendations are reflected in that rule state. You can use both features to ensure that you have enabled or disabled the most appropriate rules for each network you monitor, and then to apply enabled rules most efficiently for specific traffic.

### Related Topics

[About Cisco Recommended Rules](#), on page 2225

## Adaptive Profile Options

### Enable

Enabling this option is required for:

- access control rules to perform application and file control, including malware protection (AMP)
- intrusion rules to use service metadata

This option is enabled by default.

---

**Note** To enable Adaptive Profiles in Snort 3, both **Enable** and **Enable Profile Updates** options must be selected.

---

### Enable Profile Updates

In passive deployments, enable profile updates to defragment and reassemble IP traffic according to a profile of the operating system used by the hosts in your network map.

For Snort 3, this must be enabled if Adaptive Profiles is enabled.

### Adaptive Profiles - Attribute Update Interval

When profile updates are enabled, you can control how frequently in minutes network map data is synced from the management center to its managed devices. The system uses the data to determine what profiles should be used when processing traffic. Increasing the value for this option can improve performance in a large network.

### Adaptive Profiles - Networks

Optionally, when profile updates are enabled, you can improve performance by constraining profile updates to a comma-separated list of IP addresses, address blocks, and network variables. If you use a network variable, the system uses the variable's value in the variable set linked to the default intrusion policy for your access control policy. For example, you could enter: `192.168.1.101, 192.168.4.0/24, $HOME_NET`. IPv4 and IPv6 are supported.

The default value (`0.0.0.0/0`) applies adaptive profile updates to all networks.

[Variable Set](#), on page 1541

## Configuring Adaptive Profiles

In a passive deployment, Cisco recommends that you configure adaptive profile updates. In an inline deployment, configure the inline normalization preprocessor with the **Normalize TCP Payload** option enabled.

---

**Caution** Adaptive profiling **must** be enabled (its default state) as described in this procedure for access control rules to perform application or file control, including AMP, and for intrusion rules to use service metadata.

---

### Before you begin

The access control policy must have a network discovery policy that is enabled to do host/service discovery, or host data must be imported from a third-party source.

### Procedure

- 
- Step 1** In the access control policy editor, click **Edit** (✎) on the policy you want to modify.
  - Step 2** Click **More > Advanced Settings**, and then click **Edit** (✎) next to the **Detection Enhancement Settings** section.

If **View** (👁) appears instead, settings are inherited from an ancestor policy, or you do not have permission to modify the settings. If the configuration is unlocked, uncheck **Inherit from base policy** to enable editing.

- Step 3** Set adaptive profile options as described in [Adaptive Profile Options, on page 2939](#).
- Step 4** Click **OK**.
- Step 5** Click **Save** to save the policy.
- 

#### What to do next

- Deploy configuration changes.

### Security Cloud Control Platform Maintenance Schedule

Security Cloud Control updates its platform every week with new features and quality improvements. Updates are made during a 3 hour period according to this schedule:

Day of the Week	Time of Day (24-hour time, UTC)
Thursday	09:00 UTC - 12:00 UTC

During this maintenance period, you can still access your tenant and if you have a cloud-delivered Firewall Management Center or Multicloud Defense Controller, you can access those portals as well. Additionally, the devices you have onboarded to Security Cloud Control continue to enforce their security policies.

**Note**

- We advise against using Security Cloud Control to deploy configuration changes on the devices it manages during maintenance periods.
- If there is any issue that stops Security Cloud Control from communicating, we address that failure on all affected tenants as quickly as possible, even if it is outside the maintenance window.

## Navigate from Security Cloud Control to Cloud-delivered Firewall Management Center

1. In the Security Cloud Control dashboard, click **Administration** > **Firewall Management Center**.
2. With cloud-delivered Firewall Management Center selected, click **Devices** in the Management pane.

## What does the default action "Analyze all tunnel traffic" for prefiltering mean?

"Analyze all tunnel traffic" means subject all network traffic to the rules in the access control policy after they have been analyzed by the prefilter policy.

## How Security Cloud Control Processes Personal Information

To learn how Security Cloud Control processes your personal identifiable information, see the [Cisco Security Cloud Control Privacy Data Sheet](#).

## Can I restore a backup from a different device?

Yes, if the devices are the same model, are running the same software version, have the same number of network modules, and the same number of physical interfaces.

## Does deploying a new prefilter policy immediately affect ongoing sessions?

No. When you deploy a prefilter policy, its rules are not applied on the existing tunnel sessions. Hence, traffic on an existing connection is not bound by the new policy that is deployed. In addition, the policy hit count is incremented only for the first packet of a connection that matches a policy. Thus, the traffic on an existing connection that could match a policy is omitted from the hit count.

## How do I keep my security databases and feeds up to date?

If the management center has internet access, the system can often obtain updates on security databases and feeds directly from Cisco. We recommend you schedule or enable automatic content updates whenever possible. Some updates are auto-enabled by the initial setup process or when you enable the related feature. Other updates you must schedule yourself. After initial setup, we recommend you review all auto-updates and adjust them if necessary.

- There are several security databases and feeds you should update:
- [Vulnerability database \(VDB\)](#)
- [Geolocation database \(GeoDB\)](#)
- [Intrusion rules \(SRU/LSP\)](#)
- [Security Intelligence Feeds](#)
- [URL categories and reputations](#)

## What version of Secure Firewall Threat Defense can I manage with cloud-delivered Firewall Management Center?

Cloud-delivered Firewall Management Center supports these versions of Secure Firewall Threat Defense:

- Verion 7.0.3 or later 7.0.x versions.
- Version 7.2 and later versions.

---

**Note** Software Version 7.1 is `_not_` supported.

---

All hardware and virtual deployments which can run these software versions are supported.

## How do I exclude specific traffic (Webex, Zoom, etc) from the remote access VPN?

You can exclude specific traffic from the remote access VPN using dynamic split tunneling based on DNS domain names.

Excluded domains are not blocked. Instead, traffic to those domains is kept outside the VPN tunnel. For example, you could send traffic to Cisco WebEx on the public Internet, thus freeing bandwidth in your VPN tunnel for traffic that is targeted to servers within your protected network.

## Procedure

- 
- Step 1** From the Security Cloud Control home page, in the navigation bar, click **Inventory**.
- Step 2** Find the Secure Firewall Threat Defense device you want to add this rule to. You can use the filter or search field to find the device.
- Step 3** Select the device, and in the Device Management pane at the right, click **Device Overview**.
- Step 4** Configure the group policy to use Dynamic Split Tunnel.
- Choose **Devices > Remote Access**.
  - Click **Edit** on the remote access VPN policy for which you want to configure dynamic split tunneling.
  - Click **Edit** on the required connection profile.
  - Click **Edit Group Policy**.
- Step 5** Configure the Secure Client custom attribute in the Add/Edit Group Policy dialog box.
- Click the Secure Client tab.
  - Click **Custom Attributes** and click +.
  - Choose **Dynamic Split Tunneling** from the Secure Client Attribute drop-down list.
  - Click + to create a new custom attribute object.
  - Enter the name for the custom attribute object.
  - Exclude domains—Specify domain names that will be excluded from the remote access VPN.
  - Click **Save**.
  - Click **Add**.
- Step 6** Verify the configured custom attribute and click **Save**.
- Step 7** When you are ready to deploy this change to the device, click **Deploy** in the menu bar at the top of the page.
- 

# How do I prevent users from accessing undesirable external network resources, such as inappropriate websites?

## Procedure

- 
- Step 1** From the Security Cloud Control home page, click **Inventory** in the navigation bar.
- Step 2** Find the Secure Firewall Threat Defense device you want to add these rules to. You can use the filter or search field to find the device.
- Step 3** Select the device and in the Policies pane at the right, click **Access Control**.
- Step 4** Click the policy you want to update.
- Step 5** Click **Add Rule**.
- Step 6** Give the rule a name.
- Step 7** In the **Action** field, select **Block**.
- Step 8** Insert the rule into either the Mandatory or into the Default policy.

- Step 9** Click the **URLs** tab.
- Step 10** In the Categories section, check the categories you want to block and accept the default value for "Any Reputation".
- Step 11** Click **Add URL**.
- Step 12** If there are specific URLs that you want to block, you can do that by entering them in the **Manually Enter URL** field and then click **Add URL**.
- Step 13** Click **Apply**.
- Step 14** On the policy page, click **Save**.
- Step 15** When you are ready to deploy this change to the device, click **Deploy** in the menu bar at the top of the page.

**Note** Note: This instruction assumes you have the URL filtering license

---

## Security Feed Questions

### Related Information

## How do I update intrusion rules (SRU/LSP)?

Follow this procedure to configure recurring Intrusion Rule update downloads.

### Procedure

- 
- Step 1** From the cloud-delivered Firewall Management Center home page, navigate **System (gear icon) > Updates > Rule Updates**.
- Step 2** Under **Recurring Rule Update Imports**, check **Enable Recurring Rule Update Imports**.
- Step 3** Specify the **Import Frequency** and start time.

**Note** As updates are published multiple times each week, it is recommended to check on a Daily basis.

- Step 4** (Optional, but recommended) Check **Reapply all policies...** to deploy after each update.

**Caution** Deploying intrusion rule updates can cause a Snort restart in rare occasions. It is recommended to deploy intrusion rule updates during a maintenance window.

- Step 5** Click **Save**.

- Step 6** Deploy your changes when you are ready.

**Caution** Deploying intrusion rule updates can cause a Snort restart. We recommend you deploy intrusion rule updates during a maintenance window.

---

## How do I update my Cisco vulnerability database (VDB)?

The initial setup on the management center automatically downloads and installs the latest VDB from Cisco as a one-time operation. It also schedules a weekly task to download the latest available software updates, which includes the latest VDB. We recommend you review this weekly task and adjust if necessary, by navigating in cdFMC to **System gear icon > Tools > Scheduling**. Updating the Vulnerability Database is a two-step process:

### Before you begin

You must be in the global domain to perform this task.

### Procedure

---

**Step 1** Download the latest VDB Version using one of these methods:

- The manual way.
- The automated way.

**Step 2** Install the downloaded VDB.

- a. substep
  - b. substep
- 

## How do I update my Geolocation database?

As a part of initial configuration, the system configures a weekly automatic Geolocation (GeoDB) update. If configuring the update fails, we recommend you configure regular GeoDB updates as described in this procedure.

### Procedure

---

**Step 1** From the cloud-delivered Firewall Management Center home page, **System (gear icon) > Updates > Updates > Geolocation Updates**.

**Step 2** Under **Recurring Geolocation Updates**, check **Enable Recurring Weekly Updates from the Support Site**.

**Step 3** Specify the **Update Start Time**.

**Step 4** Click **Save**.

---

## How do I update Security Intelligence feeds?

By default, the built-in feeds on cdFMC are updated every two hours, with updates being pushed immediately to managed devices.

To change the update configuration, perform the following steps:

### Procedure

- 
- Step 1** From the cloud-delivered Firewall Management Center home page, navigate **Objects > Object Management**.
  - Step 2** Expand the Security Intelligence node, then choose the feed type whose frequency you want to change.
  - Step 3** Next to the feed you want to update, click the pencil icon to **Edit** the update frequency.
    - Note** The system-provided URL feed is combined with the domain feed under DNS Lists and Feeds.
  - Step 4** Edit the **Update Frequency**.
  - Step 5** Click **Save**.
- 

## How do I update URL reputations?

If you Enable Automatic Updates, by default, automatic URL updates are enabled. The management center checks Talos updates every 30 minutes. If you need strict control over when the system contacts external resources, disable automatic updates and instead create a recurring task using the scheduler. Although daily updates tend to be small, if it has been more than five days since your last update, new URL filtering data may take up to 20 minutes to download, depending on your bandwidth. Then, it may take up to 30 minutes to perform the update itself.

### Procedure

- 
- Step 1** From the cloud-delivered Firewall Management Center home page, navigate **Integration > Other Integrations**.
  - Step 2** Click **Cloud Services**.
  - Step 3** In the URL Filtering pane:
    - a) Enable URL filtering.
    - b) Enable automatic updates.
  - Step 4** Click **Save**.
-

# How do I setup Rate-Based Attack Prevention on the FTD using Snort 2?

Dynamic rule states are policy-specific.

A **Revert** appears in a field when you enter an invalid value; click it to revert to the last valid value for that field or to clear the field if there was no previous value.

---

**Note** Dynamic rule states cannot enable disabled rules or drop traffic that matches disabled rules.

---

Procedure:

## Procedure

- 
- Step 1** On the Security Cloud Control menu bar, click **Administration > Firewall Management Center** to view the Services page.
- Step 2** Choose Cloud-Delivered FMC and click the links in the Actions, Management, or System pane to navigate to cloud-delivered Firewall Management Center to perform various actions. See [View Services Page Information](#).
- Step 3** Choose **Policies > Access Control > Intrusion**.
- Step 4** Click Snort 2 Version next to the policy you want to edit.
- If View (View button) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 5** Click **Rules** immediately under **Policy Information** in the navigation pane.
- Step 6** Choose the rule or rules where you want to add a dynamic rule state.
- Step 7** Choose **Dynamic State > Add Rate-Based Rule State**.
- Step 8** Choose a value from the Track By drop-down list.
- Step 9** If you set Track By to Source or Destination, enter the address of each host you want to track in the Network field. You can specify a single IP address, address block, variable, or a comma-separated list comprised of any combination of these.
- Step 10** Next to Rate, specify the number of rule matches per time period to set the attack rate:
- Step 11** From the New State drop-down list, specify the new action to be taken when the conditions are met.
- Step 12** Enter a value in the Timeout field.
- After the timeout occurs, the rule reverts to its original state. Specify 0 or leave the Timeout field blank to prevent the new action from timing out.
- Step 13** Click OK.
- Note** The system displays a Dynamic State next to the rule in the Dynamic State column. If you add multiple dynamic rule state filters to a rule, a number over the filter indicates the number of filters.

**Note** To delete all dynamic rule settings for a set of rules, choose the rules on the Rules page, then choose Dynamic State > Remove Rate-Based States. You can also delete individual rate-based rule state filters from the rule details for the rule by choosing the rule, clicking Show details, then clicking Delete by the rate-based filter you want to remove.

**Step 14** To save changes you made in this policy since the last policy commit, click Policy Information, then click Commit Changes.

If you leave the policy without committing changes, changes since the last commit are discarded if you edit a different policy.

---

## Complete the Initial Configuration of a Secure Firewall Threat Defense Device Using the CLI

Connect to the device's CLI to perform initial setup, including setting the management IP address, gateway, and other basic networking settings using the setup wizard. Ensure all DNS and firewall ports are accessible for communication.

The dedicated management interface is a special interface with its own network settings. If you do not want to use the management interface, you can use the CLI to configure a data interface instead.

This configuration is ideal for devices that are going to be onboarded with their CLI registration key.

---

**Note** Do **not** use this configuration procedure for devices that are onboarding with zero-touch provisioning.

---

### Procedure

---

**Step 1** Connect to the device's CLI, either from the console port or using SSH to the management interface. If you intend to change the network settings, we recommend using the console port so you do not get disconnected.

(Firepower and Secure Firewall hardware models) The console port connects to the FXOS CLI. The SSH session connects directly to the threat defense CLI.

**Step 2** Log in with the username **admin** and the password **Admin123**.

(Firepower and Secure Firewall hardware models) At the console port, you connect to the FXOS CLI. The first time you log in to FXOS, you are prompted to change the password. This password is also used for the threat defense login for SSH.

**Note** If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default.

For Firepower and Secure Firewall hardware, see the [Reimage Procedures](#) in the [Cisco FXOS Troubleshooting Guide for the Firepower 1000/2100 and Secure Firewall 3100/4200 with Threat Defense](#).

For the ISA 3000, see the [Cisco Secure Firewall ASA and Secure Firewall Threat Defense Reimage Guide](#).

#### Example:

```
firepower login: admin
Password: Admin123
Successful login attempts for user 'admin' : 1

[...]

Hello admin. You must change your password.
Enter new password: *****
Confirm new password: *****
Your password was updated successfully.

[...]

firepower#
```

**Step 3** (Firepower and Secure Firewall hardware models) If you connected to FXOS on the console port, connect to the threat defense CLI.

**connect ftd**

#### Example:

```
firepower# connect ftd
>
```

**Step 4** The first time you log in to the device, you are prompted to accept the End User License Agreement (EULA) and, if using an SSH connection, to change the admin password. You are then presented with the CLI setup script.

**Note** You cannot repeat the CLI setup wizard unless you clear the configuration; for example, by reimaging. However, all of these settings can be changed later at the CLI using **configure network** commands. See the [threat defense command reference](#).

Defaults or previously entered values appear in brackets. To accept previously entered values, press **Enter**.

**Note** The management interface settings are used even when you enable threat defense access on a data interface. For example, the management traffic that is routed over the backplane through the data interface will resolve FQDNs using the management interface DNS servers, and not the data interface DNS servers.

See the following guidelines:

- **Configure IPv4 via DHCP or manually?**—If you want to use a data interface for threat defense access instead of the management interface, choose **manual**. Although you do not plan to use the management interface, you must set an IP address, for example, a private address. You cannot configure a data interface

for management if the management interface is set to DHCP, because the default route, which must be **data-interfaces** (see the next bullet), might be overwritten with one received from the DHCP server.

- **Enter the IPv4 default gateway for the management interface**—If you want to use a data interface for threat defense access instead of the management interface, set the gateway to be **data-interfaces**. This setting forwards management traffic over the backplane so it can be routed through the FMC access data interface.
- **If your networking information has changed, you will need to reconnect**—If you are connected with SSH but you change the IP address at initial setup, you will be disconnected. Reconnect with the new IP address and password. Console connections are not affected.
- **Manage the device locally?**—Enter **YES** to configure the device for the device to be managed by either the cloud-delivered Firewall Management Center or Secure Firewall device manager.  
**Manage the device locally?**—Enter **NO** to configure the device for remote management with the on-premises management center.
- **Configure firewall mode?**—We recommend that you set the firewall mode at initial configuration. Changing the firewall mode after initial setup erases your running configuration. Note that data interface threat defense access is only supported in routed firewall mode.

**Step 5** (Optional) Configure a data interface for management center access.

#### **configure network management-data-interface**

You are then prompted to configure basic network settings for the data interface.

**Note** You should use the console port when using this command. If you use SSH to the Management interface, you might get disconnected and have to reconnect to the console port. See below for more information about SSH usage.

See the following details for using this command. See [About Data Interfaces, on page 48](#) for more informatio.

- The original management interface cannot use DHCP if you want to use a data interface for management. If you did not set the IP address manually during initial setup, you can set it now using the **configure network {ipv4 | ipv6} manual** command. If you did not already set the management interface gateway to **data-interfaces**, this command will set it now.
- When you onboard the device for threat defense management through Security Cloud Control, Security Cloud Control discovers and maintains the interface configuration, including the following settings: interface name and IP address, static route to the gateway, DNS servers, and DDNS server. For more information about the DNS server configuration, see below. You can later make changes to the access interface configuration, but make sure you don't make changes that can prevent the device or Security Cloud Control from re-establishing the management connection. If the management connection is disrupted, the device includes the **configure policy rollback** command to restore the previous deployment.
- This command sets the *data* interface DNS server. The Management DNS server that you set with the setup script (or using the **configure network dns servers** command) is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface.

Also, local DNS servers are only retained if the DNS servers were discovered at initial registration. For example, if you registered the device using the Management interface, but then later configure a data interface using the **configure network management-data-interface** command, then you must manually configure all of these settings in Security Cloud Control, including the DNS servers, to match the device configuration.

- You can change the management interface after you onboard the threat defense for threat defense management through threat defense, to either the management interface or another data interface.
- The FQDN that you set in the setup wizard will be used for this interface.
- You can clear the entire device configuration as part of the command; you might use this option in a recovery scenario, but we do not suggest you use it for initial setup or normal operation.
- To disable data management, enter the **configure network management-data-interface disable** command.

**Example:**

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]:
IP address (manual / dhcp) [dhcp]:
DDNS server update URL [none]:
https://jcrichton:pa$$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>
Do you wish to clear all the device configuration before applying ? (y/n) [n]:

Configuration done with option to allow FMC access from any network, if you wish to change
the FMC access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

**Example:**

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]:

Configuration done with option to allow FMC access from any network, if you wish to change
the FMC access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>
```

**Step 6** (Optional) Limit data interface access to Security Cloud Control on a specific network.

**configure network management-data-interface client *ip\_address netmask***

By default, all networks are allowed.

## CHAPTER 111

# Secure Firewall Management Center Command Line Reference

---

This reference explains the command line interface (CLI) for the Secure Firewall Management Center.

---

**Note** For Secure Firewall Threat Defense, see the [Cisco Secure Firewall Threat Defense Command Reference](#).

---

- [About the Secure Firewall Management Center CLI, on page 2957](#)
- [Secure Firewall Management Center CLI Management Commands, on page 2958](#)
- [Secure Firewall Management Center CLI Show Commands, on page 2959](#)
- [Secure Firewall Management Center CLI Configuration Commands, on page 2960](#)
- [Secure Firewall Management Center CLI System Commands, on page 2961](#)

## About the Secure Firewall Management Center CLI

When you use SSH to log into the management center, you access the CLI. Although we strongly discourage it, you can then access the Linux shell using the `expert` command .

---

**Caution** We strongly recommend that you do not access the Linux shell unless directed by Cisco TAC or explicit instructions in the Secure Firewall user documentation.

---

---

**Caution** Users with Linux shell access can obtain root privileges, which can present a security risk. For system security reasons, we strongly recommend:

- If you establish external authentication, make sure that you restrict the list of users with Linux shell access appropriately.
  - Do not establish Linux shell users in addition to the pre-defined `admin` user.
- 

You can use the commands described in this appendix to view and troubleshoot your Secure Firewall Management Center, as well as perform limited configuration operations.

## Management Center CLI Modes

The CLI encompasses four modes. The default mode, CLI Management, includes commands for navigating within the CLI itself. The remaining modes contain commands addressing three different areas of management center functionality; the commands within these modes begin with the mode name: `system`, `show`, or `configure`.

When you enter a mode, the CLI prompt changes to reflect the current mode. For example, to display version information about system components, you can enter the full command at the standard CLI prompt:

```
> show version
```

If you have previously entered `show` mode, you can enter the command without the `show` keyword at the `show` mode CLI prompt:

```
show> version
```

## Secure Firewall Management Center CLI Management Commands

The CLI management commands provide the ability to interact with the CLI. These commands do not affect the operation of the device.

### exit

Moves the CLI context up to the next highest CLI context level. Issuing this command from the default mode logs the user out of the current CLI session.

#### Syntax

```
exit
```

#### Example

```
system> exit  
>
```

### expert

Invokes the Linux shell.

#### Syntax

```
expert
```

**Example**

```
> expert
```

## ? (question mark)

Displays context-sensitive help for CLI commands and parameters. Use the question mark (?) command as follows:

- To display help for the commands that are available within the current CLI context, enter a question mark (?) at the command prompt.
- To display a list of the available commands that start with a particular character set, enter the abbreviated command immediately followed by a question mark (?).
- To display help for a command's legal arguments, enter a question mark (?) in place of an argument at the command prompt.

Note that the question mark (?) is not echoed back to the console.

**Syntax**

```
?  
abbreviated_command ?  
command [arguments] ?
```

**Example**

```
> ?
```

## Secure Firewall Management Center CLI Show Commands

Show commands provide information about the state of the appliance. These commands do not change the operational mode of the appliance and running them has minimal impact on system operation.

### version

Displays the product version and build as well as the UUID and other information.

**Syntax**

```
show version
```

**Example**

```
> show version
-----[ fmc-austin ]-----
Model                : Cisco Secure Firewall Management Center for VMware (66) Version
  7.6.0 (Build 1385)
UUID                 : a904b8b2-ca9a-11ee-a583-5e804c16b2fd
Rules update version : 2024-05-13-001-vrt
LSP version          : lsp-rel-20240513-1955
VDB version          : 380
-----
```

# Secure Firewall Management Center CLI Configuration Commands

The configuration commands enable the user to configure and manage the system. These commands affect system operation.

## password

Allows the current CLI user to change their password.

---

**Caution** For system security reasons, we strongly recommend that you do not establish Linux shell users in addition to the pre-defined **admin** on any appliance.

---

---

**Note** The `password` command is not supported in expert mode. To reset password of an admin user on a secure firewall system, see [Learn more](#). If you use `password` command in expert mode to reset admin password, we recommend you to reconfigure the password using `configure user admin password` command. After you reconfigure the password, switch to expert mode and ensure that the password hash for admin user is same in `/opt/cisco/config/db/sam.config` and `/etc/shadow` files.

---

After issuing the command, the CLI prompts the user for their current (or old) password, then prompts the user to enter the new password twice.

**Syntax**

```
configure password
```

**Example**

```
> configure password
Changing password for admin.
(current) UNIX password:
```

```
New UNIX password:  
Retype new UNIX password:  
passwd: password updated successfully
```

# Secure Firewall Management Center CLI System Commands

The system commands enable the user to manage system-wide files and access control settings.

## generate-troubleshoot

Generates troubleshooting data for analysis by Cisco.

### Syntax

```
system generate-troubleshoot option1 optionN
```

Where options are one or more of the following, space-separated:

- ALL: Run all of the following options.
- SNT: Snort Performance and Configuration
- PER: Hardware Performance and Logs
- SYS: System Configuration, Policy, and Logs
- DES: Detection Configuration, Policy, and Logs
- NET: Interface and Network Related Data
- VDB: Discover, Awareness, VDB Data, and Logs
- UPG: Upgrade Data and Logs
- DBO: All Database Data
- LOG: All Log Data
- NMP: Network Map Information

### Example

```
> system generate-troubleshoot VDB NMP  
starting /usr/local/sf/bin/sf_troubleshoot.pl...  
Please, be patient. This may take several minutes.  
The troubleshoot options codes specified are VDB,NMP.  
Getting filenames from [usr/local/sf/etc/db_updates/index]  
Getting filenames from [usr/local/sf/etc/db_updates/base-6.2.3]  
Troubleshooting information successfully created at  
/var/common/results-06-14-2018-222027.tar.gz
```

## lockdown

Removes the `expert` command and access to the Linux shell on the device.

---

**Caution** This command is irreversible without a hotfix from Support. Use with care.

---

### Syntax

```
system lockdown
```

### Example

```
> system lockdown
```

## reboot

Reboots the appliance.

### Syntax

```
system reboot
```

### Example

```
> system reboot
```

## restart

Restarts the appliance application.

### Syntax

```
system restart
```

### Example

```
> system restart
```

## shutdown

Shuts down the appliance.

### Syntax

```
system shutdown
```

### Example

```
> system shutdown
```

## CHAPTER 112

# Security, Internet Access, and Communication Ports

---

The following topics provide information on system security, internet access, and communication ports:

- [Security Requirements, on page 2965](#)
- [Cisco Clouds, on page 2965](#)
- [Internet Access Requirements, on page 2966](#)
- [Communication Port Requirements, on page 2966](#)

## Security Requirements

To safeguard the Secure Firewall Management Center, you should install it on a protected internal network. Although the management center is configured to have only the necessary services and ports available, you must make sure that attacks cannot reach it (or any managed devices) from outside the firewall.

If the management center and its managed devices reside on the same network, you can connect the management interfaces on the devices to the same protected internal network as the management center. This allows you to securely control the devices from the management center. You can also configure multiple management interfaces to allow the management center to manage and isolate traffic from devices on other networks.

Regardless of how you deploy your appliances, inter-appliance communication is encrypted. However, you must still take steps to ensure that communications between appliances cannot be interrupted, blocked, or tampered with; for example, with a distributed denial of service (DDoS) or man-in-the-middle attack.

## Cisco Clouds

The management center communicates with resources in the Cisco cloud for the following features:

- **Advanced Malware Protection**

The public cloud is configured by default; to make changes, see *Change AMP Options* in the [Cisco Secure Firewall Management Center Device Configuration Guide](#).

- **URL filtering**

For more information, see the *URL filtering* chapter in the [Cisco Secure Firewall Management Center Device Configuration Guide](#).

- **Cisco Umbrella Connection**

For more information, see [Cisco Umbrella DNS Policies, on page 1958](#).

## Internet Access Requirements

Sometimes, managed devices must access the internet. For example, if your malware protection configuration uses dynamic analysis, managed devices submit files directly to the Secure Malware Analytics cloud. Or, you may synchronize a device to an external NTP server.

Additionally, your browser may contact Amplitude (amplitude.com) web analytics servers to provide non-personally-identifiable usage data to Cisco.

## Communication Port Requirements

The management center communicates with managed devices using a two-way, SSL-encrypted communication channel on port 8305/tcp. This port *must* remain open for basic communication. Other ports allow secure management, as well as access to external resources required by specific features. In general, feature-related ports remain closed until you enable or configure the associated feature. Do not change or close an open port until you understand how this action will affect your deployment.

For information on internet resources the system may contact over these ports, see [Internet Access Requirements, on page 2966](#).

### Ports for Management Center

**Table 262: Inbound Ports for Management Center**

Inbound Port	Protocol/Feature	Details
443/tcp	HTTPS	Access the web interface.
443/tcp	HTTPS	Submit queries to Cisco Security Packet Analyzer.
443/tcp	HTTPS	Communicate with integrated and third-party products using the REST API.
443/tcp	HTTPS	Integrate with Secure Endpoint. Outbound also required.
8305/tcp	Appliance communications	Securely communicate between appliances in a deployment. Outbound also required. Configurable. If you change this port, you must change it for <i>all</i> appliances in the deployment. We recommend you keep the default.
8989/tcp	Cisco Support Diagnostics	Accepts authorized requests and transmits usage information and statistics. Outbound also required.

Table 263: Outbound Ports for Management Center

Outbound Port	Protocol/Feature	Details
7/udp 514/udp 6514/tcp	Syslog (audit logging)	Verify connectivity with the syslog server when configuring audit logging (7/udp). Send audit logs to a remote syslog server, when TLS is not configured (514/udp). Send audit logs to a remote syslog server, when TLS is configured (6514/tcp).
25/tcp	SMTP	Send email notices and alerts.
53/tcp 53/udp	DNS	DNS
67/udp 68/udp	DHCP	DHCP
80/tcp	HTTP	Download custom Security Intelligence feeds over HTTP.
80/tcp	HTTP	Download or query URL category and reputation data. Outbound 443/tcp also required.
123/udp	NTP	Synchronize time.
162/udp	SNMP	Send SNMP alerts to a remote trap server.
389/tcp 636/tcp	LDAP	Communicate with an LDAP server for external authentication. Obtain metadata for detected LDAP users. Configurable.
443/tcp	HTTPS	Communicate with the Secure Malware Analytics Cloud (public or private).
443/tcp	HTTPS	Send and receive data from the internet.
443/tcp	HTTPS	Integrate with AMP for Endpoints. Inbound also required.
1812/udp 1813/udp	RADIUS	Communicate with a RADIUS server for external authentication and accounting. Configurable.
5222/tcp	ISE	Communicate with an ISE identity source.
8305/tcp	Appliance communications	Securely communicate between appliances in a deployment. Inbound also required. Configurable. If you change this port, you must change it for <i>all</i> appliances in the deployment. We recommend you keep the default.

## Ports for Managed Devices

**Table 264: Inbound Ports for Managed Devices**

Inbound Port	Protocol/Feature	Details
22/tcp	SSH	Secure remote connections to the appliance.
161/udp	SNMP	Allow access to MIBs via SNMP polling.
443/tcp	HTTPS	Communicate with integrated and third-party products using the REST API.
443/tcp	Remote access VPN (SSL/IPSec)	Allow secure VPN connections to your network from remote users.
500/udp 4500/udp	Remote access VPN (IKEv2)	Allow secure VPN connections to your network from remote users.
885/tcp	Captive portal	Communicate with a captive portal identity source.
8305/tcp	Appliance communications	Securely communicate between appliances in a deployment. Outbound also required.  Configurable. If you change this port, you must change it for <i>all</i> appliances in the deployment. We recommend you keep the default.

**Table 265: Outbound Ports for Managed Devices**

Outbound Port	Protocol/Feature	Details
53/tcp 53/udp	DNS	DNS
67/udp 68/udp	DHCP	DHCP
123/udp	NTP	Synchronize time.
162/udp	SNMP	Send SNMP alerts to a remote trap server.
1812/udp 1813/udp	RADIUS	Communicate with a RADIUS server for external authentication and accounting.  Configurable.
389/tcp 636/tcp	LDAP	Communicate with an LDAP server for external authentication.  Configurable.
443/tcp	HTTPS	Send and receive data from the internet.
514/udp	Syslog (audit logging)	Send audit logs to a remote syslog server, when TLS is not configured.

Outbound Port	Protocol/Feature	Details
8305/tcp	Appliance communications	Securely communicate between appliances in a deployment. Inbound also required. Configurable. If you change this port, you must change it for <i>all</i> appliances in the deployment. We recommend you keep the default.
8514/UDP	Secure Network Analytics Manager	Send syslog messages to Secure Network Analytics using Security Analytics and Logging (On Premises)
