**Step 7** (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU — CPU utilization, including the CPU usage by process and by physical cores.
- Memory — Device memory utilization, including data plane and Snort memory usage.
- Interfaces — Interface status and aggregate traffic statistics.

- Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort — Statistics that are related to the Snort process.
- ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See [Cisco Secure Firewall Threat Defense Health Metrics](#) for a comprehensive list of the supported device metrics.

**Step 8** Click the plus sign (+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

## Cluster Metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

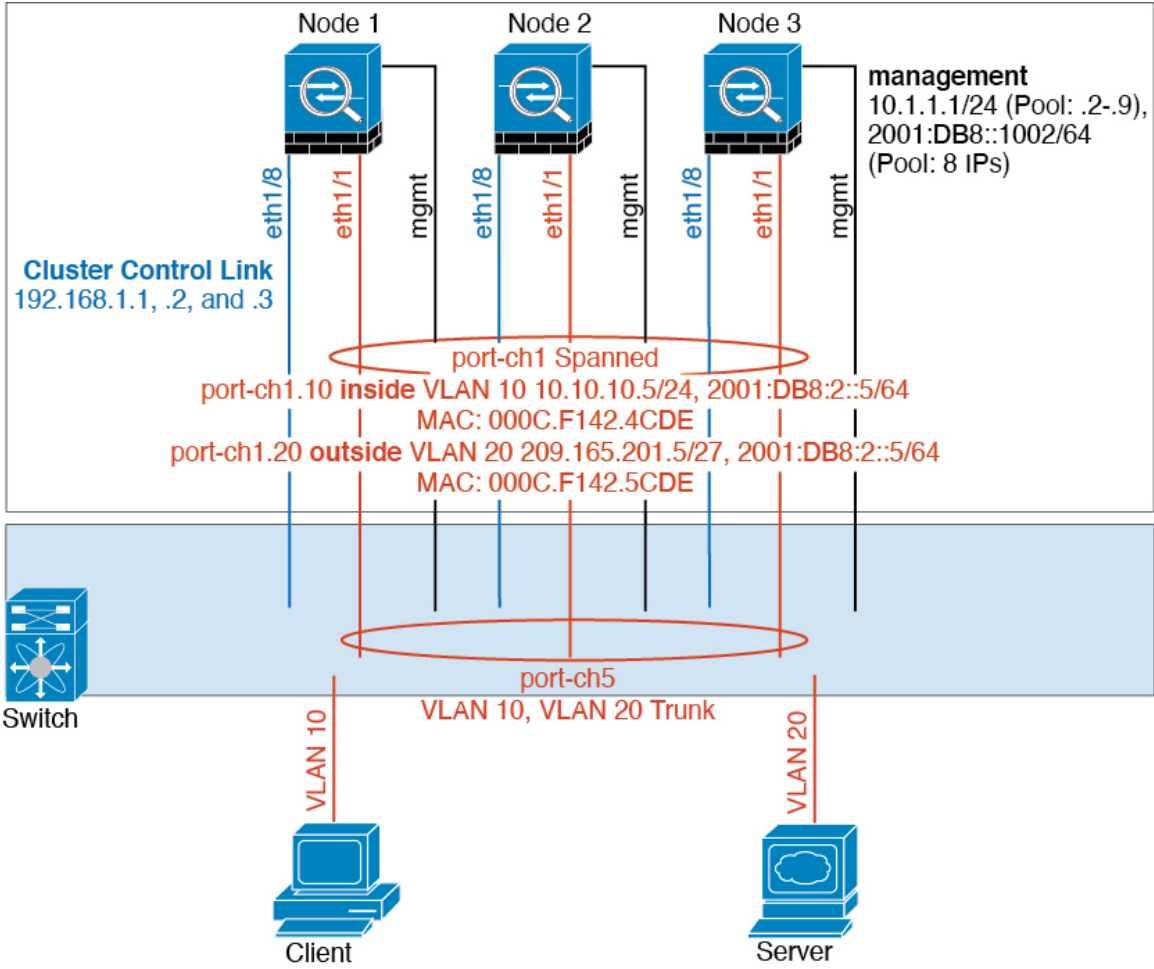

**Table 67: Cluster Metrics**

| Metric           | Description                                                                                  | Format     |
|------------------|----------------------------------------------------------------------------------------------|------------|
| CPU              | Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).    | percentage |
| Memory           | Average of memory metrics on the nodes of a cluster (individually for data plane and snort). | percentage |
| Data Throughput  | Incoming and outgoing data traffic statistics for a cluster.                                 | bytes      |
| CCL Throughput   | Incoming and outgoing CCL traffic statistics for a cluster.                                  | bytes      |
| Connections      | Count of active connections in a cluster.                                                    | number     |
| NAT Translations | Count of NAT translations for a cluster.                                                     | number     |
| Distribution     | Connection distribution count in the cluster for every second.                               | number     |
| Packets          | Packet distribution count in the cluster for every second.                                   | number     |

## Examples for Clustering

These examples include typical deployments.

# Firewall on a Stick

Data traffic from different security domains are associated with different VLANs, for example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. This is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the becomes unavailable, the switch will rebalance traffic between the remaining units.

## Traffic Segregation

You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

## Reference for Clustering

This section includes more information about how clustering operates.

## Threat Defense Features and Clustering

Some threat defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

## Unsupported Features with Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

---

**Note** To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2703](#).

---

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Management Center UCAPL/CC mode

## Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

---

**Note** Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

---

---

**Note** To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2703](#).

---

- The following application inspections:
  - DCERPC
  - ESMTTP
  - NetBIOS
  - PPTP
  - RSH
  - SQLNET
  - SUNRPC

- TFTP
- XDMCP
- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

## Connection Settings

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

## Dynamic Routing and Clustering

The routing process only runs on the control unit, and routes are learned through the control unit and replicated to secondaries. If a routing packet arrives at a data unit, it is redirected to the control unit.

**Figure 251: Dynamic Routing**

After the data units learn the routes from the control unit, each unit makes forwarding decisions independently. The OSPF LSA database is not synchronized from the control unit to data units. If there is a control unit switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a

consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

## FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

## Multicast Routing and Clustering

The control unit handles all multicast routing packets and data packets until fast-path forwarding is established. After the connection is established, each data unit can forward multicast data packets.

## NAT and Clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different threat defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the threat defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number

of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.

- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

## SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

## SNMP and Clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

## Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

## TLS/SSL Connections and Clustering

The decryption states of TLS/SSL connections are not synchronized, and if the connection owner fails, then the decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

## Cisco TrustSec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

## VPN and Clustering

Site-to-site VPN is a centralized feature; only the control unit supports VPN connections.

---

**Note** Remote access VPN is not supported with clustering.

---

VPN functionality is limited to the control unit and does not take advantage of the cluster high availability capabilities. If the control unit fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control unit is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned interface address, connections are automatically forwarded to the control unit.

VPN-related keys and certificates are replicated to all units.

## Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, for TCP throughput, the Firepower 9300 with 3 SM-40 modules can handle approximately 135 Gbps of real world firewall traffic when running alone. For 2 chassis, the maximum combined throughput will be approximately 80% of 270 Gbps (2 chassis x 135 Gbps): 216 Gbps.

## Control Unit Election

Members of the cluster communicate over the cluster control link to elect a control unit as follows:

1. When you deploy the cluster, each unit broadcasts an election request every 3 seconds.

2. Any other units with a higher priority respond to the election request; the priority is set when you deploy the cluster and is not configurable.
3. If after 45 seconds, a unit does not receive a response from another unit with a higher priority, then it becomes the control unit.

---

**Note** If multiple units tie for the highest priority, the cluster unit name and then the serial number is used to determine the control unit.

---

4. If a unit later joins the cluster with a higher priority, it does not automatically become the control unit; the existing control unit always remains as the control unit unless it stops responding, at which point a new control unit is elected.
5. In a "split brain" scenario when there are temporarily multiple control units, then the unit with highest priority retains the role while the other units return to data unit roles.

---

**Note** You can manually force a unit to become the control unit. For centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

---

## High Availability Within the Cluster

Clustering provides high availability by monitoring chassis, unit, and interface health and by replicating connection states between units.

### Chassis-Application Monitoring

Chassis-application health monitoring is always enabled. The Firepower 4100/9300 chassis supervisor checks the threat defense application periodically (every second). If the threat defense device is up and cannot communicate with the Firepower 4100/9300 chassis supervisor for 3 seconds, the threat defense device generates a syslog message and leaves the cluster.

If the Firepower 4100/9300 chassis supervisor cannot communicate with the application after 45 seconds, it reloads the threat defense device. If the threat defense device cannot communicate with the supervisor, it removes itself from the cluster.

### Unit Health Monitoring

Each unit periodically sends a broadcast keepaliveheartbeat packet over the cluster control link. If the control node does not receive any keepaliveheartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining node.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail

in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role. See [Control Unit Election, on page 890](#) for more information.

## Interface Monitoring

Each node monitors the link status of all hardware interfaces in use, and reports status changes to the control node. For clustering on multiple chassis, Spanned EtherChannels use the cluster Link Aggregation Control Protocol (cLACP). Each chassis monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel, and informs the threat defense application if the interface is down. When you enable health monitoring, all physical interfaces are monitored by default (including the main EtherChannel for EtherChannel interfaces). Only named interfaces that are in an Up state can be monitored. For example, all member ports of an EtherChannel must fail before a *named* EtherChannel is removed from the cluster. You can optionally disable monitoring per interface.

If a monitored interface fails on a particular node, but it is active on other nodes, then the node is removed from the cluster. The amount of time before the threat defense device removes a node from the cluster depends on whether the node is an established member or is joining the cluster. The threat defense device does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the threat defense device to be removed from the cluster. For an established member, the node is removed after 500 ms.

For clustering on multiple chassis, if you add or delete an EtherChannel from the cluster, interface health-monitoring is suspended for 95 seconds to ensure that you have time to make the changes on each chassis.

## Decorator Application Monitoring

When you install a decorator application on an interface, such as the Radware DefensePro application, then both the threat defense device and the decorator application must be operational to remain in the cluster. The unit does not join the cluster until both applications are operational. Once in the cluster, the unit monitors the decorator application health every 3 seconds. If the decorator application is down, the unit is removed from the cluster.

## Status After Failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The threat defense automatically tries to rejoin the cluster, depending on the failure event.

---

**Note** When the threat defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

---

## Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The threat defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The threat defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the threat defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The threat defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from management center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.
- Failed Chassis-Application Communication—When the threat defense application detects that the chassis-application health has recovered, it tries to rejoin the cluster automatically.

## Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

**Table 68: Features Replicated Across the Cluster**

| Traffic                | State Support | Notes                              |
|------------------------|---------------|------------------------------------|
| Up time                | Yes           | Keeps track of the system up time. |
| ARP Table              | Yes           | —                                  |
| MAC address table      | Yes           | —                                  |
| User Identity          | Yes           | —                                  |
| IPv6 Neighbor database | Yes           | —                                  |
| Dynamic routing        | Yes           | —                                  |
| SNMP Engine ID         | <b>No</b>     | —                                  |

## How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

### Connection Roles

See the following roles defined for each connection:

- **Owner**—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- **Backup owner**—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- **Director**—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

ICMP/ICMPv6 hash details:

- For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- **Forwarder**—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

**Note** We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

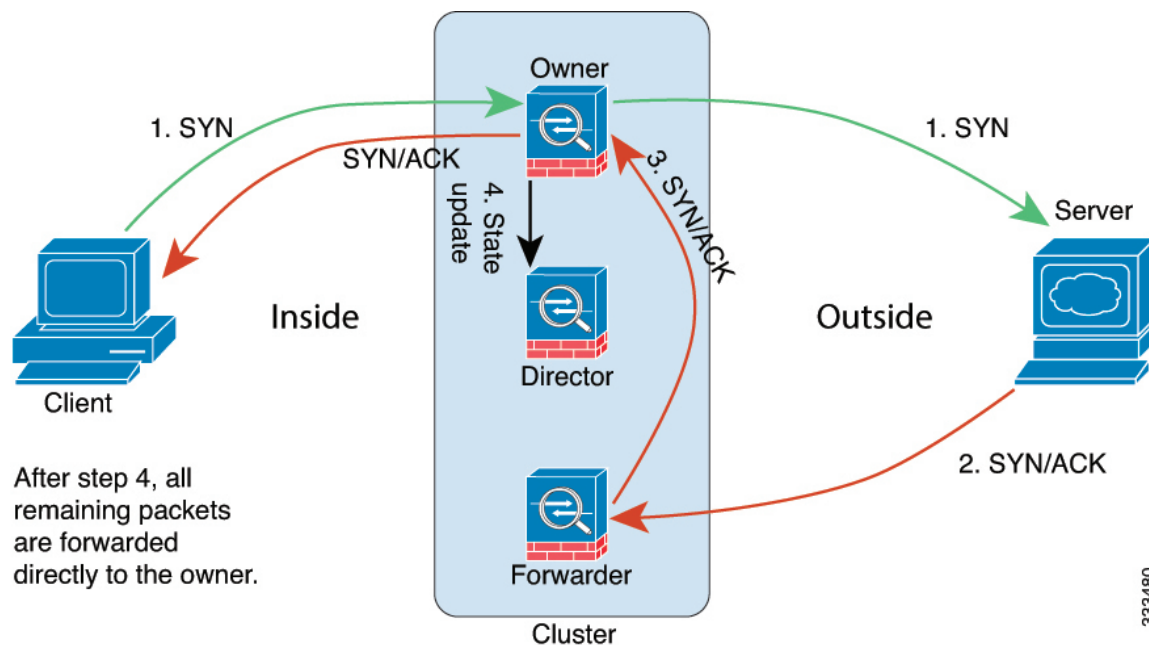

- **Fragment Owner**—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

## New Connection Ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

## Sample Data Flow for TCP

The following example shows the establishment of a new connection.

1. The SYN packet originates from the client and is delivered to one threat defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different threat defense (based on the load balancing method). This threat defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

## Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 252: ICMP and UDP Data Flow*

The first UDP packet originates from the client and is delivered to one threat defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

## History for Clustering

*Table 69:*

| Feature                                                   | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-----------------------------------------------------------|---------------------------|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cluster health monitor settings.                          | 20221213                  | Any                    | <p>You can now edit cluster health monitor settings.</p> <p>New/Modified screens: <b>Devices &gt; Device Management &gt; Cluster &gt; Cluster Health Monitor Settings</b></p> <p><b>Note</b> If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.</p> |
| Cluster health monitor dashboard.                         | 20221213                  | Any                    | <p>You can now view cluster health on the cluster health monitor dashboard.</p> <p>New/Modified screens: <b>System (⚙️) &gt; Health &gt; Monitor</b></p>                                                                                                                                                                                                                                                                    |
| Support for 16-node clusters.                             | 20220609                  | 7.2.0                  | <p>You can now configure 16 node clusters for the Firepower 4100/9300. Previously, the maximum was 6 units.</p> <p>New/Modified screens: none.</p> <p>Supported platforms: Firepower 4100/9300</p>                                                                                                                                                                                                                          |
| Cluster deployment for firewall changes completes faster. | 20220609                  | 7.2.0                  | <p>Cluster deployment for firewall changes now completes faster.</p> <p>New/Modified screens: none.</p>                                                                                                                                                                                                                                                                                                                     |

| Feature                                                                                         | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------------------------------------------------------------|---------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Improved PAT port block allocation for clustering.                                              | 20220609                  | 7.0.3                  | <p>The improved PAT port block allocation ensures that the control unit keeps ports in reserve for joining nodes, and proactively reclaims unused ports. To best optimize the allocation, you can set the maximum nodes you plan to have in the cluster using the <b>cluster-member-limit</b> command using FlexConfig. The control unit can then allocate port blocks to the planned number of nodes, and it will not have to reserve ports for extra nodes you don't plan to use. The default is 16 nodes. You can also monitor syslog 747046 to ensure that there are enough ports available for a new node.</p> <p>New/Modified commands: <b>cluster-member-limit</b> (FlexConfig), <b>show nat pool cluster [summary]</b>, <b>show nat pool ip detail</b></p> |
| Cluster deployment for Snort changes completes faster, and fails faster when there is an event. | 20220609                  | 7.0.3                  | <p>Cluster deployment for Snort changes now completes faster. Also, when a cluster has an event that causes a management center deployment to fail, the failure now occurs more quickly.</p> <p>New/Modified screens: none.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Improved cluster management.                                                                    | 20220609                  | 7.0.3                  | <p>Management Center has improved cluster management functionality that formerly you could only accomplish using the CLI, including:</p> <ul style="list-style-type: none"> <li>• Enable and disable cluster units</li> <li>• Show cluster status from the Device Management page, including History and Summary per unit</li> <li>• Change the role to the control unit</li> </ul> <p>New/Modified screens:</p> <ul style="list-style-type: none"> <li>• <b>Devices &gt; Device Management &gt; More</b> menu</li> <li>• <b>Devices &gt; Device Management &gt; Cluster &gt; General area &gt; Cluster Live Status</b> link <b>Cluster Status</b></li> </ul> <p>Supported platforms: Firepower 4100/9300</p>                                                      |

| Feature                                                                                                | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------------------------------|---------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Multi-instance clustering.                                                                             | 20220609                  | 7.0.3                  | <p>You can now create a cluster using container instances. On the Firepower 9300, you must include one container instance on each module in the cluster. You cannot add more than one container instance to the cluster per security engine/module. We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster.</p> <p>New/Modified FXOS commands: <b>set port-type cluster</b></p> <p>New/modified Firepower Chassis Manager screens:</p> <ul style="list-style-type: none"> <li>• <b>Logical Devices &gt; Add Cluster</b></li> <li>• <b>Interfaces &gt; All Interfaces &gt; Add New</b> drop-down menu &gt; <b>Subinterface &gt; Type</b> field</li> </ul> <p>Supported platforms: threat defense on the Firepower 4100/9300</p> |
| Configuration sync to data units in parallel.                                                          | 20220609                  | 7.0.3                  | <p>The control unit now syncs configuration changes with data units in parallel by default. Formerly, syncing occurred sequentially.</p> <p>New/Modified screens: none.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Messages for cluster join failure or eviction added to <b>show cluster history</b> .                   | 20220609                  | 7.0.3                  | <p>New messages were added to the <b>show cluster history</b> command for when a cluster unit either fails to join the cluster or leaves the cluster.</p> <p>New/Modified commands: <b>show cluster history</b></p> <p>New/Modified screens: none.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| Initiator and responder information for Dead Connection Detection (DCD), and DCD support in a cluster. | 20220609                  | 7.0.3                  | <p>If you enable Dead Connection Detection (DCD), you can use the <b>show conn detail</b> command to get information about the initiator and responder. Dead Connection Detection allows you to maintain an inactive connection, and the <b>show conn</b> output tells you how often the endpoints have been probed. In addition, DCD is now supported in a cluster.</p> <p>New/Modified commands: <b>show conn</b> (output only).</p> <p>Supported platforms: threat defense on the Firepower 4100/9300</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| Feature                                                                | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## CHAPTER 35

# Interface Overview

---

The threat defense device includes data interfaces that you can configure in different modes, as well as a management interface.

- [Management Interface, on page 905](#)
- [Interface Mode and Types, on page 906](#)

- [Merge the Management and Diagnostic Interfaces, on page 939](#)
- [History for Interfaces, on page 946](#)

## Management Interface

In Version 7.3 and earlier, the physical management interface is shared between the Diagnostic logical interface and the Management logical interface. In Version 7.4 and later, the Diagnostic interface is merged with Management for a simplified user experience.

## Management Interface

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the management center. It uses its own IP address and static routing. You can configure its settings at the CLI using the **configure network** command. You can also view its status on the **Devices > Device Management > Devices > Interfaces** page. If you change the IP address at the CLI after you add it to the management center, you can match the IP address in the Secure Firewall Management Center in the **Devices > Device Management > Devices > Management** area.

You can alternatively manage the threat defense using a data interface instead of the Management interface.

## Diagnostic Interface

For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available.

If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically.

If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Note that support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. To manually merge the Management and Diagnostic interfaces, see [Merge the Management and Diagnostic Interfaces, on page 939](#). Configurations that prevent an automatic merge include the following:

- A data interface named "management"—This name is reserved for use with the merged Management interface.
- IP Address on Diagnostic
- DNS enabled on Diagnostic
- Syslog, SNMP, RADIUS or AD (for remote access VPN) source interface is Diagnostic
- RADIUS or AD (for remote access VPN) with no source interface specified, and there is at least one interface configured as management-only (including Diagnostic)—The default route lookup for these services has changed from the management-only routing table to the data routing table, with no fallback to management. Therefore, you cannot use a management-only interface other than Management.
- Static routes on Diagnostic
- Dynamic routing on Diagnostic
- HTTP server on Diagnostic
- ICMP on Diagnostic
- DDNS for Diagnostic
- FlexConfig using Diagnostic

For more information about how the legacy Diagnostic interface operates, see the 7.3 version of this guide.

## Interface Mode and Types

You can deploy threat defense interfaces in two modes: Regular firewall mode and IPS-only mode. You can include both firewall and IPS-only interfaces on the same device.

### Regular Firewall Mode

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See [Transparent or Routed Firewall Mode, on page 491](#) for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the threat defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the threat defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

### IPS-Only Mode

IPS-only mode interfaces bypass many firewall checks and only support IPS security policy. You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

---

**Note** The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes.

---

IPS-only interfaces can be deployed as the following types:

- Inline Set, with optional Tap mode—An inline set acts like a bump on the wire, and binds two interfaces together to slot into an existing network. This function allows the threat defense to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of an inline set unless explicitly dropped.

With tap mode, the threat defense is deployed inline, but the network traffic flow is undisturbed. Instead, the threat defense makes a copy of each packet so that it can analyze the packets. Note that rules of these types do generate intrusion events when they are triggered, and the table view of intrusion events indicates that the triggering packets would have dropped in an inline deployment. There are benefits to using tap mode with FTDs that are deployed inline. For example, you can set up the cabling between the threat defense and the network as if the threat defense were inline and analyze the kinds of intrusion events the threat defense generates. Based on the results, you can modify your intrusion policy and add the drop rules that best protect your network without impacting its efficiency. When you are ready to deploy the threat defense inline, you can disable tap mode and begin dropping suspicious traffic without having to reconfigure the cabling between the threat defense and the network.

---

**Note** Tap mode *significantly* impacts threat defense performance, depending on the traffic.

---

---

**Note** Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode or the firewall-type interfaces.

---

- Passive or ERSPAN Passive—Passive interfaces monitor traffic flowing across a network using a switch SPAN or mirror port. The SPAN or mirror port allows for traffic to be copied from other ports on the

switch. This function provides the system visibility within the network without being in the flow of network traffic. When you configure the threat defense in a passive deployment, the threat defense cannot take certain actions such as blocking or shaping traffic. Passive interfaces receive all traffic unconditionally, and no traffic received on these interfaces is retransmitted. Encapsulated remote switched port analyzer (ERSPAN) interfaces allow you to monitor traffic from source ports distributed over multiple switches, and uses GRE to encapsulate the traffic. ERSPAN interfaces are only allowed when the threat defense is in routed firewall mode.

---

**Note** Using SR-IOV interfaces as passive interfaces on NGFWv is not supported on some Intel network adapters (such as Intel X710 or 82599) using SR-IOV drivers due to a promiscuous mode restriction. In such cases, use a network adapter that supports this functionality. See [Intel Ethernet Products](#) for more information on Intel network adapters.

---

## Security Zones and Interface Groups

Each interface can be assigned to a *security zone* and/or *interface group*. You then apply your security policy based on zones or groups. For example, you can assign the "inside" interface on one or more devices to the "inside" zone; and the "outside" interfaces to the "outside" zone. You can then configure your access control policy to enable traffic to go from the inside zone to the outside zone for every device using the same zones.

To view the interfaces that belong to each object, choose **Objects > Object Management** and click **Interface**. This page lists the security zones and interface groups configured on your managed devices. You can expand each interface object to view the type of interfaces in each interface object.

---

**Note** Policies that apply to **any** zone (a global policy) apply to interfaces in zones as well as any interfaces that are not assigned to a zone.

---

---

**Note** The Management interface does not belong to a zone or interface group.

---

### Security Zones Vs. Interface Groups

There are two types of interface objects:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

You can use interface groups in NAT policies, prefilter policies, and QoS policies, as well as features that let you specify the interface name directly, such as Syslog servers or DNS servers.

Some policies only support security zones, while other policies support zones and groups. Unless you need the functionality an interface group provides, you should default to using security zones because security zones are supported for all features.

You cannot change an existing security zone to an interface group or vice-versa; instead you must create a new interface object.

---

**Note** Although tunnel zones are not interface objects, you can use them in place of security zones in certain configurations; see [Tunnel Zones and Prefiltering, on page 1988](#).

---

### Interface Object Types

See the following interface object types:

- Passive—For IPS-only passive or ERSPAN interfaces.
- Inline—For IPS-only inline set interfaces.
- Switched—For regular firewall bridge group interfaces.
- Routed—For regular firewall routed interfaces.
- ASA—(Security zones only) For legacy ASA FirePOWER device interfaces.
- Management—(Interface groups only) For management-only interfaces.
- Loopback—(Interface groups only) For loopback interfaces.

All interfaces in an interface object must be of the same type. After you create an interface object, you cannot change the type of interfaces it contains.

### Interface Names

Note that the interface (or zone name) itself does not provide any default behavior in regards to the security policy. We recommend using names that are self-describing to avoid mistakes in future configuration. A good name signifies a logical segment or traffic specification, for example:

- Names of internal interfaces—InsideV110, InsideV160, InsideV195
- Names of DMZ interfaces—DMZV11, DMZV12, DMZV-TEST
- Names of external interfaces—Outside-ASN78, Outside-ASN91

## Auto-MDI/MDIX Feature

For RJ-45 interfaces, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. For Gigabit Ethernet, when the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

# Default Settings for Interfaces

This section lists default settings for interfaces.

## Default State of Interfaces

The default state of an interface depends on the type.

- Physical interfaces—Disabled. The exception is the Management interface that is enabled for initial setup. Physical interfaces includes switch ports.
- VLAN subinterfaces—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.
- EtherChannel port-channel interfaces (ISA 3000)—Enabled. However, for traffic to pass through the EtherChannel, the channel group physical interfaces must also be enabled.
- EtherChannel port-channel interfaces (Firepower and Secure Firewall models)—Disabled.

---

**Note** For the Firepower 4100/9300, you can administratively enable and disable interfaces in both the chassis and in the management center. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and management center.

---

## Default Speed and Duplex

By default, the speed and duplex for copper (RJ-45) interfaces are set to auto-negotiate.

By default, the speed and duplex for fiber (SFP) interfaces are set to the maximum speed, with auto-negotiation enabled.

For the Secure Firewall 3100/4200, the speed is set to detect the installed SFP speed.

# Create Security Zone and Interface Group Objects

Add security zones and interface groups to which you can assign device interfaces.

---

**Tip** You can create empty interface objects and add interfaces to them later. To add an interface, the interface must have a name. You can also create security zones (but not interface groups) while configuring interfaces.

---

## Before you begin

Understand the usage requirements and restrictions for each type of interface object. See [Security Zones and Interface Groups, on page 908](#).

## Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- You can alternatively choose **Objects > Other FTD Objects** to create objects.
- Step 2** Choose **Interface** from the list of object types.
- Step 3** Click **Add > Security Zone** or **Add > Interface Group**.
- Step 4** Enter a **Name**.
- Step 5** Choose an **Interface Type**.
- Step 6** (Optional) From the **Device > Interfaces** drop-down list, choose a device that contains interfaces you want to add.
- You do not need to assign interfaces on this screen; you can instead assign interfaces to the zone or group when you configure the interface.
- Step 7** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes.

# Enable the Physical Interface and Configure Ethernet Settings

This section describes how to:

- Enable the physical interface. By default, physical interfaces are disabled (with the exception of the Management interface).
- Set a specific speed and duplex. By default, speed and duplex are set to Auto.

This procedure only covers a small subset of Interface settings. Refrain from setting other parameters at this point. For example, you cannot name an interface that you want to use as part of an EtherChannel interface.

---

**Note** For the Firepower 4100/9300, you configure basic interface settings in FXOS. See [Configure a Physical Interface, on page 536](#) for more information.

---

---

**Note** For Firepower 1010 and Secure Firewall 1210/1220 switch ports, see [Configure Firepower 1010 and Secure Firewall 1210/1220 Switch Ports, on page 950](#).

---

### Before you begin

If you changed the physical interfaces on the device after you added it to the management center, you need to refresh the interface listing by clicking **Sync Interfaces from device** on the top left of **Interfaces**. For the Secure Firewall 3100/4200, which supports hot swapping, see [Manage the Network Module for the Secure Firewall 3100/4200, on page 925](#) before you change interfaces on a device.

### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Enable the interface by checking the **Enabled** check box.
- Step 4** (Optional) Add a description in the **Description** field.  
The description can be up to 200 characters on a single line, without carriage returns.
- Step 5** (Optional) Set the duplex and speed by clicking **Hardware Configuration > Speed**.
- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
  - **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100/4200 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.
  - **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.
  - **Forward Error Correction Mode**—(Secure Firewall 3100/4200 only) For 25 Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

*Table 70: Default FEC for Auto Setting*

| Transceiver Type | Fixed Port Default FEC (Ethernet 1/9 through 1/16) | Network Module Default FEC |
|------------------|----------------------------------------------------|----------------------------|
| 25G-SR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |

| 25/50/100G       | Clause 91 RS-FEC                                   | Clause 91 RS-FEC           |

**Step 6** (Optional) (Firepower 1100/Secure Firewall 1200/3100/4200) Enable Link Layer Discovery Protocol (LLDP) by clicking **Hardware Configuration > Network Connectivity**.

- **Enable LLDP Receive**—Enables the firewall to receive LLDP packets from its peers.
- **Enable LLDP Transmit**—Enables the firewall to send LLDP packets to its peers.

**Step 7** (Optional) (Secure Firewall 3100/4200) Enable pause (XOFF) frames for flow control by clicking **Hardware Configuration > Network Connectivity**, and checking **Flow Control Send**.

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If the threat defense port experiences congestion (exhaustion of queuing resources on the internal switch) and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

**Note** The threat defense supports transmitting pause frames so that the remote peer can rate-control the traffic.

However, receiving of pause frames is not supported.

The internal switch has a global pool of 8000 buffers of 250 bytes each, and the switch allocates buffers dynamically to each port. A pause frame is sent out every interface with flowcontrol enabled when the buffer usage exceeds the global high-water mark (2 MB (8000 buffers)); and a pause frame is sent out of a particular interface when its buffer exceeds the port high-water mark (.3125 MB (1250 buffers)). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark (1.25 MB globally (5000 buffers); .25 MB per port (1000 buffers)). The link partner can resume traffic after receiving an XON frame.

Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

**Step 8** In the **Mode** drop-down list, choose one of the following:

- **None**—Choose this setting for regular firewall interfaces and inline sets. The mode will automatically be changed to Routed, Switched, or Inline based on further configuration.
- **Passive**—Choose this setting for passive IPS-only interfaces.
- **Ers span**—Choose this setting for ERSPAN passive IPS-only interfaces.

**Step 9** In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to distribute the traffic across multiple egress interfaces.

**Step 10** Click **OK**.

**Step 11** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

**Step 12** Continue configuring interfaces.

- [Regular Firewall Interfaces, on page 949](#)

- [Inline Sets and Passive Interfaces, on page 1023](#)

## Configure EtherChannel Interfaces

This section tells how to configure EtherChannel interfaces.

---

**Note** For the Firepower 4100/9300, you configure EtherChannels in FXOS. See [Add an EtherChannel \(Port Channel\), on page 537](#) for more information.

---

## About EtherChannels

This section describes EtherChannels.

### About EtherChannels

An 802.3ad EtherChannel is a logical interface (called a port-channel interface) consisting of a bundle of individual Ethernet links (a channel group) so that you increase the bandwidth for a single network. A port channel interface is used in the same way as a physical interface when you configure interface-related features.

You can configure up to 48 EtherChannels, depending on how many interfaces your model supports.

### Channel Group Interfaces

Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.

All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.

The EtherChannel aggregates the traffic across all the available active interfaces in the channel. The interface is selected using a proprietary hash algorithm, based on source or destination MAC addresses, IP addresses, TCP and UDP port numbers and VLAN numbers.

### Connecting to an EtherChannel on Another Device

The device to which you connect the threat defense EtherChannel must also support 802.3ad EtherChannels; for example, you can connect to the Catalyst 6500 switch or the Cisco Nexus 7000.

When the switch is part of a Virtual Switching System (VSS) or Virtual Port Channel (vPC), then you can connect threat defense interfaces within the same EtherChannel to separate switches in the VSS/vPC. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch.

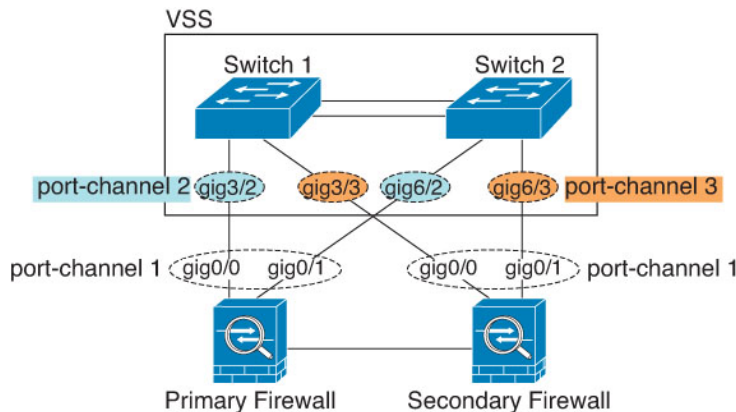

Figure 253: Connecting to a VSS/vPC

**Note** If the threat defense device is in transparent firewall mode, and you place the threat defense device between two sets of VSS/vPC switches, then be sure to disable Unidirectional Link Detection (UDLD) on any switch ports connected to the threat defense device with an EtherChannel. If you enable UDLD, then a switch port may receive UDLD packets sourced from both switches in the other VSS/vPC pair. The receiving switch will place the receiving interface in a down state with the reason "UDLD Neighbor mismatch".

If you use the threat defense device in an Active/Standby failover deployment, then you need to create separate EtherChannels on the switches in the VSS/vPC, one for each threat defense device. On each threat defense device, a single EtherChannel connects to both switches. Even if you could group all switch interfaces into a single EtherChannel connecting to both threat defense devices (in this case, the EtherChannel will not be established because of the separate threat defense system IDs), a single EtherChannel would not be desirable because you do not want traffic sent to the standby threat defense device.

Figure 254: Active/Standby Failover and VSS/vPC

### Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDU) between two network devices.

You can configure each physical interface in an EtherChannel to be:

- **Active**—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- **Passive**—Receives LACP updates. A passive EtherChannel can only establish connectivity with an active EtherChannel. Not supported on hardware models.
- **On**—The EtherChannel is always on, and LACP is not used. An “on” EtherChannel can only establish a connection with another “on” EtherChannel.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. “On” mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

## Load Balancing

The threat defense device distributes packets to the interfaces in the EtherChannel by hashing the source and destination IP address of the packet (this criteria is configurable). The resulting hash is divided by the number of active links in a modulo operation where the resulting remainder determines which interface owns the flow. All packets with a *hash\_value mod active\_links* result of 0 go to the first interface in the EtherChannel, packets with a result of 1 go to the second interface, packets with a result of 2 go to the third interface, and so on. For example, if you have 15 active links, then the modulo operation provides values from 0 to 14. For 6 active links, the values are 0 to 5, and so on.

If an active interface goes down and is not replaced by a standby interface, then traffic is rebalanced between the remaining links. The failure is masked from both Spanning Tree at Layer 2 and the routing table at Layer 3, so the switchover is transparent to other network devices.

## EtherChannel MAC Address

All interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links.

### Firepower and Secure Firewall Hardware

The port-channel interface uses the MAC address of the internal interface Internal-Data 0/1. Alternatively you can manually configure a MAC address for the port-channel interface. All EtherChannel interfaces on a chassis use the same MAC address, so be aware that if you use SNMP polling, for example, multiple interfaces will have the same MAC address.

---

**Note** Member interfaces only use the Internal-Data 0/1 MAC address after a reboot. Prior to rebooting, the member interface uses its own MAC address. If you add a new member interface after a reboot, you will have to perform another reboot to update its MAC address.

---

# Guidelines for EtherChannels

## Bridge Group

In routed mode, Management Center-defined EtherChannels are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.

## High Availability

- When you use an EtherChannel interface as a High Availability link, it must be pre-configured on both units in the High Availability pair; you cannot configure it on the primary unit and expect it to replicate to the secondary unit because *the High Availability link itself is required for replication*.
- If you use an EtherChannel interface for the state link, no special configuration is required; the configuration can replicate from the primary unit as normal. For the Firepower 4100/9300 chassis, all interfaces, including EtherChannels, need to be pre-configured on both units.
- You can monitor EtherChannel interfaces for High Availability. When an active member interface fails over to a standby interface, this activity does not cause the EtherChannel interface to appear to be failed when being monitored for device-level High Availability. Only when all physical interfaces fail does the EtherChannel interface appear to be failed (for an EtherChannel interface, the number of member interfaces allowed to fail is configurable).
- If you use an EtherChannel interface for a High Availability or state link, then to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a High Availability link. To alter the configuration, you need to temporarily disable High Availability, which prevents High Availability from occurring for the duration.

## Model Support

- You cannot add EtherChannels in the management center for the Firepower 4100/9300 or the threat defense virtual. The Firepower 4100/9300 supports EtherChannels, but you must perform all hardware configuration of EtherChannels in FXOS on the chassis.
- You cannot use Firepower 1010 or Secure Firewall 1210/1220 switch ports or VLAN interfaces in EtherChannels.

## General EtherChannel Guidelines

- You can configure up to 48 EtherChannels, depending on how many interfaces are available on your model.
- Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- All interfaces in the channel group must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, except for the Secure Firewall 1200/3100/4200, which supports different interface capacities as long as the speed is set to Detect SFP; in this case the lowest common speed is used.

- The device to which you connect the threat defense EtherChannel must also support 802.3ad EtherChannels.
- The threat defense device does not support LACPDU s that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **vlan dot1Q tag native** command, then the threat defense device will drop the tagged LACPDU s. Be sure to disable native VLAN tagging on the neighboring switch.
- The LACP rate depends on the model. When you set the rate (normal or fast), the device requests that rate from the connecting switch. In return, the device will send at the rate requested by the connecting switch. We recommend that you set the same rate on both sides.
  - Firepower 4100/9300—The LACP rate is set to fast by default in FXOS, but you can configure it as normal (also known as slow).
  - Secure Firewall 3100/4200—The LACP rate is set to normal (slow) by default, but you can configure it as fast on the device.
  - All other models—The LACP rate set to normal (also known as slow), and it is not configurable, which means the device will always request a slow rate from the connecting switch. We recommend setting the rate on the switch to slow, so both sides send LACP messages at the same rate.
- In Cisco IOS software versions earlier than 15.1(1)S2, threat defense did not support connecting an EtherChannel to a switch stack. With default switch settings, if the threat defense EtherChannel is connected cross stack, and if the primary switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- All the threat defense configuration refers to the logical EtherChannel interface instead of the member physical interfaces.

## Configure an EtherChannel

This section describes how to create an EtherChannel port-channel interface, assign interfaces to the EtherChannel, and customize the EtherChannel.

### Guidelines

- You can configure up to 48 EtherChannels, depending on the number of interfaces for your model.
- Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- All interfaces in the channel group must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, except for the Secure Firewall 1200/3100/4200, which supports different interface capacities as long as the speed is set to Detect SFP; in this case the lowest common speed is used.

---

**Note** For the Firepower 4100/9300, you configure EtherChannels in FXOS. See [Add an EtherChannel \(Port Channel\), on page 537](#) for more information.

---

#### Before you begin

- You cannot add a physical interface to the channel group if you configured a name for it. You must first remove the name.

---

**Note** If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

---

### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Enable the member interfaces according to [Enable the Physical Interface and Configure Ethernet Settings, on page 911](#).
- Step 3** Click **Add Interfaces > Ether Channel Interface**.
- Step 4** On the **General** tab, set the **Ether Channel ID** to a number between 1 and 48 (1 and 8 for the Firepower 1010 and Secure Firewall 1210, 1 and 10 for the Secure Firewall 1220).

Figure 255: Add EtherChannel Interface

**Add Ether Channel Interface**

General IPv4 IPv6 Hardware Configuration Path Monitoring Advanced

Name:

Enabled  
 Management Only

Description:

Mode:

Security Zone:

MTU:   
(64 - 9198)

Priority:   
(0 - 65535)

Propagate Security Group Tag:

Ether Channel ID \*:

Cancel OK

**Step 5** In the **Available Interfaces** area, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members.

Make sure all interfaces are the same type and speed capability.

Figure 256: Available Interfaces

**Step 6** (Optional) Click the **Advanced** tab to customize the EtherChannel. Set the following parameters on the **Information** sub-tab:

Figure 257: Advanced

- (ISA 3000 only) **Load Balancing**—Select the criteria used to load balance the packets across the group channel interfaces. By default, the threat defense device balances the packet load on interfaces according to the source and destination IP address of the packet. If you want to change the properties on which the packet is categorized, choose a different set of criteria. For example, if your traffic is biased heavily towards the same source and destination IP addresses, then the traffic assignment to interfaces in the EtherChannel will be unbalanced. Changing to a different algorithm can result in more evenly distributed traffic. For more information about load balancing, see [Load Balancing, on page 916](#).
- **LACP Mode**—Choose Active, Passive, or On. We recommend using Active mode (the default). Passive mode is only available for the ISA 3000 only.
- (Secure Firewall 3100/4200 only) **LACP Rate**—Choose Default, Normal, or Fast. The default is Normal (also known as slow). Sets the LACP data unit receive rate for a physical interface in the channel group. We recommend that you set the same rate on both sides.

- (ISA 3000 only) **Active Physical Interface: Range**—From the left drop-down list, choose the minimum number of active interfaces required for the EtherChannel to be active, between 1 and 16. The default is 1. From the right drop-down list, choose the maximum number of active interfaces allowed in the EtherChannel, between 1 and 16. The default is 16. If your switch does not support 16 active interfaces, be sure to set this command to 8 or fewer.
- **Active Mac Address**—Set a manual MAC address if desired. The `mac_address` is in H.H.H format, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE is entered as 000C.F142.4CDE.

**Step 7** Click the **Hardware Configuration** tab and set the Duplex and Speed for all member interfaces.

**Step 8** Click **OK**.

**Step 9** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

**Step 10** (Optional) For regular firewall interfaces, add a VLAN subinterface. See [Add a Subinterface, on page 967](#).

**Step 11** For regular firewall interfaces, configure the routed or transparent mode interface parameters: [Configure Routed Mode Interfaces, on page 985](#) or [Configure Bridge Group Interfaces, on page 990](#). For IPS-only interfaces, see [Inline Sets and Passive Interfaces, on page 1023](#).

## Sync Interface Changes with the Management Center

Interface configuration changes on the device can cause the management center and the device to get out of sync. The management center can detect interface changes by one of the following methods:

- Event sent from the device
- Sync when you deploy from the management center

If the management center detects interface changes when it attempts to deploy, the deploy will fail. You must first accept the interface changes.

- Manual sync

There are two types of interface changes performed outside of management center that need to be synced:

- Addition or deletion of physical interfaces—Adding a new interface, or deleting an unused interface has minimal impact on the threat defense configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the threat defense configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the management center.

When the management center detects changes, the **Interface** page shows status (removed, changed, or added) to the left of each interface.

- Management Center access interface changes—If you configure a data interface for managing using the `configure network management-data-interface` command, you must manually make matching

configuration changes in and then acknowledge the changes. These interface changes cannot be made automatically.

This procedure describes how to manually sync device changes if required and how to acknowledge the detected changes. If device changes are temporary, you should not save the changes in the management center; you should wait until the device is stable, and then re-sync.

### Before you begin

## Procedure

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** If required, click **Sync Device** on the top left of **Interfaces**.
- Step 3** After the changes are detected, see the following steps.

### Addition or Deletion of Physical Interfaces

- You will see a red banner on **Interfaces** indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.
- Click **Validate Changes** to make sure your policy will still work with the interface changes.  
If there are any errors, you need to change your policy and rerun the validation.
- Click **Save**.  
You can now go to **Deploy > Deployment** and deploy the policy to assigned devices.

### FMC Access Interface Changes

- You will see a yellow banner in the top right of the **Device** page indicating that the management center access configuration has changed. Click the **View details** link to view the interface changes.

The **FMC Access - Configuration Details** dialog box opens.

- Take note of all highlighted configurations, especially the pink highlighted ones. You need to match any values on the threat defense by manually configuring them on the management center.

For example, the pink highlights below show configuration that exists on the threat defense but not yet on the management center.

| IPv6 Gateway                      |                            |                            |

Legend: Above configurations will be ■ added, ■ modified or ■ disassociated from FMC Access interface on next deploy to FTD.

Acknowledge Close

c) Click **Acknowledge**.

We recommend that you do not click **Acknowledge** until you have finished the management center configuration, and are ready to deploy. Clicking **Acknowledge** removes the block on deployment. The next time you deploy, the management center configuration will overwrite any remaining conflicting

settings on the threat defense. It is your responsibility to manually fix the configuration in the management center before you re-deploy.

- d) You can now go to **Deploy > Deployment** and deploy the policy to assigned devices.

## Manage the Network Module for the Secure Firewall 3100/4200

If you install a network module before you first power on the device, no action is required; the network module is enabled and ready for use.

To view physical interface details for the device, and to manage the network module, open the **Chassis Operations** page. From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit. The **Chassis Operations** page opens for the device.

### Physical Interfaces

This view lists only the physical interfaces to perform chassis related advanced operations. To view complete list of physical and logical interfaces, navigate to [Interface page in device details](#)

| Interface Name | Duplex | Auto Negotiation | Admin FEC | Admin Speed | Media Type |
|----------------|--------|------------------|-----------|-------------|------------|
| Ethernet1/1    | FULL   | No               | AUTO      | 1 gbps      | rj45       |
| Ethernet1/2    | FULL   | No               | AUTO      | 1 gbps      | rj45       |
| Ethernet1/3    | FULL   | No               | AUTO      | 1 gbps      | rj45       |
| Ethernet1/4    | FULL   | No               | AUTO      | 1 gbps      | rj45       |

Click **Refresh** to refresh interface status. Click **Sync Modules** if you made a hardware change on the device that you need to detect.

If you need to make changes to your network module installation after initial bootup, then see the following procedures.

## Configure Breakout Ports

You can configure 10GB breakout ports for each 40GB or higher interface. This procedure tells you how to break out and rejoin the ports. Breakout ports can be used just like any other physical Ethernet port, including being added to EtherChannels.

Changes are immediate; you do not need to deploy to the device. After you break or rejoin, you cannot roll back to the previous interface state.

### Before you begin

- You must use a supported breakout cable. See the hardware installation guide for more information.
- The interface cannot be in use for the following before breaking or rejoining:
  - Failover link
  - Cluster control link
  - Have a subinterface
  - EtherChannel member
  - BVI member
  - Manager access interface
- Breaking or rejoining an interface that is used directly in your security policy can impact the configuration; however, the action is not blocked.

### Procedure

- Step 1** From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

*Figure 259: Manage Chassis*

| <input type="checkbox"/> | Name                                               | Model                        | Version | Chassis                |
|--------------------------|----------------------------------------------------|------------------------------|---------|------------------------|
| <input type="checkbox"/> | Ungrouped (2)                                      |                              |         |                        |
| <input type="checkbox"/> | 172.16.0.51 (Snort 3)<br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <a href="#">Manage</a> |

The **Chassis Operations** page opens for the device (in multi-instance mode, this page is called **Chassis Manager**). This page shows physical interface details for the device.

- Step 2** Break out 10GB ports from a 40GB or higher interface.

- a) click **Break** (🔌) to the right of the interface.

Click **Yes** on the confirmation dialog box. If the interface is in use, you will see an error message. You must resolve any use cases before you can retry the breakout.

For example, to break out the Ethernet2/1 40GB interface, the resulting child interfaces will be identified as Ethernet2/1/1, Ethernet2/1/2, Ethernet2/1/3, and Ethernet2/1/4.

On the interfaces graphic, a port that is broken out has this appearance:

**Figure 260: Breakout Ports**

- b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

**Figure 261: Go to Interface Page**

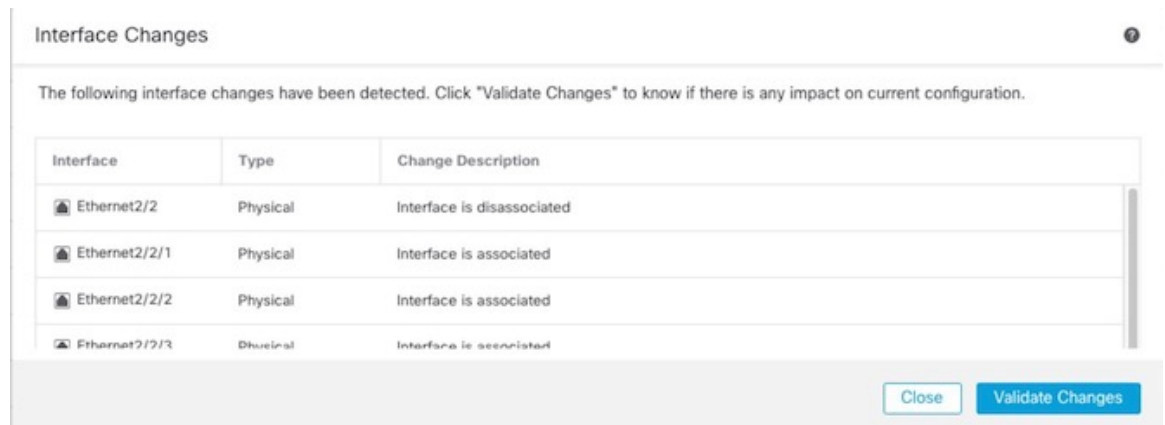

▲ This device has configuration changes that were performed directly on the device. Visit [Interface page in device details](#)

- c) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

**Figure 262: View Interface Changes**

Interface configuration has changed on device. [Click to know more.](#)

**Figure 263: Interface Changes**

- d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Replacing the parent interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

- e) Click **Close** to return to the **Interfaces** page.  
 f) Click **Save** to save the interface changes to the firewall.  
 g) If you had to change any configuration, go to **Deploy > Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

**Step 3** Rejoin breakout ports.

You must rejoin all child ports for the interface.

- a) Click **Join** (↪) to the right of the interface.

Click **Yes** on the confirmation dialog box. If any child ports are in use, you will see an error message. You must resolve any use cases before you can retry the rejoin.

- b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

**Figure 264: Go to Interface Page**

▲ This device has configuration changes that were performed directly on the device. Visit [Interface page in device details](#)

- c) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

**Figure 265: View Interface Changes**

Interface configuration has changed on device. [Click to know more.](#)

**Figure 266: Interface Changes**

| Interface     | Type     | Change Description         |
|---------------|----------|----------------------------|
| Ethernet2/2   | Physical | Interface is disassociated |
| Ethernet2/2/1 | Physical | Interface is associated    |
| Ethernet2/2/2 | Physical | Interface is associated    |
| Ethernet2/2/3 | Physical | Interface is associated    |

- d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Replacing the child interfaces that are used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

- e) Click **Close** to return to the **Interfaces** page.  
 f) Click **Save** to save the interface changes to the firewall.  
 g) If you had to change any configuration, go to **Deploy > Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

## Add a Network Module

To add a network module to a firewall after initial bootup, perform the following steps. Adding a new module requires a reboot.

### Procedure

- Step 1** Install the network module according to the hardware installation guide.  
For clustering or High Availability, install the network module on all nodes.
- Step 2** Reboot the firewall; see [Shut Down or Restart the Device, on page 89](#).  
For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see [Switch the Active Peer in the Threat Defense High Availability Pair, on page 632](#)), and reboot the former control node/active unit.
- Step 3** From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

**Figure 267: Manage Chassis**

| <input type="checkbox"/> | Name                                             | Model                        | Version | Chassis       |
|--------------------------|--------------------------------------------------|------------------------------|---------|---------------|
| <input type="checkbox"/> | ▼ Ungrouped (2)                                  |                              |         |               |
| <input type="checkbox"/> | 172.16.0.51 Snort 3<br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <b>Manage</b> |

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

- Step 4** Click **Sync Modules** to update the page with the new network module details.
- Step 5** On the interfaces graphic, click the slider (  ) to enable the network module.

**Figure 268: Enable the Network Module**

- Step 6** You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 269: Confirm Enable

**Step 7** You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

Figure 270: Go to Interface Page

**Step 8** (Optional) At the top of the **Interfaces** page, you see a message that the interface configuration has changed. You can click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 271: View Interface Changes

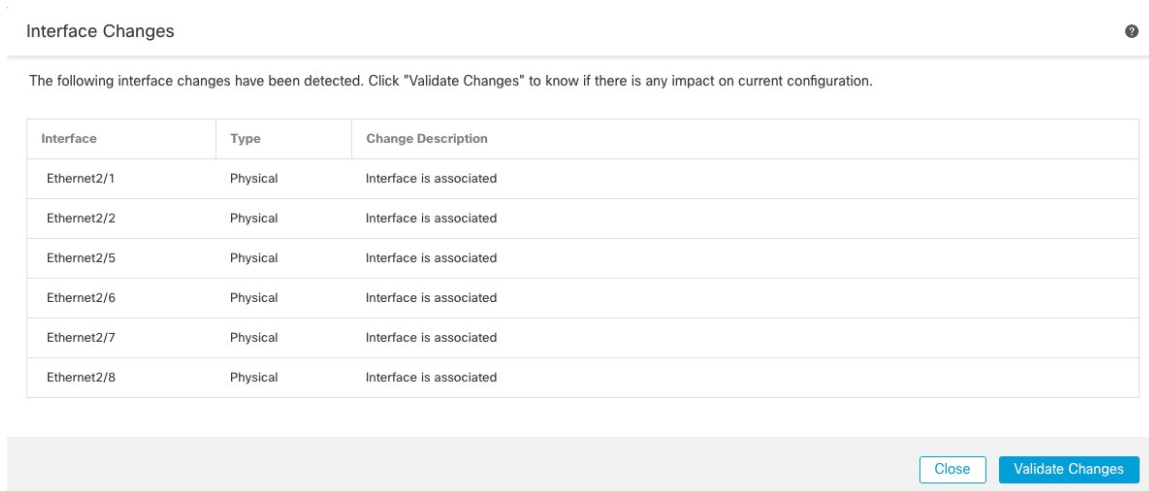

Figure 272: Interface Changes

Click **Close** to return to the **Interfaces** page. (Because you are adding a new module, there shouldn't be any configuration impact, so you do not need to click **Validate Changes**.)

**Step 9** Click **Save** to save the interface changes to the firewall.

## Hot Swap the Network Module

You can hot swap a network module for a new module of the same type without having to reboot. However, you must shut down the current module to remove it safely. This procedure describes how to shut down the old module, install a new module, and enable it.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit. You cannot disable a network module if the cluster control link/failover link is on the module.

### Before you begin

### Procedure

**Step 1** For clustering or High Availability, perform the following steps.

- **Clustering**—Ensure the unit you want to perform the hot swap on is a data node; then break the node so it is no longer in the cluster.

You will add the node back to the cluster after you perform the hot swap. Alternatively, you can perform all operations on the control node, and the network module changes will sync to all data nodes. However, you will lose use of those interfaces on all nodes during the hot swap.

- **High Availability**—To avoid failing over when you disable the network module:
  - If the failover link is on the network module, you must break High Availability. See [Break a High Availability Pair, on page 636](#). Disabling the network module with an active failover link is not allowed.
  - Disable interface monitoring for interfaces on the network module. See [Configure Standby IP Addresses and Interface Monitoring, on page 630](#).

**Step 2** From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

*Figure 273: Manage Chassis*

| <input type="checkbox"/> | Name                                             | Model                        | Version | Chassis                |
|--------------------------|--------------------------------------------------|------------------------------|---------|------------------------|
| <input type="checkbox"/> | Ungrouped (2)                                    |                              |         |                        |
| <input type="checkbox"/> | 172.16.0.51 Snort 3<br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <a href="#">Manage</a> |

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

**Step 3** On the interfaces graphic, click the slider () to disable the network module.

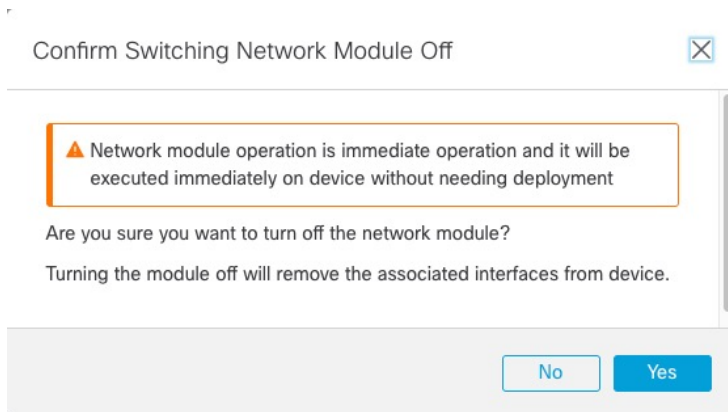

Figure 274: Disable the Network Module

Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

**Step 4** You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 275: Confirm Disable

**Step 5** On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.

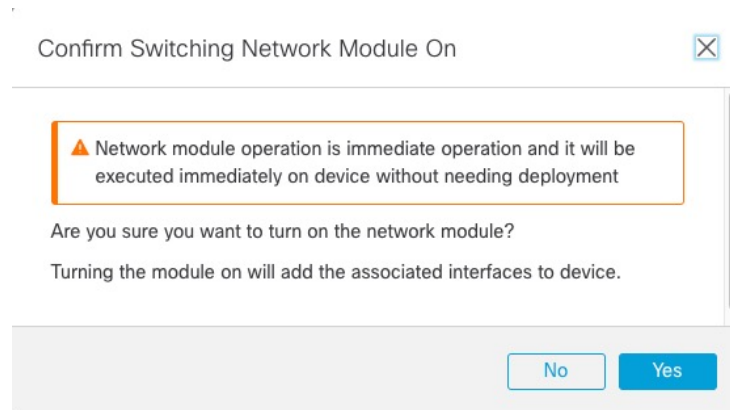

**Step 6** In the management center, enable the new module by clicking the slider (  ).

Figure 276: Enable the Network Module

**Step 7** You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 277: Confirm Enable

**Step 8** For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster.
- **High Availability**—
  - If you broke High Availability, then reform High Availability. See [Add a High Availability Pair, on page 627](#).
  - Reenable interface monitoring for interfaces on the network module. See [Configure Standby IP Addresses and Interface Monitoring, on page 630](#).

---

## Replace the Network Module with a Different Type

If you replace a network module with a different type, then a reboot is required. If the new module has fewer interfaces than the old module, you will have to manually remove any configuration related to interfaces that will no longer be present.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit.

### Before you begin

For High Availability, you cannot disable a network module if the failover link is on the module. You will have to break High Availability (see [Break a High Availability Pair, on page 636](#)), which means you will have downtime when you reboot the active unit. After the units finish rebooting, you can reform High Availability.

### Procedure

---

**Step 1** For clustering or High Availability, perform the following steps.

- **Clustering**—To avoid downtime, you can break each node one at a time so it is no longer in the cluster while you perform the network module replacement.  
You will add the node back to the cluster after you perform the replacement.

## Replace the Network Module with a Different Type

- **High Availability**—To avoid failing over when you replace the network module, disable interface monitoring for interfaces on the network module. See [Configure Standby IP Addresses and Interface Monitoring](#), on page 630.

**Step 2** From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

**Figure 278: Manage Chassis**

| <input type="checkbox"/> | Name                                               | Model                        | Version | Chassis       |
|--------------------------|----------------------------------------------------|------------------------------|---------|---------------|
| <input type="checkbox"/> | ▼ Ungrouped (2)                                    |                              |         |               |
| <input type="checkbox"/> | 172.16.0.51 - Snort 3<br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <b>Manage</b> |

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

**Step 3** On the interfaces graphic, click the slider () to disable the network module.

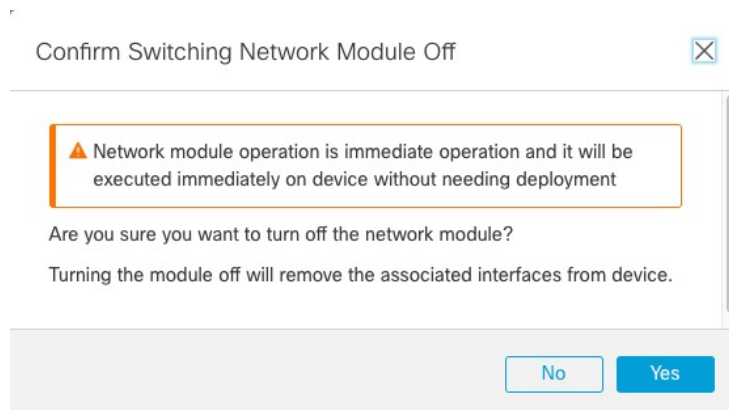

**Figure 279: Disable the Network Module**

Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

**Step 4** You are prompted to confirm that you want to turn the network module off. Click **Yes**.

**Figure 280: Confirm Disable**

**Step 5** On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.

**Step 6** Reboot the firewall; see [Shut Down or Restart the Device, on page 89](#).  
 For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see [Switch the Active Peer in the Threat Defense High Availability Pair, on page 632](#)), and reboot the former control node/active unit.

**Step 7** In the management center, click **Sync Modules** to update the page with the new network module details.

**Step 8** Enable the new module by clicking the slider ()

**Figure 281: Enable the Network Module**

**Step 9** You are prompted to confirm that you want to turn the network module on. Click **Yes**.

**Figure 282: Confirm Enable**

**Step 10** Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

**Figure 283: Go to Interface Page**

**Step 11** If the network module has *fewer* interfaces:  
 a) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

**Figure 284: View Interface Changes**

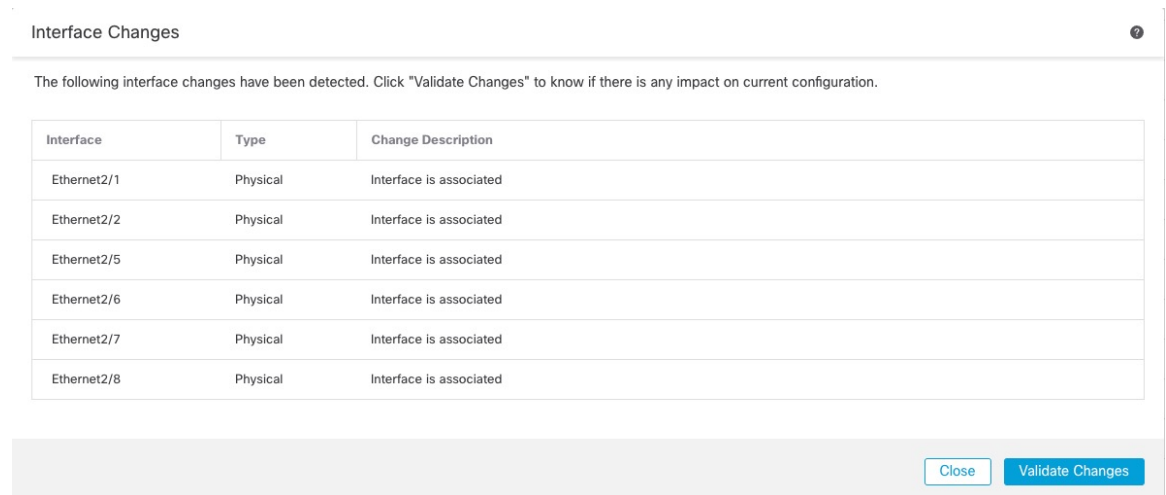

Figure 285: Interface Changes

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

**Step 12** To change the interface speed, see [Enable the Physical Interface and Configure Ethernet Settings, on page 911](#).

The default speed is set to Detect SFP, which detects the correct speed from the SFP installed. You only need to fix the speed if you manually set the speed to a particular value and you now need a new speed.

**Step 13** Click **Save** to save the interface changes to the firewall.

**Step 14** If you had to change any configuration, go to **Deploy > Deployment** and deploy the policy.

You do not need to deploy just to save the network module changes.

**Step 15** For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster.
- **High Availability**—Reenable interface monitoring for interfaces on the network module. See [Configure Standby IP Addresses and Interface Monitoring, on page 630](#).

## Remove the Network Module

If you want to permanently remove the network module, follow these steps. Removing a network module requires a reboot.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit.

**Before you begin**

For clustering or High Availability, make sure the cluster/failover link is not on the network module.

**Procedure**

**Step 1** From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

*Figure 286: Manage Chassis*

| <input type="checkbox"/> | Name                                             | Model                        | Version | Chassis                |
|--------------------------|--------------------------------------------------|------------------------------|---------|------------------------|
| <input type="checkbox"/> | Ungrouped (2)                                    |                              |         |                        |
| <input type="checkbox"/> | 172.16.0.51 Snort 3<br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <a href="#">Manage</a> |

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

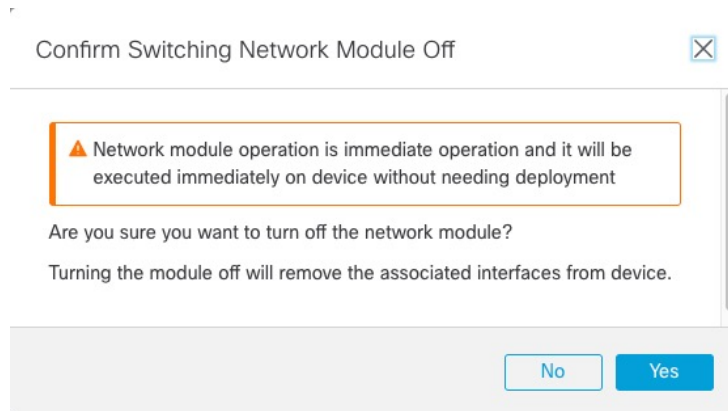

**Step 2** On the interfaces graphic, click the slider () to disable the network module.

*Figure 287: Disable the Network Module*

**Step 3** You are prompted to confirm that you want to turn the network module off. Click **Yes**.

*Figure 288: Confirm Disable*

**Step 4** You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

**Figure 289: Go to Interface Page**

▲ This device has configuration changes that were performed directly on the device. Visit [Interface page in device details](#)

**Step 5** At the top of the **Interfaces** page, you see a message that the interface configuration has changed.

**Figure 290: View Interface Changes**

Interface configuration has changed on device. [Click to know more.](#)

a) Click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

**Figure 291: Interface Changes**

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

**Step 6** Click **Save** to save the interface changes to the firewall.

**Step 7** If you had to change any configuration, go to **Deploy > Deployment** and deploy the policy.

**Step 8** Reboot the firewall; see [Shut Down or Restart the Device, on page 89](#).

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node or active unit (see [Switch the Active Peer in the Threat Defense High Availability Pair, on page 632](#)), and reboot the former control node/active unit.

# Merge the Management and Diagnostic Interfaces

Threat Defense 7.4 and later supports a merged Management and Diagnostic interface. If you have any configuration using the Diagnostic interface, then the interfaces will not be merged automatically, and you will need to perform the following procedure. This procedure requires you to acknowledge configuration changes, and in some cases, manually fix the configuration.

The Backup/Restore and management center configuration rollback functions save and restore the merged state, either non-merged or merged. For example, if you merge the interfaces, and then restore an old non-merged configuration, then the restored configuration will be in a non-merged state.

The following table shows the available configuration on the legacy Diagnostic interface, and how the merge is completed.

**Table 71: Management Center Merged Management Interface Support**

| Legacy Diagnostic Interface Configuration                           | Merge Behavior                                                                                                                                                      | Supported on Management?                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interfaces                                                          |                                                                                                                                                                     | The "management" interface is now shown in read-only mode on the <b>Interfaces</b> page.                                                                                                                                                                                                                                                                                                                                                                                              |
| <ul style="list-style-type: none"> <li>IP address</li> </ul>        | Manual removal required.                                                                                                                                            | <p>The current Management IP address is used instead.</p> <p>For High Availability and clustering, the Management interface does not support a standby IP address or IP address pool; each unit has its own IP address that is maintained across failovers. Therefore, you cannot use a single management IP address to communicate with the current active/control unit.</p> <p>Set at the CLI using the <b>configure network ipv4</b> or <b>configure network ipv6</b> command.</p> |
| <ul style="list-style-type: none"> <li>"diagnostic" name</li> </ul> | <p>Automatically changed to "management".</p> <p><b>Note</b> No other interfaces can be named "management". You must change the name to proceed with the merge.</p> | Changed to "management".                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Legacy Diagnostic Interface Configuration | Merge Behavior                               | Supported on Management?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------------------------------|----------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Static Routes                             | Manual removal required.                     | <p><b>No support.</b></p> <p>The Management interface has a separate Linux routing table from the data interfaces. The threat defense actually has two "data" routing tables: for data interfaces and for management-only interfaces (which used to include Diagnostic, but also includes any interfaces you set to management-only). Depending on the traffic type, the threat defense checks one routing table, and then falls back to the other routing table. This route lookup no longer includes the Diagnostic interface, and does not include the Linux routing table for Management. See <a href="#">Routing Table for Management Traffic, on page 1277</a> for more information.</p> <p>You can add static routes for the Linux routing table at the CLI using the <b>configure network static-routes</b> command</p> <p><b>Note</b> The <i>default</i> route is set with the <b>configure network ipv4</b> or <b>configure network ipv6</b> command.</p> |
| Dynamic Routing                           | Manual removal required.                     | <p><b>No support.</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| HTTP server                               | No change.                                   | <p><b>No support.</b></p> <p>This setting will no longer work on the merged device, but it is not removed from the Platform Settings. Platform Settings can be used for multiple devices, some of which may not yet be merged.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| ICMP                                      | No change.                                   | <p><b>No support.</b></p> <p>This setting will no longer work on the merged device, but it is not removed from the Platform Settings. Platform Settings can be used for multiple devices, some of which may not yet be merged.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Syslog Server                             | Automatically moved to Management interface. | <p>Yes.</p> <p>The syslog server configuration already has the option to send syslogs out of the Management interface (starting in 6.3). If you had specifically chosen the Diagnostic interface for syslogs, it will be moved to use Management.</p> <p><b>Note</b> If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices.</p> <p><b>Note</b> The merged Management interface does not support Secure Syslogs.</p>                                                                                                                                                                                                                                                                                                                                                                                                               |
| SMTP                                      | No change.                                   | <p><b>No support.</b></p> <p>The threat defense checks the data routing table only for the SMTP server, so you cannot use the Management interface or any other management-only interfaces. See <a href="#">Routing Table for Management Traffic, on page 1277</a> for more information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Legacy Diagnostic Interface Configuration | Merge Behavior                               | Supported on Management?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Other management-only interfaces cannot be used.</p>                                                                                                                                                                                                                                                                                                             |
| AD server                                 | Automatically moved to Management interface. | <p>Yes.</p> <p>If you had specifically chosen the Diagnostic interface, it will be moved to use Management.</p> <p><b>Note</b> If you specified a route lookup to find the source interface, then the threat defense will no longer be able to send traffic out of a management-only interface; you must explicitly select Management as the source interface. Other management-only interfaces cannot be used.</p>                                                                                                                                                                                                                                                                                                             |
| DDNS                                      | Manual removal required.                     | <b>No support.</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DHCP server                               | Manual removal required.                     | <b>No support.</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| DNS server                                | Automatically moved to Management interface. | <p>Yes.</p> <p>If you checked the <b>Enable DNS Lookup via diagnostic interface also</b> check box, then it will be moved to use Management. There is a routing lookup change when you do not choose any interfaces or check the <b>Enable DNS Lookup via diagnostic/management interface also</b> check box: the threat defense uses the data routing table only, and does not fall back to using the management-only routing table. Therefore, you cannot use a management-only interface for DNS other than the Management interface.</p> <p><b>Note</b> The Management interface also has a separate DNS lookup setting for its management traffic only. Set at the CLI using the <b>configure network dns</b> command.</p> |

| Legacy Diagnostic Interface Configuration | Merge Behavior           | Supported on Management? |
|-------------------------------------------|--------------------------|--------------------------|
| FlexConfig                                | Manual removal required. | <b>No support.</b>       |

### Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the threat defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

The following output shows that the Management interfaces are not merged:

```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

### Procedure

- 
- Step 1** Choose **Devices > Device Management**, and click **Edit** (✎) for your threat defense. The **Interfaces** page is selected by default.
  - Step 2** Edit the Diagnostic interface, and remove the IP address.  
You cannot complete the merge until after you have removed the Diagnostic IP address.
  - Step 3** Click **Management Interface Merge** in the **Management Interface action needed** area.  
The **Management Interface Merge** dialog box shows all the occurrences of the Diagnostic interface in the configuration. For any occurrences that require you to manually remove or change the configuration, they will appear with a warning icon. Platform Settings that will no longer work on your device are marked with a caution icon and require your acknowledgement.

**Management Interface Merge** ? X

- The management interface merge will be synced to the standby unit. The IP addresses shown in the "Review Uses" section shows the active unit's active address.
- After you click Proceed, IP address changes will be saved, and you cannot revert the management interface merge, even if you discard the deployment.
- Diagnostic interface static routing is no longer supported; you must delete the route before you can proceed. [Learn more](#)
- HA monitoring for diagnostic interface is not supported.

In this release, you can merge the Management and Diagnostic interfaces to use the single IP instead of two IP addresses. The merged interface will be called Management and use the current management IP address. You will need to update all external services that communicate with Diagnostic IP address.

**Step 4** If you need to manually remove or change any listed configurations, do the following.

- a) Click **Cancel** to close the **Management Interface Merge** dialog box.
- b) Navigate to the feature area. You can then delete the item, or choose a data interface instead.
- c) Reopen the **Management Interface Merge** dialog box.

There should no longer be any warnings.

**Step 5** For each configuration caution, click the box in **Do you acknowledge the change?** column, and then click **Proceed**.

Proceed

After the configuration is merged, you see a success banner:

✔ The Management interface merge was saved and is ready to be deployed. ✕  
Note that you cannot undo the configuration changes related to merge; you must manually reconfigure the Diagnostic interface and related configuration.

**Step 6** Deploy the new merged configuration.

**Caution** After you deploy the merged configuration, you can unmerge the interfaces from management center; however the Diagnostic interface will have to be reconfigured manually. See [Unmerge the Management Interface, on page 945](#). Also, if you restore a configuration that is unmerged, or roll back to an unmerged configuration, then the device will revert to that unmerged configuration.

After the merge, the Management interface is shown on the **Interfaces** page, although it is read-only.

**Step 7** After the merge, if you had any external services that communicated with the Diagnostic interface, you need to change their configuration to use the Management interface IP address.

For example:

- SNMP client
- RADIUS server—RADIUS servers often verify the IP address for incoming traffic, so you need to change that IP address to the Management address. Moreover, for a High Availability pair, you need to allow

both the primary and secondary Management IP addresses; the Diagnostic interface used to support a single "floating" IP address that stayed with the active unit, but Management does not support that functionality.

## Unmerge the Management Interface

The threat defense 7.4 and later supports a merged Management and Diagnostic interface. If you need to unmerge your interfaces, perform this procedure. We recommend using unmerged mode temporarily while you migrate your network to a merged mode deployment. Separate Management and Diagnostic interfaces may not be supported in all future releases.

Unmerging the interfaces does not restore your original Diagnostic configuration (if you upgraded and then merged your interfaces). You will need to reconfigure the Diagnostic interface manually. Also, the Management interface will now be named "management"; you cannot rename it "diagnostic."

Alternatively, if you used the Backup function to save an old unmerged configuration, you can restore that configuration or you can use the or management center configuration rollback feature, and the device will be in an unmerged state with the Diagnostic configuration intact.

### Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the threat defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

The following output shows that the Management interfaces are not merged:

```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

### Procedure

**Step 1** Choose **Devices > Device Management**, and click **Edit** (✎) for your threat defense. The **Interfaces** page is selected by default. .

**Step 2** For the Management interface, click **Unmerge Management Interface** (↺).

*Figure 292: Management Interface Selection*

**Step 3** Click **Yes** to confirm that you want to unmerge the interface.

Figure 293: Unmerge Confirmation

**Management Interface Unmerge**

---

Management interface static routes that have been configured at the FTD CLI will not be migrated to Diagnostic1/1 interface. You must manually add static routes to Diagnostic1/1 interface on the Interface page. Are you sure you want to unmerge the interface?

**Step 4** Deploy the new unmerged configuration.

**Note** If you restore a configuration that is merged, or roll back to a merged configuration, then the device will revert to that merged configuration.

After the merge, the Management interface is no longer shown on the **Interfaces** page.

## History for Interfaces

| Feature                                              | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Merged Management and Diagnostic interfaces                                                                                                                           | Any                       | 7.4                    | <p>For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available. If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically.</p> <p>If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Note that support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible.</p> <p>Merged mode also changes the behavior of AAA traffic to use the data routing table by default. The management-only routing table can now only be used if you specify the management-only interface (including Management) in the configuration.</p> <p>New/Modified screens: <b>Devices &gt; Device Management &gt; Interfaces</b></p> <p>New/Modified commands: <b>show management-interface convergence</b></p> |
| Default Forward Error Correction (FEC) on Secure Firewall 3100 fixed ports changed to Clause 108 RS-FEC from Clause 74 FC-FEC for 25 GB+ SR, CSR, and LR transceivers | Any                       | 7.2.4/7.3              | <p>When you set the FEC to Auto on the Secure Firewall 3100 fixed ports, the default type is now set to Clause 108 RS-FEC instead of Clause 74 FC-FEC for 25 GB+ SR, CSR, and LR transceivers.</p> <p>Supported platforms: Secure Firewall 3100</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

You could not disable it.<br><br>Now, you can deselect <b>Auto-negotiation</b> and set the speed to 1000 to disable flow control and link status negotiation. You cannot disable negotiation at 10000 Mbps.<br><br>New/modified screens: <b>Devices &gt; Device Management &gt; Interfaces &gt; Hardware Configuration &gt; Speed</b><br><br>Supported platforms: Firepower 1100, 2100 |

## CHAPTER 36

# Regular Firewall Interfaces

This chapter includes regular firewall threat defense interface configuration including EtherChannels, VLAN subinterfaces, IP addressing, and more.

**Note** For initial interface configuration on the Firepower 4100/9300, see [Configure Interfaces, on page 536](#).

# Configure Firepower 1010 and Secure Firewall 1210/1220 Switch Ports

You can configure each Firepower 1010 and Secure Firewall 1210/1220 interface to run as a regular firewall interface or as a Layer 2 hardware switch port. This section includes tasks for starting your switch port configuration, including enabling or disabling the switch mode and creating VLAN interfaces and assigning them to switch ports. This section also describes how to customize Power over Ethernet (PoE) on supported interfaces.

## About Firepower 1010 and Secure Firewall 1210/1220 Switch Ports

This section describes the switch ports of the Firepower 1010 and Secure Firewall 1210/1220.

### Understanding Switch Ports and Interfaces

#### Ports and Interfaces

For each physical Firepower 1010 or Secure Firewall 1210/1220 interface, you can set its operation as a firewall interface or as a switch port. See the following information about physical interface and port types as well as logical VLAN interfaces to which you assign switch ports:

- **Physical firewall interface**—In routed mode, these interfaces forward traffic between networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces are bridge group members that forward traffic between the interfaces on the same network at Layer 2, using the configured security policy to apply firewall services. In routed mode, you can also use Integrated Routing and Bridging with some interfaces as bridge group members and others as Layer 3 interfaces. By default, the Ethernet 1/1 interface is configured as a firewall interface. You can also configure these interfaces to be IPS-only (inline sets and passive interfaces).
- **Physical switch port**—Switch ports forward traffic at Layer 2, using the switching function in hardware. Switch ports on the same VLAN can communicate with each other using hardware switching, and traffic is not subject to the threat defense security policy. Access ports accept only untagged traffic, and you can assign them to a single VLAN. Trunk ports accept untagged and tagged traffic, and can belong to more than one VLAN. By default, Ethernet 1/2 through 1/8 (1010 and 1210) or Ethernet 1/2 through 1/10 (1220) are configured as access switch ports on VLAN 1. You cannot configure the Management interface as a switch port.
- **Logical VLAN interface**—These interfaces operate the same as physical firewall interfaces, with the exception being that you cannot create subinterfaces, IPS-only interfaces (inline sets and passive interfaces), or EtherChannel interfaces. When a switch port needs to communicate with another network, then the threat defense device applies the security policy to the VLAN interface and routes to another logical VLAN interface or firewall interface. You can even use Integrated Routing and Bridging with VLAN interfaces as bridge group members. Traffic between switch ports on the same VLAN are not subject to the threat defense security policy, but traffic between VLANs in a bridge group are subject to the security policy, so you may choose to layer bridge groups and switch ports to enforce the security policy between certain segments.

### Power Over Ethernet

Power over Ethernet+ (PoE+) is supported on Ethernet 1/7 and Ethernet 1/8 on the Firepower 1010.

## Auto-MDI/MDIX Feature

For all switch ports, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. When the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

## Guidelines and Limitations for Switch Ports

### High Availability and Clustering

- No cluster support.
- You should not use the switch port functionality when using High Availability. Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High Availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High Availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Theoretically, you can put a single switch port on a VLAN and successfully use High Availability, but a simpler setup is to use physical firewall interfaces instead.
- You can only use a firewall interface as the failover link.

### Logical VLAN Interfaces

- You can create up to 60 VLAN interfaces.
- If you also use VLAN subinterfaces on a firewall interface, you cannot use the same VLAN ID as for a logical VLAN interface.
- MAC Addresses:
  - Routed firewall mode—All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See [Configure the MAC Address, on page 1011](#).
  - Transparent firewall mode—Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See [Configure the MAC Address, on page 1011](#).

### Bridge Groups

You cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.

### VLAN Interface and Switch Port Unsupported Features

VLAN interfaces and switch ports do not support:

- Dynamic routing
- Multicast routing
- Equal-Cost Multi-Path routing (ECMP)
- Inline sets or Passive interfaces
- EtherChannels
- Failover and state link
- Security group tagging (SGT)

### Other Guidelines and Limitations

- You can configure a maximum of 60 named interfaces on the Firepower 1010 and Secure Firewall 1210/1220.
- You cannot configure the Management interface as a switch port.

### Default Settings

- Ethernet 1/1 is a firewall interface.
- On Firepower 1010 and Secure Firewall 1210, Ethernet 1/2 through Ethernet 1/8 are switch ports assigned to VLAN 1.
- On Secure Firewall 1220, Ethernet 1/2 through Ethernet 1/10 are switch ports assigned to VLAN 1.
- Default Speed and Duplex—By default, the speed and duplex are set to auto-negotiate.

## Configure Switch Ports and Power Over Ethernet

To configure switch ports and PoE, complete the following tasks.

### Enable or Disable Switch Port Mode

You can set each interface independently to be either a firewall interface or a switch port. By default, Ethernet 1/1 is a firewall interface, and the remaining Ethernet interfaces are configured as switch ports.

#### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** () for your threat defense device. The **Interfaces** page is selected by default.
  - Step 2** Set the switch port mode by clicking the slider in the **SwitchPort** column so it shows as **Slider enabled** () or **Slider disabled** ()

By default, switch ports are set to access mode in VLAN 1. You must manually add a logical VLAN 1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the threat defense security policy (see [Configure a VLAN Interface, on page 953](#)). You cannot set the Management interface to switch port mode. When you change the switch port mode, all unsupported configuration is removed:

---

## Configure a VLAN Interface

This section describes how to configure VLAN interfaces for use with associated switch ports. By default, switch ports are assigned to VLAN1; however, you must manually add the logical VLAN1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the threat defense security policy.

### Procedure

---

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Add Interfaces > VLAN Interface**.
- Step 3** On **General**, set the following VLAN-specific parameters:

### Add VLAN Interface ?

General
IPv4
IPv6
Advanced

Name:

Enabled

Description:

Mode:

Security Zone:

MTU:  
  
(64 - 9198)

Priority:  
 (0 - 65535)

VLAN ID \*:  
  
(1 - 4070)

Disable Forwarding on Interface Vlan:

| Associated Interface  | Port Mode |
|-----------------------|-----------|
| No records to display |           |

If you are editing an existing VLAN interface, the **Associated Interface** table shows switch ports on this VLAN.

- a) Set the **VLAN ID**, between 1 and 4070, excluding IDs in the range 3968 to 4047, which are reserved for internal use.

You cannot change the VLAN ID after you save the interface; the VLAN ID is both the VLAN tag used, and the interface ID in your configuration.

- b) (Optional) Choose a VLAN ID for **Disable Forwarding on Interface VLAN** to disable forwarding to another VLAN.

For example, you have one VLAN assigned to the outside for internet access, one VLAN assigned to an inside business network, and a third VLAN assigned to your home network. The home network does not need to access the business network, so you can disable forwarding on the home VLAN; the business network can access the home network, but the home network cannot access the business network.

- Step 4** To complete the interface configuration, see one of the following procedures:
- [Configure Routed Mode Interfaces, on page 985](#)
  - [Configure General Bridge Group Member Interface Parameters, on page 990](#)
- Step 5** Click **OK**.
- Step 6** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure Switch Ports as Access Ports

To assign a switch port to a single VLAN, configure it as an access port. Access ports accept only untagged traffic. By default, Ethernet1/2 through Ethernet 1/8 switch ports are assigned to VLAN 1 on the Firepower 1010 and Secure Firewall 1210. On Secure Firewall 1220, by default, Ethernet1/2 through Ethernet 1/10 switch ports are assigned to VLAN 1.

---

**Note** The device does not support Spanning Tree Protocol for loop detection in the network. Therefore you must ensure that any connection with the threat defense does not end up in a network loop.

---

### Procedure

---

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.

Figure 294: Edit Physical Interface

Edit Physical Interface

General Hardware Configuration

Interface ID:  
Ethernet1/2

Enabled

Description:

Port Mode:  
Access

VLAN ID:  
1  
(1 - 4070)

Protected:

**Step 3** Enable the interface by checking the **Enabled** check box.

**Step 4** (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

**Step 5** Set the **Port Mode** to **Access**.

**Step 6** In the **VLAN ID** field, set the VLAN for this switch port, between 1 and 4070.

The default VLAN ID is 1.

**Step 7** (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

**Step 8** (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

Figure 295: Hardware Configuration

The screenshot shows the 'Edit Physical Interface' configuration window. The 'Hardware Configuration' tab is selected. Under the 'Speed' section, the 'Duplex' dropdown is set to 'full' and the 'Speed' dropdown is set to '1gbps'. The 'Auto-negotiation' checkbox is checked.

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

**Step 9** Click **OK**.

**Step 10** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure Switch Ports as Trunk Ports

This procedure describes how to create a trunk port that can carry multiple VLANs using 802.1Q tagging. Trunk ports accept untagged and tagged traffic. Traffic on allowed VLANs pass through the trunk port unchanged.

When the trunk receives untagged traffic, it tags it to the native VLAN ID so that the ASA can forward the traffic to the correct switch ports, or can route it to another firewall interface. When the ASA sends native VLAN ID traffic out of the trunk port, it removes the VLAN tag. Be sure to set the same native VLAN on the trunk port on the other switch so that the untagged traffic will be tagged to the same VLAN.

### Procedure

**Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

**Step 2** Click **Edit** (✎) for the interface you want to edit.

Figure 296: Set Trunk Port Mode

Edit Physical Interface

General Hardware Configuration

Interface ID:  
Ethernet1/2

Enabled

Description:

Port Mode:  
Trunk

Native VLAN ID:  
1  
(1 - 4070)

Allowed VLAN IDs:  
100,200,300  
(1 - 4070)

Protected:

**Step 3** Enable the interface by checking the **Enabled** check box.

**Step 4** (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

**Step 5** Set the **Port Mode** to **Trunk**.

**Step 6** In the **Native VLAN ID** field, set the native VLAN for this switch port, between 1 and 4070.

The default native VLAN ID is 1.

Each port can only have one native VLAN, but every port can have either the same or a different native VLAN.

**Step 7** In the **Allowed VLAN IDs** field, enter the VLANs for this trunk port between 1 and 4070.

You can identify up to 20 IDs in one of the following ways:

- A single number (n)
- A range (n-x)
- Numbers and ranges separated by commas, for example:

5,7-10,13,45-100

You can enter spaces instead of commas.

If you include the native VLAN in this field, it is ignored; the trunk port always removes the VLAN tagging when sending native VLAN traffic out of the port. Moreover, it will not receive traffic that still has native VLAN tagging.

**Step 8** (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

**Step 9** (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The screenshot shows a window titled "Edit Physical Interface" with a "Hardware Configuration" tab selected. Under "Duplex:", the dropdown menu is set to "auto". Under "Speed:", the dropdown menu is also set to "auto". The "Auto-negotiation:" checkbox is checked. At the bottom right, there are "OK" and "Cancel" buttons.

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

**Step 10** Click **OK**.

**Step 11** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure Power Over Ethernet

On Firepower 1010, Ethernet 1/7 and Ethernet 1/8 support Power over Ethernet (PoE) for devices such as IP phones or wireless access points. On Secure Firewall 1210CP, Ethernet 1/5-1/8 support PoE. The Firepower 1010 and Secure Firewall 1210CP supports both IEEE 802.3af (PoE) and 802.3at (PoE+). PoE+ uses Link Layer Discovery Protocol (LLDP) to negotiate the power level. PoE+ can deliver up to 30 watts to a powered device. Power is only supplied when needed.

If you shut down the switch port, or configure the port as a firewall interface, then you disable power to the device.

On Firepower 1010, PoE is enabled by default on Ethernet 1/7 and Ethernet 1/8. On Secure Firewall 1210CP, PoE is enabled by default on Ethernet 1/5-1/8. This procedure describes how to disable and enable PoE and how to set optional parameters.

## Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
  - Step 2** Click **Edit** (✎) for Ethernet1/7 or 1/8 on Firepower 1010 or for any interface from Ethernet 1/5-1/8 on Secure Firewall 1210CP.
  - Step 3** Click **PoE**.

*Figure 297: PoE*

The screenshot shows the 'Edit Physical Interface' configuration page. The 'PoE' tab is selected. The 'Enable PoE' checkbox is checked. The 'Auto Negotiate' checkbox is also checked. The 'Consumption Wattage' field is empty, with a range of (4000 - 30000)mW indicated.

- Step 4** Check the **Enable PoE** check box.  
PoE is enabled by default.
- Step 5** (Optional) Uncheck the **Auto Negotiate Consumption Wattage** check box, and enter the **Consumption Wattage** if you know the exact wattage you need.

By default, PoE delivers power automatically to the powered device using a wattage appropriate to the class of the powered device. The Firepower 1010 and Secure Firewall 1210CP uses LLDP to further negotiate the correct wattage. If you know the specific wattage and want to disable LLDP negotiation, enter a value from 4000 to 30000 milliwatts.

- Step 6** Click **OK**.
- Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure Loopback Interfaces

This section tells how to configure loopback interfaces.

## About Loopback Interfaces

A loopback interface is a software-only interface that emulates a physical interface. This interface is reachable on IPv4 and IPv6 through multiple physical interfaces. The loopback interface helps to overcome path failures; it is accessible from any physical interface, so if one goes down, you can access the loopback interface from another.

Loopback interfaces can be used for:

- AAA
- BGP
- DNS
- HTTP
- ICMP
- IPsec flow offload—Secure Firewall 1200, 3100 and 4200 only
- NetFlow
- SNMP
- SSH
- Static and dynamic VTI tunnels
- Syslog

The threat defense can distribute the loopback address using dynamic routing protocols, or you can configure a static route on the peer device to reach the loopback IP address through one of the threat defense's physical interfaces. You cannot configure a static route on the threat defense that specifies the loopback interface.

### Related Topics

[Guidelines and Limitations for Loopback Interfaces](#), on page 961

[Configure a Loopback Interface](#), on page 962

## Guidelines and Limitations for Loopback Interfaces

### Firewall Mode

- Supported in routed mode only.

### High Availability and Clustering

- No clustering support.

### Additional Guidelines and Limitations

- TCP sequence randomization is always disabled for traffic from the physical interface to the loopback interface.

## Configure a Loopback Interface

To add a loopback interface for a device:

### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** From the **Add Interfaces** drop-down list, choose **Loopback Interface**.
- Step 3** In the **General** tab, configure the following parameters:
- Name**—Enter a name for the loopback interface.
  - Enabled**—Check the check box to enable the loopback interface.
  - Loopback ID**—Enter the loopback ID between 1 to 1024.
  - Description**—Enter a description for the loopback interface.
- Step 4** Configure the routed mode interface parameters. See [Configure Routed Mode Interfaces, on page 985](#).
- 

## Rate-Limit Traffic to the Loopback Interface

### Before you begin

You should rate-limit traffic going to the loopback interface IP address to prevent excessive load on the system. You can add a connection limit rule to the global service policy.

### Procedure

- 
- Step 1** Create an extended access list identifying traffic to the loopback interface IP address(es).
- Choose **Objects > Object Management** and choose **Access Control Lists > Extended** from the table of contents.
  - Click **Add Extended Access List** to create a new ACL.
  - In the **New Extended Access List Object** dialog box, enter a name for the ACL (no spaces allowed), and click **Add** to create a new entry.

*Figure 298: Name ACL and Add Entry*

New Extended Access List Object

Name  
rate-limiting

Entries (0)

Add

- Configure the source (any) and destination addresses (loopback IP addresses) on the **Network** tab.

Figure 299: Source and Destination Networks

**Note** Keep the default **Action** as **Allow** (match) and other settings as-is.

- **Source**—Select **any** from the **Available Networks** list, and click **Add to Source**. You can also narrow this access list by specifying the source IP addresses instead of **any**.
- **Destination**—Type an address in the edit box below the **Destination Networks** list and click **Add**. Repeat for each loopback interface.

- Click **Add** to add the entry to the ACL.
- Click **Save** to save the ACL.

Figure 300: Save ACL

**Step 2** Choose **Policies > Access Control > Access Control**, and click **Edit** (✎) for the access control policy assigned to your device.

**Step 3** Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

*Figure 301: Advanced Settings*

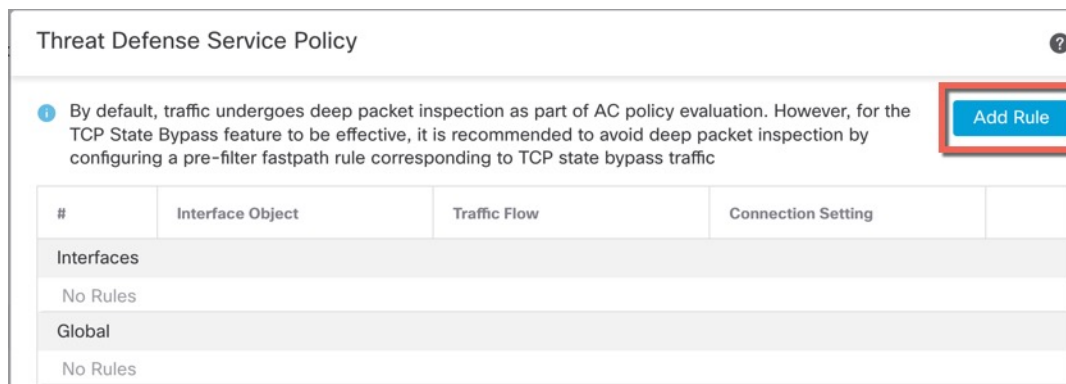

**Step 4** Click **Edit** (✎) in the **Threat Defense Service Policy** group.

*Figure 302: Threat Defense Service Policy*

**Step 5** Click **Add Rule** to create a new rule.

*Figure 303: Add Rule*

The service policy rule wizard opens to step you through the process of configuring the rule.

**Step 6** In the **Interface Object** step, click **Global** to create a global rule, which applies to all interfaces, then click **Next**.

**Figure 304: Global Policy**

**Step 7** In the **Traffic Flow** step, select the extended access list object you created in [Step 1, on page 962](#), and then click **Next**.

**Figure 305: Choose Extended Access List**

**Step 8** In the **Connection Setting** step, set the **Connections** limits.

**Figure 306: Set Connection Limits**

Set the **Maximum TCP & UDP** connections to the expected number of connections for the loopback interface, and the **Maximum Embryonic** connections to a lower number. For example, you can set it to 5/2, or 10/5, or 1024/512, depending on the expected loopback interface sessions you need.

Setting the embryonic connection limit enables TCP Intercept, which protects the system from a DoS attack perpetrated by flooding an interface with TCP SYN packets.

**Step 9** Click **Finish** to save your changes.

**Step 10** Click **OK**.

**Step 11** Click **Save** on the **Advanced Settings** window.

**Step 12** You can now deploy the changes to the affected devices.

# Configure VLAN Subinterfaces and 802.1Q Trunking

VLAN subinterfaces let you divide a physical, redundant, or EtherChannel interface into multiple logical interfaces that are tagged with different VLAN IDs. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk. Because VLANs let you keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or devices.

## Guidelines and Limitations for VLAN Subinterfaces

### Model Support

- Firepower 1010 and Secure Firewall 1210/1220—VLAN subinterfaces are not supported on switch ports or VLAN interfaces.

### High Availability and Clustering

You cannot use a subinterface for the failover or state link or for the cluster control link. The exception is for multi-instance mode: you can use a *chassis*-defined subinterface for these links.

### Additional Guidelines

- Preventing untagged packets on the physical interface—If you use subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. This property is also true for the active physical interface in a redundant interface pair and for EtherChannel links. Because the physical, redundant, or EtherChannel interface must be enabled for the subinterface to pass traffic, ensure that the physical, redundant, or EtherChannel interface does not pass traffic by not configuring a name for the interface. If you want to let the physical, redundant, or EtherChannel interface pass untagged packets, you can configure the name as usual.
- You cannot configure subinterfaces on the Management interface, either the dedicated Management interface configured at the CLI nor a data interface used for manager access.
- All subinterfaces on the same parent interface must be either bridge group members or routed interfaces; you cannot mix and match.
- The threat defense does not support the Dynamic Trunking Protocol (DTP), so you must configure the connected switch port to trunk unconditionally.
- You might want to assign unique MAC addresses to subinterfaces defined on the threat defense, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the threat defense.

## Maximum Number of VLAN Subinterfaces by Device Model

The device model limits the maximum number of VLAN subinterfaces that you can configure. Note that you can configure subinterfaces on data interfaces only, you cannot configure them on the management interface.

The following table explains the limits for each device model.

| Model                      | Maximum VLAN Subinterfaces |
|----------------------------|----------------------------|
| Firepower 1010             | 60                         |
| Firepower 1120             | 512                        |
| Firepower 1140, 1150       | 1024                       |
| Secure Firewall 1200       | 1024                       |
| Secure Firewall 3100, 4200 | 1024                       |
| Firepower 4100             | 1024                       |
| Firepower 9300             | 1024                       |
| Threat Defense Virtual     | 50                         |
| ISA 3000                   | 100                        |

## Add a Subinterface

Add one or more subinterfaces to a physical, redundant, or port-channel interface.

For the Firepower 4100/9300, you can configure subinterfaces in FXOS for use with container instances; see [Add a VLAN Subinterface for Container Instances, on page 537](#). These subinterfaces appear in the management center interface list. You can also add subinterfaces in management center, but only on parent interfaces that do not already have subinterfaces defined in FXOS.

**Note** The parent physical interface passes untagged packets. You may not want to pass untagged packets, so be sure not to include the parent interface in your security policy.

### Procedure

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Enable the parent interface according to [Enable the Physical Interface and Configure Ethernet Settings, on page 911](#).
- Step 3** Click **Add Interfaces > Sub Interface**.
- Step 4** On **General**, set the following parameters:

Figure 307: Add Subinterface

**Add Sub Interface** ?

General IPv4 IPv6 Path Monitoring Advanced

Name:  
inside-100

Enabled  
 Management Only

Description:

Security Zone:  
inside\_zone

MTU:  
1500  
(64 - 9198)

Priority:  
0  
(0 - 65535)

Propagate Security Group Tag:

Interface \*:  
Ethernet1/1

Enabled

Sub-Interface ID \*:  
100  
(1 - 4294967295)

VLAN ID:  
100  
(1 - 4094)

Cancel OK

- Interface**—Choose the physical, redundant, or port-channel interface to which you want to add the subinterface.
- Sub-Interface ID**—Enter the subinterface ID as an integer between 1 and 4294967295. The number of subinterfaces allowed depends on your platform. You cannot change the ID after you set it.
- VLAN ID**—Enter the VLAN ID between 1 and 4094 that will be used to tag the packets on this subinterface.

This VLAN ID must be unique.

**Step 5** Click **OK**.

**Step 6** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

- Step 7** Configure the routed or transparent mode interface parameters. See [Configure Routed Mode Interfaces, on page 985](#) or [Configure Bridge Group Interfaces, on page 990](#).
- 

## Configure VXLAN Interfaces

This chapter tells how to configure Virtual eXtensible LAN (VXLAN) interfaces. VXLAN interfaces act as Layer 2 virtual networks over Layer 3 physical networks to stretch Layer 2 networks.

### About VXLAN Interfaces

VXLAN provides the same Ethernet Layer 2 network services as VLAN does, but with greater extensibility and flexibility. Compared to VLAN, VXLAN offers the following benefits:

- Flexible placement of multitenant segments throughout the data center.
- Higher scalability to address more Layer 2 segments: up to 16 million VXLAN segments.

This section describes how VXLAN works. For detailed information about VXLAN, see RFC 7348. For detailed information about Geneve, see RFC 8926.

### Encapsulation

The threat defense supports two types of VXLAN encapsulation:

- VXLAN (all models)—VXLAN uses MAC Address-in-User Datagram Protocol (MAC-in-UDP) encapsulation. The original Layer 2 frame has a VXLAN header added and is then placed in a UDP-IP packet.
- Geneve (threat defense virtual only)—Geneve has a flexible inner header that is not limited to the MAC address. Geneve encapsulation is required for transparent routing of packets between an Amazon Web Services (AWS) Gateway Load Balancer and appliances, and for sending extra information.

### VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces to which you apply your security policy, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

The following figure shows two threat defenses and Virtual Server 2 acting as VTEPs across a Layer 3 network, extending the VNI 1, 2, and 3 networks between sites. The threat defenses act as bridges or gateways between VXLAN and non-VXLAN networks.

The underlying IP network between VTEPs is independent of the VXLAN overlay. Encapsulated packets are routed based on the outer IP address header, which has the initiating VTEP as the source IP address and the terminating VTEP as the destination IP address. For VXLAN encapsulation: The destination IP address can be a multicast group when the remote VTEP is not known. With Geneve, the threat defense only supports static peers. The destination port for VXLAN is UDP port 4789 by default (user configurable). The destination port for Geneve is 6081.

## VTEP Source Interface

The VTEP source interface is a regular interface (physical, EtherChannel, or even VLAN) with which you plan to associate all VNI interfaces. You can configure one VTEP source interface per threat defense virtual. Because you can only configure one VTEP source interface, you cannot configure both VXLAN and Geneve interfaces on the same device. There is an exception for threat defense virtual clustering on AWS or Azure, where you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve (AWS) or VXLAN (Azure) interface can be used for the Gateway Load Balancer.

The VTEP source interface can be devoted wholly to VXLAN traffic, although it is not restricted to that use. If desired, you can use the interface for regular traffic and apply a security policy to the interface for that traffic. For VXLAN traffic, however, all security policy must be applied to the VNI interfaces. The VTEP interface serves as a physical port only.

In transparent firewall mode, the VTEP source interface is not part of a BVI, and you do configure an IP address for it, similar to the way the management interface is treated.

## VNI Interfaces

VNI interfaces are similar to VLAN interfaces: they are virtual interfaces that keep network traffic separated on a given physical interface by using tagging. You apply your security policy directly to each VNI interface.

You can only add one VTEP interface, and all VNI interfaces are associated with the same VTEP interface. There is an exception for threat defense virtual clustering on AWS or Azure. For AWS clustering, you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve interface can be used for the AWS Gateway Load Balancer. For Azure clustering, you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a second VXLAN interface can be used for the Azure Gateway Load Balancer.

## VXLAN Packet Processing

### VXLAN

Traffic entering and exiting the VTEP source interface is subject to VXLAN processing, specifically encapsulation or decapsulation.

Encapsulation processing includes the following tasks:

- The VTEP source interface encapsulates the inner MAC frame with the VXLAN header.
- The UDP checksum field is set to zero.
- The Outer frame source IP is set to the VTEP interface IP.
- The Outer frame destination IP is decided by a remote VTEP IP lookup.

Decapsulation; the threat defense only decapsulates a VXLAN packet if:

- It is a UDP packet with the destination port set to 4789 (this value is user configurable).
- The ingress interface is the VTEP source interface.
- The ingress interface IP address is the same as the destination IP address.
- The VXLAN packet format is compliant with the standard.

### Geneve

Traffic entering and exiting the VTEP source interface is subject to Geneve processing, specifically encapsulation or decapsulation.

Encapsulation processing includes the following tasks:

- The VTEP source interface encapsulates the inner MAC frame with the Geneve header.
- The UDP checksum field is set to zero.
- The Outer frame source IP is set to the VTEP interface IP.
- The Outer frame destination IP is set the peer IP address that you configured.

Decapsulation; the ASA only decapsulates a Geneve packet if:

- It is a UDP packet with the destination port set to 6081 (this value is user configurable).
- The ingress interface is the VTEP source interface.
- The ingress interface IP address is the same as the destination IP address.
- The Geneve packet format is compliant with the standard.

## Peer VTEPs

When the threat defense sends a packet to a device behind a peer VTEP, the threat defense needs two important pieces of information:

- The destination MAC address of the remote device

- The destination IP address of the peer VTEP

The threat defense maintains a mapping of destination MAC addresses to remote VTEP IP addresses for the VNI interfaces.

### VXLAN Peer

There are two ways in which the threat defense can find this information:

- A single peer VTEP IP address can be statically configured on the threat defense.

For IPv4: The threat defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC address.

For IPv6: The threat defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A group of peer VTEP IP addresses can be statically configured on the threat defense.

For IPv4: The threat defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC addresses.

For IPv6: The threat defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A multicast group can be configured on each VNI interface (or on the VTEP as a whole).

For IPv4: The threat defense sends a VXLAN-encapsulated ARP broadcast packet within an IP multicast packet through the VTEP source interface. The response to this ARP request enables the threat defense to learn both the remote VTEP IP address along with the destination MAC address of the remote end node.

For IPv6: The threat defense sends a Multicast Listener Discovery (MLD) Report message through the VTEP source interface to indicate that the threat defense is listening on the VTEP interface for the multicast address traffic.

This option is not supported with Geneve.

### Geneve Peer

The threat defense virtual only supports statically defined peers. You can define the threat defense virtual peer IP address on the AWS Gateway Load Balancer. Because the threat defense virtual never initiates traffic to the Gateway Load Balancer, you do not also have to specify the Gateway Load Balancer IP address on the threat defense virtual; it learns the peer IP address when it receives Geneve traffic. Multicast groups are not supported with Geneve.

## VXLAN Use Cases

This section describes the use cases for implementing VXLAN on the threat defense.

### VXLAN Bridge or Gateway Overview

Each threat defense VTEP acts as a bridge or gateway between end nodes such as VMs, servers, and PCs and the VXLAN overlay network. For incoming frames received with VXLAN encapsulation over the VTEP

source interface, the threat defense strips out the VXLAN header and forwards it to a physical interface connected to a non-VXLAN network based on the destination MAC address of the inner Ethernet frame.

The threat defense always processes VXLAN packets; it does not just forward VXLAN packets untouched between two other VTEPs.

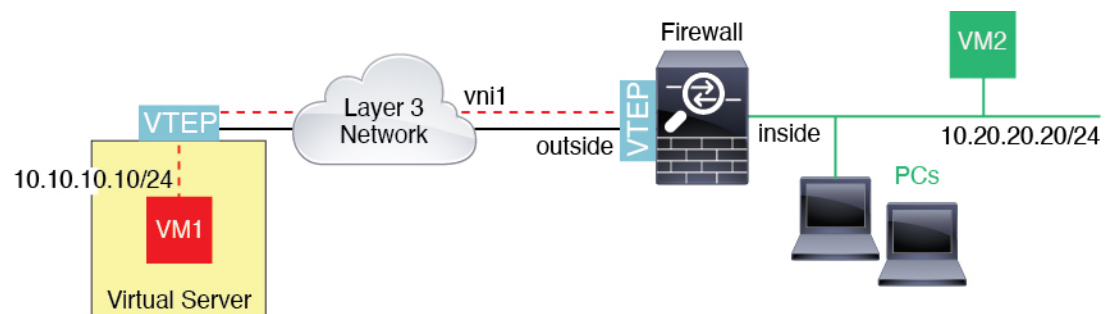

### VXLAN Bridge

When you use a bridge group (transparent firewall mode, or optionally routed mode), the threat defense can serve as a VXLAN bridge between a (remote) VXLAN segment and a local segment where both are in the same network. In this case, one member of the bridge group is a regular interface while the other member is a VNI interface.

### VXLAN Gateway (Routed Mode)

The threat defense can serve as a router between VXLAN and non-VXLAN domains, connecting devices on different networks.

## Router Between VXLAN Domains

With a VXLAN-stretched Layer 2 domain, a VM can point to an threat defense as its gateway while the threat defense is not on the same rack, or even when the threat defense is far away over the Layer 3 network.

See the following notes about this scenario:

1. For packets from VM3 to VM1, the destination MAC address is the threat defense MAC address, because the threat defense is the default gateway.
2. The VTEP source interface on Virtual Server 2 receives packets from VM3, then encapsulates the packets with VNI 3's VXLAN tag and sends them to the threat defense.
3. When the threat defense receives the packets, it decapsulates the packets to get the inner frames.
4. The threat defense uses the inner frames for route lookup, then finds that the destination is on VNI 2. If it does not already have a mapping for VM1, the threat defense sends an encapsulated ARP broadcast on the multicast group IP on VNI 2.

**Note** The threat defense must use dynamic VTEP peer discovery because it has multiple VTEP peers in this scenario.

5. The threat defense encapsulates the packets again with the VXLAN tag for VNI 2 and sends the packets to Virtual Server 1. Before encapsulation, the threat defense changes the inner frame destination MAC address to be the MAC of VM1 (multicast-encapsulated ARP might be needed for the threat defense to learn the VM1 MAC address).
6. When Virtual Server 1 receives the VXLAN packets, it decapsulates the packets and delivers the inner frames to VM1.

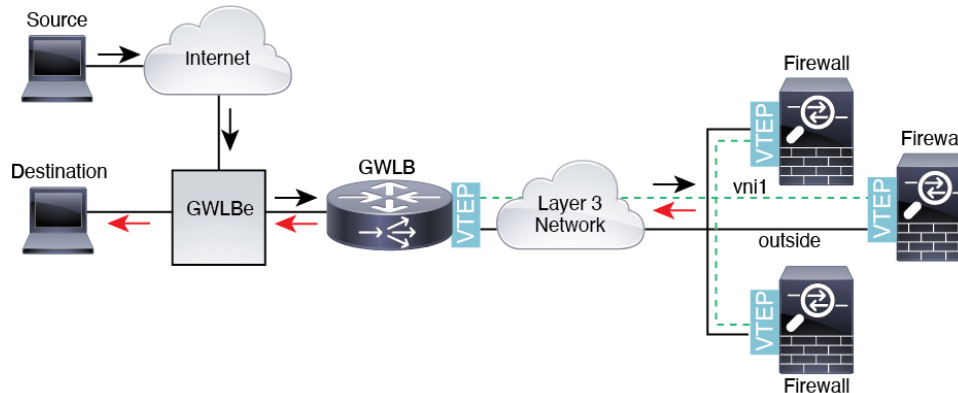

### Geneve Single-Arm Proxy

**Note** This use case is the only currently supported use case for Geneve interfaces.

The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The threat defense virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple threat defense virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

**Figure 308: Geneve Single-Arm Proxy**

### Azure Gateway Load Balancer and Paired Proxy

In an Azure service chain, threat defense virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The threat defense virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

The following figure shows traffic forwarded to the Azure Gateway Load Balancer from the Public Gateway Load Balancer on the external VXLAN segment. The Gateway Load Balancer balances traffic among multiple threat defense virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer on the internal VXLAN segment. The Azure Gateway Load Balancer then sends the traffic back to the Public Gateway Load Balancer and to the destination.

Figure 309: Azure Gateway Load Balancer with Paired Proxy

## Requirements and Prerequisites for VXLAN Interfaces

### Model Requirements

- VXLAN encapsulation is supported on all models.
- Geneve encapsulation is supported for the following models:
  - Threat Defense Virtual in Amazon Web Services (AWS)
- VXLAN in *paired proxy mode* is supported for the following models:
  - Threat Defense Virtual in Azure
- Firepower 1010 and Secure Firewall 1210/1220 switch ports and VLAN interfaces are not supported as VTEP interfaces.

## Guidelines for VXLAN Interfaces

### Firewall Mode

- Geneve interfaces are only supported in routed firewall mode.
- Paired proxy VXLAN interfaces are only supported in routed firewall mode.

### IPv6

- The VNI interface supports both IPv4 and IPv6 traffic.
- For VXLAN encapsulation, the VTEP source interface supports both IPv4 and IPv6. The threat defense virtual cluster control link VTEP source interface only supports IPv4.

For Geneve, the VTEP source interface only supports IPv4.

### Clustering

- Clustering does not support VXLAN in Individual Interface mode except for the cluster control link (threat defense virtual only) Only Spanned EtherChannel mode supports VXLAN.

An exception is made for AWS, which can use an additional Geneve interface for use with the GWLB and for Azure, which can use an additional paired proxy VXLAN interface for use with the GWLB.

### Routing

- Only static routing or Policy Based Routing is supported on the VNI interface; dynamic routing protocols are not supported.

### MTU

- VXLAN encapsulation—If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the threat defense automatically raises the MTU to 1554 bytes or 1574 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 54 bytes for IPv4 or +64 bytes for IPv6. For the threat defense virtual, this MTU requires a restart to enable jumbo frame reservation.
- Geneve encapsulation—If the source interface MTU is less than 1806 bytes, then the threat defense automatically raises the MTU to 1806 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 306 bytes. This MTU requires a restart to enable jumbo frame reservation.

## Configure VXLAN or Geneve Interfaces

You can configure either VXLAN or Geneve interfaces.

### Configure VXLAN Interfaces

To configure VXLAN, perform the following steps.

---

**Note** You can configure either VXLAN or Geneve (threat defense virtual only). For Geneve interfaces, see [Configure Geneve Interfaces, on page 980](#).

---

**Note** For Azure GWLB, the VXLAN interface is configured when you deploy the VM using the ARM template. You can use this section to change your configuration.

1. [Configure the VTEP Source Interface, on page 978.](#)
2. [Configure the VNI Interface, on page 979.](#)
3. (Azure GWLB) [Allow Gateway Load Balancer Health Checks, on page 981.](#)

## Configure the VTEP Source Interface

You can configure one VTEP source interface per threat defense device. The VTEP is defined as a Network Virtualization Endpoint (NVE). VXLAN is the default encapsulation type. An exception is made for clustering on the threat defense virtual in Azure, where you can use one VTEP source interface for the cluster control link and a second one for the data interface connected to the Azure GWLB.

### Procedure

- 
- Step 1** If you want to specify a group of peer VTEPs, add a network object with the peer IP addresses. See [Creating Network Objects, on page 1499](#).
- Step 2** Choose **Devices > Device Management**.
- Step 3** Click **Edit** (✎) next to the device on which you want to configure VXLAN.
- Step 4** (Optional) Specify that the source interface is NVE-only.
- This setting is optional for routed mode where this setting restricts traffic to VXLAN and common management traffic only on this interface. This setting is automatically enabled for transparent firewall mode.
- a) Click **Interfaces**.
  - b) Click **Edit** (✎) for the VTEP source interface.
  - c) On the **General** page, check the check box of **NVE Only**.
- Step 5** Click **VTEP** if it is not already displaying.
- Step 6** Check **Enable NVE**.
- Step 7** Click **Add VTEP**.
- Step 8** For the **Encapsulation Type**, choose **VxLAN**.
- For AWS, you can choose between **VxLAN** and **Geneve**. Other platforms have **VxLAN** chosen automatically.
- Step 9** Enter the value for the **Encapsulation port** within the specified range.
- The default value is 4789.
- Step 10** Select the **VTEP Source Interface**.
- Select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the management center automatically raises the MTU to 1554 bytes or 1574 bytes.
- Step 11** Select the **Neighbor Address**. The available options are:

- **None**—No neighbor address is specified.
- **Peer VTEP**—Specify a peer VTEP address.
- **Peer Group**—Specify a network object with the peer IP addresses.
- **Default Multicast**—Specify a default multicast group for all associated VNI interfaces. If you do not configure the multicast group per VNI interface, then this group is used. If you configure a group at the VNI interface level, then that group overrides this setting.

- Step 12** Click **OK**.
- Step 13** Click **Save**.
- Step 14** Configure the routed interface parameters. See [Configure Routed Mode Interfaces](#).

---

## Configure the VNI Interface

Add a VNI interface, associate it with the VTEP source interface, and configure basic interface parameters.

For the threat defense virtual in Azure, you can configure either a regular VXLAN interface, or you can configure a paired proxy mode VXLAN interface for use with the Azure GWLB. Paired proxy mode is the only supported mode with clustering.

## Procedure

---

- Step 1** Choose **Devices > Device Management**.
- Step 2** Click **Edit** (✎) next to the device on which you want to configure VXLAN.
- Step 3** Click **Interfaces**.
- Step 4** Click **Add Interfaces**, and then choose **VNI Interface**.
- Step 5** Enter the interface **Name** and **Description**.
- Step 6** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.
- Step 7** Enter a value for the **Priority** field within the specified range. By default, 0 is selected.
- Step 8** Enter a value for the **VNI ID** between 1 and 10000.  
This ID is only an internal interface identifier.
- Step 9** (Paired Proxy VXLAN for Azure GWLB) Enable proxy paired mode and set the required parameters.
- a) Check **Proxy Paired**.
  - b) Set the **Internal Port** between 1024 and 65535.
  - c) Set the **Internal Segment ID** between 1 and 16777215.
  - d) Set the **External Port** between 1024 and 65535.
  - e) Set the **External Segment ID** between 1 and 16777215.
- Step 10** (Regular VXLAN) Enter a value for the **VNI Segment ID** between 1 and 16777215.  
The segment ID is used for VXLAN tagging.
- Step 11** Enter the **Multicast Group IP Address**.

If you do not set the multicast group for the VNI interface, the default group from the VTEP source interface configuration is used, if available. If you manually set a VTEP peer IP for the VTEP source interface, you cannot specify a multicast group for the VNI interface.

**Step 12** Check **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.

**Step 13** Click **OK**.

**Step 14** Click **Save** to save the interface configuration.

**Step 15** Configure the routed or transparent interface parameters. See [Configure Routed and Transparent Mode Interfaces, on page 982](#).

## Configure Geneve Interfaces

To configure Geneve interfaces for threat defense virtual, perform the following steps.

**Note** You can configure either VXLAN or Geneve. For information about VXLAN interfaces, see [Configure VXLAN Interfaces, on page 977](#).

1. [Configure the VTEP Source Interface, on page 980](#).
2. [Configure the VNI, on page 981](#).
3. [Allow Gateway Load Balancer Health Checks, on page 981](#).

### Configure the VTEP Source Interface

You can configure one VTEP source interface per threat defense virtual device. The VTEP is defined as a Network Virtualization Endpoint (NVE).

#### Procedure

**Step 1** Choose **Devices > Device Management**.

**Step 2** Click **Edit** (✎) next to the device on which you want to configure Geneve.

**Step 3** Click **VTEP**.

**Step 4** Check **Enable NVE**.

**Step 5** Click **Add VTEP**.

**Step 6** For the **Encapsulation Type**, choose **Geneve**.

**Step 7** Enter the value for the **Encapsulation port** within the specified range.

We do not recommend changing the Geneve port; AWS requires a port of 6081.

**Step 8** Select the **VTEP Source Interface**.

You can select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1806 bytes, then the management center automatically raises the MTU to 1806 bytes.

- Step 9** Click **OK**.
  - Step 10** Click **Save**.
  - Step 11** Configure the routed interface parameters. See [Configure Routed Mode Interfaces](#).
- 

## Configure the VNI

Add a VNI, associate it with (VTEP) source interface, and configure basic interface parameters.

### Procedure

---

- Step 1** Choose **Devices > Device Management**.
  - Step 2** Click **Edit** (✎) next to the device on which you want to configure Geneve.
  - Step 3** Click **Interfaces**.
  - Step 4** Click **Add Interfaces**, and then choose **VNI Interface**.
  - Step 5** In the **Name** and **Description** fields, provide relevant information.
  - Step 6** In the **VNI ID** field, enter a value between 1 and 10000.
    - Note** This ID is only an internal interface identifier.
  - Step 7** Check the **Enable Proxy** check box.

This option enables single-arm proxy, and allows traffic to exit the same interface it entered (U-turn traffic). If you later edit the interface, you cannot disable single-arm proxy. To do that, you need to delete the existing interface and create a new VNI interface.

This option is only available for a Geneve VTEP.
  - Step 8** Select **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.
  - Step 9** Click **OK**.
  - Step 10** Click **Save**.
- 

### What to do next

Configure the routed interface parameters. See [Configure Routed Mode Interfaces](#).

## Allow Gateway Load Balancer Health Checks

The AWS or Azure GWLB requires appliances to answer a health check properly. The GWLB will only send traffic to appliances that are considered healthy. You must configure the threat defense virtual to respond to an SSH, HTTP, or HTTPS health check.

Configure one of the following methods.

## Procedure

### Step 1 Configure SSH. See [Configure Secure Shell](#)

Allow SSH from the GWLB IP address. The GWLB will attempt to establish a connection to the threat defense virtual, and the threat defense virtual's prompt to log in is taken as proof of health. An SSH login attempt will time out after 1 minute. You will need to configure a longer health check interval on the GWLB to accommodate this timeout.

### Step 2 Configure HTTP(S) Redirection Using Static Interface NAT with Port Translation.

You can configure the threat defense virtual to redirect health checks to a metadata HTTP(S) server. For HTTP(S) health checks, the HTTP(S) server must reply to the GWLB with a status code in the range 200 to 399. Because the threat defense virtual has limits on the number of simultaneous management connections, you may choose to offload the health check to an external server.

Static interface NAT with port translation lets you redirect a connection to a port (such as port 80) to a different IP address. For example, translate an HTTP packet from the GWLB with a destination of the threat defense virtual outside interface so that it appears to be from the threat defense virtual outside interface with a destination of the HTTP server. The threat defense virtual then forwards the packet to the mapped destination address. The HTTP server responds to the threat defense virtual outside interface, and then the threat defense virtual forwards the response back to the GWLB. You need an access rule that allows traffic from the GWLB to the HTTP server.

- a) Permit HTTP(S) traffic on the outside interface from the GWLB network in an access rule. See [Access Control Rules, on page 1853](#).
- b) For HTTP(S), translate the source GWLB IP address to the threat defense virtual outside interface IP address; then translate the destination of the outside interface IP address to the HTTP(S) server IP address. See [Configure Static Manual NAT, on page 1176](#).

# Configure Routed and Transparent Mode Interfaces

This section includes tasks to complete the regular interface configuration for all models in routed or transparent firewall mode.

## About Routed and Transparent Mode Interfaces

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See [Transparent or Routed Firewall Mode, on page 491](#) for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the threat defense device uses bridging techniques to pass traffic between

the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the threat defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

## Dual IP Stack (IPv4 and IPv6)

The threat defense device supports both IPv6 and IPv4 addresses on an interface. Make sure you configure a default route for both IPv4 and IPv6.

## 31-Bit Subnet Mask

For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. The 31-bit subnet includes only 2 addresses; normally, the first and last address in the subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4. For example, the failover link between 2 threat defenses only requires 2 addresses; any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog.

### 31-Bit Subnet and Clustering

You can use a 31-bit subnet mask for cluster interfaces, excluding the management interface and the Cluster Control Link.

### 31-Bit Subnet and Failover

For failover, when you use a 31-bit subnet for the threat defense interface IP address, you cannot configure a standby IP address for the interface because there are not enough addresses. Normally, an interface for failover should have a standby IP address so the active unit can perform interface tests to ensure standby interface health. Without a standby IP address, the threat defense cannot perform any network tests; only the link state can be tracked.

For the failover and optional separate state link, which are point-to-point connections, you can also use a 31-bit subnet.

### 31-Bit Subnet and Management

If you have a directly-connected management station, you can use a point-to-point connection for SSH or HTTP on the threat defense, or for SNMP or Syslog on the management station.

### 31-Bit Subnet Unsupported Features

The following features do not support the 31-Bit subnet:

- BVI interfaces for bridge groups—The bridge group requires at least 3 host addresses: the BVI, and two hosts connected to two bridge group member interfaces. you must use a /29 subnet or smaller.
- Multicast Routing

# Guidelines and Limitations for Routed and Transparent Mode Interfaces

## High Availability, Clustering, and Multi-Instance

- Do not configure failover links with the procedures in this chapter. See the High Availability chapter for more information.
- For cluster interfaces, see the clustering chapter for requirements.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- When you use High Availability, you must set the IP address and standby address for data interfaces manually; DHCP and PPPoE are not supported. Set the standby IP addresses on the **Devices > Device Management > High Availability** tab in the **Monitored Interfaces** area. See the High Availability chapter for more information.

## IPv6

- IPv6 is supported on all interfaces.
- You can only configure IPv6 addresses manually in transparent mode.
- The threat defense device does not support IPv6 anycast addresses.
- DHCPv6 and prefix delegation options are not supported with transparent mode, clustering, or High Availability.

## Model Guidelines

- For the threat defense virtual on VMware with bridged ixgbevf interfaces, bridge groups are not supported.
- For the Firepower 2100 series, bridge groups are not supported in routed mode.

## Transparent Mode and Bridge Group Guidelines

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The threat defense device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.
- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the threat defense device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).
- Management interfaces are not supported as bridge group members.

- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the threat defense virtual on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
- 
- For the Firepower 1010 and Secure Firewall 1210/20, you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.
- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the threat defense as the default gateway.
- In transparent mode, the *default* route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.
- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, threat defense-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the threat defense when using bridge group members. If there are two neighbors on either side of the threat defense running BFD, then the threat defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

#### Additional Guidelines and Requirements

- The threat defense supports only one 802.1Q header in a packet and does not support multiple headers (known as Q-in-Q support) for firewall interfaces. **Note:** For inline sets and passive interfaces, the FTD supports Q-in-Q up to two 802.1Q headers in a packet, with the exception of the Firepower 4100/9300, which only supports one 802.1Q header.

## Configure Routed Mode Interfaces

This procedure describes how to set the name, security zone, and IPv4 address.

---

**Note** Not all fields are supported for all interface types.

---

**Before you begin**• **Firepower 4100/9300**

1. [Configure a Physical Interface, on page 536](#)
2. (Optional) Configure any special interfaces.
  - [Add an EtherChannel \(Port Channel\), on page 537](#)
  - [Add a VLAN Subinterface for Container Instances, on page 537](#) in FXOS
  - [Configure a Loopback Interface, on page 962](#)
  - [Add a Subinterface, on page 967](#) in management center
  - [Configure VXLAN Interfaces, on page 977](#)

• (Optional) **All other models:**

- [Configure an EtherChannel, on page 918](#)
- [Configure a Loopback Interface, on page 962](#)
- [Add a Subinterface, on page 967](#)
- [Configure VXLAN Interfaces, on page 977](#)
- Threat Defense Virtual on AWS: [Configure Geneve Interfaces, on page 980](#)
- Firepower 1010 and Secure Firewall 1210/1220: [Configure a VLAN Interface, on page 953](#)

**Procedure**

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** In the **Name** field, enter a name up to 48 characters in length.  
You cannot start the name with the phrase "cluster". It is reserved for internal use.
- Step 4** Enable the interface by checking the **Enabled** check box.
- Step 5** (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.
- Step 6** (Optional) Add a description in the **Description** field.  
The description can be up to 200 characters on a single line, without carriage returns.
- Step 7** In the **Mode** drop-down list, choose **None**.  
Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types.
- Step 8** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.  
The routed interface is a Routed-type interface, and can only belong to Routed-type zones.

**Step 9** See [Configure the MTU, on page 1010](#) for information about the **MTU**.

**Step 10** In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to route the traffic across multiple egress interfaces. For more information, see [Configure Policy-Based Routing Policy, on page 1437](#).

**Step 11** Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list.

High Availability, clustering, and loopback interfaces only support static IP address configuration; DHCP and PPPoE are not supported.

- **Use Static IP**—Enter the IP address and subnet mask. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254 or /31). In this case, no IP addresses are reserved for the network or broadcast addresses. You cannot set the standby IP address in this case. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices > Device Management > High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- **Use DHCP**—Configure the following optional parameters:
  - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
  - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.

- **Use PPPoE**—If the interface is connected to a DSL, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address, configure the following parameters:

- **VPDN Group Name**—Specify a group name of your choice to represent this connection.
- **PPPoE User Name**—Specify the username provided by your ISP.
- **PPPoE Password/Confirm Password**—Specify and confirm the password provided by your ISP.
- **PPP Authentication**—Choose **PAP**, **CHAP**, or **MSCHAP**.

PAP passes a cleartext username and password during authentication and is not secure. With CHAP, the client returns the encrypted [challenge plus password], with a cleartext username in response to the server challenge. CHAP is more secure than PAP, but it does not encrypt data. MSCHAP is similar to CHAP but is more secure because the server stores and compares only encrypted passwords rather than cleartext passwords as in CHAP. MSCHAP also generates a key for data encryption by MPPE.

- **PPPoE route metric**—Assign an administrative distance to the learned route. Valid values are from 1 to 255. By default, the administrative distance for the learned routes is 1.
- **Enable Route Settings**—To manually configure the PPPoE IP address, check this box and then enter the **IP Address**.

If you select the **Enable Route Settings** check box and leave the **IP Address** blank, the **ip address pppoe setroute** command is applied as shown in this example:

```
interface GigabitEthernet0/2
nameif inside2_pppoe
cts manual
  propagate sgt preserve-untag
  policy static sgt disabled trusted
security-level 0
```

```
pppoe client vpdn group test
pppoe client route distance 10
ip address pppoe setroute
```

- **Store Username and Password in Flash**—Stores the username and password in flash memory.

The threat defense device stores the username and password in a special location of NVRAM.

**Step 12** (Optional) See [Configure IPv6 Addressing, on page 994](#) to configure IPv6 addressing on the **IPv6** tab.

**Step 13** (Optional) See [Configure the MAC Address, on page 1011](#) to manually configure the MAC address on the **Advanced** tab.

**Step 14** (Optional) Set the duplex and speed by clicking **Hardware Configuration > Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
- **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100/4200 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.
- **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.
- **Forward Error Correction Mode**—(Secure Firewall 3100/4200 only) For 25 Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

*Table 72: Default FEC for Auto Setting*

| Transceiver Type | Fixed Port Default FEC (Ethernet 1/9 through 1/16) | Network Module Default FEC |
|------------------|----------------------------------------------------|----------------------------|
| 25G-SR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 25G-LR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 10/25G-CSR       | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-AOCxM        | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-CU2.5/3M     | Auto-Negotiate                                     | Auto-Negotiate             |
| 25G-CU4/5M       | Auto-Negotiate                                     | Auto-Negotiate             |
| 25/50/100G       | Clause 91 RS-FEC                                   | Clause 91 RS-FEC           |

**Step 15** (Optional) Enable management center manager access on a data interface on the **Manager Access** page.

You can enable manager access from a data interface when you first setup the threat defense. If you want to enable or disable manager access after you added the threat defense to the management center, see:

- Enable manager access: [Change the Manager Access Interface from Management to Data, on page 152](#)

**Note** You cannot enable manager access unless you first initiate the manager interface migration from Management to a data interface. After you initiate the migration, you can enable manager access on the **Manager Access** page and save the configuration successfully.

- Disable manager access: [Change the Manager Access Interface from Data to Management, on page 156](#)

If you want to change the manager access interface from one data interface to another data interface, you must disable manager access on the original data interface, but do not disable the interface itself yet; the original data interface must be used to perform the deployment. If you want to use the same IP address on the new manager access interface, you can delete or change the IP configuration on the original interface; this change should not affect the deployment. If you use a different IP address for the new interface, then also change the device IP address shown in the management center; see [Update the Hostname or IP Address in the Management Center, on page 146](#). Be sure to also update related configuration to use the new interface such as static routes, DDNS, and DNS settings.

Manager access from a data interface has the following limitations:

- You can only enable manager access on a physical, data interface. You cannot use a subinterface or EtherChannel, nor can you create a subinterface on the manager access interface. You can also use the management center to enable manager access on a single secondary interface for redundancy.
- This interface cannot be management-only.
- Routed firewall mode only, using a routed interface.
- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the threat defense and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using the management center. Because the Management interface gateway will be changed to be the data interfaces, you also cannot SSH to the Management interface from a remote network unless you add a static route for the Management interface using the **configure network static-routes** command. For threat defense virtual on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the Management interface: add a static route for Management before you continue with your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface for manager access and you are disconnected.
- Clustering is not supported. You must use the Management interface in this case.

Figure 310: Manager Access

Edit Physical Interface

General IPv4 IPv6 Path Monitoring Hardware Configuration **Manager Access** Advanced

Enable management on this interface for the Manager

Available Networks  +

- any-ipv4
- any-ipv6
- IPv4-Benchmark-Tests
- IPv4-Link-Local
- IPv4-Multicast
- IPv4-Private-10.0.0.0-8

Add

Allowed Management Networks

any

Cancel OK

- Check **Enable management on this interface for the manager** to use this data interface for management instead of the dedicated Management interface.
- (Optional) In the **Allowed Management Networks** box, add the networks from which you want to allow manager access. By default, any networks are allowed.

**Step 16** Click **OK**.

**Step 17** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure Bridge Group Interfaces

A bridge group is a group of interfaces that the Secure Firewall Threat Defense device bridges instead of routes. Bridge groups are supported in both transparent and routed firewall mode. For more information about bridge groups, see [About Bridge Groups, on page 493](#).

To configure bridge groups and associated interfaces, perform these steps.

### Configure General Bridge Group Member Interface Parameters

This procedure describes how to set the name and security zone for each bridge group member interface. The same bridge group can include different types of interfaces: physical interfaces, VLAN subinterfaces, Firepower 1010 and Secure Firewall 1210/1220 VLAN interfaces, EtherChannels, and redundant interfaces. The Management interface is not supported. In routed mode, EtherChannels are not supported. For the Firepower 4100/9300, data-sharing type interfaces are not supported.

**Before you begin**• **Firepower 4100/9300**

1. [Configure a Physical Interface, on page 536](#)
2. (Optional) Configure any special interfaces.
  - [Add an EtherChannel \(Port Channel\), on page 537](#)
  - [Add a VLAN Subinterface for Container Instances, on page 537](#) in FXOS
  - [Add a Subinterface, on page 967](#) in management center

• (Optional) **All other models:**

- [Configure an EtherChannel, on page 918](#)
- [Add a Subinterface, on page 967](#)
- Firepower 1010 and Secure Firewall 1210/1220: [Configure a VLAN Interface, on page 953](#)

**Procedure**

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** In the **Name** field, enter a name up to 48 characters in length.  
You cannot start the name with the phrase "cluster". It is reserved for internal use.
- Step 4** Enable the interface by checking the **Enabled** check box.
- Step 5** (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.
- Step 6** (Optional) Add a description in the **Description** field.  
The description can be up to 200 characters on a single line, without carriage returns.
- Step 7** In the **Mode** drop-down list, choose **None**.  
Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types. After you assign this interface to a bridge group, the mode will show as **Switched**.
- Step 8** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.  
The bridge group member interface is a Switched-type interface, and can only belong to Switched-type zones. Do not configure any IP address settings for this interface. You will set the IP address for the Bridge Virtual Interface (BVI) only. Note that the BVI does not belong to a zone, and you cannot apply access control policies to the BVI.
- Step 9** See [Configure the MTU, on page 1010](#) for information about the **MTU**.
- Step 10** (Optional) Set the duplex and speed by clicking **Hardware Configuration > Speed**.

- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
- **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100/4200 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.
- **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.
- **Forward Error Correction Mode**—(Secure Firewall 3100/4200 only) For 25 Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 73: Default FEC for Auto Setting

| Transceiver Type | Fixed Port Default FEC (Ethernet 1/9 through 1/16) | Network Module Default FEC |
|------------------|----------------------------------------------------|----------------------------|
| 25G-SR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 25G-LR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 10/25G-CSR       | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-AOCxM        | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-CU2.5/3M     | Auto-Negotiate                                     | Auto-Negotiate             |
| 25G-CU4/5M       | Auto-Negotiate                                     | Auto-Negotiate             |
| 25/50/100G       | Clause 91 RS-FEC                                   | Clause 91 RS-FEC           |

- Step 11** (Optional) See [Configure IPv6 Addressing, on page 994](#) to configure IPv6 addressing on the **IPv6** tab.
- Step 12** (Optional) See [Configure the MAC Address, on page 1011](#) to manually configure the MAC address on the **Advanced** tab.
- Step 13** Click **OK**.
- Step 14** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure the Bridge Virtual Interface (BVI)

Each bridge group requires a BVI for which you configure an IP address. The threat defense uses this IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the connected network. For IPv4 traffic, the BVI IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations.

For routed mode, if you provide a name for the BVI, then the BVI participates in routing. Without a name, the bridge group remains isolated as in transparent firewall mode.

### Before you begin

You cannot add the BVI to a security zone; therefore, you cannot apply Access Control policies to the BVI. You must apply your policy to the bridge group member interfaces based on their zones.

## Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Choose **Add Interfaces > Bridge Group Interface**.
- Step 3** (Routed Mode) In the **Name** field, enter a name up to 48 characters in length.
- You must name the BVI if you want to route traffic outside the bridge group members, for example, to the outside interface or to members of other bridge groups. The name is not case-sensitive.
- Step 4** In the **Bridge Group ID** field, enter the bridge group ID between 1 and 250.
- Step 5** In the **Description** field, enter a description for this bridge group.
- Step 6** On the **Interfaces** tab, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members of the bridge group.
- Step 7** (Transparent Mode) Click the **IPv4** tab. In the **IP Address** field, enter the IPv4 address and subnet mask.
- Do not assign a host address (/32 or 255.255.255.255) to the BVI. Also, do not use other subnets that contain fewer than 3 host addresses (one each for the upstream router, downstream router, and transparent firewall) such as a /30 subnet (255.255.255.252). The threat defense device drops all ARP packets to or from the first and last addresses in a subnet. For example, if you use a /30 subnet and assign a reserved address from that subnet to the upstream router, then the threat defense device drops the ARP request from the downstream router to the upstream router.
- For High Availability, set the standby IP address on the **Devices > Device Management > High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- Step 8** (Routed Mode) Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list.
- High Availability and clustering interfaces only support static IP address configuration; DHCP is not supported.
- **Use Static IP**—Enter the IP address and subnet mask. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices > Device Management > High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
  - **Use DHCP**—Configure the following optional parameters:
    - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
    - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.

- Step 9** (Optional) See [Configure IPv6 Addressing, on page 994](#) to configure IPv6 addressing.
- Step 10** (Optional) See [Add a Static ARP Entry, on page 1012](#) and [Add a Static MAC Address and Disable MAC Learning for a Bridge Group, on page 1013](#) (for transparent mode only) to configure the **ARP** and **MAC** settings.
- Step 11** Click **OK**.
- Step 12** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure IPv6 Addressing

This section describes how to configure IPv6 addressing in routed and transparent mode.

### About IPv6

This section includes information about IPv6.

#### IPv6 Addressing

You can configure two types of unicast addresses for IPv6:

- **Global**—The global address is a public address that you can use on the public network. For a bridge group, this address needs to be configured for the BVI, and not per member interface. You can also configure a global IPv6 address for the management interface in transparent mode.
- **Link-local**—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the Neighbor Discovery functions such as address resolution. In a bridge group, only member interfaces have link-local addresses; the BVI does not have a link-local address.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local address is automatically configured on the interface, so you do not also need to specifically configure a link-local address. For bridge group member interfaces, when you configure the global address on the BVI, the threat defense device automatically generates link-local addresses for member interfaces. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

#### Modified EUI-64 Interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The threat defense device can enforce this requirement for hosts attached to the local link.

When this feature is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and the following system log message is generated:

```
325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link.

## Configure the IPv6 Prefix Delegation Client

The threat defense can act as a DHCPv6 Prefix Delegation client so that the client interface, for example the outside interface connected to a cable modem, can receive one or more IPv6 prefixes that the threat defense can then subnet and assign to its inside interfaces.

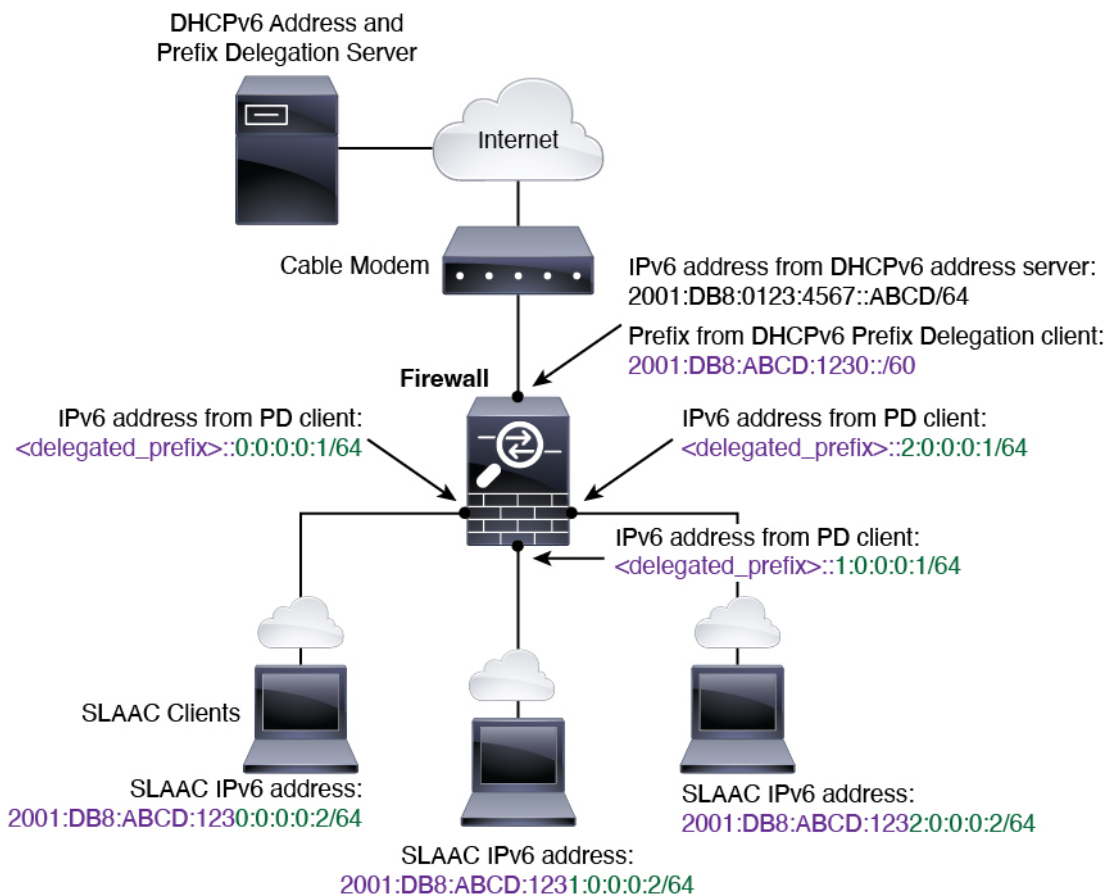

### About IPv6 Prefix Delegation

The threat defense can act as a DHCPv6 Prefix Delegation client so that the client interface, for example the outside interface connected to a cable modem, can receive one or more IPv6 prefixes that the threat defense can then subnet and assign to its inside interfaces. Hosts connected to the inside interfaces can then use Stateless Address Auto Configuration (SLAAC) to obtain global IPv6 addresses. Note that the inside threat defense interfaces do not in turn act as Prefix Delegation servers; the threat defense can only provide global IP addresses to SLAAC clients. For example, if a router is connected to the threat defense, it can act as a SLAAC client to obtain its IP address. But if you want to use a subnet of the delegated prefix for the networks behind the router, you must manually configure those addresses on the router's inside interfaces.

The threat defense includes a light DHCPv6 server so the threat defense can provide information such as the DNS server and domain name to SLAAC clients when they send Information Request (IR) packets to the threat defense. The threat defense only accepts IR packets, and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the threat defense received using Prefix Delegation.

### *IPv6 Prefix Delegation /64 Subnet Example*

The following example shows the threat defense receiving an IP address on the outside interface using the DHCPv6 address client. It also gets a delegated prefix using the DHCPv6 Prefix Delegation client. The threat defense subnets the delegated prefix into /64 networks and assigns global IPv6 addresses to its inside interfaces dynamically using the delegated prefix plus a manually configured subnet (::0, ::1, or ::2) and IPv6 address (0:0:0:1) per interface. SLAAC clients connected to those inside interfaces obtain IPv6 addresses on each /64 subnet.

IPv6 Prefix Delegation /62 Subnet Example

The following example shows the threat defense subnetting the prefix into 4 /62 subnets: 2001:DB8:ABCD:1230::/62, 2001:DB8:ABCD:1234::/62, 2001:DB8:ABCD:1238::/62, and 2001:DB8:ABCD:123C::/62. The threat defense uses one of 4 available /64 subnets on 2001:DB8:ABCD:1230::/62 for its inside network (::0). You can then manually use additional /62 subnets for downstream routers. The router shown uses 3 of 4 available /64 subnets on 2001:DB8:ABCD:1234::/62 for its inside interfaces (::4, ::5, and ::6). In this case, the inside router interfaces cannot dynamically obtain the delegated prefix, so you need to view the delegated prefix on the threat defense, and then use that prefix for your router configuration. Usually, ISPs delegate the same prefix to a given client when the lease expires, but if the threat defense receives a new prefix, you will have to modify the router configuration to use the new prefix. The DHCP unique identifier (DUID) is persistent across reboots.

### Enable the IPv6 Prefix Delegation Client

Enable the DHCPv6 Prefix Delegation client on one or more interfaces. The threat defense obtains one or more IPv6 prefixes that it can subnet and assign to inside networks. Typically, the interface on which you enable the prefix delegation client obtains its IP address using the DHCPv6 address client; only other threat defense interfaces use addresses derived from the delegated prefix.

This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

#### Before you begin

When you use Prefix Delegation, you must set the threat defense IPv6 neighbor discovery router advertisement interval to be much lower than the preferred lifetime of the prefix assigned by the DHCPv6 Server to prevent IPv6 traffic interruption. For example, if the DHCPv6 server sets the preferred Prefix Delegation lifetime to 300 seconds, you should set the threat defense RA interval to be 150 seconds. To set the preferred lifetime, use the **show ipv6 general-prefix** command. To set the threat defense RA interval, see [Configure IPv6 Neighbor Discovery, on page 1003](#); the default is 200 seconds.

## Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
  - Step 2** Click **Edit** (✎) for the interface you want to edit.
  - Step 3** Click the **IPv6** page, and then click **DHCP**.
  - Step 4** Click **Client PD Prefix Name** and enter a name for this prefix.

*Figure 311: Enable the Prefix Delegation Client*

Client PD Prefix Name  
  
 Client PD Hint Prefixes

The name can be up to 200 characters.

- Step 5** (Optional) Enter the prefix and prefix length in the **Client PD Hint Prefixes** field to provide one or more hints to the DHCP server about the delegated prefix you want to receive, then click **Add**.  
 Typically you want to request a particular prefix length, such as `::/60`, or if you have received a particular prefix before and want to ensure you get it again when the lease expires, you can enter the whole prefix as the hint. If you enter multiple hints (different prefixes or lengths), then it is up to the DHCP server which hint to honor, or whether to honor the hint at all.
- Step 6** Click **OK**.
- Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure a Global IPv6 Address

To configure a global IPv6 address for any routed mode interface and for the transparent or routed mode BVI, perform the following steps.

**Note** Configuring the global address automatically configures the link-local address, so you do not need to configure it separately. For bridge groups, configuring the global address on the BVI automatically configures link-local addresses on all member interfaces.

For subinterfaces defined on the threat defense, we recommend that you also set the MAC address manually, because they use the same burned-in MAC address of the parent interface. IPv6 link-local addresses are generated based on the MAC address, so assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the threat defense. See [Configure the MAC Address, on page 1011](#).

### Before you begin

For IPv6 neighbor discovery for bridge groups, you must explicitly allow Neighbor Solicitation (ICMPv6 type 135) and Neighbor Advertisement (ICMPv6 type 136) packets through the threat defense bridge group member interfaces using a bidirectional access rule.

### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Click the **IPv6** page.
- For routed mode, the **Basic** page is selected by default. For transparent mode, the **Address** page is selected by default.
- Step 4** (Optional) On the **Basic** page, check **Enable IPv6**.
- Use this option if you want to only configure the link-local addresses. Otherwise, configuring an IPv6 address enabled IPv6 processing automatically.
- Step 5** Configure the global IPv6 address using one of the following methods.
- For failover and clustering, and for loopback interfaces, you must set the IP address manually. For clustering, manually configuring the link-local address is also not supported.
- (Routed interface) Stateless autoconfiguration—Check the **Autoconfiguration** check box.  
Enabling stateless autoconfiguration on the interface configures IPv6 addresses based upon prefixes received in Router Advertisement messages. A link-local address, based on the Modified EUI-64 interface ID, is automatically generated for the interface when stateless autoconfiguration is enabled.  
Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send Router Advertisement messages, the threat defense device does send Router Advertisement messages in this case. Uncheck the **IPv6 > Settings > Enable RA** check box to suppress messages.
  - Manual configuration—To manually configure a global IPv6 address:
    - a. Click the **Address** page, and click (✚) **Add Address**.  
The **Add Address** dialog box appears.

- b. In the **Address** field, enter either a full global IPv6 address, including the interface ID, or enter the IPv6 prefix, along with the IPv6 prefix length. (Routed Mode) If you only enter the prefix, then be sure to check the **Enforce EUI 64** check box to generate the interface ID using the Modified EUI-64 format. For example, 2001:0DB8::BA98:0:3210/48 (full address) or 2001:0DB8::/48 (prefix, with EUI 64 checked).

For High Availability (if you did not set **Enforce EUI 64**), set the standby IP address on the **Devices > Device Management > High Availability** page in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

- (Routed interface) Obtain an address using DHCPv6—To use DHCPv6:

**Figure 312: Enable the DHCPv6 Client**

The screenshot shows the 'Edit Physical Interface' configuration page. The 'IPv6' tab is selected, and the 'DHCP' sub-tab is active. Two checkboxes are checked: 'Enable DHCP Client' and 'Enable default route using DHCP'. There are also two unchecked checkboxes labeled 'Enable' on the right side of the page.

- a. Click the **DHCP** page.
- b. Check the check box of **Enable DHCP Client**.
- c. (Optional) Check the check box of **Enable default route using DHCP** to obtain a default route from Router Advertisements.

- (Routed interface) Use a delegated prefix—To assign an IPv6 address using the delegated prefix:

This feature requires the threat defense to have the DHCPv6 Prefix Delegation client enabled *on a different interface*. See [Enable the IPv6 Prefix Delegation Client, on page 997](#).

- a. Click the **DHCP** page.
- b. Click **Add (+)**.

Figure 313: Use a Delegated Prefix

Edit Physical Interface

General IPv4 IPv6 Path Monitoring Hardware Configuration Manager Access Adva

Basic Address Prefixes Settings DHCP

No records to display

+ Add

- c. Enter the **Prefix Name** that you specified for the Prefix Delegation client (see [Enable the IPv6 Prefix Delegation Client, on page 997](#)) on another interface.

Figure 314: Specify the Prefix Name and Address

Prefixes

Prefix Name: Outside-Prefix

Prefix Length: ::1:0:0:0:1/64

Cancel OK

- d. Enter the IPv6 address and **Prefix Length**.

Typically, the delegated prefix will be /60 or smaller so you can subnet to multiple /64 networks. /64 is the supported subnet length if you want to support SLAAC for connected clients. You should specify an address that completes the /60 subnet, for example ::1:0:0:0:1. Enter :: before the address in case the prefix is smaller than /60. For example, if the delegated prefix is 2001:DB8:1234:5670::/60, then the global IP address assigned to this interface is 2001:DB8:1234:5671::1/64. The prefix that is advertised in router advertisements is 2001:DB8:1234:5671::/64. In this example, if the prefix is smaller than /60, the remaining bits of the prefix will be 0's as indicated by the leading ::. For example, if the prefix is 2001:DB8:1234::/48, then the IPv6 address will be 2001:DB8:1234::1:0:0:0:1/64.

- e. Click **OK**.

Figure 315: Prefix Delegation Table

| Prefix Name    | Prefix Length |                                                                                                                                                                         |
|----------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Outside-Prefix | ::1:0:0:1/64  |   |

- f. Optionally enable the DHCPv6 stateless server on this interface (see [Enable the DHCPv6 Stateless Server, on page 1043](#)). If you do so, we recommend that you also check the **Enable DHCP for non-address config** option.

**Step 6** For Routed interfaces, you can optionally set the following values on the **Basic** page:

- To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.
- To manually set the link-local address, enter an address in the **Link-Local address** field.

A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:fee:6a82. If you do not want to configure a global address, and only need to configure a link-local address, you have the option of manually defining the link-local address. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

Clustering does not support manual link-local addresses.

**Step 7** For Routed interfaces, you can optionally set the following values on the **DHCP** page:

- Check the **Enable DHCP for address config** check box to set the Managed Address Config flag in the IPv6 router advertisement packet.

This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain addresses, in addition to the derived stateless autoconfiguration address.

- Check the **Enable DHCP for non-address config** check box to set the Other Address Config flag in the IPv6 router advertisement packet.

This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address. Use this option when using the DHCPv6 stateless server with DHCPv6 prefix delegation.

**Step 8** For Routed interfaces, see [Configure IPv6 Neighbor Discovery, on page 1003](#) to configure settings on the **Prefixes** and **Settings** pages. For BVI interfaces, see the following parameters on the **Settings** page:

- **DAD attempts**—The maximum number of DAD attempts, between 1 and 600. Set the value to 0 to disable duplicate address detection (DAD) processing. This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses. 1 attempt is the default.
- **NS Interval**—The interval between IPv6 neighbor solicitation retransmissions on an interface, between 1000 and 3600000 ms. The default value is 1000 ms.

- **Reachable Time**—The amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred, between 0 and 3600000 ms. The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value. The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

**Step 9** Click **OK**.

**Step 10** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure IPv6 Neighbor Discovery

The IPv6 neighbor discovery process uses ICMPv6 messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the readability of a neighbor, and keep track of neighboring routers.

Nodes (hosts) use neighbor discovery to determine the link-layer addresses for neighbors known to reside on attached links and to quickly purge cached values that become invalid. Hosts also use neighbor discovery to find neighboring routers that are willing to forward packets on their behalf. In addition, nodes use the protocol to actively keep track of which neighbors are reachable and which are not, and to detect changed link-layer addresses. When a router or the path to a router fails, a host actively searches for functioning alternates.

### Before you begin

Supported in Routed mode only. For IPv6 neighbor settings supported in transparent mode, see [Configure a Global IPv6 Address, on page 998](#).

### Procedure

---

**Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

**Step 2** Click **Edit** (✎) for the interface you want to edit.

**Step 3** Click **IPv6**, and then **Prefixes**.

**Step 4** (Optional) To configure which IPv6 prefixes are included in IPv6 router advertisements, perform the following steps:

- a) Click (+) **Add Prefix**.
- b) In the **Address** field, enter the IPv6 address with the prefix length or check the **Default** check box to use the default prefix.
- c) (Optional) Uncheck the **Advertisement** check box to indicate that the IPv6 prefix is not advertised.
- d) Check the **Off Link** check box to indicate that the specified prefix is assigned to the link. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be locally reachable on the link. This prefix should not be used for on-link determination.

- e) To use the specified prefix for autoconfiguration, check the **Autoconfiguration** check box.
- f) For the **Prefix Lifetime**, click **Duration** or **Expiration Date**.
  - **Duration**—Enter a **Preferred Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being valid. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default is 2592000 (30 days). Enter a **Valid Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being preferred. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default setting is 604800 (seven days). Alternatively, check the **Infinite** check box to set an unlimited duration.
  - **Expiration Date**—Choose a **Valid** and **Preferred** date and time.
- g) Click **OK**.

**Step 5**

Click **Settings**.

**Step 6**

(Optional) Set the maximum number of **DAD attempts**, between 1 and 600. 1 attempt is the default. Set the value to 0 to disable duplicate address detection (DAD) processing.

This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses.

During the stateless autoconfiguration process, Duplicate Address Detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces.

When a duplicate address is identified, the state of the address is set to **DUPLICATE**, the address is not used, and the following error message is generated:

```
325002: Duplicate address ipv6_address/MAC_address on interface
```

If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used.

**Step 7**

(Optional) Configure the interval between IPv6 neighbor solicitation retransmissions in the **NS Interval** field, between 1000 and 3600000 ms.

The default value is 1000 ms.

Neighbor solicitation messages (ICMPv6 Type 135) are sent on the local link by nodes attempting to discover the link-layer addresses of other nodes on the local link. After receiving a neighbor solicitation message, the destination node replies by sending a neighbor advertisement message (ICPMv6 Type 136) on the local link.

After the source node receives the neighbor advertisement, the source node and destination node can communicate. Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. When a node wants to verifying the reachability of a neighbor, the destination address in a neighbor solicitation message is the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link.

**Step 8**

(Optional) Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred in the **Reachable Time** field, between 0 and 3600000 ms.

The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value.

The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

**Step 9** (Optional) To suppress the router advertisement transmissions, uncheck the **Enable RA** check box. If you enable router advertisement transmissions, you can set the RA lifetime and interval.

Router advertisement messages (ICMPv6 Type 134) are automatically sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message.

You may want to disable these messages on any interface for which you do not want the threat defense to supply the IPv6 prefix (for example, the outside interface).

- **RA Lifetime**—Configure the router lifetime value in IPv6 router advertisements, between 0 and 9000 seconds.

The default is 1800 seconds.

- **RA Interval**—Configure the interval between IPv6 router advertisement transmissions, between 3 and 1800 seconds.

The default is 200 seconds.

**Step 10** Click **OK**.

**Step 11** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure Advanced Interface Settings

This section describes how to configure MAC addresses for regular firewall mode interfaces, how to set the maximum transmission unit (MTU), and how to set other advanced parameters.

### About Advanced Interface Configuration

This section describes advanced interface settings.

#### About MAC Addresses

You can manually assign MAC addresses to override the default. For container instances, the FXOS chassis automatically generates unique MAC addresses for all interfaces.

---

**Note** You might want to assign unique MAC addresses to subinterfaces defined on the threat defense, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the threat defense device.

---

---

**Note** For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

---

## Default MAC Addresses

### For native instances:

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- VLAN interfaces (Firepower 1010 and Secure Firewall 1210/1220)—Routed firewall mode: All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See [Configure the MAC Address, on page 1011](#).  
Transparent firewall mode: Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See [Configure the MAC Address, on page 1011](#).
- EtherChannels (Firepower Models)—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.
- EtherChannels (ASA Models)—The port-channel interface uses the lowest-numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can configure a MAC address for the port-channel interface. We recommend configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.
- Subinterfaces (threat defense-defined)—All subinterfaces of a physical interface use the same burned-in MAC address. You might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the threat defense.

### For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See [Automatic MAC Addresses for Container Instance Interfaces, on page 524](#).

## About the MTU

The MTU specifies the maximum frame *payload* size that the threat defense device can transmit on a given Ethernet interface. The MTU value is the frame size *without* Ethernet headers, VLAN tagging, or other overhead. For example, when you set the MTU to 1500, the expected frame size is 1518 bytes including the headers, or 1522 when using VLAN. Do not set the MTU value higher to accommodate these headers.

For Geneve, the entire Ethernet datagram is being encapsulated, so the new IP packet is larger and requires a larger MTU: you should set the ASA VTEP source interface MTU to be the network MTU + 306 bytes.

### Path MTU Discovery

The threat defense device supports Path MTU Discovery (as defined in RFC 1191), which lets all devices in a network path between two hosts coordinate the MTU so they can standardize on the lowest MTU in the path.

### Default MTU

The default MTU on the threat defense device is 1500 bytes. This value does not include the 18-22 bytes for the Ethernet header, VLAN tagging, or other overhead.

### MTU and Fragmentation

For IPv4, if an outgoing IP packet is larger than the specified MTU, it is fragmented into 2 or more frames. Fragments are reassembled at the destination (and sometimes at intermediate hops), and fragmentation can cause performance degradation. For IPv6, packets are typically not allowed to be fragmented at all. Therefore, your IP packets should fit within the MTU size to avoid fragmentation.

For TCP packets, the endpoints typically use their MTU to determine the TCP maximum segment size (MTU - 40, for example). If additional TCP headers are added along the way, for example for site-to-site VPN tunnels, then the TCP MSS might need to be adjusted down by the tunneling entity. See [About the TCP MSS, on page 1008](#).

For UDP or ICMP, the application should take the MTU into account to avoid fragmentation.

---

**Note** The threat defense device can receive frames larger than the configured MTU as long as there is room in memory.

---

### MTU and Jumbo Frames

A larger MTU lets you send larger packets. Larger packets might be more efficient for your network. See the following guidelines:

- Matching MTUs on the traffic path—We recommend that you set the MTU on all threat defense interfaces and other device interfaces along the traffic path to be the same. Matching MTUs prevents intermediate devices from fragmenting the packets.

- Accommodating jumbo frames—You can set the MTU 9000 bytes or higher when you enable jumbo frames. The maximum depends on the model.

## About the TCP MSS

The TCP maximum segment size (MSS) is the size of the TCP payload *before* any TCP and IP headers are added. UDP packets are not affected. The client and the server exchange TCP MSS values during the three-way handshake when establishing the connection.

You can set the TCP MSS on the threat defense device for through traffic using the Sysopt\_Basic object in FlexConfig; see [#unique\\_574](#); by default, the maximum TCP MSS is set to 1380 bytes. This setting is useful when the threat defense device needs to add to the size of the packet for IPsec VPN encapsulation. However, for non-IPsec endpoints, you should disable the maximum TCP MSS on the threat defense device.

If you set a maximum TCP MSS, if either endpoint of a connection requests a TCP MSS that is larger than the value set on the threat defense device, then the threat defense device overwrites the TCP MSS in the request packet with the threat defense device maximum. If the host or server does not request a TCP MSS, then the threat defense device assumes the RFC 793-default value of 536 bytes (IPv4) or 1220 bytes (IPv6), but does not modify the packet. For example, you leave the default MTU as 1500 bytes. A host requests an MSS of 1500 minus the TCP and IP header length, which sets the MSS to 1460. If the threat defense device maximum TCP MSS is 1380 (the default), then the threat defense device changes the MSS value in the TCP request packet to 1380. The server then sends packets with 1380-byte payloads. The threat defense device can then add up to 120 bytes of headers to the packet and still fit in the MTU size of 1500.

You can also configure the minimum TCP MSS; if a host or server requests a very small TCP MSS, the threat defense device can adjust the value up. By default, the minimum TCP MSS is not enabled.

For to-the-box traffic, including for SSL VPN connections, this setting does not apply. The threat defense device uses the MTU to derive the TCP MSS: MTU - 40 (IPv4) or MTU - 60 (IPv6).

### Default TCP MSS

By default, the maximum TCP MSS on the threat defense device is 1380 bytes. This default accommodates IPv4 IPsec VPN connections where the headers can equal up to 120 bytes; this value fits within the default MTU of 1500 bytes.

### Suggested Maximum TCP MSS Setting

The default TCP MSS assumes the threat defense device acts as an IPv4 IPsec VPN endpoint and has an MTU of 1500. When the threat defense device acts as an IPv4 IPsec VPN endpoint, it needs to accommodate up to 120 bytes for TCP and IP headers.

If you change the MTU value, use IPv6, or do not use the threat defense device as an IPsec VPN endpoint, then you should change the TCP MSS setting using the Sysopt\_Basic object in FlexConfig.

---

**Note** Even if you explicitly set an MSS, if a component such as TLS/SSL decryption or server discovery needs a particular MSS, it will set that MSS based on the interface MTU and ignore your MSS setting.

---

See the following guidelines:

- Normal traffic—Disable the TCP MSS limit and accept the value established between connection endpoints. Because connection endpoints typically derive the TCP MSS from the MTU, non-IPsec packets usually fit this TCP MSS.

- IPv4 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 120. For example, if you use jumbo frames and set the MTU to 9000, then you need to set the TCP MSS to 8880 to take advantage of the new MTU.
- IPv6 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 140.

## ARP Inspection for Bridge Group Traffic

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the threat defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the threat defense device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the threat defense device to either forward the packet out all interfaces (flood), or to drop the packet.

---

**Note** The dedicated Management interface never floods packets even if this parameter is set to flood.

---

## MAC Address Table

When you use bridge groups, the threat defense learns and builds a MAC address table in a similar way as a normal bridge or switch: when a device sends a packet through the bridge group, the threat defense adds the MAC address to its table. The table associates the MAC address with the source interface so that the threat defense knows to send any packets addressed to the device out the correct interface. Because traffic between bridge group members is subject to the threat defense security policy, if the destination MAC address of a packet is not in the table, the threat defense does not flood the original packet on all interfaces as a normal bridge does. Instead, it generates the following packets for directly-connected devices or for remote devices:

- Packets for directly-connected devices—The threat defense generates an ARP request for the destination IP address, so that it can learn which interface receives the ARP response.
- Packets for remote devices—The threat defense generates a ping to the destination IP address so that it can learn which interface receives the ping reply.

The original packet is dropped.

## Default Settings

- If you enable ARP inspection, the default setting is to flood non-matching packets.
- The default timeout value for dynamic MAC address table entries is 5 minutes.
- By default, each interface automatically learns the MAC addresses of entering traffic, and the threat defense device adds corresponding entries to the MAC address table.

---

**Note** Secure Firewall Threat Defense device generates a reset packet to reset a connection that is denied by a stateful inspection engine. Here, the destination MAC address of the packet is not determined based on the ARP table lookup but instead it is taken directly from the packets (connections) that are being denied.

---

## Guidelines for ARP Inspection and the MAC Address Table

- ARP inspection is only supported for bridge groups.
- MAC address table configuration is only supported for bridge groups.

## Configure the MTU

Customize the MTU on the interface, for example, to allow jumbo frames.

For the ISA 3000 and the threat defense virtual: Changing the MTU above 1500 bytes automatically enables jumbo-frame reservation. You must restart the system before you can use jumbo frames. For the threat defense virtual that supports clustering, you can enable jumbo-frame reservation in the Day0 configuration, so in that case, you do not need to restart. After you restart, you cannot disable jumbo-frame reservation. An exception is for the threat defense virtual, where you can disable jumbo-frame reservation in the Day0 configuration, if supported. If you use an interface in an inline set, the MTU setting is not used. However, the jumbo-frame reservation setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo-frame reservation, you must set the MTU of *any* interface above 1500 bytes.

Jumbo frames are enabled by default on other platforms.

---

**Caution** Changing the highest MTU value on the device for a data interface restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Inspection is interrupted on all data interfaces, not just the interface you modified. Whether this interruption drops traffic or passes it without further inspection depends on the model of the managed device and the interface type. This caution does not apply to management-only interfaces. See [Snort Restart Traffic Behavior](#), on page 234 for more information.

---

## Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** On the **General** tab, set the **MTU**. The minimum and maximum depends on your platform.  
The default is 1500 bytes.
- Step 4** Click **OK**.
- Step 5** Click **Save**.  
You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
- Step 6** For the ISA 3000 and the threat defense virtual, if you set the MTU above 1500 bytes, restart the system to enable jumbo-frame reservation. See [Shut Down or Restart the Device, on page 89](#).
- 

## Configure the MAC Address

You might need to manually assign a MAC address. You can also set the Active and Standby MAC addresses on the **Devices > Device Management > High Availability** tab. If you set the MAC address for an interface on both screens, the addresses on the **Interfaces > Advanced** tab take precedence.

---

**Note** For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

---

## Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Click the **Advanced** tab.  
The **Information** tab is selected.
- Step 4** (For clustering in individual interface mode) Choose a MAC address pool from the drop-down list.  
You can add MAC address pools according to [Address Pools, on page 1472](#).
- Step 5** (For other modes) Set the active and standby MAC addresses.
- In the **Active MAC Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

- b) In the **Standby MAC Address** field, enter a MAC address for use with High Availability.

If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

**Step 6** Click **OK**.

**Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Add a Static ARP Entry

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection (see [ARP Inspection, on page 1073](#)). ARP inspection compares ARP packets with *static* ARP entries in the ARP table.

For routed interfaces, you can enter static ARP entries, but normally dynamic entries are sufficient. For routed interfaces, the ARP table is used to deliver packets to directly-connected hosts. Although senders identify a packet destination by an IP address, the actual delivery of the packet on Ethernet relies on the Ethernet MAC address. When a router or host wants to deliver a packet on a directly connected network, it sends an ARP request asking for the MAC address associated with the IP address, and then delivers the packet to the MAC address according to the ARP response. The host or router keeps an ARP table so it does not have to send ARP requests for every packet it needs to deliver. The ARP table is dynamically updated whenever ARP responses are sent on the network, and if an entry is not used for a period of time, it times out. If an entry is incorrect (for example, the MAC address changes for a given IP address), the entry needs to time out before it can be updated with the new information.

For transparent mode, the threat defense only uses dynamic ARP entries in the ARP table for traffic to and from the threat defense device, such as management traffic.

### Before you begin

This screen is only available for named interfaces.

### Procedure

**Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

**Step 2** Click **Edit** (✎) for the interface you want to edit.

**Step 3** Click the **Advanced** tab, and then click the **ARP** tab (called **ARP and MAC** for transparent mode).

**Step 4** Click (+) **Add ARP Config**.  
The **Add ARP Config** dialog box appears.

- Step 5** In the **IP Address** field, enter the IP address of the host.
- Step 6** In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b.
- Step 7** To perform proxy ARP for this address, check the **Enable Alias** check box.
- If the threat defense device receives an ARP request for the specified IP address, then it responds with the specified MAC address.
- Step 8** Click **OK**, and then click **OK** again to exit the Advanced settings.
- Step 9** Click **Save**.
- You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
- 

## Add a Static MAC Address and Disable MAC Learning for a Bridge Group

Normally, MAC addresses are added to the MAC address table dynamically as traffic from a particular MAC address enters an interface. You can disable MAC address learning; however, unless you statically add MAC addresses to the table, no traffic can pass through the threat defense device. You can also add static MAC addresses to the MAC address table. One benefit to adding static entries is to guard against MAC spoofing. If a client with the same MAC address as a static entry attempts to send traffic to an interface that does not match the static entry, then the threat defense device drops the traffic and generates a system message. When you add a static ARP entry (see [Add a Static ARP Entry, on page 1012](#)), a static MAC address entry is automatically added to the MAC address table.

### Before you begin

This screen is only available for named BVIs in transparent mode.

### Procedure

---

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Click the **Advanced** tab, and then click the **ARP and MAC** tab.
- Step 4** (Optional) Disable MAC learning by unchecking the **Enable MAC Learning** check box.
- Step 5** To add a static MAC address, click **Add MAC Config**.  
The **Add MAC Config** dialog box appears.
- Step 6** In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b. Click **OK**.
- Step 7** Click **OK** to exit the Advanced settings.
- Step 8** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Set Security Configuration Parameters

This section describes how to prevent IP spoofing, allow full fragment reassembly, and override the default fragment setting set for at the device level in **Platform Settings** .

### Anti-Spoofing

This section lets you enable Unicast Reverse Path Forwarding on an interface. Unicast RPF guards against IP spoofing (a packet uses an incorrect source IP address to obscure its true source) by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the threat defense device only looks at the destination address when determining where to forward the packet. Unicast RPF instructs the device to also look at the source address; this is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the threat defense device, the device routing table must include a route back to the source address. See RFC 2267 for more information.

For outside traffic, for example, the threat defense device can use the default route to satisfy the Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the device uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, then the threat defense device drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the device drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:

- ICMP packets have no session, so each packet is checked.
- UDP and TCP have sessions, so the initial packet requires a reverse route lookup. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure they arrived on the same interface used by the initial packet.

### Fragment per Packet

By default, the threat defense device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments through the threat defense device. Fragmented packets are often used as DoS attacks.

### Fragment Reassembly

The threat defense device performs the following fragment reassembly processes:

- IP fragments are collected until a fragment set is formed or until a timeout interval has elapsed.
- If a fragment set is formed, integrity checks are performed on the set. These checks include no overlapping, no tail overflow, and no chain overflow.
- IP fragments that terminate at the threat defense device are always fully reassembled.
- If **Full Fragment Reassembly** is disabled (the default), the fragment set is forwarded to the transport layer for further processing.
- If **Full Fragment Reassembly** is enabled, the fragment set is first coalesced into a single IP packet. The single IP packet is then forwarded to the transport layer for further processing.

**Before you begin**

This screen is only available for named interfaces.

**Procedure**

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Click the **Advanced** tab, and then click the **Security Configuration** tab.
- Step 4** To enable Unicast Reverse Path Forwarding, check the **Enable Anti Spoofing** check box.
- Step 5** To enable full fragment reassembly, check the **Allow Full Fragment Reassembly** check box.
- Step 6** To change the number of fragments allowed per packet, check the **Override Default Fragment Setting** check box, and set the following values:
- **Size**—Set the maximum number of packets that can be in the IP reassembly database waiting for reassembly. The default is 200. Set this value to 1 to disable fragments.
  - **Chain**—Set the maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets.
  - **Timeout**—Set the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.
- Step 7** Click **OK**.
- Step 8** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## History for Regular Firewall Interfaces for Secure Firewall Threat Defense

| Feature                                           | Minimum Management Center | Minimum Threat Defense | Details                                                                                                            |

| Geneve support for the Threat Defense Virtual | 7.1                       | Any                    | <p>Geneve encapsulation support was added for the threat defense virtual to support single-arm proxy for the Amazon Web Services (AWS) Gateway Load Balancer. The AWS Gateway Load Balancer combines a transparent network gateway (with a single entry and exit point for all traffic) and a load balancer that distributes traffic and scales threat defense virtual to match the traffic demand.</p> <p>This feature requires Snort 3.</p> <p>New/Modified screens:</p> <ul style="list-style-type: none"> <li>• <b>Devices &gt; Device Management &gt; Device &gt; VTEP</b></li> <li>• <b>Devices &gt; Device Management &gt; Device &gt; Interfaces &gt; Add Interfaces &gt; VNI Interface</b></li> <li>• <b>Devices &gt; Device Management &gt; Device &gt; Interfaces</b> edit physical interface &gt; <b>General</b></li> </ul> <p>Supported platforms: Threat Defense Virtual in AWS</p>                                 |
| 31-bit Subnet Mask                            | 7.0                       | Any                    | <p>For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. The 31-bit subnet includes only 2 addresses; normally, the first and last address in the subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4. For example, the failover link between 2 FTDs only requires 2 addresses; any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog. This feature is not supported for BVIs for bridge groups or with multicast routing.</p> <p>New/Modified screens:</p> <p><b>Devices &gt; Device Management &gt; Interfaces</b></p> |

| Synchronization between the threat defense operational link state and the physical link state for the Firepower 4100/9300 | 6.7                       | Any                    | <p>The Firepower 4100/9300 chassis can now synchronize the threat defense operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The threat defense application interface admin state is not considered. Without synchronization from threat defense, data interfaces can be in an Up state physically before the threat defense application has completely come online, for example, or can stay Up for a period of time after you initiate a threat defense shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the threat defense before the threat defense can handle it. This feature is disabled by default, and can be enabled per logical device in FXOS.</p> <p><b>Note</b> This feature is not supported for clustering, container instances, or threat defense with a Radware vDP decorator. It is also not supported for ASA.</p> <p>New/Modified Firepower Chassis Manager screens: <b>Logical Devices &gt; Enable Link State</b></p> <p>New/Modified FXOS commands: <b>set link-state-sync enabled, show interface expand detail</b></p> <p>Supported platforms: Firepower 4100/9300</p> |

| Integrated Routing and Bridging | 6.2.0                     | Any                    | <p>Integrated Routing and Bridging provides the ability to route between a bridge group and a routed interface. A bridge group is a group of interfaces that the threat defense bridges instead of routes. The threat defense is not a true bridge in that the threat defense continues to act as a firewall: access control between interfaces is controlled, and all of the usual firewall checks are in place.</p> <p>Previously, you could only configure bridge groups in transparent firewall mode, where you cannot route between bridge groups. This feature lets you configure bridge groups in routed firewall mode, and to route between bridge groups and between a bridge group and a routed interface. The bridge group participates in routing by using a Bridge Virtual Interface (BVI) to act as a gateway for the bridge group. Integrated Routing and Bridging provides an alternative to using an external Layer 2 switch if you have extra interfaces on the threat defense to assign to the bridge group. In routed mode, the BVI can be a named interface and can participate separately from member interfaces in some features, such as access rules and DHCP server.</p> <p>The following features that are supported in transparent mode are not supported in routed mode: clustering. The following features are also not supported on BVIs: dynamic routing and multicast routing.</p> <p>New/Modified screens:</p> <ul style="list-style-type: none"> <li>• <b>Devices &gt; Device Management &gt; Interfaces &gt; Edit Physical Interface</b></li> <li>• <b>Devices &gt; Device Management &gt; Interfaces &gt; Add Interfaces &gt; Bridge Group Interface</b></li> </ul> <p>Supported platforms: All except for the Firepower 2100 and the threat defense virtual</p> |

## CHAPTER 37

# Inline Sets and Passive Interfaces

You can configure IPS-only passive interfaces, passive ERSPAN interfaces, and inline sets. IPS-only mode interfaces bypass many firewall checks and only support IPS security policy. You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

- [About IPS Interfaces, on page 1023](#)
- [Requirements and Prerequisites for Inline Sets, on page 1025](#)
- [Guidelines for Inline Sets and Passive Interfaces, on page 1027](#)
- [Configure a Passive Interface, on page 1029](#)
- [Configure an Inline Set, on page 1030](#)

## About IPS Interfaces

This section describes IPS interfaces.

## IPS Interface Types

IPS-only mode interfaces bypass many firewall checks and only support IPS security policy. You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

---

**Note** The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes.

---

IPS-only interfaces can be deployed as the following types:

- **Inline Set, with optional Tap mode**—An inline set acts like a bump on the wire, and binds two interfaces together to slot into an existing network. This function allows the threat defense to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of an inline set unless explicitly dropped.

With tap mode, the threat defense is deployed inline, but the network traffic flow is undisturbed. Instead, the threat defense makes a copy of each packet so that it can analyze the packets. Note that rules of these types do generate intrusion events when they are triggered, and the table view of intrusion events indicates

that the triggering packets would have dropped in an inline deployment. There are benefits to using tap mode with FTDs that are deployed inline. For example, you can set up the cabling between the threat defense and the network as if the threat defense were inline and analyze the kinds of intrusion events the threat defense generates. Based on the results, you can modify your intrusion policy and add the drop rules that best protect your network without impacting its efficiency. When you are ready to deploy the threat defense inline, you can disable tap mode and begin dropping suspicious traffic without having to reconfigure the cabling between the threat defense and the network.

---

**Note** Tap mode *significantly* impacts threat defense performance, depending on the traffic.

---

---

**Note** Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode or the firewall-type interfaces.

---

- Passive or ERSPAN Passive—Passive interfaces monitor traffic flowing across a network using a switch SPAN or mirror port. The SPAN or mirror port allows for traffic to be copied from other ports on the switch. This function provides the system visibility within the network without being in the flow of network traffic. When you configure the threat defense in a passive deployment, the threat defense cannot take certain actions such as blocking or shaping traffic. Passive interfaces receive all traffic unconditionally, and no traffic received on these interfaces is retransmitted. Encapsulated remote switched port analyzer (ERSPAN) interfaces allow you to monitor traffic from source ports distributed over multiple switches, and uses GRE to encapsulate the traffic. ERSPAN interfaces are only allowed when the threat defense is in routed firewall mode.

---

**Note** Using SR-IOV interfaces as passive interfaces on NGFWv is not supported on some Intel network adapters (such as Intel X710 or 82599) using SR-IOV drivers due to a promiscuous mode restriction. In such cases, use a network adapter that supports this functionality. See [Intel Ethernet Products](#) for more information on Intel network adapters.

---

## About Hardware Bypass for Inline Sets

For certain interface modules on the supported models (see [Requirements and Prerequisites for Inline Sets, on page 1025](#)), you can enable the Hardware Bypass feature. Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures.

### Hardware Bypass Triggers

Hardware Bypass can be triggered in the following scenarios:

- Threat Defense crash
- Threat Defense reboot

- Security Module reboot
- Chassis crash
- Chassis reboot
- Manual trigger
- Chassis power loss
- Security Module power loss

---

**Note** Hardware bypass is intended for unplanned/unexpected failure scenarios, and is not automatically triggered during planned software upgrades. Hardware bypass only engages at the end of a planned upgrade process, when the threat defense application reboots.

---

## Hardware Bypass Switchover

When switching from normal operation to hardware bypass or from hardware bypass back to normal operation, traffic may be interrupted for several seconds. A number of factors can affect the length of the interruption; for example, copper port auto-negotiation; behavior of the optical link partner such as how it handles link faults and de-bounce timing; spanning tree protocol convergence; dynamic routing protocol convergence; and so on. During this time, you may experience dropped connections.

You may also experience dropped connections due to application identification errors when analyzing connections midstream after the return to normal operations.

## Snort Fail Open vs. Hardware Bypass

For inline sets other than those in tap mode, you can use the Snort Fail Open option to either drop traffic or allow traffic to pass without inspection when the Snort process is busy or down. Snort Fail Open is supported on all inline sets except those in tap mode, not just on interfaces that support Hardware Bypass.

The Hardware Bypass functionality allows traffic to flow during a hardware failure, including a complete power outage, and certain limited software failures. A software failure that triggers Snort Fail Open does not trigger a Hardware Bypass.

## Hardware Bypass Status

If the system has power, then the Bypass LED indicates the Hardware Bypass status. See the Firepower chassis hardware installation guide for LED descriptions.

# Requirements and Prerequisites for Inline Sets

### User Roles

- Admin
- Access Admin
- Network Admin

### Hardware Bypass Support

The threat defense supports Hardware Bypass for interface pairs on specific network modules on the following models:

- Firepower 2130 and 2140
- Secure Firewall 3100
- Firepower 4100
- Secure Firewall 4200
- Firepower 9300

---

**Note** The ISA 3000 has a separate implementation for Hardware Bypass, which you can enable using FlexConfig only (see [FlexConfig Policies, on page 2703](#)). Do not use this chapter to configure ISA 3000 Hardware Bypass.

---

---

**Note** You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

---

The supported Hardware Bypass network modules for these models include:

- Firepower 2130 and 2140:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR2K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR2K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR2K-NM-6X10LR-F)
- Secure Firewall 3100:
  - 6-port 1G SFP Fail-to-Wire Network Module, SX (multimode) (FPR3K-XNM-6X1SXF)
  - 6-port 10G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-6X10SRF)
  - 6-port 10G SFP Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X10LRF)
  - 6-port 25G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-X25SRF)
  - 6-port 25G Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X25LRF)
  - 8-port 1G Copper Fail-to-Wire Network Module, RJ45 (copper) (FPR3K-XNM-8X1GF)
- Secure Firewall 4200:
  - 6-port 1G SFP Fail-to-Wire Network Module, SX (multimode) (FPR4K-XNM-6X1SXF)
  - 6-port 10G SFP Fail-to-Wire Network Module, SR (multimode) (FPR4K-XNM-6X10SRF)
  - 6-port 10G SFP Fail-to-Wire Network Module, LR (single mode) (FPR4K-XNM-6X10LRF)
  - 6-port 25G SFP Fail-to-Wire Network Module, SR (multimode) (FPR4K-XNM-X25SRF)
  - 6-port 25G Fail-to-Wire Network Module, LR (single mode) (FPR4K-XNM-6X25LRF)

- 8-port 1G Copper Fail-to-Wire Network Module, RJ45 (copper) (FPR4K-XNM-8X1GF)
- Firepower 4100:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR4K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR4K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR4K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR4K-NM-2X40G-F)
  - Firepower 8-port 1G Copper FTW Network Module single-wide (FPR-NM-8X1G-F)
- Firepower 9300:
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR9K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR9K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR9K-NM-2X40G-F)

Hardware Bypass can only use the following port pairs:

- 1 & 2
- 3 & 4
- 5 & 6
- 7 & 8

## Guidelines for Inline Sets and Passive Interfaces

### Firewall Mode

- ERSPAN interfaces are only allowed when the device is in routed firewall mode.

### Clustering

- Link State Propagation for an inline set is not supported with clustering.

### Multi-Instance Mode

- Multi-instance shared interfaces are not supported. You must use an unshared interface.
- Multi-instance chassis-defined subinterfaces are not supported. You must use a physical interface or EtherChannel.

### General Guidelines

- Inline sets and passive interfaces support physical interfaces and EtherChannels only, and cannot use VLANs or other virtual interfaces, including multi-instance chassis-defined subinterfaces.

- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the threat defense when using inline sets. If there are two neighbors on either side of the threat defense running BFD, then the threat defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.
- For inline sets and passive interfaces, the threat defense supports up to two 802.1Q headers in a packet (also known as Q-in-Q support), with the exception of the Firepower 4100/9300, which only supports one 802.1Q header. **Note:** Firewall-type interfaces do not support Q-in-Q, and only support one 802.1Q header.

### Hardware Bypass Guidelines

- Hardware Bypass ports are supported only for inline sets.
- Hardware Bypass ports cannot be part of an EtherChannel.
- Hardware Bypass is not supported in high availability mode.
- Hardware Bypass ports are supported with intra-chassis clustering on the Firepower 9300. Ports are placed in Hardware Bypass mode when the last unit in the chassis fails. Inter-chassis clustering is not supported, because inter-chassis clustering only supports Spanned EtherChannels; Hardware Bypass ports cannot be part of an EtherChannel.
- If all modules in an intra-chassis cluster on the Firepower 9300 fail, then Hardware Bypass is triggered on the final unit, and traffic continues to pass. When units come back up, Hardware Bypass returns to standby mode. However, when you use rules that match application traffic, those connections may be dropped and need to be reestablished. Connections are dropped because state information is not retained on the cluster unit, and the unit cannot identify the traffic as belonging to an allowed application. To avoid a traffic drop, use a port-based rule instead of an application-based rule, if appropriate for your deployment.
- You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

### Unsupported Firewall Features on IPS Interfaces

- DHCP server
- DHCP relay
- DHCP client
- TCP Intercept
- Routing
- NAT
- VPN
- Application inspection
- QoS
- NetFlow

- VXLAN

## Configure a Passive Interface

This section describes how to:

- Enable the interface. By default, interfaces are disabled.
- Set the interface mode to Passive or ERSPAN. For ERSPAN interfaces, you will set the ERSPAN parameters and the IP address.
- Change the MTU. By default, the MTU is set to 1500 bytes. For more information about the MTU, see [About the MTU, on page 1007](#).
- Set a specific speed and duplex (if available). By default, speed and duplex are set to Auto.

---

**Note** For the Secure Firewall Threat Defense on the FXOS chassis, you configure basic interface settings on the Firepower 4100/9300. See [Configure a Physical Interface, on page 536](#) for more information.

---

### Before you begin

- If you are using EtherChannels, add them according to [Configure an EtherChannel, on page 918](#).

### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
  - Step 2** Click **Edit** (✎) for the interface you want to edit.
  - Step 3** In the **Mode** drop-down list, choose **Passive** or **Ersparn**.
  - Step 4** Enable the interface by checking the **Enabled** check box.
  - Step 5** In the **Name** field, enter a name up to 48 characters in length.
  - Step 6** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.
  - Step 7** (Optional) Add a description in the **Description** field.  
The description can be up to 200 characters on a single line, without carriage returns.
  - Step 8** (Optional) On **General**, set the **MTU** between 64 and 9198 bytes; for the Secure Firewall Threat Defense Virtual and Secure Firewall Threat Defense on the FXOS chassis, the maximum is 9000 bytes.  
The default is 1500 bytes.
  - Step 9** For ERSPAN interfaces, set the following parameters:
    - **Flow Id**—Configure the ID used by the source and destination sessions to identify the ERSPAN traffic, between 1 and 1023. This ID must also be entered in the ERSPAN destination session configuration.

- **Source IP**—Configure the IP address used as the source of the ERSPAN traffic.

**Step 10** For ERSPAN interfaces, set the IPv4 address and mask on **IPv4**.

**Step 11** (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.
- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.

**Step 12** Click **OK**.

**Step 13** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure an Inline Set

This section enables and names two physical interfaces or EtherChannels that you can add to an inline set. You can also optionally enable Hardware Bypass for supported interface pairs.

**Note** For the Firepower 4100/9300, you configure basic interface settings in FXOS on the chassis. See [Configure a Physical Interface, on page 536](#) for more information.

### Before you begin

- If you are using EtherChannels, add them according to [Configure an EtherChannel, on page 918](#).
- We recommend that you set STP PortFast for STP-enabled switches that connect to the threat defense inline pair interfaces. This setting is especially useful for Hardware Bypass configurations and can reduce bypass times.

### Procedure

**Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

**Step 2** Click **Edit** (✎) for the interface you want to edit.

**Step 3** In the **Mode** drop-down list, choose **None**.

After you add this interface to an inline set, this field will show Inline for the mode.

**Step 4** Enable the interface by checking the **Enabled** check box.

**Step 5** In the **Name** field, enter a name up to 48 characters in length.

Do not set the security zone yet; you must set it after you create the inline set later in this procedure.

**Step 6** (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

**Step 7** (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.
- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.

**Step 8** Click **OK**.

Do not set any other settings for this interface.

**Step 9** Click **Edit** (✎) for the second interface you want to add to the inline set.

**Step 10** Configure the settings as for the first interface.

**Step 11** Click **Inline Sets**.

**Step 12** Click **Add Inline Set**.

The **Add Inline Set** dialog box appears with **General** selected.

**Step 13** In the **Name** field, enter a name for the set.

**Step 14** (Optional) Change the **MTU** to enable jumbo frames.

For inline sets, the MTU setting is not used. However, the jumbo frame setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo frames, you must set the MTU of *any* interface on the device above 1500 bytes.

**Step 15** Configure Hardware Bypass.

**Note** Do not enable **Bypass** and **Propagate Link State** for the same inline set.

a) For the **Bypass** mode, choose one of the following options:

- **Disabled**—Set Hardware Bypass to disabled for interfaces where Hardware Bypass is supported, or use interfaces where Hardware Bypass is not supported.
- **Standby**—Set Hardware Bypass to the standby state on supported interfaces. Only pairs of Hardware Bypass interfaces are shown. In the standby state, the interfaces remain in normal operation until there is a trigger event.
- **Bypass-Force**—Manually forces the interface pair to go into a bypass state. **Inline Sets** shows **Yes** for any interface pairs that are in Bypass-Force mode.

b) In the **Available Interfaces Pairs** area, click a pair and then click **Add** to move it to the **Selected Interface Pair** area.

All possible pairings between named and enabled interfaces with the mode set to None show in this area.

**Step 16** (Optional) Click **Advanced** to set the following optional parameters:

- **Tap Mode**—Set to inline tap mode.

Note that you cannot enable this option and strict TCP enforcement on the same inline set.

**Note** If you need to enable or disable the Tap mode, you should do so during a maintenance window. Changing the mode while the device is passing traffic can cause traffic disruption.

**Note** Tap mode *significantly* impacts the threat defense performance, depending on the traffic.

- **Propagate Link State**—Configure link state propagation.

Link state propagation automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the device senses the change and updates the link state of the other interface to match it. Note that devices require up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

**Note** Do not enable **Bypass** and **Propagate Link State** for the same inline set.  
Do not enable **Propagate Link State** when using clustering.

- **Snort Fail Open**—Enable or disable either or both of the **Busy** and **Down** options if you want new and existing traffic to pass without inspection (enabled) or drop (disabled) when the Snort process is busy or down.

By default, traffic passes without inspection when the Snort process is down, and drops when it is busy.

When the Snort process is:

- **Busy**—It cannot process traffic fast enough because traffic buffers are full, indicating that there is more traffic than the device can handle, or because of other software resource issues.
- **Down**—It is restarting because you deployed a configuration that requires it to restart. See [Configurations that Restart the Snort Process When Deployed or Activated, on page 236](#).

When the Snort process is down and comes back up, it inspects *new* connections. To prevent false positives and false negatives, it does not inspect existing connections on inline, routed, or transparent interfaces because initial session information might have been lost while it was down.

**Note** When Snort fails open, features that rely on the Snort process do not function. These include application control and deep inspection. The system performs only basic access control using simple, easily determined transport and network layer characteristics.

**Note** The **Strict TCP Enforcement** option is not supported.

**Step 17** Click **Interfaces**.

**Step 18** Click **Edit** (✎) for one of the member interfaces.

**Step 19** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

You can only set the zone after you add the interface to the inline set; adding it to an inline set configures the mode to Inline and lets you choose inline-type security zones.

**Step 20** Click **OK**.

**Step 21** Set the security zone for the second interface.

**Step 22** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## CHAPTER 38

# DHCP and DDNS

The following topics explain DHCP and DDNS services and how to configure them on Threat Defense devices.

- [About DHCP and DDNS Services, on page 1035](#)
- [Requirements and Prerequisites for DHCP and DDNS, on page 1037](#)
- [Guidelines for DHCP and DDNS Services, on page 1037](#)
- [Configure the DHCPv4 Server, on page 1038](#)
- [Configure the DHCPv6 Stateless Server, on page 1040](#)
- [Configure the DHCP Relay Agent, on page 1044](#)
- [Configure Dynamic DNS, on page 1045](#)
- [History for DHCP and DDNS, on page 1051](#)

## About DHCP and DDNS Services

The following topics describe the DHCP server, DHCP relay agent, and DDNS update.

### About the DHCPv4 Server

DHCP provides network configuration parameters, such as IP addresses, to DHCP clients. The threat defense device can provide a DHCP server to DHCP clients attached to threat defense device interfaces. The DHCP server provides network configuration parameters directly to DHCP clients.

An IPv4 DHCP client uses a broadcast rather than a multicast address to reach the server. The DHCP client listens for messages on UDP port 68; the DHCP server listens for messages on UDP port 67.

The DHCP server for IPv6 is not supported; you can, however, enable DHCP relay for IPv6 traffic.

### DHCP Options

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. The configuration parameters are carried in tagged items that are stored in the Options field of the DHCP message and the data are also called options. Vendor information is also stored in Options, and all of the vendor information extensions can be used as DHCP options.

For example, Cisco IP Phones download their configuration from a TFTP server. When a Cisco IP Phone starts, if it does not have both the IP address and TFTP server IP address preconfigured, it sends a request with option 150 or 66 to the DHCP server to obtain this information.

- DHCP option 150 provides the IP addresses of a list of TFTP servers.
- DHCP option 66 gives the IP address or the hostname of a single TFTP server.
- DHCP option 3 sets the default route.

A single request might include both options 150 and 66. In this case, the ASA DHCP server provides values for both options in the response if they are already configured on the ASA.

You can use advanced DHCP options to provide DNS, WINS, and domain name parameters to DHCP clients; DHCP option 15 is used for the DNS domain suffix. You can also use the DHCP automatic configuration setting to obtain these values or define them manually. When you use more than one method to define this information, it is passed to DHCP clients in the following sequence:

1. Manually configured settings.
2. Advanced DHCP options settings.
3. DHCP automatic configuration settings.

For example, you can manually define the domain name that you want the DHCP clients to receive and then enable DHCP automatic configuration. Although DHCP automatic configuration discovers the domain together with the DNS and WINS servers, the manually defined domain name is passed to DHCP clients with the discovered DNS and WINS server names, because the domain name discovered by the DHCP automatic configuration process is superseded by the manually defined domain name.

## About the DHCPv6 Stateless Server

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature ([Enable the IPv6 Prefix Delegation Client, on page 997](#)), you can configure the threat defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the threat defense by defining a DHCP IPv6 Pool and assigning it to the DHCPv6 server. The threat defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the threat defense received using Prefix Delegation.

## About the DHCP Relay Agent

You can configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers. DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the threat defense device because it does not forward broadcast traffic. The DHCP relay agent lets you configure the interface of the threat defense device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another interface.

# Requirements and Prerequisites for DHCP and DDNS

## Model Support

Threat Defense

## User Roles

- Admin
- Access Admin
- Network Admin

# Guidelines for DHCP and DDNS Services

This section includes guidelines and limitations that you should check before configuring DHCP and DDNS services.

## Firewall Mode

- DHCP Relay is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCP Server is supported in transparent firewall mode on a bridge group member interface. In routed mode, the DHCP server is supported on the BVI interface, not the bridge group member interface. The BVI must have a name for the DHCP server to operate.
- DDNS is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCPv6 stateless server is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.

## Clustering

- DHCPv6 stateless server is not supported with clustering.

## IPv6

Supports IPv6 for DHCP stateless server and DHCP Relay.

## DHCPv4 Server

- The maximum available DHCP pool is 256 addresses.
- You can configure a DHCP server on any interface with a name and IP address, such as a physical interface, a subinterface, or a BVI in routed mode.

- You can configure only one DHCP server on each interface. Each interface can have its own pool of addresses to use. However the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.
- You cannot configure an interface as a DHCP client if that interface also has DHCP server enabled; you must use a static IP address.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- The threat defense does not support QIP DHCP servers for use with the DHCP proxy service.
- The DHCP server does not support BOOTP requests.

### DHCPv6 Server

The DHCPv6 Stateless server cannot be configured on an interface where the DHCPv6 address, Prefix Delegation client, or DHCPv6 relay is configured.

### DHCP Relay

- You can configure a maximum of 10 DHCPv4 relay servers per virtual router, global (VRF) and interface-specific servers combined, with a maximum of 4 servers per interface.
- You can configure a maximum of 10 DHCPv6 relay servers per virtual router. Interface-specific servers for IPv6 are not supported.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- DHCP relay services are not available in transparent firewall mode or in routed mode on the BVI or bridge group member interface. You can, however, allow DHCP traffic through using an access rule. To allow DHCP requests and replies through the threat defense, you need to configure two access rules, one that allows DHCP requests from the inside interface to the outside (UDP destination port 67), and one that allows the replies from the server in the other direction (UDP destination port 68).
- For IPv4, clients must be directly-connected to the threat defense and cannot send requests through another relay agent or a router. For IPv6, the threat defense supports packets from another relay server.
- The DHCP clients must be on different interfaces from the DHCP servers to which the threat defense relays requests.
- You cannot enable DHCP Relay on an interface in a traffic zone.

### DDNS Service

The firewall's DDNS supports only DynDNS service. Hence, ensure that the DDNS is configured with update URL in the following syntax:

**`https://username:password@provider-domain/path?hostname=<h>&myip=<a>`**.

## Configure the DHCPv4 Server

See the following steps to configure a DHCPv4 server.

## Procedure

- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Select **DHCP > DHCP Server**.
- Step 3** Configure the following DHCP server options:
- **Ping Timeout**—The amount of time in milliseconds that threat defense device waits to time out a DHCP ping attempt. Valid values range from 10 to 10000 milliseconds. The default value is 50 milliseconds.  
To avoid address conflicts, the threat defense device sends two ICMP ping packets to an address before assigning that address to a DHCP client.
  - **Lease Length**—The amount of time in seconds that the client may use its allocated IP address before the lease expires. Valid values range from 300 to 1048575 seconds. The default value is 3600 seconds (1 hour).
  - (Routed mode) **Auto-configuration**—Enables DHCP auto configuration on the threat defense device. Auto-configuration enables the DHCP server to provide the DHCP clients with the DNS server, domain name, and WINS server information obtained from a DHCP client running on the specified interface. Otherwise, you can disable auto configuration and add the values yourself in Step 4.
  - (Routed mode) **Interface**—Specifies the interface to be used for auto configuration. For a device with virtual routing capability, this interface can only be a global virtual router interface.
- Step 4** To override auto-configured settings, do the following:
- Enter the domain name of the interface. For example, your device may be in the Your\_Company domain.
  - From the drop-down list, choose the DNS servers (primary and secondary) configured for the interface. To add a new DNS server, see [Creating Network Objects, on page 1499](#).
  - From the drop-down list, choose the WINS servers (primary and secondary) configured for the interface. To add a new WINS server, see [Creating Network Objects, on page 1499](#).
- Step 5** Select **Server**, click **Add**, and configure the following options:
- **Interface**—Choose the interface from the drop-down list. In transparent mode, specify a named bridge group member interface. In routed mode, specify a named routed interface or a named BVI; do not specify the bridge group member interface. Note that each bridge group member interface for the BVI must also be named for the DHCP server to operate.
  - **Address Pool**—The range of IP addresses from lowest to highest that is used by the DHCP server. The range of IP addresses must be on the same subnet as the selected interface and cannot include the IP address of the interface itself.
  - **Enable DHCP Server**—Enables the DHCP server on the selected interface.
- Step 6** Click **OK** to save the DHCP server configuration.
- Step 7** (Optional) Select **Advanced**, click **Add**, and specify the type of information you want the option to return to the DHCP client:
- **Option Code**—The threat defense device supports the DHCP options listed in RFC 2132, RFC 2562, and RFC 5510 to send information. All DHCP options (1 through 255) are supported except for 1, 12,

50–54, 58–59, 61, 67, and 82. See [About the DHCPv4 Server, on page 1035](#) for more information on DHCP option codes.

**Note** The threat defense device does not verify that the option type and value that you provide match the expected type and value for the option code, as defined in RFC 2132. For more information about option codes and their associated types and expected values, see RFC 2132.

- **Type**—DHCP option type. Available options include **IP**, **ASCII**, and **HEX**. If you chose IP, you must add IP addresses in the IP Address fields. If you chose ASCII, you must add the ASCII value in the ASCII field. If you chose HEX, you must add the HEX value in the HEX field.
- **IP Address 1** and **IP Address 2**—The IP address(es) to be returned with this option code. To add a new IP address, see [Creating Network Objects, on page 1499](#).
- **ASCII**—The ASCII value that is returned to the DHCP client. The string cannot include spaces.
- **HEX**—The HEX value that is returned to the DHCP client. The string must have an even number of digits and no spaces. You do not need to use a 0x prefix.

**Step 8** Click **OK** to save the option code configuration.

**Step 9** Click **Save** on the DHCP page to save your changes.

**Step 10** To view DHCP bindings, use the following command.

**show dhcpd binding**

**Example:**

```
> show dhcpd binding
IP Address Client-id Lease Expiration Type
10.0.1.100 0100.a0c9.868e.43 84985 seconds automatic
```

## Configure the DHCPv6 Stateless Server

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature, you can configure the threat defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the threat defense.

### Create the DHCP IPv6 Pool

Create a DHCP IPv6 Pool for use with the DHCPv6 server. The DHCPv6 server provides information such as the DNS server or domain name when they clients send Information Request (IR) packets to the threat defense. The DHCP IPv6 Pool defines the parameters to sent in IR messages.

This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

#### Procedure

**Step 1** Choose **Objects > Object Management**.

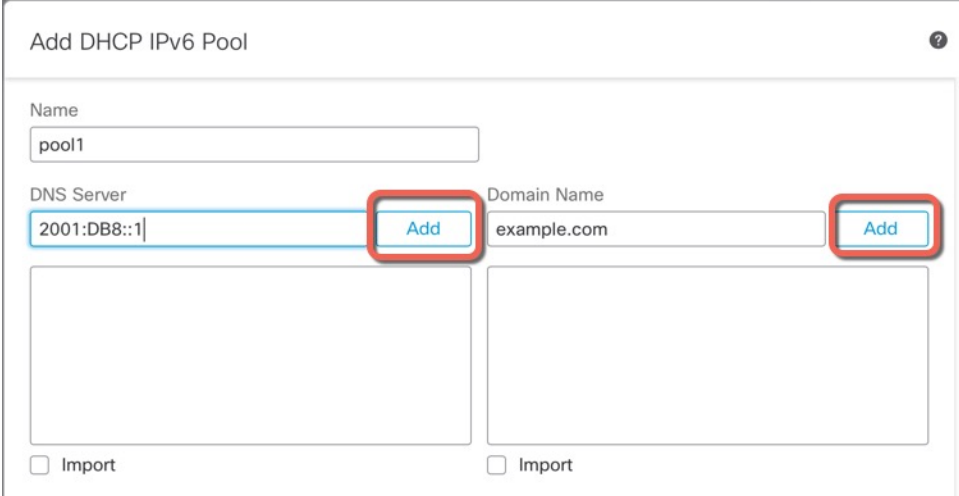

**Step 2** Choose **DHCP IPv6 Pool** from the list of object types.

**Step 3** Click **Add** ()

**Step 4** Configure the **DNS Server** and **Domain Name**.

You can either manually define the values and click **Add**, or you can check **Import** to use one or more parameters that the threat defense obtained from the DHCPv6 server on the Prefix Delegation client interface. You can mix and match manually-configured parameters with imported parameters; however, you cannot configure the same parameter manually and also use **Import**.

**Figure 316: Manually Define Values**

Add DHCP IPv6 Pool

Name  
pool1

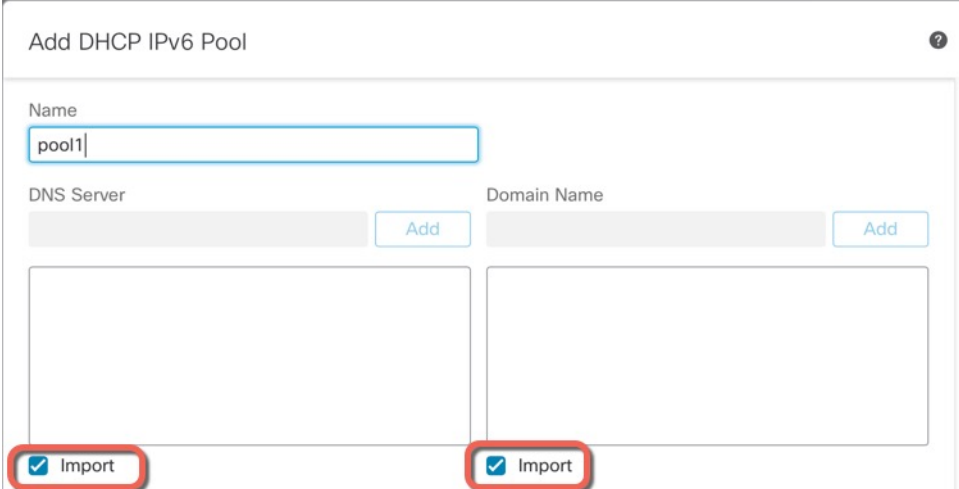

DNS Server

Domain Name  
example.com

Import

Import

**Figure 317: Import Values**

Add DHCP IPv6 Pool

Name  
pool1

DNS Server

Domain Name

Import

Import

**Step 5** Define **Other Server Options**.

You can define the domain name and IP address for the following servers:

- NIS
- NISP

- SIP
- Sntp

a) Click **Add** (+).

**Figure 318: Other Server Options**

b) Choose the server type under **Option**, and either manually define the **Domain Name** and **Address**, or check **Import**.

**Figure 319: Define Server Domain Name and Address**

**Import** uses one or more parameters that the threat defense obtained from the DHCPv6 server on the Prefix Delegation client interface. You can mix and match manually-configured parameters with imported parameters; however, you cannot configure the same parameter manually and also use **Import**.

c) Click **Save**.

d) Repeat for each server type.

**Step 6** Click **Save**.

**Step 7** Use this pool with the DHCPv6 server. See [Enable the DHCPv6 Stateless Server, on page 1043](#).

## Enable the DHCPv6 Stateless Server

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature ([Enable the IPv6 Prefix Delegation Client, on page 997](#)), you can configure the threat defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the threat defense. The threat defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the threat defense received using Prefix Delegation.

This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

### Before you begin

Add a DHCP IPv6 Pool object. See [Create the DHCP IPv6 Pool, on page 1040](#). This object defines the server parameters included in the IR messages.

### Procedure

**Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

**Step 2** Click **Edit** (✎) for the interface you want to edit.

**Step 3** Click the **IPv6** page, and then click **DHCP**.

**Step 4** Click **DHCP Server Pool**, and choose the object you created earlier.

*Figure 320: Enable the DHCPv6 Server*

Edit Physical Interface

| General                                           | IPv4                                                    | IPv6                                                     | Path Monitoring                                                        | Hardware Configuration                         | Manager Access |
|---------------------------------------------------|---------------------------------------------------------|----------------------------------------------------------|------------------------------------------------------------------------|------------------------------------------------|----------------|
| Basic                                             | Address                                                 | Prefixes                                                 | Settings                                                               | DHCP                                           |                |
| <input type="checkbox"/> Enable DHCP Client       | <input type="checkbox"/> Enable DHCP for address config | <input type="checkbox"/> Enable default route using DHCP | <input checked="" type="checkbox"/> Enable DHCP for non-address config | <input type="checkbox"/> Client PD Prefix Name |                |
| <input checked="" type="radio"/> DHCP Server pool | <input type="radio"/> Client PD Prefix Name             |                                                          |                                                                        |                                                |                |
| pool1                                             |                                                         |                                                          |                                                                        |                                                |                |

**Step 5** Check **Enable DHCP for non-address config** to inform SLAAC clients about the DHCPv6 server.

This flag informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address.

**Step 6** Click **OK**.

**Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure the DHCP Relay Agent

You can configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers. DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the threat defense device because it does not forward broadcast traffic.

You can remedy this situation by configuring the interface of the threat defense device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another interface.

**Note** DHCP Relay is not supported in transparent firewall mode.

### Procedure

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Select **DHCP > DHCP Relay**.

**Step 3** In the **IPv4 Relay Timeout** and **IPv6 Relay Timeout** fields, enter the amount of time in seconds that the threat defense device waits to time out the DHCP relay agent. Valid values range from 1 to 3600 seconds. The default value is 60 seconds.

The timeout is for address negotiation through the local DHCP Relay agent.

**Step 4** (Optional) Check **Trust All Information** to set all client interfaces as trusted.

You can configure interfaces as trusted interfaces to preserve DHCP Option 82. DHCP Option 82 is used by downstream switches and routers for DHCP snooping and IP Source Guard. Normally, if the threat defense DHCP relay agent receives a DHCP packet with Option 82 already set, but the giaddr field (which specifies the DHCP relay agent address that is set by the relay agent before it forwards the packet to the server) is set to 0, then the threat defense will drop that packet by default. You can preserve Option 82 and forward the packet by identifying an interface as a trusted interface.

**Step 5** On **DHCP Relay Agent**, click **Add**, and configure the following options:

- **Interface**—The interface connected to the DHCP clients.
- **Enable IPv4 Relay**—Enables IPv4 DHCP Relay for this interface.

- **Set Route**—(For IPv4) Changes the default gateway address in the DHCP message from the server to that of the threat defense device interface that is closest to the DHCP client, which relayed the original DHCP request. This action allows the client to set its default route to point to the threat defense device even if the DHCP server specifies a different router. If there is no default router option in the packet, the threat defense device adds one containing the interface address.
- **Enable IPv6 Relay**—Enables IPv6 DHCP Relay for this interface.

**Step 6** Click **OK** to save the DHCP relay agent changes.

**Step 7** On **DHCP Servers**, click **Add**, and configure the following options:

Add the IPv4 and IPv6 server addresses as separate entries, even if they belong to the same server.

- **Server**—The IP address of the DHCP server. Chose an IP address from the drop-down list. To add a new one, see [Creating Network Objects, on page 1499](#)
- **Interface**—The interface to which the specified DHCP server is attached. The DHCP Relay agent and the DHCP server cannot be configured on the same interface.

**Step 8** Click **OK** to save the DHCP server changes.

**Step 9** Click **Save** on the DHCP page to save your changes.

---

## Configure Dynamic DNS

When an interface uses DHCP IP addressing, the assigned IP address can change when the DHCP lease is renewed. When the interface needs to be reachable using a fully qualified domain name (FQDN), the IP address change can cause the DNS server resource records (RRs) to become stale. Dynamic DNS (DDNS) provides a mechanism to update DNS RRs whenever the IP address or hostname changes. You can also use DDNS for static or PPPoE IP addressing.

DDNS updates the following RRs on the DNS server: the A RR includes the name-to-IP address mapping, while the PTR RR maps addresses to names.

The threat defense supports the following DDNS update methods:

- **Standard DDNS**—The standard DDNS update method is defined by RFC 2136.

With this method, the threat defense and the DHCP server use DNS requests to update the DNS RRs. The threat defense or DHCP server sends a DNS request to its local DNS server for information about the hostname and, based on the response, determines the main DNS server that owns the RRs. The threat defense or DHCP server then sends an update request directly to the main DNS server. See the following typical scenarios.

- The threat defense updates the A RR, and the DHCP server updates the PTR RR.

Typically, the threat defense "owns" the A RR, while the DHCP server "owns" the PTR RR, so both entities need to request updates separately. When the IP address or hostname changes, the threat defense sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request a PTR RR update.

- The DHCP server updates both the A and PTR RR.

Use this scenario if the threat defense does not have the authority to update the A RR. When the IP address or hostname changes, the threat defense sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request an A and PTR RR update.

You can configure different ownership depending on your security needs and the requirements of the main DNS server. For example, for a static address, the threat defense should own the updates for both records.

- **Web**—The Web update method uses the DynDNS Remote API specification (<https://help.dyn.com/remote-access-api/>).

With this method when the IP address or hostname changes, the threat defense sends an HTTP request directly to a DNS provider with which you have an account.

The **DDNS** page also supports setting DHCP server settings relating to DDNS.

---

**Note** DDNS is not supported on the BVI or bridge group member interfaces.

---

### Before you begin

- Configure a DNS server group on **Objects > Object Management > DNS Server Group**, and then enable the group for the interface on **Devices > Platform Settings > DNS**. See [DNS, on page 1075](#).
- Configure the device hostname. You can configure the hostname when you perform the threat defense initial setup, or by using the **configure network hostname** command. If you do not specify the hostname per interface, then the device hostname is used.

### Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Choose **DHCP > DDNS**.
- Step 3** Standard DDNS method: Configure a DDNS update method to enable DNS requests from the threat defense. You do not need to configure a DDNS update method if the DHCP server will perform all requests.
- On **DDNS Update Methods**, click **Add**.
  - Set the **Method Name**.
  - Click **DDNS**.
  - (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.
  - Set the **Update Records** you want the threat defense to update.

This setting only affects the records you want to update directly from the threat defense; to determine the records you want the DHCP server to update, configure the DHCP client settings per interface or globally. See, [Step 5, on page 1047](#).

- **Not Defined**—Disables DNS updates from the threat defense.

- **Both A and PTR Records**—Sets the threat defense to update both A and PTR RRs. Use this option for static or PPPoE IP addressing.
- **A Records**—Sets the threat defense to update the A RR only. Use this option if you want the DHCP server to update the PTR RR.

- f) Click **OK**.
- g) Assign this method to the interface in [Step 5, on page 1047](#).

**Step 4** Web method: Configure a DDNS update method to enable HTTP update requests from the threat defense.

- a) On **DDNS Update Methods**, click **Add**.
- b) Set the **Method Name**.
- c) Click **Web**.
- d) Set the **Web Update Type** to update IPv4, IPv6, or both types of addresses.
- e) Set the **Web URL**. Specify the update URL. Check with your DNS provider for the URL required.

Use the following syntax:

**https://username:password@provider-domain/path?hostname=<h>&myip=<a>**

**Example:**

https://jcrichon:pa\$\$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>

- f) (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.
- g) Click **OK**.
- h) Assign this method to the interface in [Step 5, on page 1047](#).
- i) The web type method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection. See, [Step 9, on page 1049](#).

**Step 5** Configure interface settings for DDNS, including setting the update method, DHCP client settings, and the hostname for this interface.

- a) On **DDNS Interface Settings**, click **Add**.
- b) Choose the **Interface** from the drop-down list.
- c) Choose the **Method Name** that you created on the **DDNS Update Methods** page.

(Standard DDNS method) You do not need to assign a method if you want the DHCP server to perform all updates.

- d) Set the **Host Name** for this interface.

If you do not set the hostname, the device hostname is used. If you do not specify an FQDN, then the default domain from the DNS server group is appended (for static or PPPoE IP addressing) or the domain name from the DHCP server is appended (for DHCP IP addressing).

- e) Standard DDNS method: Configure the **DHCP Client requests DHCP server to update requests** to determine which records you want the DHCP server to update.

The threat defense sends DHCP client requests to the DHCP server. Note that the DHCP server must also be configured to support DDNS. The server can be configured to honor the client requests, or it can override the client (in which case, it will reply to the client so the client does not also try to perform updates that the server is performing).

For static or PPPoE IP addressing, these settings are ignored.

**Note** You can also set these values globally for all interfaces on the **DDNS** page. The per-interface settings take precedence over the global settings.

- **Not Selected**—Disables DDNS requests to the DHCP server. Even if the client does not request DDNS updates, the DHCP server can be configured to send updates anyway.
- **No Update**—Requests the DHCP server not to perform updates. This setting works in conjunction with a DDNS update method with **Both A and PTR Records** enabled.
- **Only PTR**—Requests that the DHCP server perform the PTR RR update. This setting works in conjunction with a DDNS update method with **A Records** enabled.
- **Both A and PTR Records**—Requests that the DHCP server perform both A and PTR RR updates. This setting does not require a DDNS update method to be associated with the interface.

f) Click **OK**.

**Note** The **Dynamic DNS Update** settings relate to DHCP server settings when you enable a DHCP server on the threat defense. See, [Step 6, on page 1048](#) for more information.

**Step 6** If you enable the DHCP server on an threat defense, you can configure DHCP server settings for DDNS.

To enable the DHCP server, see [Configure the DHCPv4 Server, on page 1038](#)). You can configure the server behavior when DHCP clients use the standard DDNS update method. If the server performs any updates, then if the client lease expires (and is not renewed), the server will request that the DNS server remove the RRs for which it was responsible.

- a) You can configure server settings globally or per interface. For global settings, see the main **DDNS** page. For per-interface settings, see the **DDNS Interface Settings** page. Interface settings take precedence over global settings.
- b) Configure which DNS RRs you want the DHCP server to update under **Dynamic DNS Update**.
  - **Not Selected**—DDNS updates are disabled, even if the client requests them.
  - **Only PTR**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will only update the PTR RR. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.
  - **Both A and PTR Records**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will update both the A and PTR RRs. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.
- c) To override the update actions requested by the DHCP client, check **Override DHCP Client Requests**. The server will reply to the client that the request was overridden, so the client does not also try to perform updates that the server is performing.

**Step 7** (Optional) Configure general DHCP client settings. These settings are not related to DDNS, but are related to how the DHCP client behaves.

- a) On the **DDNS** page, check **Enable DHCP Client Broadcast** to request that the DHCP server broadcast the DHCP reply (DHCP option 1).

- b) To force a MAC address to be stored inside a DHCP request packet for option 61 instead of the default internally generated string, on **DDNS > DHCP Client ID Interface**, choose the interface from the **Available Interfaces** list, and then click **Add** to move it to the **Selected Interfaces** list.

Some ISPs expect option 61 to be the interface MAC address. If the MAC address is not included in the DHCP request packet, then an IP address will not be assigned. This setting does not directly relate to DDNS, but is a general DHCP client setting.

**Step 8** Click **Save** on the Device page to save your changes.

**Step 9** The Web method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection.

The following example shows how to add a DDNS server's CA as a trustpoint.

- a) Obtain the DDNS server CA certificate. This procedure shows a manual import using PEM format, but you can also use PKCS12.
- b) In management center, choose **Devices > Certificates**, and click **Add**.
- c) Select a **Device**, and click **Add (+)**.

**Add New Certificate** ⓘ

Add a new certificate to the device using cert enrollment object which is used to generate CA and identify certificate.

Device\*:

Cert Enrollment\*:  
 +

The **Add Cert Enrollment** dialog box appears.

- d) Enter the following fields, and click **Save**:

### Add Cert Enrollment

Name\*  
CiscoRootCA

Description

CA Information Certificate Parameters Key Revocation

Enrollment Type: Manual

CA Only  
*Check this option if you do not require an identity certificate to be created from this CA*

```
TkL4Eq1ZKR4O  
fdX4lld  
oxYB5DC2Ae/g
```

Allow Overrides

Cancel Save

- Enter a **Name**.
- Choose **Enrollment Type** > **Manual**.
- Click **CA Only**.
- Paste in the CA text from step 9.a, on page 1049.

e) Click **Save**.

## CHAPTER 39

# SNMP for the Firepower 1000

---

This chapter describes how to configure SNMP for the Firepower 1000.

- [About SNMP for the Firepower 1000, on page 1053](#)
- [Enabling SNMP and Configuring SNMP Properties for Firepower 1000, on page 1053](#)
- [Creating an SNMP Trap for Firepower 1000, on page 1055](#)
- [Creating an SNMP User for Firepower 1000, on page 1056](#)

## About SNMP for the Firepower 1000

The Simple Network Management Protocol (SNMP) is an application-layer protocol that provides a message format for communication between SNMP managers and agents. SNMP provides a standardized framework and a common language used for the monitoring and management of devices in a network.

The SNMP framework consists of three parts:

- An SNMP manager—The system used to control and monitor the activities of network devices using SNMP.
- An SNMP agent—The software component within the Firepower 1000 chassis that maintains the data for the Firepower chassis and reports the data, as needed, to the SNMP manager. The Firepower chassis includes the agent and a collection of MIBs. To enable the SNMP agent and create the relationship between the manager and agent, enable and configure SNMP in the management center.
- A managed information base (MIB)—The collection of managed objects on the SNMP agent.

The Firepower 1000 chassis supports SNMPv1, SNMPv2c and SNMPv3. Both SNMPv1 and SNMPv2c use a community-based form of security.

## Enabling SNMP and Configuring SNMP Properties for Firepower 1000

---

**Note** This procedure only applies to the Firepower 1000.

---

## Procedure

**Step 1** Choose **Devices** > **Device Management**.

**Step 2** Click **SNMP**.

**Step 3** Complete the following fields:

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Admin State</b> check box   | Whether SNMP is enabled or disabled. Enable this service only if your system includes integration with an SNMP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Port</b> field              | The port on which the Firepower chassis communicates with the SNMP host. You cannot change the default port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Community</b> field         | <p>The default SNMPv1 or v2 community name or SNMP v3 username and password that the Firepower chassis includes on any trap messages it sends to the SNMP host.</p> <p>Enter a valid community string for SNMPv1 and SNMPv2:</p> <ul style="list-style-type: none"> <li>• Alphanumeric string between 1 and 32 characters and special characters ! (exclamation), - (hyphen), ~ (tilde), &amp;&amp; (double ampersand), [ ] (square brackets), ^ (carat), ' (single quote), " (double quotes), and &lt; &gt; (angle brackets).</li> <li>• Do not use @ (at sign), \ (backslash), ? (question mark) or an empty space.</li> <li>• The string can also be in ASCII characters ranging 0x21 to 0x7E inclusive, excluding HTML interjection vectors, namely single quote ('), double quotes ("), and angle brackets (&lt; &gt;).</li> </ul> <p>Enter a valid username and password for SNMPv3:</p> <ul style="list-style-type: none"> <li>• Username can be alphanumeric string and can include @ (at sign), \ (backslash), . (period), _ (underscore), and - (hyphen).</li> <li>• The password restrictions are same as the community string restrictions.</li> </ul> <p>Note that if the <b>Community</b> field is already set, the text to the right of the empty field reads <b>Set: Yes</b>. If the <b>Community</b> field is not yet populated with a value, the text to the right of the empty field reads <b>Set: No</b>.</p> |
| <b>System Admin Name</b> field | <p>The contact person responsible for the SNMP implementation.</p> <p>Enter a string of up to 255 characters, such as an email address or a name and telephone number.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Location</b> field          | <p>The location of the host on which the SNMP agent (server) runs.</p> <p>Enter an alphanumeric string up to 510 characters.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Step 4** Click **Save**.

#### What to do next

Create SNMP traps and users.

## Creating an SNMP Trap for Firepower 1000

**Note** This procedure only applies to the Firepower 1000.

### Procedure

- Step 1** Choose **Devices** > **Device Management**.
- Step 2** Click **SNMP**.
- Step 3** In the **SNMP Traps Configuration** area, click **Add**.
- Step 4** In the **SNMP Trap Configuration** dialog box, complete the following fields:

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Host Name</b> field | The hostname or IP address of the SNMP host to which the Firepower chassis should send the trap.                                                                                                                                                                                                                                                                                            |
| <b>Community</b> field | The SNMP v1 or v2 community name or the SNMP v3 username the Firepower chassis includes when it sends the trap to the SNMP host. This must be the same as the community or username that is configured for the SNMP service.<br><br>Enter an alphanumeric string between 1 and 32 characters. Do not use @ (at sign), \ (backslash), " (double quote), ? (question mark) or an empty space. |
| <b>Port</b> field      | The port on which the Firepower chassis communicates with the SNMP host for the trap.<br><br>Enter an integer between 1 and 65535.                                                                                                                                                                                                                                                          |
| <b>Version</b> field   | The SNMP version and model used for the trap. This can be one of the following: <ul style="list-style-type: none"> <li>• V1</li> <li>• V2</li> <li>• V3</li> </ul>                                                                                                                                                                                                                          |

| Name            | Description                                                                                                                                                                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type field      | If you select <b>V2</b> or <b>V3</b> for the version, the type of trap to send. This can be one of the following: <ul style="list-style-type: none"> <li>• <b>Traps</b></li> <li>• <b>Informs</b></li> </ul>                                                                                                                      |
| Privilege field | If you select <b>V3</b> for the version, the privilege associated with the trap. This can be one of the following: <ul style="list-style-type: none"> <li>• <b>Auth</b>—Authentication but no encryption</li> <li>• <b>Noauth</b>—No authentication or encryption</li> <li>• <b>Priv</b>—Authentication and encryption</li> </ul> |

**Step 5** Click **OK** to close the **SNMP Trap Configuration** dialog box.

**Step 6** Click **Save**.

## Creating an SNMP User for Firepower 1000

**Note** This procedure only applies to the Firepower 1000.

### Procedure

**Step 1** Choose **Devices > Device Management**.

**Step 2** Click **SNMP**.

**Step 3** In the **SNMP Users Configuration** area, click **Add**.

**Step 4** In the **SNMP User Configuration** dialog box, complete the following fields:

| Name                      | Description                                                                                                                                                                                           |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username field            | The username assigned to the SNMP user.<br><br>Enter up to 32 letters or numbers. The name must begin with a letter and you can also specify _ (underscore), . (period), @ (at sign), and - (hyphen). |
| Auth Algorithm Type field | The authorization type: <b>SHA</b> .                                                                                                                                                                  |

| Name                          | Description                                                                                                                                                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Use AES-128 checkbox          | If checked, this user uses AES-128 encryption.<br><b>Note</b> SNMPv3 does not support DES. If you leave the AES-128 box unchecked, no privacy encryption will be done and any configured privacy password will have no effect. |
| Authentication Password field | The password for the user.                                                                                                                                                                                                     |
| Confirm field                 | The password again for confirmation purposes.                                                                                                                                                                                  |
| Encryption Password field     | The privacy password for the user.                                                                                                                                                                                             |
| Confirm field                 | The privacy password again for confirmation purposes.                                                                                                                                                                          |

**Step 5** Click **OK** to close the **SNMP User Configuration** dialog box.

**Step 6** Click **Save**.

---

## CHAPTER 40

# Quality of Service

---

The following topics describe how to use the Quality of Service (QoS) feature to police network traffic using threat defense devices:

- [Introduction to QoS, on page 1059](#)
- [About QoS Policies, on page 1059](#)
- [Requirements and Prerequisites for QoS, on page 1060](#)
- [Rate Limiting with QoS Policies, on page 1060](#)

## Introduction to QoS

Quality of Service, or QoS, rate limits (polices) network traffic that is allowed or trusted by access control. The system does not rate limit traffic that was fastpathed.

Though QoS is supported only on the routed interfaces of threat defense devices, it is not supported on site-to-site VPN and VTI interfaces.

### Logging Rate-Limited Connections

There are no logging configurations for QoS. A connection can be rate limited without being logged, and you cannot log a connection simply because it was rate limited. To view QoS information in connection events, you must independently log the ends of the appropriate connections to the management center database.

Connection events for rate-limited connections contain information on how much traffic was dropped, and which QoS configurations limited the traffic. You can view this information in event views (workflows), dashboards, and reports.

## About QoS Policies

QoS policies deployed to managed devices govern rate limiting. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

The system matches traffic to QoS rules in the order you specify. The system rate limits traffic according to the first rule where all rule conditions match the traffic. Traffic that does not match any of the rules is not rate limited.

---

**Note** The total number of rules including QoS rules on the device cannot exceed 255. When this threshold is reached, a deployment warning message is displayed. You need to reduce the number of rules for a successful deployment.

---

You must constrain QoS rules by source or destination (routed) interfaces. The system enforces rate limiting *independently* on *each* of those interfaces; you cannot specify an aggregate rate limit for a set of interfaces.

QoS rules can also rate limit traffic by other network characteristics, as well as contextual information such as application, URL, user identity, and custom Security Group Tags (SGTs).

You can rate limit download and upload traffic independently. The system determines download and upload directions based on the connection initiator.

---

**Note** QoS is not subordinate to a main access control configuration; you configure QoS independently. However, the access control and QoS policies deployed to the same device share identity configurations; see [Associating Other Policies with Access Control](#), on page 1844.

---

Network Admin

## Rate Limiting with QoS Policies

To perform policy-based rate limiting, configure and deploy QoS policies to managed devices. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

## Procedure

- 
- Step 1** Choose **Devices > QoS**.
- Step 2** Click **New Policy** to create a new QoS policy and, optionally, assign target devices; see [Creating a QoS Policy, on page 1061](#).
- You can also **Copy** (📄) or **Edit** (✎) an existing policy.
- Step 3** Configure QoS rules; see [Configuring QoS Rules, on page 1062](#) and [QoS Rule Conditions, on page 1064](#).
- The Rules in the QoS policy editor lists each rule in evaluation order, and displays a summary of the rule conditions and rate limiting configurations. A right-click menu provides rule management options, including moving, enabling, and disabling.
- Helpful in larger deployments, you can **Filter by Device** to display only the rules that affect a specific device or group of devices. You can also search for and within rules; the system matches text you enter in the **Search Rules** field to rule names and condition values, including objects and object groups.
- Note** Properly creating and ordering rules is a complex task, but one that is essential to building an effective deployment. If you do not plan carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. Icons represent comments, warnings, and errors. If issues exist, click **Show Warnings** to display a list. For more information, see [Best Practices for Access Control Rules, on page 1823](#).
- Step 4** Click **Policy Assignments** to identify the managed devices targeted by the policy; see [Setting Target Devices for a QoS Policy, on page 1062](#).
- If you identified target devices during policy creation, verify your choices.
- Step 5** Save the QoS policy.
- Step 6** Because this feature must allow some packets to pass, you must configure your system to examine those packets. See [Best Practices for Handling Packets That Pass Before Traffic Identification, on page 2750](#) and [Specify a Policy to Handle Packets That Pass Before Traffic Identification, on page 2750](#).
- Step 7** Deploy configuration changes.
- 

## Creating a QoS Policy

A new QoS policy with no rules performs no rate limiting.

## Procedure

- 
- Step 1** Choose **Devices > QoS**.
- Step 2** Click **New Policy**.
- Step 3** Enter a **Name** and, optionally, a **Description**.

**Step 4** (Optional) Choose the **Available Devices** where you want to deploy the policy, then click **Add to Policy**, or drag and drop to the **Selected Devices**. To narrow the devices that appear, type a search string in the **Search** field.

You must assign devices before you deploy the policy.

**Step 5** Click **Save**.

---

#### What to do next

- Configure and deploy the QoS policy; see [Rate Limiting with QoS Policies, on page 1060](#).

## Setting Target Devices for a QoS Policy

Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

### Procedure

---

**Step 1** In the QoS policy editor, click **Policy Assignments**.

**Step 2** Build your target list:

- Add—Choose one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**.
- Delete—Click **Delete** (  ) next to a single device, or choose multiple devices, right-click, then choose **Delete Selected**.
- Search—Enter a search string in the search field. Click **Clear** (  ) to clear the search.

**Step 3** Click **OK** to save policy assignments.

**Step 4** Click **Save** to save the policy.

---

#### What to do next

- Deploy configuration changes.

## Configuring QoS Rules

When you create or edit a rule, use the upper portion of the rule editor to configure general rule properties. Use the lower portion of the rule editor to configure rule conditions and comments.

### Procedure

---

**Step 1** On Rules of the QoS policy editor:

- Add Rule—Click **Add Rule**.
- Edit Rule—Click **Edit** (✎).

**Step 2** Enter a **Name**.

**Step 3** Configure rule components:

- Enabled—Specify whether the rule is **Enabled**.
- Apply QoS On—Choose the interfaces you want to rate limit, either **Interfaces in Destination Interface Objects** or **Interfaces in Source Interface Objects**. Your choice must correspond with a populated interface constraint (not **any**).
- Traffic Limit Per Interface—Enter a **Download Limit** and an **Upload Limit** in Mbits/sec. The default value of **Unlimited** prevent matching traffic from being rate limited in that direction.
- Conditions—Click the corresponding condition you want to add. You must configure a source or destination interface condition, corresponding to your choice for **Apply QoS On**.
- Comments—Click **Comments**. To add a comment click **New Comment**, enter a comment, and click **OK**. You can edit or delete this comment until you save the rule.

For detailed information on rule components, see [QoS Rule Components, on page 1063](#).

**Step 4** Save the rule.

**Step 5** In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste.

Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

**Step 6** Click **Save** to save the policy.

---

### What to do next

- Deploy configuration changes.

### Related Topics

[Best Practices for Access Control Rules, on page 1823](#)

## QoS Rule Components

### State (Enabled/Disabled)

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

### Interfaces (Apply QoS On)

You cannot save a QoS rule that rate limits all traffic. For each QoS rule, you must apply QoS on either:

- Interfaces in Source Interface Objects—Rate limits traffic through the rule's source interfaces. If you choose this option, you must add at least one source interface constraint (cannot be **any**).
- Interfaces in Destination Interface Objects—Rate limits traffic through the rule's destination interfaces. If you choose this option, you must add at least one destination interface constraint (cannot be **any**).

### Traffic Limit Per Interface

A QoS rule enforces rate limiting *independently* on *each* of the interfaces you specify with the Apply QoS On option. You cannot specify an aggregate rate limit for a set of interfaces.

You can rate limit traffic by Mbits per second. The default value of **Unlimited** prevents matching traffic from being rate limited.

You can rate limit download and upload traffic independently. The system determines download and upload directions based on the connection initiator.

If you specify a limit greater than the maximum throughput of an interface, the system does not rate limit matching traffic. Maximum throughput may be affected by an interface's hardware configuration, which you specify in each device's properties (**Devices > Device Management**).

### Conditions

Conditions specify the specific traffic the rule handles. You can configure each rule with multiple conditions. Traffic must match all conditions to match the rule. Each condition type has its own tab in the rule editor. For more information, see [QoS Rule Conditions, on page 1064](#).

### Comments

Each time you save changes to a rule you can add comments. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change.

In the policy editor, the system displays how many comments a rule has. In the rule editor, use the Comments tab to view existing comments and add new ones.

## QoS Rule Conditions

Conditions specify the specific traffic the rule handles. You can configure each rule with multiple conditions. Traffic must match all conditions to match the rule. Each condition type has its own tab in the rule editor. You can rate limit traffic using:

See one of the following sections for more information.

### Related Topics

- [Interface Rule Conditions, on page 1064](#)

- [User Rule Conditions, on page 1065](#)
- [Application Rule Conditions, on page 1065](#)
- [Port Rule Conditions, on page 1067](#)
- [URL Rule Conditions, on page 1068](#)
- [Custom SGT Rule Conditions, on page 1068](#)

## Interface Rule Conditions

Interface rule conditions control traffic by its source and destination interfaces.

Depending on the rule type and the devices in your deployment, you can use predefined *interface objects* called *security zones* or *interface groups* to build interface conditions. Interface objects segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices; see [Interface, on page 1494](#).

---

**Tip** Constraining rules by interface is one of the best ways to improve system performance. If a rule excludes all of a device's interfaces, that rule does not affect that device's performance.

---

Just as all interfaces in an interface object must be of the same type (all inline, passive, switched, routed, or ASA FirePOWER), all interface objects used in an interface condition must be of the same type. Because devices deployed passively do not transmit traffic, in passive deployments you cannot constrain rules by destination interface.

## Network Rule Conditions

Network rule conditions control traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

---

**Note** You *cannot* use FDQN network objects in identity rules.

---

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

## User Rule Conditions

User rule conditions match traffic based the user who initiates the connection, or the group to which the user belongs. For example, you could configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in [Associating Other Policies with Access Control, on page 1844](#).

In addition to configuring users and groups for configured realms, you can set policies for the following Special Identities users:

- Failed Authentication: User that failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified; for example, users that are not downloaded by a configured realm.

## Application Rule Conditions

When the system analyzes IP traffic, it can identify and classify the commonly used applications on your network. This discovery-based *application awareness* is the basis for *application control*—the ability to control application traffic.

System-provided *application filters* help you perform application control by organizing applications according to basic characteristics: type, risk, business relevance, category, and tags. You can create reusable user-defined filters based on combinations of the system-provided filters, or on custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled for an application, the system automatically enables all system-provided detectors for the application; if none exist, the system enables the most recently modified user-defined detector for the application. For more information about application detectors, see [Application Detector Fundamentals, on page 2660](#).

You can use both application filters and individually specified applications to ensure complete coverage. However, understand the following note before you order your access control rules.

### Benefits of Application Filters

Application filters help you quickly configure application control. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

### Application Characteristics

The system characterizes each application that it detects using the criteria described in the following table. Use these characteristics as application filters.

**Table 74: Application Characteristics**

| Characteristic     | Description                                                                                                                                                                                 | Example                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Type               | Application protocols represent communications between hosts.<br>Clients represent software running on a host.<br>Web applications represent the content or requested URL for HTTP traffic. | HTTP and SSH are application protocols.<br>Web browsers and email clients are clients.<br>MPEG video and Facebook are web applications. |
| Risk               | The likelihood that the application is being used for purposes that might be against your organization's security policy.                                                                   | Peer-to-peer applications tend to have a very high risk.                                                                                |
| Business Relevance | The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.                                              | Gaming applications tend to have a very low business relevance.                                                                         |
| Category           | A general classification for the application that describes its most essential function. Each application belongs to at least one category.                                                 | Facebook is in the social networking category.                                                                                          |
| Tag                | Additional information about the application. Applications can have any number of tags, including none.                                                                                     | Video streaming web applications often are tagged high bandwidth and displays ads.                                                      |

### Related Topics

[Best Practices for Configuring Application Control](#), on page 1820

## Port Rule Conditions

Port conditions allow you to control traffic by its source and destination ports.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

### Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic.

Application filtering is also recommended for applications, like threat defense, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

### Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

### Port, Protocol, and ICMP Code Rule Conditions

Port conditions match traffic based on the source and destination ports. Depending on the rule type, “port” can represent any of the following:

- TCP and UDP—You can control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP(6)/22.
- ICMP—You can control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—You can control traffic using other protocols that do not use ports.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

### Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic. Note that application filtering is not available in prefilter rules.

Application filtering is also recommended for applications, like FTP, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

### Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

### Matching Non-TCP Traffic with Port Conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although you can configure port conditions to match non-TCP traffic, there are some restrictions:

- Access control rules—For Classic devices, you can match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, you can add only network-based conditions: zone, IP address, port, and VLAN tag. Also, the system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For threat defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support TCP port conditions only.
- ICMP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies sent in response to ICMP echo requests are ignored. For a rule to match on any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

## URL Rule Conditions

Use URL conditions to control the websites that users on your network can access.

For complete information, see [URL Filtering, on page 1919](#).

## Custom SGT Rule Conditions

If you do not configure ISE/ISE-PIC as an identity source, you can control traffic using Security Group Tags (SGTs) that were **not** assigned by ISE. SGTs specify the privileges of traffic sources within a trusted network.

*Custom* SGT rule conditions use manually created SGT objects to filter traffic, rather than ISE SGTs obtained from the system's connection to an ISE server. These manually created SGT objects correspond to the SGT attributes on the traffic you want to control. Controlling traffic using custom SGTs is not considered user control.

## ISE SGT vs Custom SGT Rule Conditions

Some rules allow you to control traffic based on assigned SGT. Depending on the rule type and your identity source configuration, you can use either ISE-assigned SGTs or custom SGTs to match traffic with assigned SGT attributes.

**Note** If you use ISE SGTs to match traffic, even if a packet does not have an assigned SGT attribute, the packet still matches an ISE SGT rule if the SGT associated with the packet's source IP address is known in ISE.

| Condition Type | Requires                       | SGTs Listed in Rule Editor                                                    |
|----------------|--------------------------------|-------------------------------------------------------------------------------|
| ISE SGT        | ISE identity source            | SGTs obtained by querying the ISE server, with automatically updated metadata |
| Custom SGT     | No ISE/ISE-PIC identity source | Static SGT objects you create                                                 |

## Autotransition from Custom SGTs to ISE SGTs

If you create rules that match custom SGTs, then configure ISE/ISE-PIC as an identity source, the system:

- Disables **Security Group Tag** options in the object manager. Although the system retains existing SGT objects, you cannot modify them or add new ones.
- Retains existing rules with custom SGT conditions. However, these rules do not match traffic. You also cannot add additional custom SGT criteria to existing rules, or create new rules with custom SGT conditions.

If you configure ISE, Cisco recommends that you delete or disable existing rules with custom SGT conditions. Instead, use ISE attribute conditions to match traffic with SGT attributes.

## CHAPTER 41

# Platform Settings

Platform settings for threat defense devices configure a range of unrelated features whose values you might want to share among several devices. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

**Note** In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices (7.3 and earlier, and some upgraded 7.4 devices).

# Introduction to Platform Settings

A platform settings policy is a shared set of features or parameters that define the aspects of a managed device that are likely to be similar to other managed devices in your deployment, such as time settings and external authentication.

A shared policy makes it possible to configure multiple managed devices at once, which provides consistency in your deployment and streamlines your management efforts. Any changes to a platform settings policy affects all the managed devices where you applied the policy. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

For example, your organization's security policies may require that your appliances have a "No Unauthorized Use" message when a user logs in. With platform settings, you can set the login banner once in a platform settings policy.

You can also benefit from having multiple platform settings policies on a single management center. For example, if you have different mail relay hosts that you use under different circumstances or if you want to test different access lists, you can create several platform settings policies and switch between them, rather than editing a single policy.

## Requirements and Prerequisites for Platform Settings Policies

### Supported Domains

Any

### User Roles

Admin

Access Admin

Network Admin

## Manage Platform Settings Policies

Use the **Platform Settings** page (**Devices > Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

### Procedure

---

**Step 1** Choose **Devices > Platform Settings**.

**Step 2** For an existing policy, you can **Copy** () , **Edit** () , or **Delete** () the policy.

**Caution** You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is good practice to deploy a different policy to those targets.

- Step 3** To create a new policy, click **New Policy**.
- Choose a device type from the drop-down list:
    - **Firepower Settings** to create a shared policy for managed Classic devices.
    - **Threat Defense Settings** to create a shared policy for managed threat defense devices.
  - Enter a **Name** for the new policy and optionally, a **Description**.
  - Optionally, choose the **Available Devices** where you want to apply the policy and click **Add** (or drag and drop) to add the selected devices. You can enter a search string in the **Search** field to narrow the list of devices.
  - Click **Save**.
- The system creates the policy and opens it for editing.

- Step 4** To change the target devices for a policy, click **Edit** (✎) next to the platform settings policy that you want to edit.
- Click **Policy Assignment**.
  - To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add**. You can also drag and drop.
  - To remove a device assignment, click **Delete** (🗑) next to a device, high-availability pair, or device group in the **Selected Devices** list.
  - Click **OK**.

---

#### What to do next

- Deploy configuration changes.

## ARP Inspection

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the threat defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the threat defense device drops the packet.

- If the ARP packet does not match any entries in the static ARP table, then you can set the threat defense device to either forward the packet out all interfaces (flood), or to drop the packet.

---

**Note** The dedicated Management interface never floods packets even if this parameter is set to flood.

---

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **ARP Inspection**.
- Step 3** Add entries to the ARP inspection table.
- Click **Add** to create a new entry, or click **Edit** if the entry already exists.
  - Select the desired options.
    - **Inspect Enabled**—To perform ARP inspection on the selected interfaces and zones.
    - **Flood Enabled**—Whether to flood ARP requests that do not match static ARP entries out all interfaces other than the originating interface or the dedicated management interface. This is the default behavior. If you do not elect to flood ARP requests, then only those requests that exactly match static ARP entries are allowed.
    - **Security Zones**—Add the zones that contain the interfaces on which to perform the selected actions. The zones must be switched zones. For interfaces not in a zone, you can type the interface name into the field below the Selected Security Zone list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.
  - Click **OK**.
- Step 4** Add static ARP entries according to [Add a Static ARP Entry, on page 1012](#).
- Step 5** Click **Save**.
- You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
- 

## Banner

You can configure messages to show users when they connect to the device command line interface (CLI).

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **Banner**.

**Step 3** Configure the banner.

Following are some tips and requirements for banners.

- Only ASCII characters are allowed. You can use line returns (press Enter), but you cannot use tabs.
- You can dynamically add the hostname or domain name of the device by including the variables **\$(hostname)** or **\$(domain)**.
- Although there is no absolute length restriction on banners, Telnet or SSH sessions will close if there is not enough system memory available to process the banner messages.
- From a security perspective, it is important that your banner discourage unauthorized access. Do not use the words "welcome" or "please," as they appear to invite intruders in. The following banner sets the correct tone for unauthorized access:

```
You have logged in to a secure device.  
If you are not authorized to access this device,  
log out immediately or risk criminal charges.
```

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## DNS

The Domain Name System (DNS) servers are used to resolve hostnames to IP addresses. There are two DNS server settings that apply to different types of traffic: data and special management traffic. Data traffic includes any services that use FQDNs for which a DNS lookup is necessary, such as access control rules and remote access VPN. Special management traffic includes traffic originating on the Management interface such as configuration and database updates. This procedure only applies to *data* DNS servers. For *management* DNS settings, see the CLI **configure network dns servers** and **configure network dns searchdomains** commands.

To determine the correct interface for DNS server communications, the managed device uses a routing lookup, but which routing table is used depends on the interfaces for which you enable DNS. See the interface settings below for more information.

You can optionally configure multiple DNS server groups and use them to resolve different DNS domains. For example, you could have a catch-all default group that uses public DNS servers, for use with connections to the Internet. You could then configure a separate group to use internal DNS servers for internal traffic, for example, any connection to a machine in the example.com domain. Thus, connections to an FQDN using your organization's domain name would be resolved using your internal DNS servers, whereas connections to public servers use external DNS servers. These resolutions are used by any feature that uses data DNS resolution, such as NAT and access control rules.

You can configure trusted DNS services for DNS snooping using the Trusted DNS Servers tab. DNS snooping is used to map the application domains to IPs in order to detect the application on the first packet. Apart from configuring the trusted DNS servers, you can include the already configured servers in DNS group, DHCP pool, DHCP relay and DHCP client as trusted DNS servers.

---

**Note** For an application-based PBR, you must configure trusted DNS servers. You must also ensure that the DNS traffic passes through threat defense in a clear-text format (encrypted DNS is not supported) so that domains can be resolved to detect applications.

---

### Before you begin

- Ensure you have created one or more DNS server groups. For more information, see [Creating DNS Server Group Objects, on page 1482](#).
- Ensure you have created interface objects to connect to the DNS servers.
- Ensure that the managed device has appropriate static or dynamic routes to access the DNS servers.

### Procedure

---

- Step 1** Choose **Devices > Platform Settings** and create or edit a Threat Defense policy.
- Step 2** Click **DNS**.
- Step 3** Click the **DNS Settings** tab.
- Step 4** Check **Enable DNS name resolution by device**.
- Step 5** Configure the DNS server groups.
- a) Do any of the following in the DNS server group list:
    - To add a group to the list, click **Add**. You cannot add another group once there are 30 filter domains configured within the existing list of server groups.
    - To edit the settings for a group, click **Edit** () next to the group.
    - To remove a group, click **Delete** () next to the group. Removing a group does not delete the DNS server group object, it simply removes it from this list.
  - b) When adding or editing a group, configure the following settings, then click **OK**:
    - **Select DNS Group**—Select an existing DNS server group object, or click + to create a new one.
    - **Make as default**—Select this option to make this group the default group. Any DNS resolution request that does not match the filters for other groups will be resolved using the servers in this group.
    - **Filter Domains**—For non-default groups only, a comma-separated list of domain names, such as example.com,example2.com. Do not include spaces.  
  
The group will be used for DNS resolutions for these domains only. You can enter a maximum of 30 separate domains across all groups added to this DNS platform settings policy. Each name can be a maximum of 127 characters.  
  
Note that these filter domains are not related to the default domain name for the group. The filter list can be different from the default domain.
- Step 6** (Optional) Enter the **Expiry Entry Timer** and **Poll Timer** values in minutes.

These options apply to FQDNs that are specified in network objects only. These do not apply to FQDNs used in other features.

- **Expire Entry Timer** specifies the minimum time-to-live (TTL) for the DNS entry, in minutes. If the expiration timer is longer than the entry's TTL, the TTL is increased to the expire entry time value. If the TTL is longer than the expiration timer, the expire entry time value is ignored: no additional time is added to the TTL in this case. Upon expiration, the entry is removed from the DNS lookup table. Removing an entry requires that the table be recompiled, so frequent removals can increase the processing load on the device. Because some DNS entries can have very short TTL (as short as three seconds), you can use this setting to virtually extend the TTL. The default is 1 minute (that is, the minimum TTL for all resolutions is 1 minute). The range is 1 to 65535 minutes.

Note that for systems running 7.0 or earlier, the expiration time is actually added to the TTL: it does not specify a minimum value.

- **Poll Timer** specifies the time limit after which the device queries the DNS server to resolve the FQDN that was defined in a network object. An FQDN is resolved periodically either when the poll timer has expired, or when the TTL of the resolved IP entry has expired, whichever occurs first.

**Step 7** Enable DNS lookups on all interfaces or on specific interfaces. These choices also affect which routing tables are used.

Note that enabling DNS lookups on an interface is not the same as specifying the source interface for lookups. The threat defense always uses a route lookup to determine the source interface. Management-only interfaces other than the dedicated Management interface cannot be used.

- No interfaces selected—Enables DNS lookups on all interfaces. The threat defense checks the data routing table only.
- Specific interfaces selected but not the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces. The threat defense checks the data routing table only.
- Specific interfaces selected plus the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces and the Management interface. The threat defense checks the data routing table, and if no route is found, falls back to the management-only routing table.
- Only the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on Management. The threat defense checks only the management-only routing table.

**Step 8** To configure the trusted DNS servers, click the **Trusted DNS Servers** tab.

**Step 9** By default, the existing DNS servers that are configured in DHCP pool, DHCP relay, DHCP client, or DNS server group are included as trusted DNS servers. If you want to exclude any of them, uncheck the appropriate check boxes.

**Step 10** To add trusted DNS servers, under **Specify DNS Servers**, click **Edit**.

**Step 11** In the **Select DNS Servers** dialog box, either choose a host object as the trusted DNS server or directly specify the IP address of the trusted DNS server:

- To choose existing host objects, under **Available Host Objects**, select the required host object and click **Add** to include it to **Selected DNS Servers**. For information on adding the host objects, see [Creating Network Objects, on page 1499](#).
- To directly provide the IP address (IPv4 or IPv6) of the trusted DNS server, enter the address in the given text field, and click **Add** to include it to **Selected DNS Servers**.

c) Click **Save**. The added DNS servers are displayed in the **Trusted DNS Servers** page.

**Note** You can configure a maximum of 12 DNS servers per policy.

**Step 12** (Optional) To search for a DNS server that was added, using either the host name or the IP address, use the search field under **Specify DNS Servers**.

**Step 13** Click **Save**.

---

### What to do next

To use FQDN objects for access control rules, create an FQDN network object which can then be assigned to an access control rule. For instructions see, [Creating Network Objects, on page 1499](#).

## External Authentication

---

**Note** You must have administrator privileges to perform this task.

When you enable external authentication for management users, the threat defense verifies the user credentials with an LDAP or RADIUS server as specified in an external authentication object.

### Sharing External Authentication Objects

External authentication objects can be used by the management center and threat defense devices. You can share the same object between the management center and devices, or create separate objects. Note that the threat defense supports defining users on the RADIUS server, while the management center requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the threat defense, but if you want to define users on the RADIUS server, you must create separate objects for the threat defense and the management center.

---

**Note** The timeout range is different for the threat defense and the management center, so if you share an object, be sure not to exceed the threat defense's smaller timeout range (1-30 seconds for LDAP, and 1-300 seconds for RADIUS). If you set the timeout to a higher value, the threat defense external authentication configuration will not work.

### Assigning External Authentication Objects to Devices

For the management center, enable the external authentication objects directly on **System > Users > External Authentication**; this setting only affects management center usage, and it does not need to be enabled for managed device usage. For threat defense devices, you must enable the external authentication object in the platform settings that you deploy to the devices, and you can only activate one external authentication object per policy. An LDAP object with CAC authentication enabled cannot also be used for CLI access. Be sure that both the threat defense and the management center can reach the LDAP server, even if you are not sharing the object. The management center is essential to retrieving the user list and downloading it to the device.

### Threat Defense Supported Fields

Only a subset of fields in the external authentication object are used for threat defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for the management center, those fields will be used. This procedure only covers the supported fields for the threat defense. For other fields, see *Configure External Authentication for the Management Center* in the [Cisco Secure Firewall Management Center Administration Guide](#).

### Username

Username must be Linux-valid usernames and be lower-case only, using alphanumeric characters plus period (.) or hyphen (-). Other special characters such as at sign (@) and slash (/) are not supported. You cannot add the **admin** user for external authentication. You can only add external users (as part of the External Authentication object) in the management center; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the management center.

If you previously configured the same username for an internal user using the **configure user add** command, the threat defense first checks the password against the internal user, and if that fails, it checks the AAA server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

### Privilege Level

LDAP users always have Config privileges. RADIUS users can be defined as either Config or Basic users.

### Before you begin

- SSH access is enabled by default on the management interface. To enable SSH access on data interfaces, see [SSH Access, on page 1089](#).
- Inform RADIUS users of the following behavior to set their expectations appropriately:
  - The first time an external user logs in, threat defense creates the required structures but cannot simultaneously create the user session. The user simply needs to authenticate again to start the session. The user will see a message similar to the following: "New external username identified. Please log in again to start a session."
  - If the user's Service-Type attribute is not defined or incorrectly configured in the RADIUS server, and when using the RADIUS-defined users for authentication, the user will see a message similar to the following: "Your username is not defined with a service type that is valid for this system. You are not authorized to access the system?."

In some cases, the SSH clients close the CLI window on an unsuccessful SSH connection, even before displaying the failure message. Hence, ensure that the user's Service-Type attribute is correctly defined in the RADIUS server.

- Similarly, if the user's Service-Type authorization was changed since the last login, the user will need to re-authenticate. The user will see a message similar to the following: "Your authorization privilege has changed. Please log in again to start a session."

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
  - Step 2** Click **External Authentication**.

**Step 3** Click the **Manage External Authentication Server** link.

You can also open the External Authentication screen by clicking **System > Users > External Authentication**.

**Step 4** Configure an LDAP Authentication Object.

- a) Click **Add External Authentication Object**.
- b) Set the **Authentication Method** to **LDAP**.
- c) Enter a **Name** and optional **Description**.
- d) Choose a **Server Type** from the drop-down list.
- e) For the **Primary Server**, enter a **Host Name/IP Address**.

**Note** If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

- f) (Optional) Change the **Port** from the default.
- g) (Optional) Enter the **Backup Sever** parameters.
- h) Enter **LDAP-Specific Parameters**.
  - **Base DN**—Enter the base distinguished name for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs**, and choose the appropriate base distinguished name from the drop-down list.
  - (Optional) **Base Filter**—For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.
  - **User Name**—Enter a distinguished name for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at our example company has a `uid` value of `NetworkAdmin`, you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.
  - **Password and Confirm Password**—Enter and confirm the password for the user.
  - (Optional) **Show Advanced Options**—Configure the following advanced options.
    - **Encryption**—Click **None**, **TLS**, or **SSL**.
 

**Note** If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS**, the port resets to the default value of 389. If you choose SSL encryption, the port resets to 636.
    - **SSL Certificate Upload Path**—For SSL or TLS encryption, you must choose a certificate by clicking **Choose File**.
    - (Not Used) **User Name Template**—Not used by the threat defense.
    - **Timeout**—Enter the number of seconds before rolling over to the backup connection between 1 and 30. The default is 30.

**Note** The timeout range is different for the threat defense and the management center, so if you share an object, be sure not to exceed the threat defense's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the threat defense external authentication configuration will not work.

- i) (Optional) Set the **CLI Access Attribute** if you want to use a shell access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` shell access attribute to retrieve shell access users by typing `sAMAccountName` in the **CLI Access Attribute** field.
- j) Set the **CLI Access Filter**.

Choose one of the following methods:

- To use the same filter you specified when configuring authentication settings, choose **Same as Base Filter**.
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.

The names on the LDAP server must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (\_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

- k) Click **Save**.

### Step 5

For LDAP, if you later add or delete users on the LDAP server, you must refresh the user list and redeploy the Platform Settings.

- a) Choose **System > Users > External Authentication**.
- b) Click **Refresh** (↻) next to the LDAP server.

If the user list changed, you will see a message advising you to deploy configuration changes for your device. The Firepower Threat Defense Platform Settings will also show that it is "Out-of-Date on x targeted devices."

- c) Deploy configuration changes; see [Deploy Configuration Changes, on page 240](#).

### Step 6

Configure a RADIUS Authentication Object.

- a) Define users on the RADIUS server using the Service-Type attribute.

The following are supported values for the Service-Type attribute:

- Administrator (6)—Provides Config access authorization to the CLI. These users can use all commands in the CLI.
- NAS Prompt (7) or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as **show** commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (\_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Alternatively, you can predefine users in the external authentication object (see Step 6.j, on page 1082). To use the same RADIUS server for the threat defense and management center while using the Service-Type attribute method for the threat defense, create two external authentication objects that identify the same RADIUS server: one object includes the predefined **CLI Access Filter** users (for use with the management center), and the other object leaves the **CLI Access Filter** empty (for use with threat defenses).

- b) In management center, click **Add External Authentication Object**.
- c) Set the **Authentication Method** to **RADIUS**.
- d) Enter a **Name** and optional **Description**.
- e) For the **Primary Server**, enter a **Host Name/IP Address**.

**Note** If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

- f) (Optional) Change the **Port** from the default.
- g) Enter a **RADIUS Secret Key**.
- h) (Optional) Enter the **Backup Sever** parameters.
- i) Enter **RADIUS-Specific Parameters**.

- **Timeout (Seconds)**—Enter the number of seconds before rolling over to the backup connection. The default is 30.
- **Retries**—Enter the number of times the primary server connection should be tried before rolling over to the backup connection. The default is 3.

- j) (Optional) Instead of using RADIUS-defined users, under **CLI Access Filter**, enter a comma-separated list of usernames in the **Administrator CLI Access User List** field. For example, enter **jchrichton, aerynsun, rygel**.

You may want to use the **CLI Access Filter** method for threat defense so you can use the same external authentication object with threat defense and other platform types. Note that if you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (\_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

**Note** If you want to only define users on the RADIUS server, you must leave this section empty.

k) Click **Save**.

**Step 7** Return to **Devices > > Platform Settings > External Authentication**.

**Step 8** Click **Refresh** (  ) to view any newly-added objects.

For LDAP when you specify SSL or TLS encryption, you must upload a certificate for the connection; otherwise, the server will not be listed on this window.

**Step 9** Click **Slider enabled** (  ) next to the External Authentication object you want to use. You can only enable one object.

**Step 10** Click **Save**.

**Step 11** Deploy configuration changes; see [Deploy Configuration Changes, on page 240](#).

---

## Enable Virtual-Router-Aware Interface for External Authentication of Platform

Authentication, Authorization, and Accounting (AAA) for the threat defense device is managed through the management interface of the device. You can also enable virtual-router-aware data interface, data sub-interface, port-channel, or sub port-channel to manage AAA for the threat defense device. When enabled, the AAA route lookup is in the Virtual Routing and Forwarding (VRF) routing domain, and the AAA management traffic is forwarded to the data interfaces. The following server configuration are supported when using virtual-router-aware data interfaces for AAA:

- RADIUS or LDAP servers for external authentication
- FQDN, IPv4, or IPv6 server addresses

To use a virtual-router-aware interface for external authentication of a threat defense device, modify its external authentication policy by associating the authentication servers with the virtual-router-aware interface of the device.

### Before you begin

- Ensure that you have configured the required Virtual Routing and Forwarding (VRF) interface with a static route for the device. For information about configuring a VRF interface, see [Configure a Virtual Router, on page 1293](#), and for information about adding a static route, see [Add a Static Route, on page 1268](#).
- Ensure that security zones or interface groups with a single virtual-router-aware interface exists. For information about creating security zones and interface groups, see [Create Security Zone and Interface Group Objects, on page 910](#).
- If the primary authentication server is configured with the FQDN of the server, ensure that the backup authentication server, if configured, is also with its FQDN. In addition, configure the DNS server in the threat defense device's management interface. For information about the DNS server configuration, see [DNS](#).

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Click **External Authentication** and edit the external authentication policy.
- Step 3** In the **External Authentication** dialog box, the available security zone and interface groups are listed. To associate a virtual-router-aware interface with the external authentication servers, select the security zone or interface group having a single virtual-router-aware interface, and then do the following:
- To associate the interface object with the primary authentication server, click **Add to Primary Server**.
  - (Optional) To associate the interface object with the backup authentication server, click **Add to Backup Server**. If the **Add to Backup Server** button is inactive, it means that a backup server for external authentication is not configured in the device.
- Step 4** Click **Ok**.
- Step 5** Save and deploy the changes.
- 

## Fragment Settings

By default, the threat defense device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments by setting **Chain** to 1. Fragmented packets are often used as Denial of Service (DoS) attacks.

---

**Note** These settings establish the defaults for devices assigned this policy. You can override these settings for specific interfaces on a device by selecting **Override Default Fragment Setting** in the interface configuration. When you edit an interface, you can find the option on **Advanced > Security Configuration**. Select **Devices > Device Management**, edit a threat defense device, and select **Interfaces** to edit interface properties..

---

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **Fragment Settings**.
- Step 3** Configure the following options. Click **Reset to Defaults** if you want to use the default settings.
- **Size (Block)**—The maximum number of packet fragments from all connections collectively that can be waiting for reassembly. The default is 200 fragments.
  - **Chain (Fragment)**—The maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets. Set this option to 1 to disallow fragments.
  - **Timeout (Sec)**—The maximum number of seconds to wait for an entire fragmented packet to arrive. The default is 5 seconds. If all fragments are not received within this time, all fragments are discarded.

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## HTTP Access

You can enable the HTTPS server to provide a health check mechanism for a cloud load balancer, for example, for the threat defense virtual on AWS using an Application Load Balancer.

Other uses for HTTPs on the threat defense are not supported; for example, the threat defense does not have a web interface for configuration in this management mode.

This configuration only applies to data interfaces, including any you have configured as management-only. It does not apply to the dedicated Management interface. The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the management center. It has a separate IP address and static routing.

To use HTTPS, you do not need an access rule allowing the host IP address. You only need to configure HTTPS access according to this section.

You can only use HTTPS to a reachable interface; if your HTTPS host is located on the outside interface, you can only initiate a management connection directly to the outside interface.

### Before you begin

- You cannot configure both HTTPS and AnyConnect VPN module of Cisco Secure Client on the same interface for the same TCP port. For example, if you configure remote access SSL VPN on the outside interface, you cannot also open the outside interface for HTTPS connections on port 443. If you must configure both features on the same interface, use different ports. For example, open HTTPS on port 4443.
- You need network objects that define the hosts or networks you will allow to make HTTPS connections to the device. You can add objects as part of the procedure, but if you want to use object groups to identify a group of IP addresses, ensure that the groups needed in the rules already exist. Select **Objects > Object Management** to configure objects.

---

**Note** You cannot use the system-provided **any** network object group. Instead, use **any-ipv4** or **any-ipv6**.

---

### Procedure

---

- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **HTTP Access**.
- Step 3** Check the **Enable HTTP Server** check box to enable the HTTP server.

**Step 4** (Optional) Change the HTTP port. The default is 443.

**Step 5** Identify the interfaces and IP addresses that allow HTTP connections.

Use this table to limit which interfaces will accept HTTP connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

- a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.
- b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make HTTP connections. Choose an object from the drop-down menu, or click + to add a new network object.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow HTTP connections. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zones/Interfaces** list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.

- c) Click **OK**.

**Step 6** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## ICMP Access

By default, you can send ICMP packets to any interface using either IPv4 or IPv6, with these exceptions:

- The threat defense does not respond to ICMP echo requests directed to a broadcast address.
- The threat defense only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.

To protect the device from attacks, you can use ICMP rules to limit ICMP access to interfaces to particular hosts, networks, or ICMP types. ICMP rules function like access rules, where the rules are ordered, and the first rule that matches a packet defines the action.

If you configure any ICMP rule for an interface, an implicit deny ICMP rule is added to the end of the ICMP rule list, changing the default behavior. Thus, if you want to simply deny a few message types, you must include a permit any rule at the end of the ICMP rule list to allow the remaining message types.

We recommend that you always grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP path MTU discovery, which can halt IPsec and PPTP traffic. Additionally ICMP packets in IPv6 are used in the IPv6 neighbor discovery process.

### Before you begin

Ensure that the objects needed in the rules already exist. Select **Objects > Object Management** to configure objects. You need network objects or groups that define the desired hosts or networks, and port objects that define the ICMP message types you want to control.

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **ICMP Access**.
- Step 3** Configure ICMP rules.
- Click **Add** to add a new rule, or click **Edit** to edit an existing rule.
  - Configure the rule properties:
    - **Action**—Whether to permit (allow) or deny (drop) matching traffic.
    - **ICMP Service**—The port object that identifies the ICMP message type.
    - **Network**—The network object or group that identifies the hosts or networks whose access you are controlling.
    - **Available Zones/Interfaces**—Add the zones that contain the interfaces that you are protecting. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zones/Interfaces** list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.
  - Click **OK**.
- Step 4** (Optional.) Set rate limits on ICMPv4 Unreachable messages.
- **Rate Limit**—Sets the rate limit of unreachable messages, between 1 and 100 messages per second. The default is 1 message per second.
  - **Burst Size**—Sets the burst rate, between 1 and 10. The system sends this number of replies, but subsequent replies are not sent until the rate limit is reached.
- Step 5** Click **Save**.
- You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
- 

## NetFlow

The NetFlow feature enables you to collect IP network traffic information as it enters or exits an interface. The collected traffic information is sent as collected records to a NetFlow Collector server or NetFlow Analyzer. You can analyze the data from NetFlow and determine information, such as source and destination of traffic, class of service, traffic pattern, bandwidth usage, type of traffic, traffic volume, and the causes of the congestion.

With the native NetFlow configuration support, the traffic information collection that was enabled through syslogs flow exports has to be disabled.

The NetFlow provides the option to configure the flow exporter and collectors along with flow event types that must be monitored.

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **NetFlow**.
- Step 3** Enable the **Enable Flow Export** toggle to enable NetFlow data export.
- Step 4** Configure the general NetFlow parameters that controls the frequency of events pushed to the collector.
- Active Refresh Interval**—For active connections, specify the time interval (in minutes) between flow-update events.
  - Delay Flow Create**—Specify the delay (in seconds) before sending a flow-create event. If you do not enter any value, there is no delay and the flow-create event is exported as soon as the flow is created.
  - Template Timeout Rate**—Specify the time interval (in minutes) at which the template records are sent to the collectors.
- Step 5** Click **Add Collector** to configure the collector. See [Add Collector in NetFlow, on page 1088](#).
- Step 6** Click **Add Traffic Class** to configure the traffic class. See [Add Traffic Class to NetFlow, on page 1089](#).
- Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Add Collector in NetFlow

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Choose **NetFlow**.
- Step 3** Enable the **Enable Flow Export** toggle to enable NetFlow data export.
- Step 4** Click **Add Collector** to configure the collector. You can configure a maximum of five collectors.
- Step 5** From the **Host** dropdown list, choose the collector host IP address (IPv4 only) of the NetFlow event collector or server to which the NetFlow packets must be sent. Alternatively, you can click the + icon to create a new network host.
- Step 6** In the **Port** field, enter the UDP port on the collector to which the NetFlow packets must be sent.
- Step 7** From **Available Interfaces or Interface Groups**, choose the interface or interface group through which the collector must be reached. You can choose multiple interfaces or interface groups. The Interface Group object can contain only one interface for a given device. A collector can be reached only through one interface. The object can include a virtual-router-aware interface.
- You can click the + icon to create a new interface group.
- Step 8** Click **Add** to add the interfaces you chose.
- Step 9** You can also enter the interface name and click **Add** to add the interface.

**Step 10** Click **OK**.

---

## Add Traffic Class to NetFlow

### Procedure

---

- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **NetFlow**.
- Step 3** Enable the **Enable Flow Export** toggle to enable NetFlow data export.
- Step 4** Click **Add Traffic Class** to configure the traffic class.
- Step 5** In the **Name** field, enter the name of the traffic class that must match the NetFlow events.
- Step 6** In the **Type** field, choose the traffic class to filter the type of traffic you want to capture:
- **Default**—The traffic class that is matched if none of the traffic classes matches the traffic.
  - **Access List**—The specific traffic class that must match the traffic captured for the NetFlow events.
- Step 7** If you chose **Access List** as the **Type**, then you must choose the access list object from the **Access List Object** dropdown list.
- Note** You can also click the + icon to create a new extended access list object. See [Configure Extended ACL Objects, on page 1468](#).
- Step 8** In **Event Types**, check the checkboxes for the different NetFlow events that you want to capture and send to the collectors.
- Step 9** Click **OK**.
- 

## SSH Access

If you enabled management center access on a data interface, such as outside, you should enable SSH on that interface using this procedure. This section describes how to enable SSH connections to one or more *data* interfaces on the threat defense.

The threat defense uses the CiscoSSH stack, which is based on OpenSSH. CiscoSSH supports FIPS compliance and regular updates, including updates from Cisco and the open source community.

---

**Note** SSH is enabled by default on the Management interface; however, this screen does not affect Management SSH access.

---

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the management center. SSH for data interfaces shares the internal and external user list with SSH for the Management interface. Other settings are configured separately: for data interfaces, enable SSH

and access lists using this screen; SSH traffic for data interfaces uses the regular routing configuration, and not any static routes configured at setup or at the CLI.

For the Management interface, to configure an SSH access list, see the **configure ssh-access-list** command in the [Cisco Secure Firewall Threat Defense Command Reference](#). To configure a static route, see the **configure network static-routes** command. By default, you configure the default route through the Management interface at initial setup.

To use SSH, you do not also need an access rule allowing the host IP address. You only need to configure SSH access according to this section.

You can SSH only to a reachable interface (including an interface in a user-defined virtual router); if your SSH host is located on the outside interface, you can only initiate a management connection directly to the outside interface. When you enable SSH in a user-defined virtual router, and you want VPN users to access SSH, be sure to terminate the VPN on the same virtual router. If the VPN is terminated on another virtual router, then you must configure route leaks between the virtual routers.

SSH supports the following ciphers and key exchange:

- Encryption—aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, aes256-ctr
- Integrity—hmac-sha2-256
- Key exchange—dh-group14-sha256

---

**Note** After you make three consecutive failed attempts to log into the CLI using SSH, the device terminates the SSH connection.

---

### Before you begin

- You can configure SSH internal users at the CLI using the **configure user add** command; see [Add an Internal User at the CLI, on page 221](#). By default, there is an **admin** user for which you configured the password during initial setup. You can also configure external users on LDAP or RADIUS by configuring **External Authentication** in platform settings. See [External Authentication, on page 1078](#).
- You need network objects that define the hosts or networks you will allow to make SSH connections to the device. You can add objects as part of the procedure, but if you want to use object groups to identify a group of IP addresses, ensure that the groups needed in the rules already exist. Select **Objects > Object Management** to configure objects.

---

**Note** You cannot use the system-provided **any** network object. Instead, use **any-ipv4** or **any-ipv6**.

---

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **SSH Access**.

**Step 3** Identify the interfaces and IP addresses that allow SSH connections.

Use this table to limit which interfaces will accept SSH connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

- a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.
- b) Configure the rule properties:
  - **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make SSH connections. Choose an object from the drop-down menu, or click + to add a new network object.
  - **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow SSH connections. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zones/Interfaces** list and click **Add**. You can also add loopback interfaces and virtual-router-aware interfaces. These rules will be applied to a device only if the device includes the selected interfaces or zones.
- c) Click **OK**.

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## SMTP Server

You must identify an SMTP server if you configure email alerts in the Syslog settings. The source email address you configure for Syslog must be a valid account on the SMTP servers.

### Before you begin

Ensure that the network objects that define the host address of the primary and secondary SMTP servers exist. Select **Objects > Object Management** to define the objects. Alternatively, you can create the objects while editing the policy.

### Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Click **SMTP Server**.

**Step 3** Select the network objects that identify the **Primary Server IP Address** and optionally, the **Secondary Server IP Address**.

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

# SNMP

Simple Network Management Protocol (SNMP) defines a standard way for network management stations running on PCs or workstations to monitor the health and status of many types of devices, including switches, routers, and security appliances. You can use the SNMP page to configure a firewall device for monitoring by SNMP management stations.

The Simple Network Management Protocol (SNMP) enables monitoring of network devices from a central location. Cisco security appliances support network monitoring using SNMP versions 1, 2c, and 3, as well as traps and SNMP read access; SNMP write access is not supported.

SNMPv3 supports read-only users and encryption with DES (deprecated), 3DES, AES256, AES192, and AES128.

---

**Note** The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for threat defenses running versions 6.6 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those threat defenses will fail.

---

---

**Note** SNMP configuration supports Routed and Diagnostic interface only.

---

---

**Note** To create an alert to an external SNMP server, access **Policies > Action > Alerts**

---

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
  - Step 2** Select **SNMP**.
  - Step 3** Enable SNMP and configure basic options.
    - **Enable SNMP Servers**—Whether to provide SNMP information to the configured SNMP hosts. You can deselect this option to disable SNMP monitoring while retaining the configuration information.
    - **Read Community String, Confirm**—Enter the password used by a SNMP management station when sending requests to the threat defense device. The SNMP community string is a shared secret among the SNMP management stations and the network nodes being managed. The security device uses the password to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces and special characters are not permitted.
    - **System Administrator Name**—Enter the name of the device administrator or other contact person. This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.

- **Location**—Enter the location of this security device (for example, Building 42, Sector 54). This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Port**—Enter the UDP port on which incoming requests will be accepted. The default is 161.

- Step 4** (SNMPv3 only.) [Add SNMPv3 Users, on page 1098.](#)
- Step 5** [Add SNMP Hosts, on page 1101.](#)
- Step 6** [Configure SNMP Traps, on page 1102.](#)
- Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## About SNMP

SNMP is an application-layer protocol that facilitates the exchange of management information between network devices and is part of the TCP/IP protocol suite. Threat Defense provides support for network monitoring using SNMP Versions 1, 2c, and 3, and support the use of all three versions simultaneously. The SNMP agent running on the threat defense interface lets you monitor the network devices through network management systems (NMSes), such as HP OpenView. Threat Defense supports SNMP read-only access through issuance of a GET request. SNMP write access is not allowed, so you cannot make changes with SNMP. In addition, the SNMP SET request is not supported.

You can configure the threat defense to send traps, which are unsolicited messages from the managed device to the management station for certain events (event notifications) to an NMS, or you can use the NMS to browse the Management Information Bases (MIBs) on the security devices. MIBs are a collection of definitions, and the threat defense maintain a database of values for each definition. Browsing a MIB means issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the NMS to determine values.

An SNMP agent notifies the designated management stations if events occur that are predefined to require a notification, for example, when a link in the network goes up or down. The notification it sends includes an SNMP OID, which identifies itself to the management stations. The agent also replies when a management station asks for information.

## SNMP Terminology

The following table lists the terms that are commonly used when working with SNMP.

*Table 75: SNMP Terminology*

| Term  | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Agent | <p>The SNMP server running on the Secure Firewall Threat Defense. The SNMP agent has the following features:</p> <ul style="list-style-type: none"> <li>• Responds to requests for information and actions from the network management station.</li> <li>• Controls access to its Management Information Base, the collection of objects that the SNMP manager can view or change.</li> <li>• Does not allow SET operations.</li> </ul> |

| Term                                | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Browsing                            | Monitoring the health of a device from the network management station by polling required information from the SNMP agent on the device. This activity may include issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the network management station to determine values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Management Information Bases (MIBs) | Standardized data structures for collecting information about packets, connections, buffers, failovers, and so on. MIBs are defined by the product, protocols, and hardware standards used by most network devices. SNMP network management stations can browse MIBs and request specific data or events be sent as they occur.                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Network management stations (NMSs)  | The PCs or workstations set up to monitor SNMP events and manage devices.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Object identifier (OID)             | The system that identifies a device to its NMS and indicates to users the source of information monitored and displayed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Trap                                | <p>Predefined events that generate a message from the SNMP agent to the NMS. Events include alarm conditions such as linkup, linkdown, coldstart, warmstart, authentication, or syslog messages.</p> <p><b>coldStart</b>—The coldStart trap occurs when the SNMP agent starts after the SNMP configuration. This trap also occurs when the agent starts after a system reboot.</p> <p><b>Note</b> For cluster and HA nodes, post a reload, if the interfaces reboot time exceeds 5 minutes (preset threshold), the trap is dropped. When the cluster and HA nodes have rebooted successfully, all other traps are sent as expected.</p> <p>The <b>snmp-server enable traps snmp coldstart</b> command is used to enable and disable transmission of these traps.</p> |

## MIBs and Traps

MIBs are either standard or enterprise-specific. Standard MIBs are created by the IETF and documented in various RFCs. A trap reports significant events occurring on a network device, most often errors or failures. SNMP traps are defined in either standard or enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. SNMP traps are compiled into the ASA software.

If needed, you can also download RFCs, standard MIBs, and standard traps from the following locations:

<http://www.ietf.org/>

Browse the SNMP Object Navigator to look up Cisco MIBs, traps, and OIDs from the following location:

<https://snmp.cloudapps.cisco.com/Support/SNMP/do/BrowseOID.do?local=en>

In addition, download Cisco OIDs by FTP from the following location:

<ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz>

## Supported Tables and Objects in MIBs

The following sections list the supported tables and objects for the specified MIBs.

**Remote Access VPN Polling***Table 76: CISCO-REMOTE-ACCESS-MONITOR-MIB*

| Counter         | OID                                                 | Description                                     |
|-----------------|-----------------------------------------------------|-------------------------------------------------|
| Active Sessions | crasNumSessions<br>(1.3.6.1.4.1.9.9.392.1.3.1)      | The number of currently active sessions.        |
| Users           | crasNumUsers<br>(1.3.6.1.4.1.9.9.392.1.3.3)         | The number of users who have active sessions.   |
| Peak Sessions   | crasNumPeakSessions<br>(1.3.6.1.4.1.9.9.392.1.3.41) | The number of peak RA sessions since system up. |

**Site-to-Site VPN Tunnel Polling***Table 77: CISCO-REMOTE-ACCESS-MONITOR-MIB*

| Counter                  | OID                                                           | Description                                                               |
|--------------------------|---------------------------------------------------------------|---------------------------------------------------------------------------|
| LAN to LAN Sessions      | crasL2LNumSessions<br>(1.3.6.1.4.1.9.9.392.1.3.29)            | The number of currently active LAN to LAN sessions.                       |
| Peak LAN to LAN Sessions | crasL2LPeakConcurrentSessions<br>(1.3.6.1.4.1.9.9.392.1.3.31) | The number of peak concurrent LAN to LAN sessions since the system is up. |

**Connection Polling***Table 78: CISCO-FIREWALL-MIB*

| Counter                | OID                                                           | Description                                                                    |
|------------------------|---------------------------------------------------------------|--------------------------------------------------------------------------------|
| Active Connections     | cfwConnectionActive<br>(1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.6) | The number of connections currently in use by the entire firewall.             |
| Peak Connections       | cfwConnectionPeak<br>(1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.7)   | The highest number of connections in use at any one time since system startup. |
| Connections Per Second | cfwConnectionPerSecond<br>(1.3.6.1.4.1.9.9.147.1.2.2.3)       | The current connections per second rate on the firewall.                       |

| Counter                     | OID                                                         | Description                                                                        |
|-----------------------------|-------------------------------------------------------------|------------------------------------------------------------------------------------|
| Peak Connections Per Second | cfwConnectionPerSecondPeak<br>(1.3.6.1.4.1.9.9.147.1.2.2.4) | The highest number of connections per second on the firewall since system startup. |

### NAT Translation Polling

*Table 79: CISCO-NAT-EXT-MIB*

| Counter                  | OID                                                          | Description                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Active Translations      | cneAddrTranslationNumActive<br>(1.3.6.1.4.1.9.9.532.1.1.1.1) | The total number of address translation entries that are currently available in the NAT device. This indicates the aggregate of the translation entries created from both the static and dynamic address translation mechanisms.                                                                                                                                    |
| Peak Active Translations | cneAddrTranslationNumPeak<br>(1.3.6.1.4.1.9.9.532.1.1.1.2)   | The maximum number of address translation entries that are active at any one time since the system startup. This indicates the high watermark of address translation entries that are active at any one time since the system startup.<br><br>This object includes the translation entries created from both the static and dynamic address translation mechanisms. |

### Routing Table Entries Polling

*Table 80: IP-FORWARD-MIB*

| Counter             | OID                                         | Description                                                        |
|---------------------|---------------------------------------------|--------------------------------------------------------------------|
| Active Translations | inetCidrRouteNumber<br>(1.3.6.1.2.1.4.24.6) | The total number of current inetCidrRouteTable entries that valid. |

**Interface Duplex Status Polling***Table 81: CISCO-IF-EXTENSION-MIB*

| Counter                | OID                                                         | Description                                                                |
|------------------------|-------------------------------------------------------------|----------------------------------------------------------------------------|
| Duplex Status          | cieIfDuplexCfgStatus<br>(1.3.6.1.4.1.9.9.276.1.1.2.1.20)    | This object specifies the configured duplex status on the given interface. |
| Detected Duplex Status | cieIfDuplexDetectStatus<br>(1.3.6.1.4.1.9.9.276.1.1.2.1.21) | This object specifies the detected duplex status on the given interface.   |

**Snort 3 Intrusion Event Rate Polling***Table 82: CISCO-UNIFIED-FIREWALL-MIB*

| Counter                      | OID                                                         | Description                                                                                                    |
|------------------------------|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| Snort 3 Intrusion Event Rate | cufwAaicIntrusionEvtRate<br>(1.3.6.1.4.1.9.9.491.1.5.3.2.1) | The rate at which intrusion events were recorded by Snort on this firewall averaged over the last 300 seconds. |

**BGP Peer-Flap Trap Notification***Table 83: BGP4-MIB*

| Counter       | OID                                                      | Description                                                                                                                 |
|---------------|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| BGP Peer-flap | bgpBackwardTransition<br>(1.3.6.1.4.1.9.9.491.1.5.3.2.1) | The BGPBackwardTransition Event is generated when the BGP FSM moves from a higher numbered state to a lower numbered state. |

**CPU Utilization Polling***Table 84: CISCO-PROCESS-MIB*

| Counter               | OID                                                     | Description                                           |
|-----------------------|---------------------------------------------------------|-------------------------------------------------------|
| CPU Total Utilization | cpmCPUTotal1minRev<br>(1.3.6.1.4.1.9.9.109.1.1.1.1.7.1) | Total system CPU utilization for the last one minute. |

| Counter                         | OID                                                                                                                                 | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Individual CPU Core Utilization | Associated parameters and values of cpmCPUTotal1minRev<br>1.3.6.1.4.1.9.9.109.1.1.1.1.7.2 to<br>1.3.6.1.4.1.9.9.109.1.1.1.1.7.(n+1) | Individual CPU core utilization values for the last one minute, where 'n' represents the number of cores.<br><br>Examples: <ul style="list-style-type: none"> <li>• 36141991091.1.1.1.7(n+2)<br/>- Aggregate system CPU utilization % (This value is same as the system cpu usage from 36141991091.1.1.1.7.1 in single context mode).</li> <li>• 36141991091.1.1.1.7(n+3)<br/>- Snort average CPU utilization % (total aggregate value of all snort instances)</li> <li>• 36141991091.1.1.1.7(n+4)<br/>- System process average % (average of "Sysproc" cores)</li> </ul> |

**Note** The SNMP OIDs 1.3.6.1.2.1.25.3.3 and 1.3.6.1.2.1.25.3.4 pertaining to CPU monitoring (hrProcessorTable and hrNetworkTable) were removed on ASA FirePOWER. You can view and monitor the CPU health details of the device only through its device manager.

In ENTITY-MIB, two new vendor OIDs were added for the dual EPM 2X100G and 4X200G cards of Secure Firewall 4200 for slot 2 and slot 3—cevFPRNM4X200Gng and cevFPRNM2X100Gng.

## Add SNMPv3 Users

**Note** You create users for SNMPv3 only. These steps are not applicable for SNMPv1 or SNMPv2c.

Note that SNMPv3 only supports read-only users.

SNMP users have a specified username, an authentication password, an encryption password, and authentication and encryption algorithms to use.

---

**Note** When using SNMPv3 with clustering or High Availability, if you add a new cluster unit after the initial cluster formation or you replace a High Availability unit, then SNMPv3 users are not replicated to the new unit. You must remove the users, re-add them, and then redeploy your configuration to force the users to replicate to the new unit.

---

The authentication algorithm options are MD5 (deprecated, pre-6.5 only), SHA, SHA224, SHA256, and SHA384.

---

**Note** The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTDs running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those threat defenses will fail.

---

The encryption algorithm options are DES (deprecated, pre-6.5 only), 3DES, AES256, AES192, and AES128.

---

**Note** The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for threat defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those threat defenses will fail.

---

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Click **SNMP > Users**.
- Step 3** Click **Add**.
- Step 4** Select the security level for the user from the **Security Level** drop-down list.
- **Auth**—Authentication but No Privacy, which means that messages are authenticated.
  - **No Auth**—No Authentication and No Privacy, which means that no security is applied to messages.
  - **Priv**—Authentication and Privacy, which means that messages are authenticated and encrypted.
- Step 5** Enter the name of the SNMP user in the **Username** field. Usernames must be 32 characters or less.
- Step 6** Select the type of password, you want to use in the **Encryption Password Type** drop-down list.
- **Clear text**—The threat defense device will still encrypt the password when deploying to the device.
  - **Encrypted**—The threat defense device will directly deploy the encrypted password.

**Step 7** In the **Auth Algorithm Type** drop-down list, select the type of authentication you want to use: SHA, SHA224, SHA256, or SHA384.

**Note** The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTDs running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those threat defenses will fail.

**Step 8** In the **Authentication Password** field, enter the password to use for authentication. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values.

**Note** The length of the password will depend on the authentication algorithm selected. For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

**Step 9** In the **Encryption Type** drop-down list, select the type of encryption you want to use: AES128, AES192, AES256, 3DES.

**Note** To use AES or 3DES encryption, you must have the appropriate license installed on the device.

**Note** The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for threat defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those threat defenses will fail.

**Step 10** Enter the password to use for encryption in the **Encryption Password** field. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values. For encrypted passwords, the length of the password depends on the encryption type selected. The password sizes are as follows (where each xx is one octal):

- AES 128 requires 16 octals
- AES 192 requires 24 octals
- AES 256 requires 32 octals
- 3DES requires 32 octals
- DES can be any size

**Note** For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

**Step 11** Click **OK**.

**Step 12** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Add SNMP Hosts

Use Host to add or edit entries in the SNMP Hosts table on the SNMP page. These entries represent SNMP management stations allowed to access the threat defense device.

You can add up to 8192 hosts. However, only 128 of this number can be for traps.

---

**Note** In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices (7.3 and earlier, and some upgraded 7.4 FTDs).

---

### Before you begin

Ensure that the network objects that define the SNMP management stations exist. Select **Device > Object Management** to configure network objects.

---

**Note** The supported network objects include IPv6 hosts, IPv4 hosts, IPv4 range and IPv4 subnet addresses.

---

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Click **SNMP > Hosts**.
- Step 3** Click **Add**.
- Step 4** In the **IP Address** field, either enter a valid IPv6 or IPv4 host or select the network object that defines the SNMP management station's host address.
- The IP address can be an IPv6 host, IPv4 host, IPv4 range or IPv4 subnet.
- Step 5** Select the appropriate SNMP version from the **SNMP version** drop-down list.
- Step 6** (SNMPv3 only.) Select the username of the SNMP user that you configured from the **User Name** drop-down list.
- Note** You can associate up to 23 SNMP users per SNMP host.
- Step 7** (SNMPv1, 2c only.) In the **Read Community String** field, enter the community string that you have already configured, for read access to the device. Re-enter the string to confirm it.
- Note** This string is required, only if the string used with this SNMP station is different from the one already defined in the **Enable SNMP Server** section.

- Step 8** Select the type of communication between the device and the SNMP management station. You can select both types.
- **Poll**—The management station periodically requests information from the device.
  - **Trap**—The device sends trap events to the management station as they occur.
- Note** When the SNMP host IP address is either an IPv4 range or an IPv4 subnet, you can configure either **Poll** or **Trap**, not both.
- Step 9** In the **Port** field, enter a UDP port number for the SNMP host. The default value is 162. The valid range is 1 to 65535.
- Step 10** Select the interface type for communication between the device and the SNMP management station under the **Reachable By** options. You can select either the device's Management interface or an available security zone/named interface.
- **Device Management Interface**—Communication between the device and the SNMP management station occurs over the Management interface.
    - When you choose this interface for SNMPv3 polling, all configured SNMPv3 users are allowed to poll and are not restricted to the user chosen in [Step 6, on page 1101](#). Here, SNMPv1 and SNMPv2c are not allowed from an SNMPv3 host.
    - When you choose this interface for SNMPv1 and SNMPv2c polling, the polling is not restricted at all to the version selected in [Step 5, on page 1101](#).
  - **Security Zones or Named Interface**—Communication between the device and the SNMP management station occurs over a security zone or interface.
    - Search for zones in the **Available Zones** field.
    - Add the zones that contain the interfaces through which the device communicates with the management station to the **Selected Zone/Interface** field. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. You can also choose a loopback interface and virtual-router-aware interfaces. The host will be configured on a device only if the device includes the selected interfaces or zones.
- Step 11** Click **OK**.
- Step 12** Click **Save**.
- You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure SNMP Traps

Use SNMP Traps to configure SNMP traps (event notifications) for the threat defense device. Traps are different from browsing; they are unsolicited “comments” from the threat defense device to the management station for certain events, such as linkup, linkdown, and syslog event generated. An SNMP object ID (OID) for the device appears in SNMP event traps sent from the device.

Some traps are not applicable to certain hardware models. These traps will be ignored if you apply the policy to one of these models. For example, not all models have field-replaceable units, so the **Field Replaceable Unit Insert/Delete** trap will not be configured on those models.

SNMP traps are defined in either standard or enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. SNMP traps are compiled into the threat defense software.

If needed, you can download RFCs, standard MIBs, and standard traps from the following location:

<http://www.ietf.org/>

Browse the complete list of Cisco MIBs, traps, and OIDs from the following location:

[SNMP Object Navigator](#)

In addition, download Cisco OIDs by FTP from the following location:

<ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz>

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Click **SNMP > SNMP Traps** to configure SNMP traps (event notifications) for the threat defense device.
- Step 3** Select the appropriate Enable Traps options. You can select either or both options.
- Check **Enable All SNMP Traps** to quickly select all traps in the subsequent four sections.
  - Check **Enable All Syslog Traps** to enable transmission of trap-related syslog messages.
- Note** SNMP traps are of higher priority than other notification messages from the threat defense as they are expected to be near real-time. When you enable all SNMP or syslog traps, it is possible for the SNMP process to consume excess resources in the agent and in the network, causing the system to hang. If you notice system delays, unfinished requests, or timeouts, you can selectively enable SNMP and syslog traps. You can also limit the rate at which syslog messages are generated by severity level or message ID. For example, all syslog message IDs that begin with the digits 212 are associated with the SNMP class; see [Limit the Rate of Syslog Message Generation, on page 1121](#).
- Step 4** The event-notification traps in the **Standard** section are enabled by default for an existing policy:
- **Authentication** – Unauthorized SNMP access. This authentication failure occurs for packets with an incorrect community string.
  - **Link Up** – One of the device’s communication links has become available (it has “come up”), as indicated in the notification.
  - **Link Down** – One of the device’s communication links has failed, as indicated in the notification.
  - **Cold Start** – The device is reinitializing itself such that its configuration or the protocol entity implementation may be altered.
  - **Warm Start** – The device is reinitializing itself such that its configuration and the protocol entity implementation is unaltered.
- Step 5** Select the desired event-notification traps in the **Entity MIB** section:
- **Field Replaceable Unit Insert** – A Field Replaceable Unit (FRU) has been inserted, as indicated. (FRUs include assemblies such as power supplies, fans, processor modules, interface modules, etc.)
  - **Field Replaceable Unit Delete** – A Field Replaceable Unit (FRU) has been removed, as indicated in the notification

- **Configuration Change** – There has been a hardware change, as indicated in the notification

**Step 6** Select the desired event-notification traps in the **Resource** section:

- **Connection Limit Reached** – This trap indicates that a connection attempt was rejected because the configured connections limit has been reached.

**Step 7** Select the desired event-notification traps in the **Other** section:

- **NAT Packet Discard** – This notification is generated when IP packets are discarded by the NAT function. Available Network Address Translation addresses or ports have fallen below configured threshold.
- **CPU Rising Threshold** – This notification is generated when rising CPU utilization exceeds a predefined threshold for a configured period of time. Check this option to enable CPU rising threshold notifications:
  - **Percentage** – The default value is 70 percent for the high threshold notification; the range is between 10 and 94 percent. The critical threshold is hardcoded at 95 percent.
  - **Period** – The default monitoring period is 1 minute; the range is between 1 and 60 minutes.
- **Memory Rising Threshold** – This notification is generated when rising memory utilization exceeds a predefined threshold, thus reducing available memory. Check this option to enable memory rising threshold notifications:
  - **Percentage** – The default value is 70 percent for the high threshold notification; the range is between 50 and 95 percent.
- **Failover** – This notification is generated when there is a change in the failover state as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Cluster** – This notification is generated when there is a change in the cluster health as reported by the CISCO-UNIFIED-FIREWALL-MIB.
- **Peer Flap** – This notification is generated when there is BGP route flapping, a situation in which BGP systems send an excessive number of update messages to advertise network reachability information.

**Step 8** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

# SSL

**Note** You must have administrator privileges and be in a leaf domain to perform this task.

You must make sure that you are running a fully licensed version of the Secure Firewall Management Center. The SSL Settings will be disabled if you are running Secure Firewall Management Center in evaluation mode. Additionally, the SSL Settings will be disabled when the licensed Secure Firewall Management Center version does not meet the export-compliance criteria. If you are using Remote Access VPN with SSL, your Smart Account must have the strong-crypto features enabled. For more information, see *License Types and Restrictions* in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Procedure

- 
- Step 1** Select **Devices > Platform Settings** and create or edit a threat defense policy.
- Step 2** Select **SSL**.
- Step 3** Add entries to the **Add SSL Configuration** table.
- Click **Add** to create a new entry, or click **Edit** if the entry already exists.
  - Select the required security configurations from the drop-down list .
    - **Protocol Version**—Specifies the TLS protocols to be used while establishing remote access VPN sessions.
    - **Security Level**—Indicates the kind of security positioning you would like to set up for the SSL.
- Step 4** Select the **Available Algorithms** based on the protocol version that you select and click **Add** to include them for the selected protocol. For more information, see [About SSL Settings, on page 1105](#).
- The algorithms are listed based on the protocol version that you select. Each security protocol identifies unique algorithm for setting up the security level.
- Step 5** Click **OK** to save the changes.
- 

### What to do next

Select **Deploy > Deployment** and click **Deploy** to deploy the policy to the assigned devices.

## About SSL Settings

The threat defense device uses the Secure Sockets Layer (SSL) protocol and Transport Layer Security (TLS) to support secure message transmission for Remote Access VPN connection from remote clients. The SSL Settings window lets you configure SSL versions and encryption algorithms that will be negotiated and used for message transmission during remote VPN access over SSL.

**Note** Though you configure management center and threat defense to operate in a security certifications (UCAPL, CC, or FIPS) compliance mode, the management center allows configuration of unsupported ciphers. For example, in a FIPS enabled mode, management center allows configuring DH Group 5 which is not FIPS-compliant. However, VPN tunnel does not negotiate due to the non-compliant cipher usage.

Configure the SSL Settings at the following location:

**Devices > Platform Settings > SSL**

### Fields

**Minimum SSL Version as Server**—Specify the minimum SSL/TLS protocol version that the threat defense device uses when acting as a server. For example, when it functions as a Remote Access VPN Gateway.

**TLS Version**—Select one of the following TLS versions from the drop-down list:

|         |                                                                  |
|---------|------------------------------------------------------------------|
| TLS V1  | Accepts SSLv2 client hellos and negotiates TLSv1 (or greater).   |
| TLSV1.1 | Accepts SSLv2 client hellos and negotiates TLSv1.1 (or greater). |
| TLSV1.2 | Accepts SSLv2 client hellos and negotiates TLSv1.2 (or greater). |
| TLSV1.3 | Accepts SSLv2 client hellos and negotiates TLSv1.3 (or greater). |

**Note** TLS 1.3 in remote access VPN requires Cisco Secure Client, Version 5.0 and above.

**DTLS Version**—Select the DTLS versions from the drop-down list, based on the selected TLS version. By default, DTLSv1 is configured on threat defense devices, you can choose the DTLS version as per your requirement.

**Note** Ensure that the TLS protocol version is higher than or equal to the DTLS protocol version selected. TLS protocol versions support the following DTLS versions:

|         |                  |
|---------|------------------|
| TLS V1  | DTLSv1           |
| TLSV1.1 | DTLSv1           |
| TLSV1.2 | DTLSv1, DTLSv1.2 |
| TLSV1.3 | DTLSv1, DTLSv1.2 |

**Diffie-Hellman Group**—Choose a group from the drop-down list. Available options are Group1 - 768-bit modulus, Group2 - 1024-bit modulus, Group5 - 1536-bit modulus, Group14 - 2048-bit modulus, 224-bit prime order, and Group24 - 2048-bit modulus, 256-bit prime order. The default is Group1.

**Elliptical Curve Diffie-Hellman Group**—Choose a group from the drop-down list. Available options are Group19 - 256-bit EC, Group20 - 384-bit EC, and Group21 - 521-bit EC. The default value is Group19.

TLSv1.2 adds support for the following ciphers:

- ECDHE-ECDSA-AES256-GCM-SHA384
- ECDHE-RSA-AES256-GCM-SHA384
- DHE-RSA-AES256-GCM-SHA384
- AES256-GCM-SHA384
- ECDHE-ECDSA-AES256-SHA384
- ECDHE-RSA-AES256-SHA384
- ECDHE-ECDSA-AES128-GCM-SHA256
- ECDHE-RSA-AES128-GCM-SHA256
- DHE-RSA-AES128-GCM-SHA256
- RSA-AES128-GCM-SHA256
- ECDHE-ECDSA-AES128-SHA256
- ECDHE-RSA-AES128-SHA256

---

**Note** ECDSA and DHE ciphers are the highest priority.

---

TLSv1.3 adds support for the following ciphers:

- TLS\_AES\_128\_GCM\_SHA256
- TLS\_CHACHA20\_POLY1305\_SHA256
- TLS\_AES\_256\_GCM\_SHA384

The SSL configuration table can be used to specify the protocol version, security level, and Cipher algorithms that you want to support on the Secure Firewall Threat Defense devices.

**Protocol Version**—Lists the protocol version that the Secure Firewall Threat Defense device supports and uses for SSL connections. Available protocol versions are:

- Default
- TLSV1
- TLSV1.1
- TLSV1.2
- TLSV1.3
- DTLSv1
- DTLSv1.2

**Security Level**—Lists the cipher security levels that threat defense device supports and uses for SSL connections.

If you have threat defense devices with evaluation license, the security level is Low by default. With threat defense smart license, the default security level is High. You can choose one of the following options to configure the required security level:

- **All** includes all ciphers, including NULL-SHA.
- **Low** includes all ciphers, except NULL-SHA.
- **Medium** includes all ciphers, except NULL-SHA, DES-CBC-SHA, RC4-SHA, and RC4-MD5 (this is the default).
- **Fips** includes all FIPS-compliant ciphers, except NULL-SHA, DES-CBC-SHA, RC4-MD5, RC4-SHA, and DES-CBC3-SHA, TLS\_CHACHA20\_POLY1305\_SHA256.
- **High** includes only AES-256 with SHA-2 ciphers and applies to TLS version 1.2 and the *default* version.
- **Custom** includes one or more ciphers that you specify in the Cipher algorithms/custom string box. This option provides you with full control of the cipher suite using OpenSSL cipher definition strings.

**Cipher Algorithms/Custom String**—Lists the cipher algorithms that the threat defense device supports and uses for SSL connections. For more information about ciphers using OpenSSL, see <https://www.openssl.org/docs/apps/ciphers.html>

The threat defense device specifies the order of priority for supported ciphers as:

Ciphers supported by TLSv1.2 only

|                               |
|-------------------------------|
| ECDHE-ECDSA-AES256-GCM-SHA384 |
| ECDHE-RSA-AES256-GCM-SHA384   |
| DHE-RSA-AES256-GCM-SHA384     |
| AES256-GCM-SHA384             |
| ECDHE-ECDSA-AES256-SHA384     |
| ECDHE-RSA-AES256-SHA384       |
| DHE-RSA-AES256-SHA256         |
| AES256-SHA256                 |
| ECDHE-ECDSA-AES128-GCM-SHA256 |
| ECDHE-RSA-AES128-GCM-SHA256   |
| DHE-RSA-AES128-GCM-SHA256     |
| AES128-GCM-SHA256             |
| ECDHE-ECDSA-AES128-SHA256     |
| ECDHE-RSA-AES128-SHA256       |
| DHE-RSA-AES128-SHA256         |
| AES128-SHA256                 |

Ciphers not supported by TLSv1.1 or TLSv1.2

|             |
|-------------|
| RC4-SHA     |
| RC4-MD5     |
| DES-CBC-SHA |
| NULL-SHA    |

## Syslog

You can enable system logging (syslog) for threat defense devices. Logging information can help you identify and isolate network or device configuration problems. You can also send some security events to a syslog server. The following topics explain logging and how to configure it.

## About Syslog

System logging is a method of collecting messages from devices to a server running a syslog daemon. Logging to a central syslog server helps in aggregation of logs and alerts. Cisco devices can send their log messages to a UNIX-style syslog service. A syslog service accepts messages and stores them in files, or prints them according to a simple configuration file. This form of logging provides protected long-term storage for logs. Logs are useful both in routine troubleshooting and in incident handling.

**Table 85: System Logs for Secure Firewall Threat Defense**

| Logs Related To                                 | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | Configure In                                                                |
|-------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Device and system health, network configuration | This syslog configuration generates messages for features running on the data plane, that is, features that are defined in the CLI configuration that you can view with the <b>show running-config</b> command. This includes features such as routing, VPN, data interfaces, DHCP server, NAT, and so forth. Data plane syslog messages are numbered, and they are the same as those generated by devices running ASA software. However, Secure Firewall Threat Defense does not necessarily generate every message type that is available for ASA Software. For information on these messages, see <i>Cisco Secure Firewall Threat Defense Syslog Messages</i> at <a href="https://www.cisco.com/c/en/us/td/docs/security/firepower/Syslogs/b_fptd_syslog_guide.html">https://www.cisco.com/c/en/us/td/docs/security/firepower/Syslogs/b_fptd_syslog_guide.html</a> . This configuration is explained in the following topics. | <b>Platform Settings</b>                                                    |
| Security events                                 | This syslog configuration generates alerts for file and malware, connection, Security Intelligence, and intrusion events.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | <b>Platform Settings</b> and the <b>Logging</b> in an access control policy |

| Logs Related To                                 | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         | Configure In                                                              |
|-------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| (All devices)<br>Policies, rules,<br>and events | This syslog configuration generates alerts for access control rules, intrusion rules, and other advanced services as described in <i>Configurations Supporting Alert Responses</i> in the <a href="#">Cisco Secure Firewall Management Center Administration Guide</a> . These messages are not numbered. For information on configuring this type of syslog, see <i>Creating a Syslog Alert Response</i> in the <a href="#">Cisco Secure Firewall Management Center Administration Guide</a> . | <b>Alert Responses</b> and the <b>Logging</b> in an access control policy |

You can configure more than one syslog server, and control the messages and events sent to each server. You can also configure different destinations, such as console, email, internal buffer, and so forth.

## Severity Levels

The following table lists the syslog message severity levels.

*Table 86: Syslog Message Severity Levels*

| Level Number | Severity Level       | Description                                                                                                                                                                                  |
|--------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0            | <b>emergencies</b>   | System is unusable.                                                                                                                                                                          |
| 1            | <b>alert</b>         | Immediate action is needed.                                                                                                                                                                  |
| 2            | <b>critical</b>      | Critical conditions.                                                                                                                                                                         |
| 3            | <b>error</b>         | Error conditions.                                                                                                                                                                            |
| 4            | <b>warning</b>       | Warning conditions.                                                                                                                                                                          |
| 5            | <b>notification</b>  | Normal but significant conditions.                                                                                                                                                           |
| 6            | <b>informational</b> | Informational messages only.                                                                                                                                                                 |
| 7            | <b>debugging</b>     | Debugging messages only.<br><br>Log at this level only temporarily, when debugging issues. This log level can potentially generate so many messages that system performance can be affected. |

**Note** ASA and Threat Defense do not generate syslog messages with a severity level of zero (emergencies).

## Syslog Message Filtering

You can filter generated syslog messages so that only certain syslog messages are sent to a particular output destination. For example, you could configure the threat defense device to send all syslog messages to one output destination and to send a subset of those syslog messages to a different output destination.

Specifically, you can direct syslog messages to an output destination according to the following criteria:

- Syslog message ID number  
(This does not apply to syslog messages for security events such as connection and intrusion events.)
- Syslog message severity level
- Syslog message class (equivalent to a functional area)  
(This does not apply to syslog messages for security events such as connection and intrusion events.)

You customize these criteria by creating a message list that you can specify when you set the output destination. Alternatively, you can configure the threat defense device to send a particular message class to each type of output destination independently of the message list.

(Message lists do not apply to syslog messages for security events such as connection and intrusion events.)

## Syslog Message Classes

**Note** This topic does not apply to messages for security events (connection, intrusion, etc.)

You can use syslog message classes in two ways:

- Specify an output location for an entire category of syslog messages.
- Create a message list that specifies the message class.

The syslog message class provides a method of categorizing syslog messages by type, equivalent to a feature or function of the device. For example, the rip class denotes RIP routing.

All syslog messages in a particular class share the same initial three digits in their syslog message ID numbers. For example, all syslog message IDs that begin with the digits 611 are associated with the vpnc (VPN client) class. Syslog messages associated with the VPN client feature range from 611101 to 611323.

In addition, most of the ISAKMP syslog messages have a common set of prepended objects to help identify the tunnel. These objects precede the descriptive text of a syslog message when available. If the object is not known at the time that the syslog message is generated, the specific heading = value combination does not appear.

The objects are prefixed as follows:

Group = *groupname*, Username = *user*, IP = *IP\_address*

Where the group is the tunnel-group, the username is the username from the local database or AAA server, and the IP address is the public IP address of the remote access client or Layer 2 peer.

The following table lists the message classes and the range of message IDs in each class.

**Table 87: Syslog Message Classes and Associated Message ID Numbers**

| Class | Definition          | Syslog Message ID Numbers |
|-------|---------------------|---------------------------|
| auth  | User Authentication | 109, 113                  |
| —     | Access Lists        | 106                       |

| Class        | Definition                                   | Syslog Message ID Numbers              |
|--------------|----------------------------------------------|----------------------------------------|
| —            | Application Firewall                         | 415                                    |
| —            | Botnet Traffic Filtering                     | 338                                    |

## Guidelines for Logging

This section includes guidelines and limitations that you should review before configuring logging.

### IPv6 Guidelines

- IPv6 is supported. Syslogs can be sent using TCP or UDP.
- Ensure that the interface configured for sending syslogs is enabled, IPv6 capable, and the syslog server is reachable through the designated interface.
- Secure logging over IPv6 is not supported.

### Additional Guidelines

- Do not configure management center as a primary syslog server. The management center can log some syslogs. However, it does not have adequate storage provision to accommodate voluminous information from connection events for every sensor, especially when multiple sensors are used and all send syslogs.
- The syslog server must run a server program called `syslogd`. Windows provides a syslog server as part of its operating system.
- The syslog server operates based on the `syslog-ng` process of the firewall system. Do not use external configuration files, like the `scwx.conf` file from SecureWorks. Such files are not compatible with the device. Using them will lead to parsing error and eventually the `syslog-ng` process will fail.
- To view logs generated by the threat defense device, you must specify a logging output destination. If you enable logging without specifying a logging output destination, the threat defense device generates messages but does not save them to a location from which you can view them. You must specify each different logging output destination separately.
- If you use TCP as the transport protocol, the system opens 4 connections to the syslog server to ensure that messages are not lost. If you are using the syslog server to collect messages from a very large number of devices, and the combined connection overhead is too much for the server, use UDP instead.
- It is not possible to have two different lists or classes being assigned to different syslog servers or same locations.
- You can configure up to 16 syslog servers.

- The syslog server should be reachable through the threat defense device. You should configure the device to deny ICMP unreachable messages on the interface through which the syslog server is reachable and to send syslogs to the same server. Make sure that you have enabled logging for all severity levels. To prevent the syslog server from crashing, suppress the generation of syslogs 313001, 313004, and 313005.
- The number of UDP connections for syslog is directly related to the number of CPUs on the hardware platform and the number of syslog servers you configure. At any point in time, there can be as many UDP syslog connections as there are CPUs times the number of configured syslog servers. This is the expected behavior. Note that the global UDP connection idle timeout applies to these sessions, and the default is 2 minutes. You can adjust that setting if you want to close these session more quickly, but the timeout applies to all UDP connections, not just syslog.
- When the threat defense device sends syslogs via TCP, the connection takes about one minute to initiate after the syslogd service restarts.

## Configure Syslog Logging for Threat Defense Devices

**Tip** If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most threat defense platform settings do not apply to these messages. See [Threat Defense Platform Settings That Apply to Security Event Syslog Messages, on page 1116](#).

To configure syslog settings, perform the following steps:

### Before you begin

See requirements in [Guidelines for Logging, on page 1114](#).

### Procedure

- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Click **Syslog** from the table of contents.
- Step 3** Click **Logging Setup** to enable logging, specify FTP Server settings, and specify Flash usage. For more information, see [Enable Logging and Configure Basic Settings, on page 1116](#)
- Step 4** Click **Logging Destinations** to enable logging to specific destinations and to specify filtering on message severity level, event class, or on a custom event list. For more information, see [Enable Logging Destinations, on page 1118](#)  
You must enable a logging destination to see messages at that destination.
- Step 5** Click **E-mail Setup** to specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages. For more information, see [Send Syslog Messages to an E-mail Address, on page 1119](#)
- Step 6** Click **Events List** to define a custom event list that includes an event class, a severity level, and an event ID. For more information, see [Create a Custom Event List, on page 1120](#)
- Step 7** Click **Rate Limit** to specify the volume of messages being sent to all configured destinations and define the message severity level to which you want to assign rate limits. For more information, see [Limit the Rate of Syslog Message Generation, on page 1121](#)

- Step 8** Click **Syslog Settings** to specify the logging facility, enable the inclusion of a time stamp, and enable other settings to set up a server as a syslog destination. For more information, see [Configure Syslog Settings, on page 1121](#)
- Step 9** Click **Syslog Servers** to specify the IP address, protocol used, format, and security zone for the syslog server that is designated as a logging destination. For more information, see [Configure a Syslog Server, on page 1123](#)

## Threat Defense Platform Settings That Apply to Security Event Syslog Messages

"Security events" include connection, Security Intelligence, intrusion, and file and malware events.

Some of the syslog settings on the **Devices > Platform Settings > Threat Defense Settings > Syslog** page and its tabs apply to syslog messages for security events, but most apply only to messages for events related to system health and networking.

The following settings apply to syslog messages for security events:

- **Logging Setup** tab:
  - **Send syslogs in EMBLEM format**
- **Syslog Settings** tab:
  - **Enable Timestamp on Syslog Messages**
  - **Timestamp Format**
  - **Enable Syslog Device ID**
- **Syslog Servers** tab:
  - All options on the **Add Syslog Server** form (and the list of configured servers).

## Enable Logging and Configure Basic Settings

Enable logging and configure the basic settings for the system to generate syslog messages for data plane events. You can also set up archiving on flash or an FTP server as a storage location when the local buffer becomes full. You can manipulate logging data after it is saved. For example, you could specify actions to be executed when certain types of syslog messages are logged, extract data from the log and save the records to another file for reporting, or track statistics using a site-specific script.

The following procedure explains some of the basic syslog settings.

**Tip** If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most threat defense platform settings do not apply to these messages. See [Threat Defense Platform Settings That Apply to Security Event Syslog Messages, on page 1116](#).

### Procedure

- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **Syslog > Logging Setup**.

**Step 3** Enable logging and configure basic logging settings.

- **Enable Logging**—Turns on the data plane system logging for the threat defense device.
- **Enable Logging on the Failover Standby Unit**—Turns on logging for the standby for the threat defense device, if available.
- **Send syslogs in EMBLEM format**—Enables EMBLEM format logging for every logging destination. If you enable EMBLEM, you must use the UDP protocol to publish syslog messages; EMBLEM is not compatible with TCP.

**Note** Syslog messages in RFC5424 format, typically displays the priority value (PRI). However, in management center, if you want to display the PRI value in the syslog messages of the managed threat defense device, ensure to enable the EMBLEM format. For more information on PRI, see [RFC5424](#).

- **Send debug messages as syslogs**—Redirects all the debug trace output to the syslog. The syslog message does not appear in the console if this option is enabled. Therefore, to see debug messages, you must enable logging at the console and configure it as the destination for the debug syslog message number and logging level. The syslog message number used is 711001. The default logging level for this syslog is debug.
- **Memory Size of Internal Buffer**—Specify the size of the internal buffer to which syslog messages are saved if the logging buffer is enabled. When the buffer fills up, it is overwritten. The default is 4096 bytes. The range is 4096 to 52428800.

**Step 4** (Optional) Configure the syslog message logging to the Security Cloud Control.

- a) Click the **All Logs** radio button to enable logging all the troubleshooting syslog messages corresponding to the selected severity level or click the **VPN Logs** radio button to enable logging only the VPN troubleshooting messages corresponding to the selected severity level.
- b) Choose the syslog severity level for the logging messages from the **Logging Level** drop-down list.

- The logging level for **All Logs** is set to **critical** by default. You can choose to send syslog messages with severity levels **critical**, **alerts**, or **emergencies** to the management center.

- The logging level for the VPN messages is set to **errors** by default.

VPN troubleshooting syslogs can add excessive load on the management center. Hence, enable this option with caution. Also, when you configure a device with site-to-site or remote access VPN, it automatically enables sending VPN syslogs to the management center by default. We recommend that you limit the logging level to **error** and above to restrict the excessive flow of syslogs to the management center, especially in case of RAVPN, where multiple devices are involved.

For information on the levels, see [Severity Levels, on page 1110](#).

**Step 5** (Optional) Configure an FTP server if you want to save log buffer contents to the server before the buffer is overwritten. Specify the FTP Server information.

- **FTP Server Buffer Wrap**—To save the buffer contents to the FTP server before it is overwritten, check this box and enter the necessary destination information in the following fields. To remove the FTP configuration, deselect this option.
- **IP Address**—Select the host network object that contains the IP address of the FTP server.
- **User Name**—Enter the username to use when connecting to the FTP server.
- **Path**—Enter the path, relative to the FTP root, where the buffer contents should be saved.

- **Password/ Confirm**—Enter and confirm the password used to authenticate the username to the FTP server.

**Step 6** (Optional) Specify Flash size if you want to save log buffer contents to flash before the buffer is overwritten.

- **Flash**—To save the buffer contents to the flash memory before it is overwritten, check this box.
- **Maximum flash to be used by logging (KB)**—Specify the maximum space to be used in the flash memory for logging (in kilobytes). The range is 4-8044176 kilobytes.
- **Minimum free space to be preserved (KB)**—Specifies the minimum free space to be preserved in flash memory (in KB). The range is 0-8044176 kilobytes.

**Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Enable Logging Destinations

You must enable a logging destination to see messages at that destination. When enabling a destination, you must also specify the message filter for the destination.

**Tip** If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most threat defense platform settings do not apply to these messages. See [Threat Defense Platform Settings That Apply to Security Event Syslog Messages, on page 1116](#).

### Procedure

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **Syslog > Logging Destinations**.

**Step 3** Click **Add** to enable a destination and apply a logging filter, or edit an existing destination.

**Step 4** In the **Logging Destinations** dialog box, select a destination and configure the filter to use for a destination:

- Choose the destination you are enabling in the **Logging Destination** drop-down list. You can create one filter per destination: Console, E-Mail, Internal buffer, SNMP trap, SSH Sessions, and Syslog servers.

**Note** Console and SSH session logging works in the diagnostic CLI only. Enter **system support diagnostic-cli**.

- In **Event Class**, choose the filter that will apply to all classes not listed in the table.

You can configure these filters:

- **Filter on severity** —Select the severity level. Messages at this level or higher are sent to the destination
- **Use Event List** —Select the event list that defines the filter. You create these lists on the **Event Lists** page.
- **Disable Logging** —Prevents messages from being sent to this destination.

- c) If you want to create filters per event class, click **Add** to create a new filter, or edit an existing filter, and select the event class and severity level to limit messages in that class. Click **OK** to save the filter.

For an explanation of the event classes, see [Syslog Message Classes, on page 1111](#).

- d) Click **OK**.

**Step 5** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Send Syslog Messages to an E-mail Address

You can set up a list of recipients for syslog messages to be sent as e-mails.

---

**Tip** If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most threat defense platform settings do not apply to these messages. See [Threat Defense Platform Settings That Apply to Security Event Syslog Messages, on page 1116](#).

---

### Before you begin

- Configure an SMTP server on the SMTP Server platform settings page
- [Enable Logging and Configure Basic Settings, on page 1116](#)
- [Enable Logging Destinations](#)

### Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **Syslog > Email Setup**.

**Step 3** Specify the e-mail address that is used as the source address for syslog messages that are sent as e-mail messages.

**Step 4** Click **Add** to enter a new e-mail address recipient of the specified syslog messages.

**Step 5** Choose the severity level of the syslog messages that are sent to the recipient from the drop-down list.

The syslog message severity filter used for the destination e-mail address causes messages of the specified severity level and higher to be sent. For information on the levels, see [Severity Levels, on page 1110](#).

**Step 6** Click **OK**.

**Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Create a Custom Event List

An event list is a custom filter you can apply to a logging destination to control which messages are sent to the destination. Normally, you filter messages for a destination based on severity only, but you can use an event list to fine-tune which messages are sent based on a combination of event class, severity, and message identifier (ID).

Creating a custom event list is a two-step process. You create a custom list in the **Event Lists**, and then use the event list to define the logging filter for the various types of destination, in the **Logging Destinations**.

**Tip** If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most threat defense platform settings do not apply to these messages. See [Threat Defense Platform Settings That Apply to Security Event Syslog Messages, on page 1116](#).

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **Syslog > Events List**.
- Step 3** Configure an event list.
- Click **Add** to add a new list, or edit an existing list.
  - Enter a name for the event list in the **Name** field. Spaces are not allowed.
  - To identify messages based on severity or event class, select the **Severity/Event Class** tab and add or edit entries.
 

For information on the available classes see [Syslog Message Classes, on page 1111](#).

For information on the levels, see [Severity Levels, on page 1110](#).

Certain event classes are not applicable for the device in transparent mode. If such options are configured then they will be bypassed and not deployed.
  - To identify messages specifically by message ID, select the **Message ID** and add or edit the IDs.
 

You can enter a range of IDs using a hyphen, for example, 100000-200000. IDs are six digits. For information on how the initial three digits map to features, see [Syslog Message Classes, on page 1111](#).

For specific message numbers, see [Cisco ASA Series Syslog Messages](#).
  - Click **OK** to save the event list.
- Step 4** Click **Logging Destinations** and add or edit the destination that should use the filter.
- See [Enable Logging Destinations, on page 1118](#).
- Step 5** Click **Save**.
- You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
-

## Limit the Rate of Syslog Message Generation

You can limit the rate at which syslog messages are generated by severity level or message ID. You can specify individual limits for each logging level and each Syslog message ID. If the settings conflict, the Syslog message ID limits take precedence.

---

**Tip** If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), most threat defense platform settings do not apply to these messages. See [Threat Defense Platform Settings That Apply to Security Event Syslog Messages, on page 1116](#).

---

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **Syslog > Rate Limit**.
- Step 3** To limit message generation by severity level, click **Logging Level > Add** and configure the following options:
- **Logging Level**—The severity level you are rate limiting. For information on the levels, see [Severity Levels, on page 1110](#).
  - **Number of messages**—The maximum number of messages of the specified type allowed in the specified time period.
  - **Interval**—The number of seconds before the rate limit counter resets.
- Step 4** Click **OK**.
- Step 5** To limit message generation by syslog message ID, click **Syslog Level > Add** and configure the following options:
- **Syslog ID**—The syslog message ID you are rate limiting. For specific message numbers, see [Cisco ASA Series Syslog Messages](#).
  - **Number of messages**—The maximum number of messages of the specified type allowed in the specified time period.
  - **Interval**—The number of seconds before the rate limit counter resets.
- Step 6** Click **OK**.
- Step 7** Click **Save**.
- You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
- 

## Configure Syslog Settings

You can configure general syslog settings to set the facility code to be included in syslog messages that are sent to syslog servers, specify whether a timestamp is included in each message, specify the device ID to include in messages, view and modify the severity levels for messages, and disable the generation of specific messages.

If you are configuring devices to send syslog messages about security events (such as connection and intrusion events), some settings on this page do not apply to these messages. See *Threat Defense Platform Settings That*

Apply to Security Event Syslog Messages in the [Cisco Secure Firewall Management Center Administration Guide](#).

## Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **Syslog > Syslog Settings**.
- Step 3** Select a system log facility for syslog servers to use as a basis to file messages in the **Facility** drop-down list. The default is LOCAL4(20), which is what most UNIX systems expect. However, because your network devices share available facilities, you might need to change this value for system logs. Facility values are not typically relevant for security events.
- Step 4** Select the **Enable timestamp on each syslog message** check box to include the date and time a message was generated in the syslog message.
- Step 5** Select the **Timestamp Format** for the syslog message:
- The Legacy (MMM dd yyyy HH:mm:ss) format is the default format for syslog messages. When this timestamp format is selected, the messages do not indicate the time zone, which is always UTC.
  - RFC 5424 (yyyy-MM-ddTHH:mm:ssZ) uses the ISO 8601 timestamp format as specified in the RFC 5424 syslog format. If you select the RFC 5424 format, a “Z” is appended to the end of each timestamp to indicate that the timestamp uses the UTC time zone.
- Step 6** If you want to add a device identifier to syslog messages (which is placed at the beginning of the message), check the **Enable Syslog Device ID** check box and then select the type of ID.
- **Interface**—To use the IP address of the selected interface, regardless of the interface through which the appliance sends the message. Select the security zone that identifies the interface. The zone must map to a single interface.
  - **User Defined ID**—To use a text string (up to 16 characters) of your choice.
  - **Host Name**—To use the hostname of the device.
- Step 7** Use the Syslog Message table to alter the default settings for specific syslog messages. You need to configure rules in this table only if you want to change the default settings. You can change the severity assigned to a message, or you can disable the generation of a message. By default, Netflow is enabled and the entries are shown in the table.
- a) To suppress syslog messages that are redundant because of Netflow, select **Netflow Equivalent Syslogs**. This adds the messages to the table as suppressed messages.
 

**Note** If any of these syslog equivalents are already in the table, your existing rules are not overwritten.
  - b) To add a rule, click **Add**.
  - c) You select the message number whose configuration you want to change, from the **Syslog ID** drop down list and then select the new severity level from the **Logging Level** drop down list, or select **Suppressed**

to disable the generation of the message. Typically, you would not change the severity level and disable the message, but you can make changes to both fields if desired.

d) Click **OK** to add the rule to the table.

**Step 8** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

#### What to do next

- Deploy configuration changes.

## Configure a Syslog Server

To configure a syslog server to handle messages generated from your system, perform the following steps.

If you want this syslog server to receive security events such as connection and intrusion events, see also [Threat Defense Platform Settings That Apply to Security Event Syslog Messages, on page 1116](#).

---

**Note** In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and unmerged devices (7.3 and earlier, and some upgraded 7.4 threat defenses).

---

#### Before you begin

- See requirements in [Guidelines for Logging, on page 1114](#).
- Make sure your devices can reach your syslog collector on the network.

## Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **Syslog > Syslog Server**.

**Step 3** Check the **Allow user traffic to pass when TCP syslog server is down (Recommended)** check box, to allow traffic if any syslog server that is using the TCP protocol is down.

- Note**
- This option is enabled by default. Unless required, we recommend that you allow connections through the threat defense device when the external TCP syslog server is unreachable by the device.
  - When the **Allow user traffic to pass when TCP syslog server is down** option is disabled in management center version 6.2.x or earlier, it persists to be in the Disable state even after upgrading to version 6.3 or later. Ensure that you manually enable it.
  - With this option disabled, and when more than one TCP syslog server is configured in the device, the user traffic is allowed to pass if at least one of the servers is reachable by the threat defense device. Thus, the disabled option is applied only when none of the TCP syslog servers configured in the device are reachable. The device generates the following syslog that describes the root cause of the denied traffic through the device:

```
%FTD-3-414003: TCP Syslog Server intf : IP_Address /port not responding. New
connections are denied based on logging permit-hostdown policy
```

- Step 4** In the **Message queue size (messages)** field, enter a size of the queue for storing syslog messages on the security appliance when the syslog server is busy. The minimum is 1 message. The default is 512. Specify 0 to allow an unlimited number of messages to be queued (subject to available block memory).

When the messages exceed the configured queue size, they are dropped and result in missing syslog. To determine the ideal queue size, you need to identify the available block memory. Use the **show blocks** command to know the current memory utilization. For more information on the command and its attributes, see *Cisco Secure Firewall ASA Series Command Reference Guide*. For further assistance, contact Cisco TAC.

- Step 5** Click **Add** to add a new syslog server.

- In the **IP Address** drop-down list, select a network host object that contains the IP address of the syslog server.
- Choose the protocol (either TCP or UDP) and enter the port number for communications between the threat defense device and the syslog server.

UDP is faster and uses less resources on the device than TCP.

The default port for UDP is 514. You must manually configure port 1470 for TCP. Valid non-default port values for either protocol are 1025 through 65535.

- Check the **Log messages in Cisco EMBLEM format (UDP only)** check box to specify whether to log messages in Cisco EMBLEM format (available only if UDP is selected as the protocol).

**Note** Syslog messages in RFC5424 format, typically displays the priority value (PRI). However, in management center, only when you enable logging in Cisco EMBLEM format, the PRI value in the syslog messages of the managed threat defense is displayed. For more information on PRI, see [RFC5424](#).

- Check the **Enable Secure Syslog** check box to encrypt the connection between the device and server using SSL/TLS over TCP.

**Note** You must select TCP as the protocol and its port value ranging between 1025 and 65535 to use this option. You must also upload the certificate required to communicate with the syslog server on the **Devices > Certificates** page. Finally, upload the certificate from the threat defense device to the syslog server to complete the secure relationship and allow it to decrypt the traffic. The **Enable Secure Syslog** option is not supported on the device Management interface.

- e) Select **Device Management Interface** or **Security Zones or Named Interfaces** to communicate with the syslog server.
- **Device Management Interface:** Send syslogs out of the Management interface. We recommend that you use this option when configuring syslog on Snort events.
 

**Note** The **Device Management Interface** option does not support the **Enable Secure Syslog** option.
  - **Security Zones or Named Interfaces:** Select the interfaces from the list of **Available Zones** and click **Add**. You can also add virtual-router-aware interfaces.
 

**Important** The threat defense data plane (Lina) syslog messages cannot be sent out through the diagnostic interface. Configure other interfaces or the Management interface (Br1/Management0) to send out the data plane syslog messages.
- f) Click **OK**.

**Step 6**

Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

**What to do next**

- Deploy configuration changes.

## Timeouts

You can set the global idle timeout durations for the connection and translation slots of various protocols. If the slot has not been used for the idle time specified, the resource is returned to the free pool.

You can also set a time out for console sessions with the device.

**Procedure**

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **Timeouts**.

**Step 3** Configure the timeouts you want to change.

For any given setting, select **Custom** to define your own value, **Default** to return to the system default value. In most cases, the maximum timeout is 1193 hours.

You can disable some timeouts by selecting **Disable**.

- **Console Timeout**—The idle time until a connection to the console is closed, range is 0 or 5 to 1440 minutes. The default is 0, which means the session does not time out. If you change the value, existing console sessions use the old timeout value. The new value applies to new connections only.

- **Translation Slot (xlate)**—The idle time until a NAT translation slot is freed. This duration must be at least 1 minute. The default is 3 hours.
- **Connection (Conn)**—The idle time until a connection slot is freed. This duration must be at least 5 minutes. The default is 1 hour.
- **Half-Closed**—The idle time until a TCP half-closed connection closes. A connection is considered half-closed if both the FIN and FIN-ACK have been seen. If only the FIN has been seen, the regular connection timeout applies. The minimum is 30 seconds. The default is 10 minutes.
- **UDP**—The idle time until a UDP connection closes. This duration must be at least 1 minute. The default is 2 minutes.
- **ICMP**—The idle time after which general ICMP states are closed. The default (and minimum) is 2 seconds.
- **RPC/Sun RPC**—The idle time until a SunRPC slot is freed. This duration must be at least 1 minute. The default is 10 minutes.

In a Sun RPC-based connection, when the parent connection is deleted or timed-out, a new child connection may not be considered as a part of the parent-child connection, and thereby the new connection could be evaluated as per the policy or rules set in the system. After the parent connection has timed-out the existing child connections are valid only until the timeout value set is reached.

- **H.225**—The idle time until an H.225 signaling connection closes. The default is 1 hour. To close a connection immediately after all calls are cleared, a timeout of 1 second (0:0:1) is recommended.
- **H.323**—The idle time after which H.245 (TCP) and H.323 (UDP) media connections close. The default (and minimum) is 5 minutes. Because the same connection flag is set on both H.245 and H.323 media connections, the H.245 (TCP) connection shares the idle timeout with the H.323 (RTP and RTCP) media connection.
- **SIP**—The idle time until a SIP signaling port connection closes. This duration must be at least 5 minutes. The default is 30 minutes.
- **SIP Media**—The idle time until a SIP media port connection closes. This duration must be at least 1 minute. The default is 2 minutes. The SIP media timer is used for SIP RTP/RTCP with SIP UDP media packets, instead of the UDP inactivity timeout.
- **SIP Disconnect**—The idle time after which SIP session is deleted if the 200 OK is not received for a CANCEL or a BYE message, between 0:0:1 and 0:10:0. The default is 2 minutes (0:2:0).
- **SIP Invite**—The idle time after which pinholes for PROVISIONAL responses and media xlates will be closed, between 0:1:0 and 00:30:0. The default is 3 minutes (0:3:0).
- **SIP Provisional Media**—The timeout value for SIP provisional media connections, between 1 and 30 minutes. The default is 2 minutes.
- **Floating Connection**—When multiple routes exist to a network with different metrics, the system uses the one with the best metric at the time of connection creation. If a better route becomes available, then this timeout lets connections be closed so a connection can be reestablished to use the better route. The default is 0 (the connection never times out). To make it possible to use better routes, set the timeout to a value between 0:0:30 and 1193:0:0. This timer does not apply to connections through virtual tunnel interfaces (VTI). If a connection through a VTI gets stuck, you must manually clear it.

- **Xlate PAT**—The idle time until a PAT translation slot is freed, between 0:0:30 and 0:5:0. The default is 30 seconds. You may want to increase the timeout if upstream routers reject new connections using a freed PAT port because the previous connection might still be open on the upstream device.
- **TCP Proxy Reassembly**—The idle timeout after which buffered packets waiting for reassembly are dropped, between 0:0:10 and 1193:0:0. The default is 1 minute (0:1:0).
- **ARP Timeout**—The number of seconds between ARP table rebuilds, from 60 to 4294967. The default is 14,400 seconds (4 hours).

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Time Synchronization

Use a Network Time Protocol (NTP) server to synchronize the clock settings on your devices. We recommend you configure all threat defenses managed by a management center to use the same NTP server as the management center. The threat defense gets its time directly from the configured NTP server. If the threat defense's configured NTP servers are not reachable for any reason, it synchronizes its time with the management center.

The device supports NTPv4.

---

**Note** If you are deploying threat defense on the Firepower 4100/9300 chassis, you must configure NTP on the Firepower 4100/9300 chassis so that Smart Licensing will work properly and to ensure proper timestamps on device registrations. You should use the same NTP server for the Firepower 4100/9300 chassis and the management center.

---

### Before you begin

- If your organization has one or more NTP servers that your threat defense can reach, use the same NTP server or servers for your devices that you have configured for Time Synchronization on the **System > Configuration** page on your management center.
- If you selected **Use the authenticated NTP server only** when configuring NTP server or servers for the management center, for your devices use only the NTP server or servers that are configured to authenticate with the management center. (The managed devices will use the same NTP servers as the management center, but their NTP connections will not use authentication.)
- If your device cannot reach an NTP server or your organization does not have one, you must use the **Via NTP from Defense Center** option as discussed in the following procedure.

## Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **Time Synchronization**.

**Step 3** Configure one of the following clock options:

- **Via NTP from Defense Center**—(Default). The managed device gets time from the NTP servers you configured for the management center (except for authenticated NTP servers) and synchronizes time with those servers directly. However, if any of the following are true, the managed device synchronizes time from the management center:
  - The management center's NTP servers are not reachable by the device.
  - The management center has no unauthenticated servers.
- **Via NTP from**—If your management center is using NTP servers on the network, select this option and enter the fully-qualified DNS name (such as ntp.example.com), or IPv4 or IPv6 address, of the same NTP servers you specified in **System > Configuration > Time Synchronization**. If the NTP servers are not reachable, the management center acts as an NTP server.

When multiple NTP servers are configured, the device uses the NTP server that is deemed appropriate based on the criteria defined in RFC. Thus, the status of "Being used" for a specific NTP server indicates that the server is currently used by the device.

**Step 4** Click **Save**.

---

### What to do next

- Deploy configuration changes.

## Time Zone

By default, the system uses the UTC time zone. To designate a different time zone for a device, use this procedure.

The time zone you specify will be used only for time-based policy application in policies that support this functionality.

---

**Note** Time-based ACLs is supported in Snort 3 also from management center 7.0 onwards.

---

## Procedure

---

**Step 1** Select **Devices > Platform Settings** and create or edit an threat defense policy.

You can also create time zone objects from the **Objects > Object Management > Time Zone** page.

- Step 2** Create a new time zone object by clicking +.
- Step 3** Select the time zone.
- Step 4** Click **Save**.

---

#### What to do next

- Create time range objects, select applicable time ranges in access control and prefilter rules, and assign the parent policies to devices associated with the correct time zone.
- Deploy configuration changes.

## UCAPL/CC Compliance

For more information about this setting and how to enable it for the management center, see the [Cisco Secure Firewall Management Center Administration Guide](#).

---

**Caution** After you enable this setting, you cannot disable it. If you need to take the appliance out of CC or UCAPL mode, you must reimage.

---

#### Before you begin

- Secure Firewall Threat Defense devices cannot use an evaluation license; your Smart Software Manager account must be enabled for export-controlled features.
- Secure Firewall Threat Defense devices must be deployed in routed mode.
- You must be an Admin user to perform this task.

#### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
  - Step 2** Click **UCAPL/CC Compliance**.
  - Step 3** To *permanently* enable security certifications compliance on the appliance, you have two choices:
    - To enable security certifications compliance in Common Criteria mode, choose **CC** from the drop-down list.
    - To enable security certifications compliance in Unified Capabilities Approved Products List mode, choose **UCAPL** from the drop-down list.
  - Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Performance Profile

The performance profile determines how the CPU cores on the device are assigned to two of the main system processes: the data plane (Lina) and Snort. The data plane handles VPN connections, routing, and other basic layer 3/4 processing. Snort provides advanced inspection, including intrusion and malware prevention, URL filtering, application filtering, and other features that require deep packet inspection.

If you use a balance of basic and advanced features, do not change the performance profile. The system is designed to provide a balanced assignment of cores to these processes. The assignment differs based on the hardware model.

However, if you use the device primarily for VPN, or for intrusion and other advanced inspection, you can skew the performance profile so that more cores are assigned to the more heavily used features. This might improve system performance.

### Before you begin

- These settings apply to systems running release 7.3+ only.
- Performance profile is supported on the following device types:
  - Firepower 4100/9300
  - Secure Firewall 3100/4200 (7.4+)
  - Secure Firewall Threat Defense Virtual
- Changing the performance profile is not supported on units in a cluster or high-availability group, or those configured for multi-instance. Deployment is blocked if you assign the profile to anything but standalone devices.
- The minimum number for core allocation is 2. Cores are assigned in even numbers based on the selected performance profile.

### Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **Performance Profile**.

**Step 3** Select a profile:

- **Default**—This is the recommended setting and is the best option if you configure both VPN and intrusion inspection.
- **VPN Heavy with prefilter fastpath**—If you primarily use the device as a VPN endpoint or headend, and you configure rules in the prefilter policy to fastpath VPN traffic, you can choose this option to assign the majority of CPU cores to the data plane. The allocation is 90% data plane, 10% Snort.

- **VPN Heavy with inspection**—If you primarily use the device as a VPN endpoint or headend, but do not use the prefilter policy to fastpath VPN traffic, you can choose this option to assign the majority of CPU cores to the data plane. This option assumes that you leave intrusion inspection, URL filtering, and other advanced functions that use Snort, to a different device in the network. The allocation is 60% data plane, 40% Snort.
- **IPS Heavy**—If you do not configure VPN, but you do use the device for intrusion prevention, you can choose this option to assign the majority of CPU core to the Snort process. The allocation is 30% data plane, 70% Snort.

- Step 4** Click **Save**.
- Step 5** Deploy the policy.
- Step 6** After deployment completes, you must reboot each affected device so that the new core assignments can be made.
-

## CHAPTER 42

# Network Address Translation

The following topics explain Network Address Translation (NAT) and how to configure it on threat defense devices.

- [Why Use NAT?, on page 1133](#)
- [NAT Basics, on page 1134](#)
- [Requirements and Prerequisites for NAT Policies, on page 1142](#)
- [Guidelines for NAT, on page 1143](#)
- [Manage NAT Policies, on page 1149](#)
- [Configure NAT for Threat Defense, on page 1151](#)
- [Translating IPv6 Networks, on page 1189](#)
- [Monitoring NAT, on page 1202](#)
- [Examples for NAT, on page 1203](#)

## Why Use NAT?

Each computer and device within an IP network is assigned a unique IP address that identifies the host. Because of a shortage of public IPv4 addresses, most of these IP addresses are private, not routable anywhere outside of the private company network. RFC 1918 defines the private IP addresses you can use internally that should not be advertised:

- 10.0.0.0 through 10.255.255.255
- 172.16.0.0 through 172.31.255.255
- 192.168.0.0 through 192.168.255.255

One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into legal, routable addresses that can be used on the public Internet. In this way, NAT conserves public addresses because it can be configured to advertise at a minimum only one public address for the entire network to the outside world.

Other functions of NAT include:

- Security—Keeping internal IP addresses hidden discourages direct attacks.
- IP routing solutions—Overlapping IP addresses are not a problem when you use NAT.

- Flexibility—You can change internal IP addressing schemes without affecting the public addresses available externally; for example, for a server accessible to the Internet, you can maintain a fixed IP address for Internet use, but internally, you can change the server address.
- Translating between IPv4 and IPv6 (Routed mode only) —If you want to connect an IPv6 network to an IPv4 network, NAT lets you translate between the two types of addresses.

---

**Note** NAT is not required. If you do not configure NAT for a given set of traffic, that traffic will not be translated, but will have all of the security policies applied as normal.

---

## NAT Basics

The following topics explain some of the basics of NAT.

## NAT Terminology

This document uses the following terminology:

- Real address/host/network/interface—The real address is the address that is defined on the host, before it is translated. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the inside network would be the “real” network. Note that you can translate any network connected to the device, not just an inside network. Therefore if you configure NAT to translate outside addresses, “real” can refer to the outside network when it accesses the inside network.
- Mapped address/host/network/interface—The mapped address is the address that the real address is translated to. In a typical NAT scenario where you want to translate the inside network when it accesses the outside, the outside network would be the “mapped” network.

---

**Note** During address translation, IP addresses configured for the device interfaces are not translated.

---

- Bidirectional initiation—Static NAT allows connections to be initiated *bidirectionally*, meaning both to the host and from the host.
- Source and destination NAT—For any given packet, both the source and destination IP addresses are compared to the NAT rules, and one or both can be translated/untranslated. For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address.

## NAT Types

You can implement NAT using the following methods:

- Dynamic NAT—A group of real IP addresses are mapped to a (usually smaller) group of mapped IP addresses, on a first come, first served basis. Only the real host can initiate traffic. See [Dynamic NAT, on page 1156](#).
- Dynamic Port Address Translation (PAT)—A group of real IP addresses are mapped to a single IP address using a unique source port of that IP address. See [Dynamic PAT, on page 1161](#).
- Static NAT—A consistent mapping between a real and mapped IP address. Allows bidirectional traffic initiation. See [Static NAT, on page 1171](#).
- Identity NAT—A real address is statically translated to itself, essentially bypassing NAT. You might want to configure NAT this way when you want to translate a large group of addresses, but then want to exempt a smaller subset of addresses. See [Identity NAT, on page 1179](#).

## NAT in Routed and Transparent Mode

You can configure NAT in both routed and transparent firewall mode. You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. The following sections describe typical usage for each firewall mode.

### NAT in Routed Mode

The following figure shows a typical NAT example in routed mode, with a private network on the inside.

**Figure 321: NAT Example: Routed Mode**

1. When the inside host at 10.1.2.27 sends a packet to a web server, the real source address of the packet, 10.1.2.27, is translated to a mapped address, 209.165.201.10.
2. When the server responds, it sends the response to the mapped address, 209.165.201.10, and the threat defense device receives the packet because the threat defense device performs proxy ARP to claim the packet.

- The threat defense device then changes the translation of the mapped address, 209.165.201.10, back to the real address, 10.1.2.27, before sending it to the host.

## NAT in Transparent Mode or Within a Bridge Group

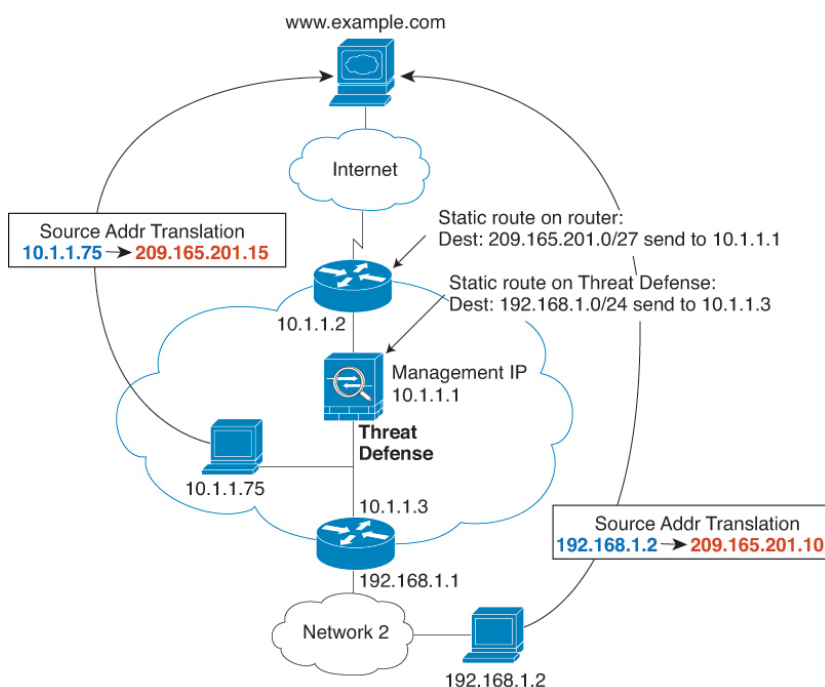

Using NAT in transparent mode eliminates the need for the upstream or downstream routers to perform NAT for their networks. It can perform a similar function within a bridge group in routed mode.

NAT in transparent mode, or in routed mode between members of the same bridge group, has the following requirements and limitations:

- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- ARP inspection is not supported. Moreover, if for some reason a host on one side of the threat defense sends an ARP request to a host on the other side of the threat defense, and the initiating host real address is mapped to a different address on the same subnet, then the real address remains visible in the ARP request.
- Translating between IPv4 and IPv6 networks is not supported. Translating between two IPv6 networks, or between two IPv4 networks is supported.

The following figure shows a typical NAT scenario in transparent mode, with the same network on the inside and outside interfaces. The transparent firewall in this scenario is performing the NAT service so that the upstream router does not have to perform NAT.

**Figure 322: NAT Example: Transparent Mode**

- When the inside host at 10.1.1.75 sends a packet to a web server, the real source address of the packet, 10.1.1.75, is changed to a mapped address, 209.165.201.15.

2. When the server responds, it sends the response to the mapped address, 209.165.201.15, and the threat defense receives the packet because the upstream router includes this mapped network in a static route directed to the threat defense management IP address.
3. The threat defense then undoes the translation of the mapped address, 209.165.201.15, back to the real address, 10.1.1.1.75. Because the real address is directly-connected, the threat defense sends it directly to the host.
4. For host 192.168.1.2, the same process occurs, except for returning traffic, the threat defense looks up the route in its routing table and sends the packet to the downstream router at 10.1.1.3 based on the threat defense static route for 192.168.1.0/24.

## Auto NAT and Manual NAT

You can implement address translation in two ways: *auto NAT* and *manual NAT*.

We recommend using auto NAT unless you need the extra features that manual NAT provides. It is easier to configure auto NAT, and it might be more reliable for applications such as Voice over IP (VoIP). (For VoIP, you might see a failure in the translation of indirect addresses that do not belong to either of the objects used in the rule.)

### Auto NAT

All NAT rules that are configured as a parameter of a network object are considered to be *auto NAT* rules. This is a quick and easy way to configure NAT for a network object. You cannot create these rules for a group object, however.

Although these rules are configured as part of the object itself, you cannot see the NAT configuration in the object definition through the object manager.

When a packet enters an interface, both the source and destination IP addresses are checked against the auto NAT rules. The source and destination address in the packet can be translated by separate rules if separate matches are made. These rules are not tied to each other; different combinations of rules can be used depending on the traffic.

Because the rules are never paired, you cannot specify that sourceA/destinationA should have a different translation than sourceA/destinationB. Use manual NAT for that kind of functionality, where you can identify the source and destination address in a single rule.

### Manual NAT

Manual NAT lets you identify both the source and destination address in a single rule. Specifying both the source and destination addresses lets you specify that sourceA/destinationA can have a different translation than sourceA/destinationB.

---

**Note** For static NAT, the rule is bidirectional, so be aware that “source” and “destination” are used in commands and descriptions throughout this guide even though a given connection might originate at the “destination” address. For example, if you configure static NAT with port address translation, and specify the source address as a Telnet server, and you want all traffic going to that Telnet server to have the port translated from 2323 to 23, then you must specify the *source* ports to be translated (real: 23, mapped: 2323). You specify the source ports because you specified the Telnet server address as the source address.

---

The destination address is optional. If you specify the destination address, you can either map it to itself (identity NAT), or you can map it to a different address. The destination mapping is always a static mapping.

## Comparing Auto NAT and Manual NAT

The main differences between these two NAT types are:

- How you define the real address.
  - Auto NAT—The NAT rule becomes a parameter for a network object. The network object IP address serves as the original (real) address.
  - Manual NAT—You identify a network object or network object group for both the real and mapped addresses. In this case, NAT is not a parameter of the network object; the network object or group is a parameter of the NAT configuration. The ability to use a network object *group* for the real address means that manual NAT is more scalable.
- How source and destination NAT is implemented.
  - Auto NAT— Each rule can apply to either the source or destination of a packet. So two rules might be used, one for the source IP address, and one for the destination IP address. These two rules cannot be tied together to enforce a specific translation for a source/destination combination.
  - Manual NAT—A single rule translates both the source and destination. A packet matches one rule only, and further rules are not checked. Even if you do not configure the optional destination address, a matching packet still matches one manual NAT rule only. The source and destination are tied together, so you can enforce different translations depending on the source/destination combination. For example, sourceA/destinationA can have a different translation than sourceA/destinationB.
- Order of NAT Rules.
  - Auto NAT—Automatically ordered in the NAT table.
  - Manual NAT—Manually ordered in the NAT table (before or after auto NAT rules).

## NAT Rule Order

Auto NAT and manual NAT rules are stored in a single table that is divided into three sections. Section 1 rules are applied first, then section 2, and finally section 3, until a match is found. For example, if a match is found in section 1, sections 2 and 3 are not evaluated. The following table shows the order of rules within each section.

---

**Note** There is also a Section 0, which contains any NAT rules that the system creates for its own use. These rules have priority over all others. The system automatically creates these rules and clears xlates as needed. You cannot add, edit, or modify rules in Section 0.

---

Table 88: NAT Rule Table

| Table Section | Rule Type  | Order of Rules within the Section                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Section 1     | Manual NAT | <p>Applied on a first match basis, in the order they appear in the configuration. Because the first match is applied, you must ensure that specific rules come before more general rules, or the specific rules might not be applied as desired. By default, manual NAT rules are added to section 1.</p> <p>By "specific rules first," we mean:</p> <ul style="list-style-type: none"> <li>• Static rules should come before dynamic rules.</li> <li>• Rules that include destination translation should come before rules with source translation only.</li> </ul> <p>If you cannot eliminate overlapping rules, where more than one rule might apply based on the source or destination address, be especially careful to follow these recommendations.</p>                                                               |
| Section 2     | Auto NAT   | <p>If a match in section 1 is not found, section 2 rules are applied in the following order:</p> <ol style="list-style-type: none"> <li>1. Static rules.</li> <li>2. Dynamic rules.</li> </ol> <p><b>Within each rule type, the following ordering guidelines are used:</b></p> <ol style="list-style-type: none"> <li>1. Quantity of real IP addresses—From smallest to largest. For example, an object with one address will be assessed before an object with 10 addresses.</li> <li>2. For quantities that are the same, then the IP address number is used, from lowest to highest. For example, 10.1.1.0 is assessed before 11.1.1.0.</li> <li>3. If the same IP address is used, then the name of the network object is used, in alphabetical order. For example, abracadabra is assessed before catwoman.</li> </ol> |
| Section 3     | Manual NAT | <p>If a match is still not found, section 3 rules are applied on a first match basis, in the order they appear in the configuration. This section should contain your most general rules. You must also ensure that any specific rules in this section come before general rules that would otherwise apply.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

For section 2 rules, for example, you have the following IP addresses defined within network objects:

- 192.168.1.0/24 (static)
- 192.168.1.0/24 (dynamic)
- 10.1.1.0/24 (static)

- 192.168.1.1/32 (static)
- 172.16.1.0/24 (dynamic) (object def)
- 172.16.1.0/24 (dynamic) (object abc)

The resultant ordering would be:

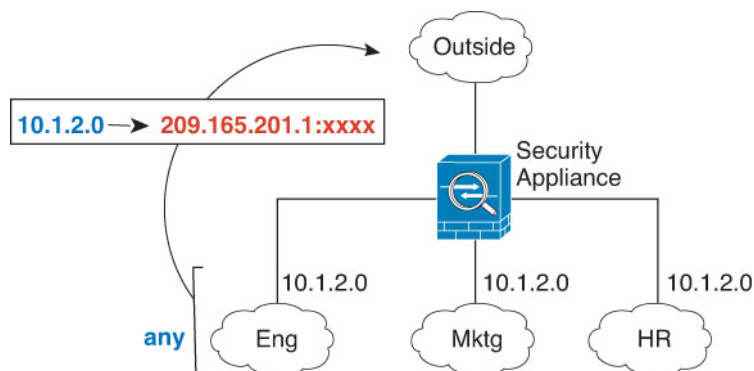

- 192.168.1.1/32 (static)
- 10.1.1.0/24 (static)
- 192.168.1.0/24 (static)
- 172.16.1.0/24 (dynamic) (object abc)
- 172.16.1.0/24 (dynamic) (object def)
- 192.168.1.0/24 (dynamic)

## NAT Interfaces

Except for bridge group member interfaces, you can configure a NAT rule to apply to any interface (in other words, all interfaces), or you can identify specific real and mapped interfaces. You can also specify any interface for the real address, and a specific interface for the mapped address, or vice versa.

For example, you might want to specify any interface for the real address and specify the outside interface for the mapped address if you use the same private addresses on multiple interfaces, and you want to translate them all to the same global pool when accessing the outside.

**Figure 323: Specifying Any Interface**

However, the concept of “any” interface does not apply to bridge group member interfaces. When you specify “any” interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. This could result in many similar rules where only one interface is different. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

**Note** You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes. When specifying interfaces, you do so indirectly by selecting the interface object that contains the interface.

## NAT Exemption

When internet edge devices have a site-to-site VPN configured on an interface and also have NAT rules for that interface, you must exempt the VPN traffic from the NAT rules. If you do not exempt the VPN traffic from NAT translation, the traffic gets dropped or is not routed through the VPN tunnel to the remote peer.

NAT exemption allows you to exclude traffic from being translated by NAT rules. When you create a policy-based site-to-site VPN using the management center VPN wizard, you can select the **NAT Exempt** option to create the rules automatically (**Device > Site To Site**). You can view the NAT exemptions for a device in the NAT policy page (**Device > NAT > NAT Exemptions**).

The management center supports NAT exemption for all policy-based site-to-site VPN topology types. For more information, see [Configure a Policy-based Site-to-Site VPN, on page 1624](#).

Consider the following example, which shows a site-to-site VPN tunnel connecting Site A and Site B. For traffic that must go to the Internet, NAT translates the private IPs to a public IP address to access the Internet. For traffic that must go over the VPN tunnel, you must configure NAT exemption for the device in the VPN wizard.

**Figure 324: Site-to-site VPN Topology with NAT Exemption**

## Configuring Routing for NAT

The threat defense device needs to be the destination for any packets sent to the translated (mapped) address.

When sending packets, the device uses the destination interface if you specify one, or a routing table lookup if you do not, to determine the egress interface. For identity NAT, you have the option to use a route lookup even if you specify a destination interface.

The type of routing configuration needed depends on the type of mapped address, as explained in the following topics.

### Addresses on the Same Network as the Mapped Interface

If you use addresses on the same network as the destination (mapped) interface, the threat defense device uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the threat defense device does not have to be the gateway for any additional networks. This solution is ideal if the outside network contains an adequate number of free addresses, a consideration if you are using a 1:1 translation like dynamic NAT or static NAT. Dynamic PAT greatly extends the number of translations you can use with a small number of addresses, so even if the

available addresses on the outside network is small, this method can be used. For PAT, you can even use the IP address of the mapped interface.

**Note** If you configure the mapped interface to be any interface, and you specify a mapped address on the same network as one of the mapped interfaces, then if an ARP request for that mapped address comes in on a *different* interface, then you need to manually configure an ARP entry for that network on the ingress interface, specifying its MAC address. Typically, if you specify any interface for the mapped interface, then you use a unique network for the mapped addresses, so this situation would not occur. Configure the ARP table in the ingress interface's **Advanced** settings.

## Addresses on a Unique Network

If you need more addresses than are available on the destination (mapped) interface network, you can identify addresses on a different subnet. The upstream router needs a static route for the mapped addresses that points to the threat defense device.

Alternatively for routed mode, you can configure a static route on the threat defense device for the mapped addresses using any IP address on the destination network as the gateway, and then redistribute the route using your routing protocol. For example, if you use NAT for the inside network (10.1.1.0/24) and use the mapped IP address 209.165.201.5, then you can configure a static route for 209.165.201.5 255.255.255.255 (host address) to the 10.1.1.99 gateway that can be redistributed.

For transparent mode, if the real host is directly-connected, configure the static route on the upstream router to point to the threat defense device: specify the bridge group IP address. For remote hosts in transparent mode, in the static route on the upstream router, you can alternatively specify the downstream router IP address.

## The Same Address as the Real Address (Identity NAT)

The default behavior for identity NAT has proxy ARP enabled, matching other static NAT rules. You can disable proxy ARP if desired. You can also disable proxy ARP for regular static NAT if desired, in which case you need to be sure to have proper routes on the upstream router.

Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues. For example, if you configure a broad identity NAT rule for “any” IP address, then leaving proxy ARP enabled can cause problems for hosts on the network directly connected to the mapped interface. In this case, when a host on the mapped network wants to communicate with another host on the same network, then the address in the ARP request matches the NAT rule (which matches “any” address). The threat defense device will then proxy ARP for the address, even though the packet is not actually destined for the threat defense device. (Note that this problem occurs even if you have a manual NAT rule; although the NAT rule must match both the source and destination addresses, the proxy ARP decision is made only on the “source” address). If the threat defense device ARP response is received before the actual host ARP response, then traffic will be mistakenly sent to the threat defense device.

## Guidelines for NAT

The following topics provide detailed guidelines for implementing NAT.

### Firewall Mode Guidelines for NAT

NAT is supported in routed and transparent firewall mode.

However, configuring NAT on bridge group member interfaces (interfaces that are part of a Bridge Group Virtual Interface, or BVI) has the following restrictions:

- When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself.
- When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify “any” as the interface.
- You cannot configure interface PAT when the mapped address is a bridge group member interface, because there is no IP address attached to the interface.
- You cannot translate between IPv4 and IPv6 networks (NAT64/46) when the source and destination interfaces are members of the same bridge group. Static NAT/PAT 44/66, dynamic NAT44/66, and dynamic PAT44 are the only allowed methods; dynamic PAT66 is not supported. However, you can do NAT64/46 between members of different bridge groups, or between a bridge group member (source) and standard routed interface (destination).

---

**Note** You cannot configure NAT for interfaces operating in inline, inline tap, or passive modes.

---

### IPv6 NAT Guidelines

NAT supports IPv6 with the following guidelines and restrictions.

- For standard routed mode interfaces, you can also translate between IPv4 and IPv6.
- You cannot translate between IPv4 and IPv6 for interfaces that are members of the same bridge group. You can translate between two IPv6 or two IPv4 networks only. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.
- You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.

- For static NAT, you can specify an IPv6 subnet up to /64. Larger subnets are not supported.
- When using FTP with NAT46, when an IPv4 FTP client connects to an IPv6 FTP server, the client must use either the extended passive mode (EPSV) or extended port mode (EPRT); PASV and PORT commands are not supported with IPv6.

## IPv6 NAT Best Practices

You can use NAT to translate between IPv6 networks, and also to translate between IPv4 and IPv6 networks (routed mode only). We recommend the following best practices:

- NAT66 (IPv6-to-IPv6)—We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only).
- NAT46 (IPv4-to-IPv6)—We recommend using static NAT. Because the IPv6 address space is so much larger than the IPv4 address space, you can easily accommodate a static translation. If you do not want to allow returning traffic, you can make the static NAT rule unidirectional (manual NAT only). When translating to an IPv6 subnet (/96 or lower), the resulting mapped address is by default an IPv4-embedded IPv6 address, where the 32-bits of the IPv4 address is embedded after the IPv6 prefix. For example, if the IPv6 prefix is a /96 prefix, then the IPv4 address is appended in the last 32-bits of the address. For example, if you map 192.168.1.0/24 to 201b::0/96, then 192.168.1.4 will be mapped to 201b::0.192.168.1.4 (shown with mixed notation). If the prefix is smaller, such as /64, then the IPv4 address is appended after the prefix, and a suffix of 0s is appended after the IPv4 address. You can also optionally translate the addresses net-to-net, where the first IPv4 address maps to the first IPv6 address, the second to the second, and so on.
- NAT64 (IPv6-to-IPv4)—You may not have enough IPv4 addresses to accommodate the number of IPv6 addresses. We recommend using a dynamic PAT pool to provide a large number of IPv4 translations.

## NAT Support for Inspected Protocols

Some application layer protocols that open secondary connections, or that embedded IP addresses in packets, are inspected to provide the following services:

- Pinhole creation—Some application protocols open secondary TCP or UDP connections either on standard or negotiated ports. Inspection opens pinholes for these secondary ports so that you do not need to create access control rules to allow them.
- NAT rewrite—Protocols such as FTP embed IP addresses and ports for the secondary connections in packet data as part of the protocol. If there is NAT translation involved for either of the endpoints, the inspection engines rewrite the packet data to reflect the NAT translation of the embedded addresses and ports. The secondary connections would not work without NAT rewrite.
- Protocol enforcement—Some inspections enforce some degree of conformance to the RFCs for the inspected protocol.

The following table lists the inspected protocols that apply NAT rewrite and their NAT limitations. Keep these limitations in mind when writing NAT rules that include these protocols. Inspected protocols not listed here do not apply NAT rewrite. These inspections include GTP, HTTP, IMAP, POP, SMTP, SSH, and SSL.

**Note** NAT rewrite is supported on the listed ports only. For some of these protocols, you can extend inspection to other ports using Network Analysis Policies, but NAT rewrite is not extended to those ports. This includes DCERPC, DNS, FTP, and Sun RPC inspection. If you use these protocols on non-standard ports, do not use NAT on the connections.

**Table 89: NAT Supported Application Inspection**

| Application                               | Inspected Protocol, Port                                                  | NAT Limitations                                                       | Pinholes Created |
|-------------------------------------------|---------------------------------------------------------------------------|-----------------------------------------------------------------------|------------------|
| DCERPC                                    | TCP/135                                                                   | No NAT64.                                                             | Yes              |
| DNS over UDP                              | UDP/53                                                                    | No NAT support is available for name resolution through WINS.         | No               |
| ESMTP                                     | TCP/25                                                                    | No NAT64.                                                             | No               |
| FTP                                       | TCP/21                                                                    | (Clustering) No static PAT.                                           | Yes              |
| H.323 H.225 (Call signaling)<br>H.323 RAS | TCP/1720<br>UDP/1718<br>For RAS,<br>UDP/1718-1719                         | (Clustering) No static PAT.<br>No extended PAT.<br>No NAT64.          | Yes              |
| ICMP<br>ICMP Error                        | ICMP<br>(ICMP traffic directed to a device interface is never inspected.) | No limitations.                                                       | No               |
| IP Options                                | RSVP                                                                      | No NAT64.                                                             | No               |
| NetBIOS Name Server over IP               | UDP/137, 138 (Source ports)                                               | No extended PAT.<br>No NAT64.                                         | No               |
| RSH                                       | TCP/514                                                                   | No PAT.<br>No NAT64.<br>(Clustering) No static PAT.                   | Yes              |

## FQDN Destination Guidelines

You can specify the translated (mapped) destination in a manual NAT rule using a fully-qualified domain name (FQDN) network object instead of an IP address. For example, you can create a rule based on traffic that is destined for the `www.example.com` web server.

When using an FQDN, the system obtains the DNS resolution and writes the NAT rule based on the returned address. If you are using multiple DNS server groups, the filter domains are honored and the address is requested from the appropriate group based on the filters. If more than one address is obtained from the DNS server, the address used is based on the following:

- If there is an address on the same subnet as the specified interface, that address is used. If there isn't one on the same subnet, the first address returned is used.
- The IP type for the translated source and translated destination must match. For example, if the translated source address is IPv6, the FQDN object must specify IPv6 as the address type. If the translated source is IPv4, the FQDN object can specify IPv4 or both IPv4 and IPv6. In this case, an IPv4 address is selected.

You cannot include an FQDN object in a network group that is used for manual NAT destination. In NAT, an FQDN object must be used alone, as only a single destination host makes sense for this type of NAT rule.

If the FQDN cannot be resolved to an IP address, the rule is not functional until a DNS resolution is obtained.

## Additional Guidelines for NAT

- For interfaces that are members of a bridge group, you write NAT rules for the member interfaces. You cannot write NAT rules for the Bridge Virtual Interface (BVI) itself.
- You cannot write NAT rules for a Virtual Tunnel Interface (VTI), which are used in site-to-site VPN. Writing rules for the VTI's source interface will not apply NAT to the VPN tunnel. To write NAT rules that will apply to VPN traffic tunneled on a VTI, you must use "any" as the interface; you cannot explicitly specify interface names.
- (Auto NAT only.) You can only define a single NAT rule for a given object; if you want to configure multiple NAT rules for an object, you need to create multiple objects with different names that specify the same IP address.
- If a VPN is defined on an interface, inbound ESP traffic on the interface is not subject to the NAT rules. The system allows the ESP traffic for established VPN tunnels only, dropping traffic not associated with an existing tunnel. This restriction applies to ESP and UDP ports 500 and 4500.
- If you define a site-to-site VPN on a device that is behind a device that is applying dynamic PAT, so that UDP ports 500 and 4500 are not the ones actually used, you must initiate the connection from the device that is behind the PAT device. The responder cannot initiate the security association (SA) because it does not know the correct port numbers.
- If you change the NAT configuration, and you do not want to wait for existing translations to time out before the new NAT configuration is used, you can clear the translation table using the **clear xlate** command in the device CLI. However, clearing the translation table disconnects all current connections that use translations.

If you create a new NAT rule that should apply to an existing connection (such as a VPN tunnel), you need to use **clear conn** to end the connection. Then, the attempt to re-establish the connection should hit the NAT rule and the connection should be NAT'ed correctly.

---

**Note** If you remove a dynamic NAT or PAT rule, and then add a new rule with mapped addresses that overlap the addresses in the removed rule, then the new rule will not be used until all connections associated with the removed rule time out or are cleared using the **clear xlate** or **clear conn** commands. This safeguard ensures that the same address is not assigned to multiple hosts.

---

- You cannot use an object group with both IPv4 and IPv6 addresses; the object group must include only one type of address.
- A network object used in NAT cannot include more than 131,838 IP addresses, either explicitly or implied in a range of addresses or a subnet. Break up the address space into smaller ranges and write separate rules for the smaller objects.
- (Manual NAT only.) When using **any** as the source address in a NAT rule, the definition of "any" traffic (IPv4 vs. IPv6) depends on the rule. Before the threat defense device performs NAT on a packet, the packet must be IPv6-to-IPv6 or IPv4-to-IPv4; with this prerequisite, the threat defense device can determine the value of **any** in a NAT rule. For example, if you configure a rule from "any" to an IPv6 server, and that server was mapped from an IPv4 address, then **any** means "any IPv6 traffic." If you configure a rule from "any" to "any," and you map the source to the interface IPv4 address, then **any** means "any IPv4 traffic" because the mapped interface address implies that the destination is also IPv4.

- You can use the same mapped object or group in multiple NAT rules.
- The mapped IP address pool cannot include:
  - The mapped interface IP address. If you specify “any” interface for the rule, then all interface IP addresses are disallowed. For interface PAT (routed mode only), specify the interface name instead of the interface address.
  - The failover interface IP address.
  - (Transparent mode.) The management IP address.
  - (Dynamic NAT.) The standby interface IP address when VPN is enabled.
- Avoid using overlapping addresses in static and dynamic NAT policies. For example, with overlapping addresses, a PPTP connection can fail to get established if the secondary connection for PPTP hits the static instead of dynamic xlate.
- You cannot use overlapping addresses in the source address of a NAT rule and a remote access VPN address pool.
- If you specify a destination interface in a rule, then that interface is used as the egress interface rather than looking up the route in the routing table. However, for identity NAT, you have the option to use a route lookup instead.
- If you use PAT on Sun RPC traffic, which is used to connect to NFS servers, be aware that the NFS server might reject connections if the PAT'ed port is above 1024. The default configuration of NFS servers is to reject connections from ports higher than 1024. The error is typically "Permission Denied." Mapping ports above 1024 happens if you do not select the option to include the reserved ports (1-1023) in the port range of a PAT pool. You can avoid this problem by changing the NFS server configuration to allow all port numbers.
- NAT applies to through traffic only. Traffic generated by the system is not subject to NAT.
- Do not name a network object or group pat-pool, using any combination of upper- or lower-case letters.
- The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.
- You cannot use NAT on the internal payload of Protocol Independent Multicast (PIM) registers.
- (Manual NAT) When writing NAT rules for a dual ISP interface setup (primary and backup interfaces using service level agreements in the routing configuration), do not specify destination criteria in the rule. Ensure the rule for the primary interface comes before the rule for the backup interface. This allows the device to choose the correct NAT destination interface based on the current routing state when the primary ISP is unavailable. If you specify destination objects, the NAT rule will always select the primary interface for the otherwise duplicate rules.
- If you get the ASP drop reason nat-no-xlate-to-pat-pool for traffic that should not match the NAT rules defined for the interface, configure identity NAT rules for the affected traffic so the traffic can pass untranslated.
- If you configure NAT for GRE tunnel endpoints, you must disable keepalives on the endpoints or the tunnel cannot be established. The endpoints send keepalives to the original addresses.

- DHCP and BOOTP share ports UDP/67-68. Because BOOTP is obsolete, writing NAT rules for the bootps port can cause port allocation problems when also running DHCP. Consider using DHCP relay instead for transmitting DHCP requests between network segments.

## Manage NAT Policies

Network Address Translation (NAT) converts the IP address of an incoming packet to a different address in the outgoing packet. One of the main functions of NAT is to enable private IP networks to connect to the Internet. NAT replaces a private IP address with a public IP address, translating the private addresses in the internal private network into routable addresses that can be used on the public Internet. NAT keeps track of the translations, also known as xlates, to ensure that return traffic is directed to the correct untranslated host address.

### Procedure

---

**Step 1** Choose **Devices > NAT** .

**Step 2** Manage your NAT policies:

- Create—Click **New Policy** and select **Threat Defense NAT**. See [Creating NAT Policies, on page 1149](#).
- Copy—Click **Copy** (📄) next to the policy you want to copy. You are prompted to give the copy a new, unique name. The copy includes all policy rules and configurations, but does not include device assignments.
- Report—Click **Report** (📄) for the policy. You are prompted to save the PDF report, which includes policy attributes, device assignments, rules, and object usage information.
- Edit—Click **Edit** (✎) next to the policy you want to edit. See [Configure NAT for Threat Defense, on page 1151](#).
- Delete—Click **Delete** (🗑) next to the policy you want to delete, then click **OK**. When prompted whether to continue, you are also informed if another user has unsaved changes in the policy.

**Caution** After you have deployed a NAT policy to a managed device, you cannot delete the policy from the device. Instead, you must deploy a NAT policy with no rules to remove the NAT rules already present on the managed device. You also cannot delete a policy that is the last deployed policy on any of its target devices, even if it is out of date. Before you can delete the policy completely, you must deploy a different policy to those targets.

---

## Creating NAT Policies

When you create a new NAT policy you must, at minimum, give it a unique name. Although you are not required to identify policy targets at policy creation time, you must perform this step before you can deploy the policy. If you apply a NAT policy with no rules to a device, the system removes all NAT rules from that device.

## Procedure

- 
- Step 1** Choose **Devices > NAT** .
- Step 2** Click **New Policy** and from the drop-down list, choose **Threat Defense NAT** for threat defense devices. **Firepower NAT** is for older devices that are not covered in this document.
- Step 3** Enter a unique **Name**.
- Step 4** Optionally, enter a **Description**.
- Step 5** Choose the devices where you want to deploy the policy:
- Choose a device in the **Available Devices** list, and click **Add to Policy**.
  - Click and drag a device from the **Available Devices** list to the **Selected Devices** list.
  - Remove a device from the **Selected Devices** list by clicking **Delete** (  ) next to the device.
- Step 6** Click **Save**.
- 

## Configuring NAT Policy Targets

You can identify the managed devices you want to target with your policy while creating or editing a policy. You can search a list of available devices and high-availability pairs, and add them to a list of selected devices.

## Procedure

- 
- Step 1** Choose **Devices > NAT** .
- Step 2** Click **Edit** (  ) next to the NAT policy you want to modify.
- If **View** (  ) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 3** Click **Policy Assignments**.
- Step 4** Do any of the following:
- To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add to Policy**. You can also drag and drop.
  - To remove a device assignment, click **Delete** (  ) next to a device, high-availability pair, or device group in the **Selected Devices** list.
- Step 5** Click **OK**.
-

# Configure NAT for Threat Defense

Network address translation can be very complex. We recommend that you keep your rules as simple as possible to avoid translation problems and difficult troubleshooting situations. Careful planning before you implement NAT is critical. The following procedure provides the basic approach.

The NAT policy is a shared policy. You assign the policy to devices that should have similar NAT rules.

Whether a given rule in the policy applies to an assigned device is determined by the interface objects (security zones or interface groups) used in the rule. If the interface objects include one or more interface for the device, the rule is deployed to the device. Thus, you can configure rules that apply to subsets of devices within a single shared policy by carefully designing your interface objects. Rules that apply to “any” interface object are deployed to all devices.

If you change the type of an interface to a type that is not valid for use with a NAT policy that targets a device with that interface, the policy labels the interface as deleted. Click **Save** in the NAT policy to automatically remove the interface from the policy.

You can configure multiple NAT policies if groups of your devices require significantly different rules.

## Procedure

- 
- Step 1** [Navigate from Security Cloud Control to Cloud-delivered Firewall Management Center, on page 2946](#)
- Step 2** Select **Devices > NAT**.
- Click **New Policy > Threat Defense NAT** to create a new policy. Give the policy a name, optionally assign devices to it, and click **Save**.  
You can change device assignments later by editing the policy and clicking **Policy Assignments**.
  - Click **Edit** (✎) to edit an existing threat defense NAT policy. Note that the page also shows Firepower NAT policies, which are not used by threat defense devices.  
If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.
- Step 3** Decide what kinds of rules you need.  
You can create dynamic NAT, dynamic PAT, static NAT, and identity NAT rules. For an overview, see [NAT Types, on page 1134](#).
- Step 4** Decide which rules should be implemented as manual or auto NAT.  
For a comparison of these two implementation options, see [Auto NAT and Manual NAT, on page 1137](#).
- Step 5** Decide which rules should be custom per device.  
Because you can assign a NAT policy to multiple devices, you can configure a single rule on many devices. However, you might have rules that should be interpreted differently by each device, or some rules that should apply to a subset of devices only.  
Use interface objects to control on which devices a rule is configured. Then, use object overrides on network objects to customize the addresses used per device.

For detailed information, see [Customizing NAT Rules for Multiple Devices, on page 1152](#).

**Step 6** Create the rules as explained in the following sections.

- [Dynamic NAT, on page 1156](#)
- [Dynamic PAT, on page 1161](#)
- [Static NAT, on page 1171](#)
- [Identity NAT, on page 1179](#)

**Step 7** Manage the NAT policy and rules.

You can do the following to manage the policy and its rules.

- To edit the policy name or description, click in those fields, type in your changes, and click outside the fields.
- To view only those rules that apply to a specific device, click **Filter by Device** and select the desired device. A rule applies to a device if it uses an interface object that includes an interface on the device.
- To view any warnings or errors in the policy, click **Show Warnings**, then choose a **Device**. Warnings and errors mark configurations that could adversely affect traffic flow or prevent the policy from deploying.
- To change the devices to which the policy is assigned, click the **Policy Assignments** link and modify the selected devices list as desired.
- To change whether a rule is enabled or disabled, right click the rule and select the desired option from the **State** command. You can temporarily disable a rule without deleting it using these controls.
- To add a rule, click the **Add Rule** button.
- To edit a rule, click **Edit** (✎) for the rule.
- To delete a rule, click **Delete** (🗑) for the rule.
- To change the number of rules displayed on the page, use the **Rows Per Page** drop-down list.
- To select more than one rule to enable, disable, or delete, click the checkbox for the rules, or the checkbox in the header, then perform the action.

**Step 8** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Customizing NAT Rules for Multiple Devices

Because the NAT policy is shared, you can assign a given policy to more than one device. However, you can configure at most one auto NAT rule for a given object. Thus, if you want to configure different translations for an object based on the specific device doing the translation, you need to carefully configure the interface objects (security zones or interface groups) and define network object overrides for the translated address.

The interface objects determine on which devices a rule gets configured. The network object overrides determine what IP addresses are used by a given device for that object.

Consider the following scenario:

- FTD-A and FTD-B have inside networks 192.168.1.0/24 attached to the interface named “inside.”
- On FTD-A, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.100.10.10 - 10.100.10.200 range when going to the “outside” interface.
- On FTD-B, you want to translate all 192.168.1.0/24 addresses to a NAT pool in the 10.200.10.10 - 10.200.10.200 range when going to the “outside” interface.

To accomplish the above, you would do the following. Although this example rule is for dynamic auto NAT, you can generalize the technique for any type of NAT rule.

## Procedure

- 
- Step 1** Create the security zones for the inside and outside interfaces.
- a) Choose **Objects > Object Management**.
  - b) Select **Interface Objects** from the table of contents and click **Add > Security Zone**. (You can use interface groups instead of zones.)
  - c) Configure the inside zone properties.
    - **Name**—Enter a name, for example, **inside-zone**.
    - **Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
    - **Selected Interfaces**—Add the FTD-A/inside and FTD-B/inside interfaces to the selected list.
  - d) Click **Save**.
  - e) Click **Add > Security Zone** and define the outside zone properties.
    - **Name**—Enter a name, for example, **outside-zone**.
    - **Interface Type**—Select **Routed** for routed-mode devices, **Switched** for transparent mode.
    - **Selected Interfaces**—Add the FTD-A/outside and FTD-B/outside interfaces to the selected list.
  - f) Click **Save**.
- Step 2** Create the network object for the original inside network on the Object Management page.
- a) Select **Network** from the table of contents and click **Add Network > Add Object**.
  - b) Configure the inside network properties.
    - **Name**—Enter a name, for example, **inside-network**.
    - **Network**—Enter the network address, for example, **192.168.1.0/24**.
  - c) Click **Save**.
- Step 3** Create the network object for the translated NAT pool and define overrides.
- a) Click **Add Network > Add Object**.
  - b) Configure the NAT pool properties for FTD-A.

- **Name**—Enter a name, for example, **NAT-pool**.
  - **Network**—Enter the range of addresses to include in the pool for FTD-A, for example, **10.100.10.10-10.100.10.200**.
- c) Select **Allow Overrides**.
  - d) Click the **Overrides** heading to open the list of object overrides.
  - e) Click **Add** to open the Add Object Override dialog box.
  - f) Select FTD-B and **Add** it to the Selected Devices list.
  - g) Click **Override** and change **Network** to **10.200.10.10-10.200.10.200**
  - h) Click **Add** to add the override to the device.

By defining an override for FTD-B, whenever the system configures this object on FTD-B, it will use the override value instead of the value defined in the original object.

- i) Click **Save**.

#### Step 4 Configure the NAT rule.

- a) Select **Devices > NAT** and create or edit the threat defense NAT policy.
- b) Click **Add Rule**.
- c) Configure the following properties:
  - **NAT Rule** = Auto NAT Rule.
  - **Type** = Dynamic.
- d) On **Interface Objects**, configure the following:
  - **Source Interface Objects** = inside-zone.
  - **Destination Interface Objects** = outside-zone.

**Note** The interface objects control on which devices the rule is configured. Because in this example the zones contain interfaces for FTD-A and FTD-B only, even if the NAT policy were assigned to additional devices, the rule would be deployed to those 2 devices only.

- e) On **Translation**, configure the following:
  - **Original Source** = inside-network object.
  - **Translated Source > Address**= NAT-pool object.
- f) Click **Save**.

You now have a single rule that will be interpreted differently for FTD-A and FTD-B, providing unique translations for the inside networks protected by each firewall.

## Searching and Filtering the NAT Rule Table

You can search and filter the NAT rule table to help you find rules that you need to modify or view. When you filter the table, only matching rules are shown. Note that although the rule numbers change to be sequentially 1, 2, and so forth, filtering does not change the actual rule number or the rule's location in the

table relative to hidden rules. Filtering simply changes what you can see to help you locate rules that interest you.

When editing the NAT policy, you can use the fields above the table to do the following types of search/filter:

- **Filter by Device**—Click **Filter by Device**, then select the devices whose rules you want to see and click **OK**. Whether a rule applies to a device is determined by the rule's interface constraints. If you specify a security zone or interface group for either the source or destination interface, the rule applies to a device if at least one interface for the device is in the zone or group. If a NAT rule applies to any source and any destination interface, then it applies to all devices.

If you also do a text or multiple-attribute search, the results are constrained to the selected devices.

To remove this filter, click **Filter by Device** and deselect the devices, or select **All**, and click **OK**.

- **Simple Text Search**—In the **Filter** box, type a string and press Enter. The string is compared to all values in the rules. For example, if you enter “network-object-1,” which is the name of a network object, you would get rules that use the object in source, destination, and PAT pool attributes.

For network and port objects, the string is also compared to the contents of the objects used in the rule. For example, if a PAT pool object includes the range 10.100.10.3-10.100.10.100, searching on either 10.100.10.3 or 10.100.10.100 (or a partial 10.100.10) will include rules that use that PAT pool object. However, the match must be exact: searching on 10.100.10.5 will not match this PAT pool object, even though the IP address is within the object's IP address range.

To remove the filter, click the **x** on the right side of the Filter box.

- **Multiple-Attribute Search**—If a simple text search gives you too many hits, you can configure multiple values for the search. Click in the **Filter** box to open the list of attributes, then select or enter strings for the attributes you intend to search and click the **Filter** button. These attributes are the same as the ones you would configure within a NAT rule. The attributes are AND'ed, so filtered results include only those rules that match all attributes you configured.

- For binary attributes, such as the rule state (enabled/disabled), whether a PAT pool is configured (enabled/disabled), the direction of the rule (uni/bi), or rule type (static/dynamic), simply check or uncheck the boxes as appropriate. Select both boxes if you do not care about the attribute value. If you deselect both boxes, no rules will match the filter.
- For string attributes, type a full or partial string relevant to that attribute. These will be object names, either for security zones/interface groups, network objects, or port objects. It can also be the network or port object contents, which are matched the same way they are for simple text searches.

To remove the filter, click the **x** on the right side of the Filter box, or click in the Filter box to open the drop-down list, and click the Clear button.

## Enabling, Disabling, or Deleting Multiple Rules

You can enable or disable manual NAT rules, or delete any NAT rule, one by one. You can also select multiple rules and apply changes to all of them at once. Because enable/disable applies to manual NAT only, if you select a mix of rule types, you can delete them only.

Note that when you enable or disable rules, it does not matter if you select some rules that were already enabled or disabled. For example, enabling an already enabled rule simply leaves the rule enabled.

## Procedure

---

**Step 1** Select **Devices > NAT**, and edit a threat defense NAT policy.

**Step 2** (Optional.) Filter the NAT rules to locate the ones you want to change.

Filtering is especially useful if you have a large NAT policy. For example, you could search on disabled rules to find ones that need to be enabled.

**Step 3** Select the rules you want to change.

- Click the checkbox in the left column of the rule to select (or deselect) individual rules.
- Click the checkbox in the table header to select all the rules on the currently displayed page.

Your selection is preserved as you go from page to page. However, in practice, it makes most sense to perform your actions on the rules selected on a page before going to the next page.

**Step 4** Perform the desired action. When selecting multiple rules, you are asked to confirm the action.

Note that these actions are also available on the right-click menu.

- To enable all rules, click **Select Bulk Action > Enable**.
  - To disable all rules, click **Select Bulk Action > Disable**.
  - To delete all rules, click **Select Bulk Action > Delete**.
- 

## Dynamic NAT

The following topics explain dynamic NAT and how to configure it.

### About Dynamic NAT

Dynamic NAT translates a group of real addresses to a pool of mapped addresses that are routable on the destination network. The mapped pool typically includes fewer addresses than the real group. When a host you want to translate accesses the destination network, NAT assigns the host an IP address from the mapped pool. The translation is created only when the real host initiates the connection. The translation is in place only for the duration of the connection, and a given user does not keep the same IP address after the translation times out. Users on the destination network, therefore, cannot initiate a reliable connection to a host that uses dynamic NAT, even if the connection is allowed by an access rule.

---

**Note** For the duration of the translation, a remote host can initiate a connection to the translated host if an access rule allows it. Because the address is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule. A successful connection from a remote host can reset the idle timer for the connection.

---

The following figure shows a typical dynamic NAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back.

**Figure 325: Dynamic NAT**

The following figure shows a remote host attempting to initiate a connection to a mapped address. This address is not currently in the translation table; therefore, the packet is dropped.

**Figure 326: Remote Host Attempts to Initiate a Connection to a Mapped Address**

## Dynamic NAT Disadvantages and Advantages

Dynamic NAT has these disadvantages:

- If the mapped pool has fewer addresses than the real group, you could run out of addresses if the amount of traffic is more than expected.

Use PAT or a PAT fall-back method if this event occurs often because PAT provides over 64,000 translations using ports of a single address.

- You have to use a large number of routable addresses in the mapped pool, and routable addresses may not be available in large quantities.

The advantage of dynamic NAT is that some protocols cannot use PAT. PAT does not work with the following:

- IP protocols that do not have a port to overload, such as GRE version 0.
- Some multimedia applications that have a data stream on one port, the control path on another port, and are not open standard.

## Configure Dynamic Auto NAT

Use dynamic auto NAT rules to translate addresses to different IP addresses that are routable on the destination network.

### Before you begin

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.

### Procedure

- 
- Step 1** Select **Devices > NAT** and create or edit the threat defense NAT policy.
- Step 2** Do one of the following:
- Click the **Add Rule** button to create a new rule.
  - Click **Edit** (✎) to edit an existing rule.
- The right click menu also has options to cut, copy, paste, insert, and delete rules.
- Step 3** Configure the basic rule options:
- **NAT Rule**—Select **Auto NAT Rule**.
  - **Type**—Select **Dynamic**.
- Step 4** On **Interface Objects**, configure the following options:
- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.
- Step 5** On **Translation**, configure the following options:
- **Original Source**—The network object that contains the addresses you are translating.
  - **Translated Source**—The network object or group that contains the mapped addresses.
- Step 6** (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see [Rewriting DNS Queries and Responses Using NAT, on page 1233](#).
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

**Step 7** Click **Save** to add the rule.

**Step 8** Click **Save** on the NAT page to save your changes.

---

## Configure Dynamic Manual NAT

Use dynamic manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic NAT translates addresses to different IP addresses that are routable on the destination network.

### Before you begin

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—This can be a network object or group, but it cannot include a subnet. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

### Procedure

---

**Step 1** Select **Devices > NAT** and create or edit the threat defense NAT policy.

**Step 2** Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3** Configure the basic rule options:

- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

**Step 4** On **Interface Objects**, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

**Step 5** (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Step 6** Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The network object or group that contains the mapped addresses.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

**Step 7** (Optional.) Identify the destination service ports for service translation: **Original Destination Port**, **Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

**Step 8** (Optional.) On **Advanced**, select the desired options:

- (For source translation only.) **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see [Rewriting DNS Queries and Responses Using NAT, on page 1233](#).
- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

**Step 9** Click **Save** to add the rule.

**Step 10** Click **Save** on the NAT page to save your changes.

---

## Dynamic PAT

The following topics describe dynamic PAT.

### About Dynamic PAT

Dynamic PAT translates multiple real addresses to a single mapped IP address by translating the real address and source port to the mapped address and a unique port.

Each connection requires a separate translation session because the source port differs for each connection. For example, 10.1.1.1:1025 requires a separate translation from 10.1.1.1:1026.

The following figure shows a typical dynamic PAT scenario. Only real hosts can create a NAT session, and responding traffic is allowed back. The mapped address is the same for each translation, but the port is dynamically assigned.

Figure 327: Dynamic PAT

For the duration of the translation, a remote host on the destination network can initiate a connection to the translated host if an access rule allows it. Because the port address (both real and mapped) is unpredictable, a connection to the host is unlikely. Nevertheless, in this case you can rely on the security of the access rule.

After the connection expires, the port translation also expires.

**Note** We recommend that you use different PAT pools for each interface. If you use the same pool for multiple interfaces, especially if you use it for "any" interface, the pool can be quickly exhausted, with no ports available for new translations.

## Dynamic PAT Disadvantages and Advantages

Dynamic PAT lets you use a single mapped address, thus conserving routable addresses. You can even use the threat defense device interface IP address as the PAT address.

You cannot use dynamic PAT for IPv6 (NAT66) when translating between interfaces in the same bridge group. This restriction does not apply when the interfaces are members of different bridge groups, or between a bridge group member and a standard routed interface.

Dynamic PAT does not work with some multimedia applications that have a data stream that is different from the control path. For more information, see [NAT Support for Inspected Protocols, on page 1144](#).

Dynamic PAT might also create a large number of connections appearing to come from a single IP address, and servers might interpret the traffic as a DoS attack. You can configure a PAT pool of addresses and use a round-robin assignment of PAT addresses to mitigate this situation.

## PAT Pool Object Guidelines

When creating network objects for a PAT pool, follow these guidelines.

### For a PAT pool

- Ports are mapped to an available port in the 1024 to 65535 range. You can optionally include the reserved ports, those below 1024, to make the entire port range available for translations.

When operating in a cluster, blocks of 512 ports per address are allocated to the members of the cluster, and mappings are made within these port blocks. If you also enable block allocation, the ports are distributed according to the block allocation size, whose default is also 512.

- If you enable block allocation for a PAT pool, port blocks are allocated in the 1024-65535 range only. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application

requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host.

- If you use the same PAT pool object in two separate rules, then be sure to specify the same options for each rule. For example, if one rule specifies extended PAT, then the other rule must also specify extended PAT.
- If a host has an existing connection, then subsequent connections from that host use the same PAT IP address. If no ports are available, this can prevent the connection. Use the round robin option to avoid this problem.
- For best performance, limit the number of IP addresses within a PAT pool to 10,000.

#### For extended PAT for a PAT pool

- Many application inspections do not support extended PAT.
- If you enable extended PAT for a dynamic PAT rule, then you cannot also use an address in the PAT pool as the PAT address in a separate static NAT with port translation rule. For example, if the PAT pool includes 10.1.1.1, then you cannot create a static NAT-with-port-translation rule using 10.1.1.1 as the PAT address.
- If you use a PAT pool and specify an interface for fallback, you cannot specify extended PAT.
- For VoIP deployments that use ICE or TURN, do not use extended PAT. ICE and TURN rely on the PAT binding to be the same for all destinations.
- You cannot use extended PAT on units in a cluster.
- Extended PAT increases memory usage on the device.

#### For round robin for a PAT pool

- If a host has an existing connection, then subsequent connections from that host will use the same PAT IP address if ports are available. However, this “stickiness” does not survive a failover. If the device fails over, then subsequent connections from a host might not use the initial IP address.
- IP address “stickiness” is also impacted if you mix PAT pool/round robin rules with interface PAT rules on the same interface. For any given interface, choose either a PAT pool or interface PAT; do not create competing PAT rules.
- Round robin, especially when combined with extended PAT, can consume a large amount of memory. Because NAT pools are created for every mapped protocol/IP address/port range, round robin results in a large number of concurrent NAT pools, which use memory. Extended PAT results in an even larger number of concurrent NAT pools.

## Configure Dynamic Auto PAT

Use dynamic auto PAT rules to translate addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

### Before you begin

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.

### Procedure

- 
- Step 1** Select **Devices > NAT** and create or edit the threat defense NAT policy.
- Step 2** Do one of the following:
- Click the **Add Rule** button to create a new rule.
  - Click **Edit** (✎) to edit an existing rule.
- The right click menu also has options to cut, copy, paste, insert, and delete rules.
- Step 3** Configure the basic rule options:
- **NAT Rule**—Select **Auto NAT Rule**.
  - **Type**—Select **Dynamic**.
- Step 4** On **Interface Objects**, configure the following options:
- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.
- Step 5** On **Translation**, configure the following options:
- **Original Source**—The network object that contains the addresses you are translating.
  - **Translated Source**—One of the following:
    - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
    - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
    - To use a PAT pool, leave **Translated Source** empty.

**Step 6** If you are using a PAT pool, select the **PAT Pool** page and do the following:

- a) Select **Enable PAT pool**.
- b) Select the network object group that contains the addresses for the pool in the **PAT > Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.
- **Flat Port Range, Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the threat defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

**Step 7** (Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address or PAT pool.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

**Step 8** Click **Save** to add the rule.

**Step 9** Click **Save** on the NAT page to save your changes.

---

## Configure Dynamic Manual PAT

Use dynamic manual PAT rules when auto PAT does not meet your needs. For example, if you want to do different translations based on the destination. Dynamic PAT translates addresses to unique IP address/port combinations, rather than to multiple IP addresses only. You can translate to a single address (either the destination interface's address or another address), or use a PAT pool of addresses to provide a larger number of possible translations.

### Before you begin

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the PAT address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object.
  - **Single PAT address**—Create a network object containing a single host.
  - **PAT pool**—Create a network object that includes a range, or create a network object group that contains hosts, ranges, or both. You cannot include subnets.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule.

For dynamic NAT, you can also perform port translation on the destination. In the Object Manager, ensure that there are port objects you can use for the **Original Destination Port** and **Translated Destination Port**. If you specify the source port, it will be ignored.

### Procedure

---

**Step 1** Select **Devices > NAT** and create or edit the threat defense NAT policy.

**Step 2** Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3** Configure the basic rule options:

- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Dynamic**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

**Step 4** On **Interface Objects**, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

**Step 5** (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Step 6** Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Skip the step for configuring a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Skip the step for configuring a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

**Step 7** (Optional.) Identify the destination service ports for service translation: **Original Destination Port, Translated Destination Port**.

Dynamic NAT does not support port translation, so leave the **Original Source Port** and **Translated Source Port** fields empty. However, because the destination translation is always static, you can perform port translation for the destination port.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

### Step 8

If you are using a PAT pool, select the **PAT Pool** page and do the following:

- a) Select **Enable PAT pool**.
- b) Select the network object group that contains the addresses for the pool in the **PAT > Address** field.

You can alternatively select **Destination Interface IP**, which is another way to implement interface PAT.

- c) (Optional) Select the following options as needed:

- **Use Round Robin Allocation**—To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.
- **Extended PAT Table**—To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.
- **Flat Port Range, Include Reserved Ports**—To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the threat defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.
- **Block Allocation**—To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024–65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

### Step 9

(Optional.) On **Advanced**, select the desired options:

- **Fallthrough to Interface PAT (Destination Interface)**—Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.

- Step 10** Click **Save** to add the rule.
- Step 11** Click **Save** on the NAT page to save your changes.

---

## Configure PAT with Port Block Allocation

For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time (see RFC 6888). If you allocate a block of ports, subsequent connections from the host use new randomly-selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Blocks are freed when the last xlate that uses a port in the block is removed.

The main reason for allocating port blocks is reduced logging. The port block allocation is logged, connections are logged, but xlates created within the port block are not logged. On the other hand, this makes log analysis more difficult.

Port blocks are allocated in the 1024-65535 range only. Thus, if an application requires a low port number (1-1023), it might not work. For example, an application requesting port 22 (SSH) will get a mapped port within the range of 1024-65535 and within the block allocated to the host. You can create a separate NAT rule that does not use block allocation for applications that use low port numbers; for twice NAT, ensure the rule comes before the block allocation rule.

### Before you begin

Usage notes for NAT rules:

- You can include the **Use Round Robin Allocation** option, but you cannot include the options for extending PAT uniqueness, using a flat range, including the reserved ports, or falling through to interface PAT. Other source/destination address and port information is also allowed.
- As with all NAT changes, if you replace an existing rule, you must clear xlates related to the replaced rule to have the new rule take effect. You can clear them explicitly or simply wait for them to time out. When operating in a cluster, you must clear xlates globally across the cluster.

---

**Note** If you are switching between a regular PAT and block allocation PAT rule, for object NAT, you must first delete the rule, then clear xlates. You can then create the new object NAT rule. Otherwise, you will see `pat-port-block-state-mismatch` drops in the **show asp drop** output.

---

- For a given PAT pool, you must specify (or not specify) block allocation for all rules that use the pool. You cannot allocate blocks in one rule and not in another. PAT pools that overlap also cannot mix block allocation settings. You also cannot overlap static NAT with port translation rules with the pool.

## Procedure

- 
- Step 1** (Optional.) Configure global PAT port block allocation settings.

There are a few global settings that control port block allocation. If you want to change the defaults for these options, you must configure a FlexConfig object and add it to your FlexConfig policy.

- a) Select **Objects > Object Management > FlexConfig > FlexConfig Object** and create a new object.
- b) Configure the block allocation size, which is the number of ports in each block.

**xlate block-allocation size** *value*

The range is 32-4096. The default is 512. Use the “no” form to return to the default.

If you do not use the default, ensure that the size you choose divides evenly into 64,512 (the number of ports in the 1024-65535 range). Otherwise, there will be ports that cannot be used. For example, if you specify 100, there will be 12 unused ports.

- c) Configure the maximum blocks that can be allocated per host.

**xlate block-allocation maximum-per-host** *number*

The limit is per protocol, so a limit of 4 means at most 4 UDP blocks, 4 TCP blocks, and 4 ICMP blocks per host. The range is 1-8, the default is 4. Use the “no” form to return to the default.

- d) (Optional.) Enable interim syslog generation.

**xlate block-allocation pba-interim-logging** *seconds*

By default, the system generates syslog messages during port block creation and deletion. If you enable interim logging, the system generates the following message at the interval you specify. The messages report all active port blocks allocated at that time, including the protocol (ICMP, TCP, UDP) and source and destination interface and IP address, and the port block. You can specify an interval from 21600-604800 seconds (6 hours to 7 days).

%ASA-6-305017: Pba-interim-logging: Active *protocol* block of ports for translation from *real\_interface:real\_host\_ip* to *mapped\_interface:mapped\_ip\_address/start\_port\_num-end\_port\_num*

**Example:**

The following example sets the block allocation size to 64, the per-host maximum to 8, and enables interim logging every 6 hours.

```
xlate block-allocation size 64
xlate block-allocation maximum-per-host 8
xlate block-allocation pba-interim-logging 21600
```

- e) Select the following options in the FlexConfig object:
  - **Deployment = Everytime**
  - **Type = Append**
- f) Click **Save** to create the FlexConfig object.
- g) Select **Devices > FlexConfig**, and create or edit the FlexConfig policy that is assigned to the devices that need to have these settings adjusted.
- h) Select your object in the available objects list and click > to move it to the selected objects list.
- i) Click **Save**.

You can click **Preview Config**, select one of the target devices, and verify that the xlate commands appear correctly.

**Step 2** Add NAT rules that use PAT pool port block allocation.

- a) Select **Devices > NAT** and add or edit the threat defense NAT policy.
- b) Add or edit a NAT rule and configure at least the following options.

- **Type = Dynamic**
- In **Translation > Original Source**, select the object that defines the source address.
- On **PAT Pool**, configure the following options:
  - Select **Enable PAT Pool**
  - In **PAT > Address**, select a network object or group that defines the pat pool.
  - Select the **Block Allocation** option.

c) Save your changes to the rule and to the NAT policy.

## Static NAT

The following topics explain static NAT and how to implement it.

### About Static NAT

Static NAT creates a fixed translation of a real address to a mapped address. Because the mapped address is the same for each consecutive connection, static NAT allows bidirectional connection initiation, both to and from the host (if an access rule exists that allows it). With dynamic NAT and PAT, on the other hand, each host uses a different address or port for each subsequent translation, so bidirectional initiation is not supported.

The following figure shows a typical static NAT scenario. The translation is always active so both real and remote hosts can initiate connections.

**Figure 328: Static NAT**

**Note** You can disable bidirectionality if desired.

### Static NAT with Port Translation

Static NAT with port translation lets you specify a real and mapped protocol and port.

When you specify the port with static NAT, you can choose to map the port and/or the IP address to the same value or to a different value.

The following figure shows a typical static NAT with port translation scenario showing both a port that is mapped to itself and a port that is mapped to a different value; the IP address is mapped to a different value in both cases. The translation is always active so both translated and remote hosts can initiate connections.

**Figure 329: Typical Static NAT with Port Translation Scenario**

Static NAT-with-port-translation rules limit access to the destination IP address for the specified port only. If you try to access the destination IP address on a different port not covered by a NAT rule, then the connection is blocked. In addition, for manual NAT, traffic that does not match the source IP address of the NAT rule will be dropped if it matches the destination IP address, regardless of the destination port. Therefore, you must add additional rules for all other traffic allowed to the destination IP address. For example, you can configure a static NAT rule for the IP address, without port specification, and place it after the port translation rule.

**Note** For applications that require application inspection for secondary channels (for example, FTP and VoIP), NAT automatically translates the secondary ports.

Following are some other uses of static NAT with port translation.

#### Static NAT with Identity Port Translation

You can simplify external access to internal resources. For example, if you have three separate servers that provide services on different ports (such as FTP, HTTP, and SMTP), you can give external users a single IP address to access those services. You can then configure static NAT with identity port translation to map the single external IP address to the correct IP addresses of the real servers based on the port they are trying to access. You do not need to change the port, because the servers are using the standard ones (21, 80, and 25 respectively).

#### Static NAT with Port Translation for Non-Standard Ports

You can also use static NAT with port translation to translate a well-known port to a non-standard port or vice versa. For example, if inside web servers use port 8080, you can allow outside users to connect to port 80, and then undo translation to the original port 8080. Similarly, to provide extra security, you can tell web users to connect to non-standard port 6785, and then undo translation to port 80.

#### Static Interface NAT with Port Translation

You can configure static NAT to map a real address to an interface address/port combination. For example, if you want to redirect Telnet access for the device's outside interface to an inside host, then you can map the inside host IP address/port 23 to the outside interface address/port 23.

## One-to-Many Static NAT

Typically, you configure static NAT with a one-to-one mapping. However, in some cases, you might want to configure a single real address to several mapped addresses (one-to-many). When you configure one-to-many

static NAT, when the real host initiates traffic, it always uses the first mapped address. However, for traffic initiated to the host, you can initiate traffic to any of the mapped addresses, and they will be untranslated to the single real address.

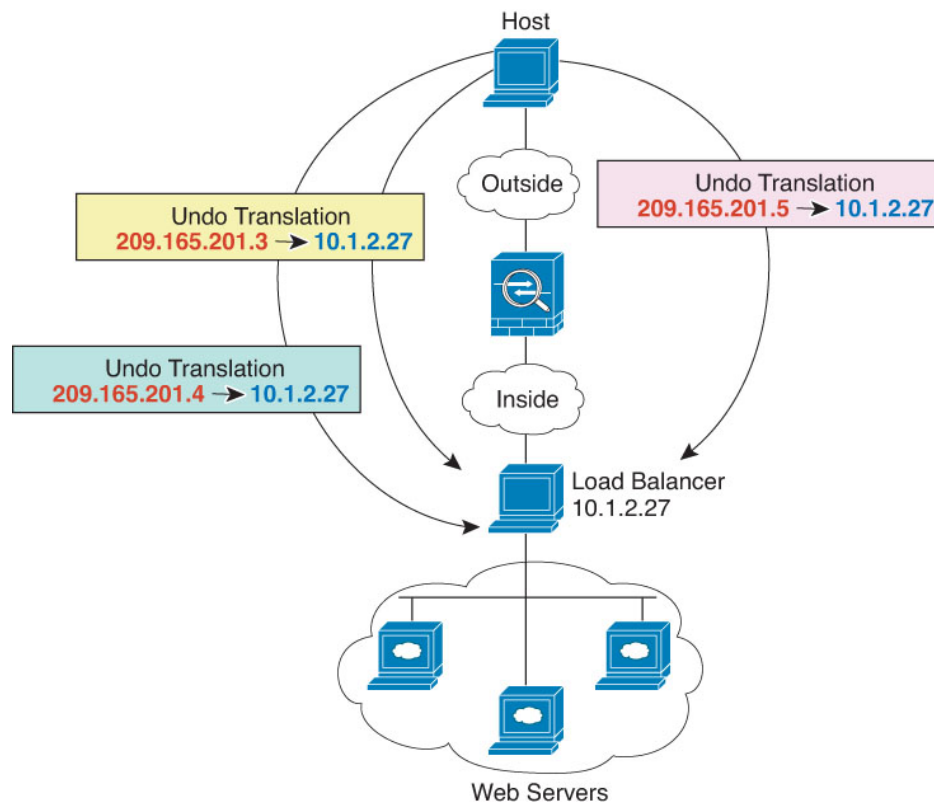

The following figure shows a typical one-to-many static NAT scenario. Because initiation by the real host always uses the first mapped address, the translation of real host IP/first mapped IP is technically the only bidirectional translation.

**Figure 330: One-to-Many Static NAT**

For example, you have a load balancer at 10.1.2.27. Depending on the URL requested, it redirects traffic to the correct web server.

**Figure 331: One-to-Many Static NAT Example**

## Other Mapping Scenarios (Not Recommended)

NAT has the flexibility to allow any kind of static mapping scenario: one-to-one, one-to-many, but also few-to-many, many-to-few, and many-to-one mappings. We recommend using only one-to-one or one-to-many mappings. These other mapping options might result in unintended consequences.

Functionally, few-to-many is the same as one-to-many; but because the configuration is more complicated and the actual mappings may not be obvious at a glance, we recommend creating a one-to-many configuration for each real address that requires it. For example, for a few-to-many scenario, the few real addresses are mapped to the many mapped addresses in order (A to 1, B to 2, C to 3). When all real addresses are mapped, the next mapped address is mapped to the first real address, and so on until all mapped addresses are mapped (A to 4, B to 5, C to 6). This results in multiple mapped addresses for each real address. Just like a one-to-many configuration, only the first mappings are bidirectional; subsequent mappings allow traffic to be initiated *to* the real host, but all traffic *from* the real host uses only the first mapped address for the source.

The following figure shows a typical few-to-many static NAT scenario.

**Figure 332: Few-to-Many Static NAT**

For a many-to-few or many-to-one configuration, where you have more real addresses than mapped addresses, you run out of mapped addresses before you run out of real addresses. Only the mappings between the lowest real IP addresses and the mapped pool result in bidirectional initiation. The remaining higher real addresses can initiate traffic, but traffic cannot be initiated to them (returning traffic for a connection is directed to the correct real address because of the unique 5-tuple (source IP, destination IP, source port, destination port, protocol) for the connection).

**Note** Many-to-few or many-to-one NAT is not PAT. If two real hosts use the same source port number and go to the same outside server and the same TCP destination port, and both hosts are translated to the same IP address, then both connections will be reset because of an address conflict (the 5-tuple is not unique).

The following figure shows a typical many-to-few static NAT scenario.

**Figure 333: Many-to-Few Static NAT**

Instead of using a static rule this way, we suggest that you create a one-to-one rule for the traffic that needs bidirectional initiation, and then create a dynamic rule for the rest of your addresses.

## Configure Static Auto NAT

Use static auto NAT rules to translate addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

### Before you begin

Select **Objects** > **Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
  - **Address**—Create a network object or group containing hosts, ranges, or subnets. A group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

### Procedure

---

**Step 1** Select **Devices** > **NAT** and create or edit the threat defense NAT policy.

**Step 2** Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3** Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

**Step 4** On **Interface Objects**, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

**Step 5** On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- (Optional.) **Original Port, Translated Port**—If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary.

**Step 6** (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see [Rewriting DNS Queries and Responses Using NAT, on page 1233](#). This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

**Step 7** Click **Save** to add the rule.

**Step 8** Click **Save** on the NAT page to save your changes.

## Configure Static Manual NAT

Use static manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Static NAT translates addresses to different IP addresses that are routable on the destination network. You can also do port translation with the static NAT rule.

### Before you begin

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—You have the following options to specify the translated address:
  - **Destination Interface**—To use the destination interface address, you do not need a network object. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
  - **Address**—Create a network object or group containing hosts, range, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports.

### Procedure

---

**Step 1** Select **Devices > NAT** and create or edit the threat defense NAT policy.

**Step 2** Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3** Configure the basic rule options:

- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

**Step 4** On **Interface Objects**, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic

exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

**Step 5** (On the **Translation** page.) Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Step 6** Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

**Step 7** (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port, Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port, Translated Destination Port**—Defines a port translation for the destination address.

**Step 8** (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see [Rewriting DNS Queries and Responses Using NAT, on page 1233](#). This option is not available if you are doing port translation.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Net to Net Mapping**—For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

**Step 9** Click **Save** to add the rule.

**Step 10** Click **Save** on the NAT page to save your changes.

## Identity NAT

You might have a NAT configuration in which you need to translate an IP address to itself. For example, if you create a broad rule that applies NAT to every network, but want to exclude one network from NAT, you can create a static NAT rule to translate an address to itself.

The following figure shows a typical identity NAT scenario.

Figure 334: Identity NAT

The following topics explain how to configure identity NAT.

## Configure Identity Auto NAT

Use static identity auto NAT rules to prevent the translation of an address. That is, to translate the address to itself.

### Before you begin

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Alternatively, you can create the objects while defining the NAT rule. The objects must meet the following requirements:

- **Original Source**—This must be a network object (not a group), and it can be a host, range, or subnet.
- **Translated Source**—A network object or group with the exact same contents as the original source object. You can use the same object.

### Procedure

**Step 1** Select **Devices > NAT** and create or edit the threat defense NAT policy.

**Step 2** Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3** Configure the basic rule options:

- **NAT Rule**—Select **Auto NAT Rule**.
- **Type**—Select **Static**.

**Step 4** On **Interface Objects**, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

**Step 5** On **Translation**, configure the following options:

- **Original Source**—The network object that contains the addresses you are translating.
- **Translated Source**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

Do not configure the **Original Port** and **Translated Port** options for identity NAT.

**Step 6** (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Do not configure this option for identity NAT.
- **Net to Net Mapping**—Do not configure this option for identity NAT.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

**Step 7** Click **Save** to add the rule.

**Step 8** Click **Save** on the NAT page to save your changes.

---

## Configure Identity Manual NAT

Use static identity manual NAT rules when auto NAT does not meet your needs. For example, if you want to do different translations based on the destination. Use static identity NAT rules to prevent the translation of an address. That is, to translate the address to itself.

### Before you begin

Select **Objects > Object Management** and create the network objects or groups needed in the rule. Groups cannot contain both IPv4 and IPv6 addresses; they must contain one type only. Alternatively, you can create the objects while defining the NAT rule. The objects must also meet the following requirements:

- **Original Source**—This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can skip this step and specify **Any** in the rule.
- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.

You can also create network objects or groups for the **Original Destination** and **Translated Destination** if you are configuring a static translation for those addresses in the rule. If you want to configure destination static interface NAT with port translation only, you can skip adding an object for the destination mapped addresses and specify the interface in the rule.

You can also perform port translation on the source, destination, or both. In the Object Manager, ensure that there are port objects you can use for the original and translated ports. You can use the same object for identity NAT.

## Procedure

**Step 1** Select **Devices > NAT** and create or edit the threat defense NAT policy.

**Step 2** Do one of the following:

- Click the **Add Rule** button to create a new rule.
- Click **Edit** (✎) to edit an existing rule.

The right click menu also has options to cut, copy, paste, insert, and delete rules.

**Step 3** Configure the basic rule options:

- **NAT Rule**—Select **Manual NAT Rule**.
- **Type**—Select **Static**. This setting only applies to the source address. If you define a translation for the destination address, the translation is always static.
- **Enable**—Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page.
- **Insert**—Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

**Step 4** On **Interface Objects**, configure the following options:

- **Source Interface Objects, Destination Interface Objects**—(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

**Step 5** Identify the original packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear in the original packet.

See the following figure for an example of the original packet vs. the translated packet where you perform identity NAT on the inside host but translate the outside host.

- **Original Source**—The network object or group that contains the addresses you are translating.
- **Original Destination**—(Optional.) The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If

you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Interface Object** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

**Step 6** Identify the translated packet addresses, either IPv4 or IPv6; namely, the packet addresses as they appear on the destination interface network. You can translate between IPv4 and IPv6 if desired.

- **Translated Source**—The same object or group as the original source. Optionally, you can select a different object that has the exact same contents.
- **Translated Destination**—(Optional.) The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

**Step 7** (Optional.) Identify the source or destination service ports for service translation.

If you are configuring static NAT with port translation, you can translate ports for the source, destination, or both. For example, you can translate between TCP/80 and TCP/8080.

NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

- **Original Source Port, Translated Source Port**—Defines a port translation for the source address.
- **Original Destination Port, Translated Destination Port**—Defines a port translation for the destination address.

**Step 8** (Optional.) On **Advanced**, select the desired options:

- **Translate DNS replies that match this rule**—Do not configure this option for identity NAT.
- **IPv6**—Whether to use the IPv6 address of the destination interface for interface PAT.
- **Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.
- **Perform Route Lookup for Destination Interface**— If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.
- **Unidirectional**—Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

**Step 9** Click **Save** to add the rule.

**Step 10** Click **Save** on the NAT page to save your changes.

## NAT Rule Properties for Threat Defense

Use Network Address Translation (NAT) rules to translate IP addresses to other IP addresses. You would typically use NAT rules to convert private addresses to publicly routable addresses. The translation can be from one address to another, or you can use Port Address Translation (PAT) to translate many addresses to one or a few addresses, using port numbers to distinguish among the source addresses.

NAT rules include the following basic properties. The properties are the same for auto NAT and manual NAT rules except where indicated.

### NAT Type

Whether you want to configure a **Manual NAT Rule** or an **Auto NAT Rule**. Auto NAT translates the source address only, and you cannot make different translations based on the destination address. Because auto NAT is more simple to configure, use it unless you need the added features of manual NAT. For more information on the differences, see [Auto NAT and Manual NAT, on page 1137](#).

### Type

Whether the translation rule is **Dynamic** or **Static**. Dynamic translation automatically chooses the mapped address from a pool of addresses, or an address/port combination when implementing PAT. Use static translation if you want to precisely define the mapped address/port.

### Enable (Manual NAT only.)

Whether you want the rule to be active. You can later activate or deactivate the rule using the right-click menu on the rules page. You cannot disable auto NAT rules.

### Insert (Manual NAT only.)

Where you want to add the rule. You can insert it in a category (before or after auto NAT rules), or above or below the rule number you specify.

### Description (Optional. Manual NAT only.)

A description of the purpose of the rule.

The following topics describe the tabs for the NAT rules properties.

## Interface Objects NAT Properties

Interface objects (security zones or interface groups) define the interfaces to which a NAT rule applies. In routed mode, you can use the default "any" for both source and destination to apply to all interfaces of all assigned devices. However, you typically want to select specific source and destination interfaces.

### Notes

- The concept of "any" interface does not apply to bridge group member interfaces. When you specify "any" interface, all bridge group member interfaces are excluded. Thus, to apply NAT to bridge group members, you must specify the member interface. You cannot configure NAT for the Bridge Virtual Interface (BVI) itself, you can configure NAT for member interfaces only.

If you select interface objects, a NAT rule will be configured on an assigned device only if the device has interfaces included in all selected objects. For example, if you select both source and destination security zones, both zones must contain one or more interface for a given device.

- If more than one interface in an interface object exists on a given device, identical rules are created for each interface. This can become an issue for static NAT rules that include destination translation. Because NAT rules are applied based on first hit rule, only the rule created for the first interface configured for

the object matches traffic. When configuring static NAT with destination translation, use interface objects that include at most one interface per device assigned to the NAT policy to ensure you are getting the desired results.

### Source Interface Objects, Destination Interface Objects

(Required for bridge group member interfaces.) The interface objects (security zones or interface groups) that identify the interfaces where this NAT rule applies. **Source** is the object containing the real interface, the one through which the traffic enters the device. **Destination** is the object containing the mapped interface, the one through which traffic exits the device. By default, the rule applies to all interfaces (**Any**) except for bridge group member interfaces.

## Translation Properties for Auto NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to auto NAT only.

### Original Source (Always required.)

The network object that contains the addresses you are translating. This must be a network object (not a group), and it can be a host, range, or subnet.

You cannot create auto NAT rules for the system-defined any-ipv4 or any-ipv6 objects.

### Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.

- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

#### Original Port, Translated Port (Static NAT only.)

If you need to translate a TCP or UDP port, select the protocol in **Original Port**, and type the original and translated port numbers. For example, you can translate TCP/80 to 8080 if necessary. Do not configure these options for identity NAT.

## Translation Properties for Manual NAT

Use the **Translation** options to define the source addresses and the mapped translated addresses. The following properties apply to manual NAT only. All are optional except as indicated.

#### Original Source (Always required.)

The network object or group that contains the addresses you are translating. This can be a network object or group, and it can contain a host, range, or subnet. If you want to translate all original source traffic, you can specify **Any** in the rule.

#### Translated Source (Usually required.)

The mapped addresses, the ones to which you are translating. What you select here depends on the type of translation rule you are defining.

- **Dynamic NAT**—The network object or group that contains the mapped addresses. This can be a network object or group, but it cannot include a subnet. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only. If a group contains both ranges and host IP addresses, then the ranges are used for dynamic NAT, and then the host IP addresses are used as a PAT fallback.
- **Dynamic PAT**—One of the following:
  - (Interface PAT.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on **Advanced**. Do not configure a PAT pool.
  - To use a single address other than the destination interface address, select the host network object you created for this purpose. Do not configure a PAT pool.
  - To use a PAT pool, leave **Translated Source** empty. Select the PAT pool object on **PAT Pool**.
- **Static NAT**—One of the following:
  - To use a set group of addresses, select **Address** and the network object or group that contains the mapped addresses. The object or group can contain hosts, ranges, or subnets. Typically, you configure the same number of mapped addresses as real addresses for a one-to-one mapping. You can, however, have a mismatched number of addresses.
  - (Static interface NAT with port translation.) To use the address of the destination interface, select **Destination Interface IP**. You must also select a specific destination interface object. To use the IPv6 address of the interface, you must also select the **IPv6** option on the **Advanced** tab. This configures static interface NAT with port translation: the source address/port is translated to the interface's address and the same port number.
- **Identity NAT**—The same object as the original source. Optionally, you can select a different object that has the exact same contents.

### Original Destination

The network object or group that contains the addresses of the destinations. If you leave this blank, the source address translation applies regardless of destination. If you do specify the destination address, you can configure a static translation for that address or just use identity NAT for it.

You can select **Source Interface IP** to base the original destination on the source interface (which cannot be Any). If you select this option, you must also select a translated destination object. To implement a static interface NAT with port translation for the destination addresses, select this option and also select the appropriate port objects for the destination ports.

### Translated Destination

The network object or group that contains the destination addresses used in the translated packet. If you selected an object for **Original Destination**, you can set up identity NAT (that is, no translation) by selecting the same object.

You can use a network object that specifies a fully-qualified domain name as the translated destination; for more information, see [FQDN Destination Guidelines, on page 1146](#).

### Original Source Port, Translated Source Port, Original Destination Port, Translated Destination Port

The port objects that define the source and destination services for the original and translated packets. You can translate the ports, or select the same object to make the rule sensitive to the service without translating the ports. Keep the following rules in mind when configuring services:

- (Dynamic NAT or PAT.) You cannot do translation on the **Original Source Port** and **Translated Source Port**. You can do translation on the destination port only.
- NAT only supports TCP or UDP. When translating a port, be sure the protocols in the real and mapped service objects are identical (both TCP or both UDP). For identity NAT, you can use the same service object for both the real and mapped ports.

## PAT Pool NAT Properties

When you configure dynamic NAT, you can define a pool of addresses to use for Port Address Translation using the properties on the **PAT Pool** tab.

### Enable PAT Pool

Select this option to configure a pool of addresses for PAT.

### PAT

The addresses to use for the PAT pool, one of the following:

- **Address**—The object that defines the PAT pool addresses, either a network object that includes a range, or a network object group that contains hosts, ranges, or both. You cannot include subnets. The group cannot contain both IPv4 and IPv6 addresses; it must contain one type only.
- **Destination Interface IP**—Indicates that you want to use the destination interface as the PAT address. For this option, you must select a specific **Destination Interface Object**; you cannot use **Any** as the destination interface. This is another way to implement interface PAT.

### Round Robin

To assign addresses/ports in a round-robin fashion. By default without round robin, all ports for a PAT address will be allocated before the next PAT address is used. The round-robin method assigns one

address/port from each PAT address in the pool before returning to use the first address again, and then the second address, and so on.

### Extended PAT Table

To use extended PAT. Extended PAT uses 65535 ports per *service*, as opposed to per IP address, by including the destination address and port in the translation information. Normally, the destination port and address are not considered when creating PAT translations, so you are limited to 65535 ports per PAT address. For example, with extended PAT, you can create a translation of 10.1.1.1:1027 when going to 192.168.1.7:23 as well as a translation of 10.1.1.1:1027 when going to 192.168.1.7:80. You cannot use this option with interface PAT or interface PAT fallback.

### Flat Port Range; Include Reserved Ports

To use the 1024 to 65535 port range as a single flat range when allocating TCP/UDP ports. (Pre-6.7) When choosing the mapped port number for a translation, PAT uses the real source port number if it is available. However, without this option, if the real port is *not* available, by default the mapped ports are chosen from the same range of ports as the real port number: 1 to 511, 512 to 1023, and 1024 to 65535. To avoid running out of ports at the low ranges, configure this setting. To use the entire range of 1 to 65535, also check the **Include Reserved Ports** option. For the threat defense devices running version 6.7 or higher, the flat port range is always configured, whether you select the option or not. You can still select the **Include Reserved Ports** option for these systems, and that setting is honored.

### Block Allocation

To enable port block allocation. For carrier-grade or large-scale PAT, you can allocate a block of ports for each host, rather than have NAT allocate one port translation at a time. If you allocate a block of ports, subsequent connections from the host use new randomly selected ports within the block. If necessary, additional blocks are allocated if the host has active connections for all ports in the original block. Port blocks are allocated in the 1024-65535 range only. Port block allocation is compatible with round robin, but you cannot use it with the extended PAT or flat port range options. You also cannot use interface PAT fallback.

## Advanced NAT Properties

When you configure NAT, you can configure properties that provide specialized services in the **Advanced** options. All of these properties are optional: configure them only if you need the service.

### Translate DNS replies that match this rule

Whether to translate the IP address in DNS replies. For DNS replies traversing from a mapped interface to a real interface, the Address (the IPv4 A or IPv6 AAAA) record is rewritten from the mapped value to the real value. Conversely, for DNS replies traversing from a real interface to a mapped interface, the record is rewritten from the real value to the mapped value. This option is used in specific circumstances, and is sometimes needed for NAT64/46 translation, where the rewrite also converts between A and AAAA records. For more information, see [Rewriting DNS Queries and Responses Using NAT, on page 1233](#). This option is not available if you are doing port translation in a static NAT rule.

### Fallthrough to Interface PAT (Destination Interface) (Dynamic NAT only.)

Whether to use the IP address of the destination interface as a backup method when the other mapped addresses are already allocated (interface PAT fallback). This option is available only if you select a destination interface that is not a member of a bridge group. To use the IPv6 address of the interface, also check the **IPv6** option. You cannot select this option if you already configured interface PAT as the translated address. You also cannot select the option if you configure a PAT pool.

## IPv6

Whether to use the IPv6 address of the destination interface for interface PAT.

### Net to Net Mapping (Static NAT only.)

For NAT 46, select this option to translate the first IPv4 address to the first IPv6 address, the second to the second, and so on. Without this option, the IPv4-embedded method is used. For a one-to-one translation, you must use this option.

### Do not proxy ARP on Destination Interface (Static NAT only.)

Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router. Normally for identity NAT, proxy ARP is not required, and in some cases can cause connectivity issues.

### Perform Route Lookup for Destination Interface (Static Identity NAT only. Routed mode only.)

If you select source and destination interfaces when selecting the same object for original and translated source address, you can select this option to have the system determine the destination interface based on the routing table rather than using the destination interface configured in the NAT rule.

### Unidirectional (Manual NAT only, static NAT only.)

Select this option to prevent the destination addresses from initiating traffic to the source addresses. The unidirectional option is mainly useful for testing purposes and might not work with all protocols. For example, SIP requires protocol inspection to translate SIP headers using NAT, but this will not occur if you make the translation unidirectional.

# Translating IPv6 Networks

In cases where you need to pass traffic between IPv6-only and IPv4-only networks, you need to use NAT to convert between the address types. Even with two IPv6 networks, you might want to hide internal addresses from the outside network.

You can use the following translation types with IPv6 networks:

- NAT64, NAT46—Translates IPv6 packets into IPv4 and vice versa. You need to define two policies, one for the IPv6 to IPv4 translation, and one for the IPv4 to IPv6 translation. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

---

**Note** NAT46 supports static mappings only.

---

- NAT66—Translates IPv6 packets to a different IPv6 address. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

**Note** NAT64 and NAT 46 are possible on standard routed interfaces only. NAT66 is possible on both routed and bridge group member interfaces.

## NAT64/46: Translating IPv6 Addresses to IPv4

When traffic goes from an IPv6 network to an IPv4-only network, you need to convert the IPv6 address to IPv4, and return traffic from IPv4 to IPv6. You need to define two address pools, an IPv4 address pool to bind IPv6 addresses in the IPv4 network, and an IPv6 address pool to bind IPv4 addresses in the IPv6 network.

- The IPv4 address pool for the NAT64 rule is normally small and typically might not have enough addresses to map one-to-one with the IPv6 client addresses. Dynamic PAT might more easily meet the possible large number of IPv6 client addresses compared to dynamic or static NAT.
- The IPv6 address pool for the NAT46 rule can be equal to or larger than the number of IPv4 addresses to be mapped. This allows each IPv4 address to be mapped to a different IPv6 address. NAT46 supports static mappings only, so you cannot use dynamic PAT.

You need to define two policies, one for the source IPv6 network, and one for the destination IPv4 network. Although you can accomplish this with a single manual NAT rule, if the DNS server is on the external network, you probably need to rewrite the DNS response. Because you cannot enable DNS rewrite on a manual NAT rule when you specify a destination, creating two auto NAT rules is the better solution.

### NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet

Following is a straight-forward example where you have an inside IPv6-only network, and you want to convert to IPv4 for traffic sent to the Internet. This example assumes you do not need DNS translation, so you can perform both the NAT64 and NAT46 translations in a single manual NAT rule.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network.

## Procedure

**Step 1** Create the network object that defines the inside IPv6 network.

- Choose **Objects > Object Management**.
- Select **Network** from the table of contents and click **Add Network > Add Object**.
- Define the inside IPv6 network.

Name the network object (for example, `inside_v6`) and enter the network address, `2001:db8::/96`.

### New Network Object

Name

Description

Network

Host  Range  Network  FQDN

Allow Overrides

- Click **Save**.

**Step 2** Create the manual NAT rule to translate the IPv6 network to IPv4 and back again.

- Select **Devices > NAT** and create or edit the threat defense NAT policy.
- Click **Add Rule**.
- Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

- On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

- On **Translation**, configure the following:

- **Original Source** = `inside_v6` network object.
- **Translated Source** = **Destination Interface IP**.
- **Original Destination** = `inside_v6` network object.

- **Translated Destination** = any-ipv4 network object.

## Add NAT Rule

| Original Packet                                                                  | Translated Packet                                                                                                                                        |
|----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Original Source:*                                                                | Translated Source:                                                                                                                                       |
| <input type="text" value="inside_v6"/> +                                         | <input type="text" value="Destination Interface IP"/><br>ⓘ The values selected for Destination Interface Objects in 'Interface Objects' tab will be used |
| Original Destination:                                                            | Translated Destination:                                                                                                                                  |
| <input type="text" value="Address"/><br><input type="text" value="inside_v6"/> + | <input type="text" value="any-ipv4"/> +                                                                                                                  |

- f) Click **OK**.

With this rule, any traffic from the 2001:db8::/96 subnet on the inside interface going to the outside interface gets a NAT64 PAT translation using the IPv4 address of the outside interface. Conversely, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method.

- g) Click **Save** on the NAT rules page.

## NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet and DNS Translation

Following is a typical example where you have an inside IPv6-only network, but there are some IPv4-only services on the outside Internet that internal users need.

In this example, you translate the inside IPv6 network to IPv4 using dynamic interface PAT with the IP address of the outside interface. Outside IPv4 traffic is statically translated to addresses on the 2001:db8::/96 network, allowing transmission on the inside network. You enable DNS rewrite on the NAT46 rule, so that replies from the external DNS server can be converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

Following is a typical sequence for a web request where a client at 2001:DB8::100 on the internal IPv6 network tries to open www.example.com.

- The client's computer sends a DNS request to the DNS server at 2001:DB8::D1A5:CA81. The NAT rules make the following translations to the source and destination in the DNS request:
  - 2001:DB8::100 to a unique port on 209.165.201.1 (The NAT64 interface PAT rule.)
  - 2001:DB8::D1A5:CA81 to 209.165.202.129 (The NAT46 rule. D1A5:CA81 is the IPv6 equivalent of 209.165.202.129.)
- The DNS server responds with an A record indicating that www.example.com is at 209.165.200.225. The NAT46 rule, with DNS rewrite enabled, converts the A record to the IPv6-equivalent AAAA record, and translates 209.165.200.225 to 2001:db8:D1A5:C8E1 in the AAAA record. In addition, the source and destination addresses in the DNS response are untranslated:
  - 209.165.202.129 to 2001:DB8::D1A5:CA81
  - 209.165.201.1 to 2001:db8::100
- The IPv6 client now has the IP address of the web server, and makes an HTTP request to www.example.com at 2001:db8:D1A5:C8E1. (D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225.) The source and destination of the HTTP request are translated:
  - 2001:DB8::100 to a unique port on 209.156.101.54 (The NAT64 interface PAT rule.)
  - 2001:db8:D1A5:C8E1 to 209.165.200.225 (The NAT46 rule.)

The following procedure explains how to configure this example.

### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

## Procedure

**Step 1** Create the network objects that define the inside IPv6 and outside IPv4 networks.

- Choose **Objects > Object Management**.
- Select **Network** from the table of contents and click **Add Network > Add Object**.
- Define the inside IPv6 network.

Name the network object (for example, `inside_v6`) and enter the network address, `2001:db8::/96`.

### New Network Object

Name

Description

Network

Host  Range  Network  FQDN

Allow Overrides

- Click **Save**.
- Click **Add Network > Add Object** and define the outside IPv4 network.

Name the network object (for example, `outside_v4_any`) and enter the network address `0.0.0.0/0`.

## New Network Object

Name

Description

Network

Host  Range  Network  FQDN

Allow Overrides

f) Click **Save**.

**Step 2** Configure the NAT64 dynamic PAT rule for the inside IPv6 network.

**Step 3** Configure the static NAT46 rule for the outside IPv4 network.

a) Click **Add Rule**.

b) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

c) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

d) On **Translation**, configure the following:

- **Original Source** = outside\_v4\_any network object.
- **Translated Source > Address** = inside\_v6 network object.

e) On **Advanced**, select **Translate DNS replies that match this rule**.

## Add NAT Rule

NAT Rule:

Type:

Enable

Interface Objects   Translation   PAT Pool   Advanced

| Original Packet                               | Translated Packet                      |
|-----------------------------------------------|----------------------------------------|
| Original Source:*                             | Translated Source:                     |
| <input type="text" value="outside_v4_any"/> + | <input type="text" value="Address"/> + |
| Original Port:                                | Translated Port:                       |
| <input type="text" value="TCP"/>              | <input type="text" value="inside_v6"/> |
| <input type="text"/>                          | <input type="text"/>                   |

f) Click **OK**.

With this rule, any IPv4 address on the outside network coming to the inside interface is translated to an address on the 2001:db8::/96 network using the embedded IPv4 address method. In addition, DNS responses are converted from A (IPv4) to AAAA (IPv6) records, and the addresses converted from IPv4 to IPv6.

## NAT66: Translating IPv6 Addresses to Different IPv6 Addresses

When going from an IPv6 network to another IPv6 network, you can translate the addresses to different IPv6 addresses on the outside network. We recommend using static NAT. Although you can use dynamic NAT or PAT, IPv6 addresses are in such large supply, you do not have to use dynamic NAT.

Because you are not translating between different address types, you need a single rule for NAT66 translations. You can easily model these rules using auto NAT. However, if you do not want to allow returning traffic, you can make the static NAT rule unidirectional using manual NAT only.

### NAT66 Example, Static Translation between Networks

You can configure a static translation between IPv6 address pools using auto NAT. The following example explains how to convert inside addresses on the 2001:db8:122:2091::/96 network to outside addresses on the 2001:db8:122:2999::/96 network.

### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

### Procedure

- 
- Step 1** Create the network objects that define the inside IPv6 and outside IPv6 NAT networks.
- Choose **Objects > Object Management**.
  - Select **Network** from the table of contents and click **Add Network > Add Object**.
  - Define the inside IPv6 network.
 

Name the network object (for example, `inside_v6`) and enter the network address, `2001:db8:122:2091::/96`.

## New Network Object

Name

inside\_v6

Description

Network

 Host
  Range
  Network
  FQDN

2001:db8:122:2091::/96

 Allow Overrides

- d) Click **Save**.
- e) Click **Add Network** > **Add Object** and define the outside IPv6 NAT network.

Name the network object (for example, outside\_nat\_v6) and enter the network address 2001:db8:122:2999::/96.

## New Network Object

Name

outside\_nat\_v6

Description

Network

 Host
  Range
  Network
  FQDN

2001:db8:122:2999::/96

 Allow Overrides

- f) Click **Save**.

**Step 2**

Configure the static NAT rule for the inside IPv6 network.

- Select **Devices** > **NAT** and create or edit the threat defense NAT policy.
- Click **Add Rule**.
- Configure the following properties:
  - **NAT Rule** = Auto NAT Rule.
  - **Type** = Static.

- d) On **Interface Objects**, configure the following:
- **Source Interface Objects** = inside.
  - **Destination Interface Objects** = outside.
- e) On **Translation**, configure the following:
- **Original Source** = inside\_v6 network object.
  - **Translated Source > Address** = outside\_nat\_v6 network object.

### Add NAT Rule

NAT Rule:

Type:

Enable

Interface Objects   Translation   PAT Pool   Advanced

| Original Packet                        |   | Translated Packet                           |
|----------------------------------------|---|---------------------------------------------|
| Original Source:*                      |   | Translated Source:                          |
| <input type="text" value="inside_v6"/> | + | <input type="text" value="Address"/>        |
| Original Port:                         |   | <input type="text" value="outside_nat_v6"/> |
| <input type="text" value="TCP"/>       |   | Translated Port:                            |
| <input type="text"/>                   |   | <input type="text"/>                        |

- f) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a static NAT66 translation to an address on the 2001:db8:122:2999::/96 network.

## NAT66 Example, Simple IPv6 Interface PAT

A simple approach for implementing NAT66 is to dynamically assign internal addresses to different ports on the outside interface IPv6 address.

When you configure an interface PAT rule for NAT66, all the global addresses that are configured on that interface are used for PAT mapping. Link-local or site-local addresses for the interface are not used for PAT.

### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

### Procedure

**Step 1** Create the network object that defines the inside IPv6 network.

- Choose **Objects > Object Management**.
- Select **Network** from the table of contents and click **Add Network > Add Object**.
- Define the inside IPv6 network.

Name the network object (for example, `inside_v6`) and enter the network address, `2001:db8:122:2091::/96`.

## New Network Object

Name

Description

Network

Host  Range  Network  FQDN

Allow Overrides

d) Click **Save**.

### Step 2

Configure the dynamic PAT rule for the inside IPv6 network.

- a) Select **Devices > NAT** and create or edit the threat defense NAT policy.
- b) Click **Add Rule**.
- c) Configure the following properties:
  - **NAT Rule** = Auto NAT Rule.
  - **Type** = Dynamic.
- d) On **Interface Objects**, configure the following:
  - **Source Interface Objects** = inside.
  - **Destination Interface Objects** = outside.
- e) On **Translation**, configure the following:

- **Original Source** = inside\_v6 network object.
- **Translated Source** = **Destination Interface IP**.

f) On **Advanced**, select **IPv6**, which indicates that the IPv6 address of the destination interface should be used.

## Add NAT Rule

NAT Rule:

Type:

Enable

Interface Objects   **Translation**   PAT Pool   Advanced

---

Original Packet

Original Source:\*

 +

Original Port:

Translated Packet

Translated Source:

**i** The values selected for Destination Interface Objects in 'Interface Objects' tab will be used

Translated Port:

g) Click **OK**.

With this rule, any traffic from the 2001:db8:122:2091::/96 subnet on the inside interface going to the outside interface gets a NAT66 PAT translation to one of the IPv6 global addresses configured for the outside interface.

## Monitoring NAT

To monitor and troubleshoot NAT connections, log into the device CLI and use the following commands.

- **show nat** displays the NAT rules and per-rule hit counts. There are additional keywords to show other aspects of NAT.
- **show xlate** displays the actual NAT translations that are currently active.
- **clear xlate** lets you remove an active NAT translation. You might need to remove active translations if you alter NAT rules, because existing connections continue to use the old translation slot until the

connection ends. Clearing a translation allows the system to build a new translation for a client on the client's next connection attempt based on your new rules.

## Examples for NAT

The following topics provide examples for configuring NAT on Threat Defense devices.

### Providing Access to an Inside Web Server (Static Auto NAT)

The following example performs static NAT for an inside web server. The real address is on a private network, so a public address is required. Static NAT is necessary so hosts can initiate traffic to the web server at a fixed address.

*Figure 335: Static NAT for an Inside Web Server*

#### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

#### Procedure

- Step 1** Create the network objects that define the server's private and public host addresses.
- Choose **Objects > Object Management**.

- b) Select **Network** from the table of contents and click **Add Network > Add Object**.
- c) Define the web server's private address.

Name the network object (for example, WebServerPrivate) and enter the real host IP address, 10.1.2.27.

### New Network Object

Name

Description

Network

Host  Range  Network  FQDN

► Override (0)

- d) Click **Save**.
- e) Click **Add Network > Add Object** and define the public address.

Name the network object (for example, WebServerPublic) and enter the host address 209.165.201.10.

### New Network Object

Name

Description

Network

Host  Range  Network  FQDN

Allow Overrides

► Override (0)

- f) Click **Save**.

**Step 2** Configure static NAT for the object.

- a) Select **Devices > NAT** and create or edit the threat defense NAT policy.
- b) Click **Add Rule**.
- c) Configure the following properties:
  - **NAT Rule** = Auto NAT Rule.
  - **Type** = Static.
- d) On **Interface Objects**, configure the following:
  - **Source Interface Objects** = inside.
  - **Destination Interface Objects** = outside.
- e) On **Translation**, configure the following:
  - **Original Source** = WebServerPrivate network object.
  - **Translated Source > Address** = WebServerPublic network object.

### Add NAT Rule

NAT Rule:

Type:

Enable

Interface Objects   **Translation**   PAT Pool   Advanced

| Original Packet                                                      | Translated Packet                                            |
|----------------------------------------------------------------------|--------------------------------------------------------------|
| Original Source:*<br><input type="text" value="WebServerPrivate"/> + | Translated Source:<br><input type="text" value="Address"/> + |
| Original Port:<br><input type="text" value="TCP"/>                   | Translated Port:<br><input type="text"/>                     |

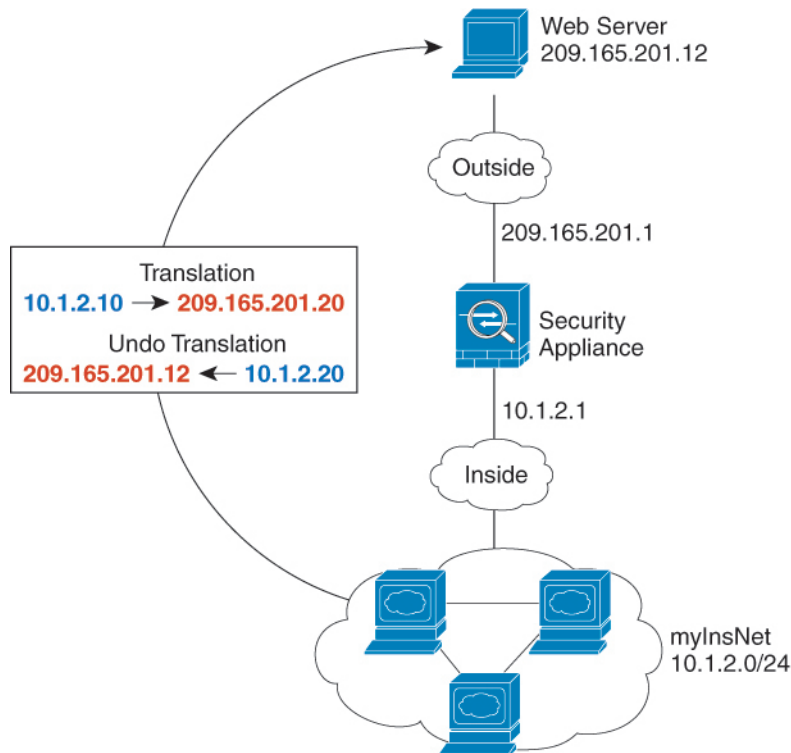

- f) Click **Save**.

**Step 3** Click **Save** on the NAT rule page.

## Dynamic Auto NAT for Inside Hosts and Static NAT for an Outside Web Server

The following example configures dynamic NAT for inside users on a private network when they access the outside. Also, when inside users connect to an outside web server, that web server address is translated to an address that appears to be on the inside network.

Figure 336: Dynamic NAT for Inside, Static NAT for Outside Web Server

### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

### Procedure

- Step 1** Create a network object for the dynamic NAT pool to which you want to translate the inside addresses.
- Choose **Objects > Object Management**.
  - Select **Network** from the table of contents and click **Add Network > Add Object**.
  - Define the dynamic NAT pool.

Name the network object (for example, myNATpool) and enter the network range 209.165.201.20-209.165.201.30.

| <input type="text"/>                       | <input type="text"/>                   |

e) Click **Save**.

**Step 7** Click **Save** on the NAT rule page.

## Inside Load Balancer with Multiple Mapped Addresses (Static Auto NAT, One-to-Many)

The following example shows an inside load balancer that is translated to multiple IP addresses. When an outside host accesses one of the mapped IP addresses, it is untranslated to the single load balancer address. Depending on the URL requested, it redirects traffic to the correct web server.

Figure 337: Static NAT with One-to-Many for an Inside Load Balancer

### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the web server. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

### Procedure

- Step 1** Create a network object for the addresses to which you want to map the load balancer.
- Choose **Objects > Object Management**.
  - Select **Network** from the table of contents and click **Add Network > Add Object**.
  - Define the addresses.

Name the network object (for example, myPublicIPs) and enter the network range 209.165.201.3-209.165.201.5.

New Network Object

Name  
myPublicIPs

Description

Network  
 Host  Range  Network  FQDN  
 209.165.201.3-209.165.201.5

Allow Overrides

d) Click **Save**.

## Step 2

Create a network object for the load balancer.

a) Click **Add Network > Add Object**.

b) Name the network object (for example, myLBHost), enter the host address 10.1.2.27.

### New Network Object

Name  
myLBHost

Description

Network  
 Host  Range  Network  FQDN  
 10.1.2.27

Allow Overrides

c) Click **Save**.

## Step 3

Configure static NAT for the load balancer.

a) Select **Devices > NAT** and create or edit the threat defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = outside.

e) On **Translation**, configure the following:

- **Original Source** = myLBHost network object.
- **Translated Source > Address**= myPublicIPs network group.

### Add NAT Rule

NAT Rule:

Type:

Enable

Interface Objects   Translation   PAT Pool   Advanced

|                                                                                                                                                                                      |                                                                                                                                                                                                           |

f) Click **Save**.

**Step 4** Click **Save** on the NAT rule page.

## Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation)

The following static NAT-with-port-translation example provides a single address for remote users to access FTP, HTTP, and SMTP. These servers are actually different devices on the real network, but for each server, you can specify static NAT-with-port-translation rules that use the same mapped IP address, but different ports.

Figure 338: Static NAT-with-Port-Translation

**Before you begin**

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

**Procedure****Step 1**

Create a network object for the FTP server.

- a) Choose **Objects > Object Management**.
- b) Select **Network** from the table of contents and click **Add Network > Add Object**.
- c) Name the network object (for example, FTPserver), and enter the real IP address for the FTP server, 10.1.2.27.

New Network Object

Name  
FTPserver

Description

Network  
 Host  Range  Network  FQDN  
 10.1.2.27

Allow Overrides

d) Click **Save**.

### Step 2

Create a network object for the HTTP server.

- a) Click **Add Network > Add Object**.
- b) Name the network object (for example, HTTPserver), enter the host address 10.1.2.28.

New Network Object

Name  
HTTPserver

Description

Network  
 Host  Range  Network  FQDN  
 10.1.2.28

Allow Overrides

c) Click **Save**.

### Step 3

Create a network object for the SMTP server.

- a) Click **Add Network > Add Object**.
- b) Name the network object (for example, SMTPserver), enter the host address 10.1.2.29.

New Network Object

Name  
SMTPserver

Description

Network  
 Host  Range  Network  FQDN  
 10.1.2.29

Allow Overrides

c) Click **Save**.

### Step 4

Create a network object for the public IP address used for the three servers.

- a) Click **Add Network > Add Object**.
- b) Name the network object (for example, ServerPublicIP) and enter the host address 209.165.201.3.

New Network Object

---

Name

Description

Network  
 Host  Range  Network  FQDN

Allow Overrides

c) Click **Save**.

### Step 5

Configure static NAT with port translation for the FTP server, mapping the FTP port to itself.

- a) Select **Devices > NAT** and create or edit the threat defense NAT policy.
- b) Click **Add Rule**.
- c) Configure the following properties:
  - **NAT Rule** = Auto NAT Rule.
  - **Type** = Static.
- d) On **Interface Objects**, configure the following:
  - **Source Interface Objects** = inside.
  - **Destination Interface Objects** = outside.
- e) On **Translation**, configure the following:
  - **Original Source** = FTPserver network object.
  - **Translated Source > Address** = ServerPublicIP network object.
  - **Original Port > TCP** = 21.
  - **Translated Port** = 21.

Add NAT Rule

NAT Rule:

## Different Translation Depending on the Destination (Dynamic Manual PAT)

The following figure shows a host on the 10.1.2.0/24 network accessing two different servers. When the host accesses the server at 209.165.201.11, the real address is translated to 209.165.202.129:port. When the host accesses the server at 209.165.200.225, the real address is translated to 209.165.202.130:port.

Figure 339: Manual NAT with Different Destination Addresses

**Before you begin**

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

**Procedure**

**Step 1** Create a network object for the inside network.

- Choose **Objects > Object Management**.
- Select **Network** from the table of contents and click **Add Network > Add Object**.
- Name the network object (for example, myInsideNetwork), and enter the real network address, 10.1.2.0/24.

New Network Object

Name  
myInsideNetwork

Description

Network  
 Host  Range  Network  FQDN  
 10.1.2.0/24

Allow Overrides

- Click **Save**.

**Step 2** Create a network object for the DMZ network 1.

- a) Click **Add Network > Add Object**.
- b) Name the network object (for example, DMZnetwork1) and enter the network address 209.165.201.0/27 (subnet mask of 255.255.255.224).

New Network Object

---

Name

Description

Network  
 Host  Range  Network  FQDN

Allow Overrides

- c) Click **Save**.

**Step 3** Create a network object for the PAT address for DMZ network 1.

- a) Click **Add Network > Add Object**.
- b) Name the network object (for example, PATAddress1) and enter the host address 209.165.202.129.

New Network Object

---

Name

Description

Network  
 Host  Range  Network  FQDN

Allow Overrides

- c) Click **Save**.

**Step 4** Create a network object for the DMZ network 2.

- a) Click **Add Network > Add Object**.
- b) Name the network object (for example, DMZnetwork2) and enter the network address 209.165.200.224/27 (subnet mask of 255.255.255.224).

New Network Object

---

Name

Description

Network  
 Host  Range  Network  FQDN

Allow Overrides

- c) Click **Save**.

**Step 5** Create a network object for the PAT address for DMZ network 2.

- a) Click **Add Network > Add Object**.
- b) Name the network object (for example, PATaddress2) and enter the host address 209.165.202.130.

New Network Object

---

Name

Description

Network  
 Host  Range  Network  FQDN

Allow Overrides

- c) Click **Save**.

**Step 6** Configure dynamic manual PAT for DMZ network 1.

- a) Select **Devices > NAT** and create or edit the threat defense NAT policy.
- b) Click **Add Rule**.
- c) Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
- **Type** = Dynamic.

- d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = inside.
- **Destination Interface Objects** = dmz.

- e) On **Translation**, configure the following:

- **Original Source** = myInsideNetwork network object.
- **Translated Source > Address** = PATaddress1 network object.
- **Original Destination > Address** = DMZnetwork1 network object.
- **Translated Destination** = DMZnetwork1 network object.

**Note** Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank.

**Step 8** Click **Save** on the NAT rule page.

## Different Translation Depending on the Destination Address and Port (Dynamic Manual PAT)

The following figure shows the use of source and destination ports. The host on the 10.1.2.0/24 network accesses a single host for both web services and Telnet services. When the host accesses the server for Telnet services, the real address is translated to 209.165.202.129:*port*. When the host accesses the same server for web services, the real address is translated to 209.165.202.130:*port*.

Figure 340: Manual NAT with Different Destination Ports

**Before you begin**

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device that protects the servers. In this example, we will assume the interface objects are security zones named **inside** and **dmz**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

**Procedure**

- Step 1** Create a network object for the inside network.
- Choose **Objects > Object Management**.
  - Select **Network** from the table of contents and click **Add Network > Add Object**.
  - Name the network object (for example, myInsideNetwork) and enter the real network address, 10.1.2.0/24.

New Network Object

- e) Click **Save**.

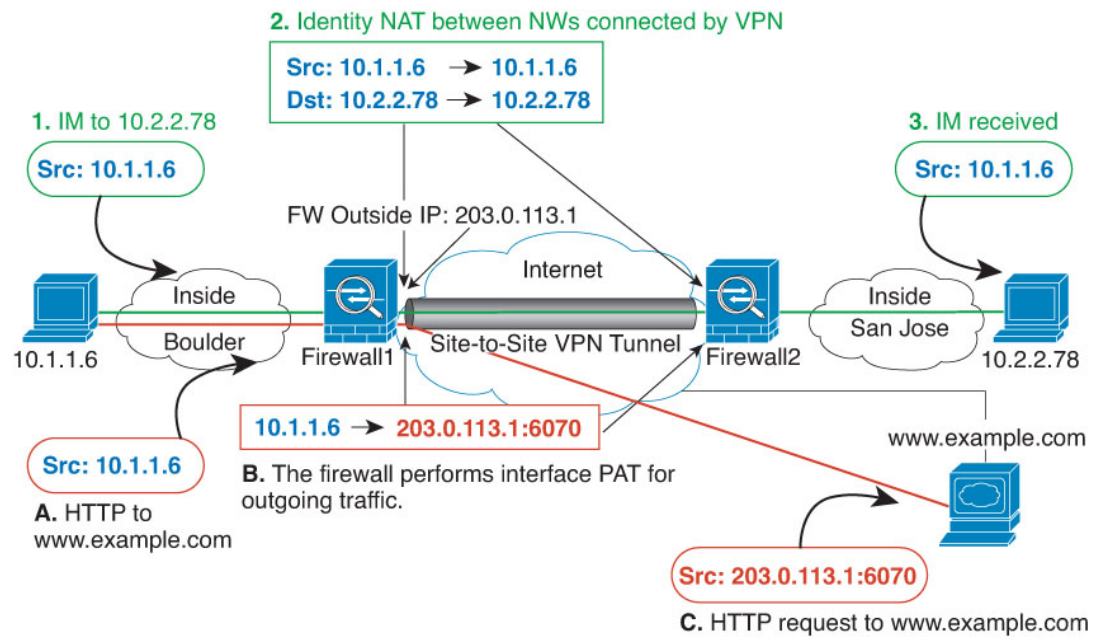

**Step 7** Click **Save** on the NAT rule page.

## NAT and Site-to-Site VPN

When you create a policy-based site-to-site VPN using the management center VPN wizard (**Device > Site To Site**), you can select the NAT Exempt option to create the rules automatically. You can view the NAT exemptions for a device in the NAT policy page (**Device > NAT > NAT Exemptions**). If you do not want to configure NAT Exempt in the VPN wizard, you can use the following procedure for NAT exemption.

The following figure shows a site-to-site tunnel connecting the Boulder and San Jose offices. For traffic that you want to go to the Internet (for example from 10.1.1.6 in Boulder to www.example.com), you need a public IP address provided by NAT to access the Internet. The below example uses interface PAT rules. However, for traffic that you want to go over the VPN tunnel (for example from 10.1.1.6 in Boulder to 10.2.2.78 in San Jose), you do not want to perform NAT; you need to exempt that traffic by creating an identity NAT rule. Identity NAT simply translates an address to the same address.

Figure 341: Interface PAT and Identity NAT for Site-to-Site VPN

The following example explains the configuration for Firewall1 (Boulder).

### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the devices in the VPN. In this example, we will assume the interface objects are security zones named **inside-boulder** and **outside-boulder** for the Firewall1 (Boulder) interfaces. To configure interface objects, select **Objects > Object Management**, then select **Interfaces**.

### Procedure

- Step 1** Create the objects to define the various networks.
- Choose **Objects > Object Management**.
  - Select **Network** from the table of contents and click **Add Network > Add Object**.

- c) Identify the Boulder inside network.

Name the network object (for example, boulder-network) and enter the network address, 10.1.1.0/24.

### New Network Object

Name

Description

Network

Host  Range  Network  FQDN

Allow Overrides

- d) Click **Save**.

- e) Click **Add Network** > **Add Object** and define the inside San Jose network.

Name the network object (for example, sanjose-network) and enter the network address 10.2.2.0/24.

### New Network Object

Name

Description

Network

Host  Range  Network  FQDN

Allow Overrides

- f) Click **Save**.

**Step 2** Configure manual identity NAT for the Boulder network when going over the VPN to San Jose on Firewall1 (Boulder).

- Select **Devices** > **NAT** and create or edit the threat defense NAT policy.
- Click **Add Rule**.
- Configure the following properties:

- **NAT Rule** = Manual NAT Rule.
  - **Type** = Static.
- d) On **Interface Objects**, configure the following:
- **Source Interface Objects** = inside-boulder.
  - **Destination Interface Objects** = outside-boulder.
- e) On **Translation**, configure the following:
- **Original Source** = boulder-network object.
  - **Translated Source > Address** = boulder-network object.
  - **Original Destination > Address** = sanjose-network object.
  - **Translated Destination** = sanjose-network object.
- Note** Because you do not want to translate the destination address, you need to configure identity NAT for it by specifying the same address for the original and translated destination addresses. Leave all of the port fields blank. This rule configures identity NAT for both source and destination.
- f) On **Advanced**, select **Do not proxy ARP on Destination interface**.

## Add NAT Rule

Manual NAT Rule

Insert:  
 In Category: NAT Rules Before

Type:  
Static

Enable

Description:

Interface Objects   **Translation**   PAT Pool   Advanced

| Original Packet                                                                                   | Translated Packet                                                                                       |
|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------|
| Original Source:*<br><span style="border: 1px solid #ccc; padding: 2px;">boulder-network</span> + | Translated Source:<br><span style="border: 1px solid #ccc; padding: 2px;">Address</span>                |
| Original Destination:<br><span style="border: 1px solid #ccc; padding: 2px;">Address</span>       | <span style="border: 1px solid #ccc; padding: 2px;">boulder-network</span> +                            |
| <span style="border: 1px solid #ccc; padding: 2px;">sanjose-network</span> +                      | Translated Destination:<br><span style="border: 1px solid #ccc; padding: 2px;">sanjose-network</span> + |

g) Click **Save**.

**Step 3** Configure manual dynamic interface PAT when going to the Internet for the inside Boulder network on Firewall1 (Boulder).

- a) Click **Add Rule**.
- b) Configure the following properties:
  - **NAT Rule** = Manual NAT Rule.
  - **Type** = Dynamic.
  - **Insert Rule** = any position after the first rule. Because this rule will apply to any destination address, the rule that uses sanjose-network as the destination must come before this rule, or the sanjose-network rule will never be matched. The default is to place new manual NAT rules at the end of the "NAT Rules Before Auto NAT" section.
- c) On **Interface Objects**, configure the following:
  - **Source Interface Objects** = inside-boulder.
  - **Destination Interface Objects** = outside-boulder.
- d) On **Translation**, configure the following:
  - **Original Source** = boulder-network object.

- **Translated Source = Destination Interface IP.** This option configures interface PAT using the interface contained in the destination interface object.
- **Original Destination > Address = any** (leave blank).
- **Translated Destination = any** (leave blank).

## Add NAT Rule

NAT Rule:

Insert:

Type:

Enable

Description:

Interface Objects   **Translation**   PAT Pool   Advanced

|                                                                                                                                                                          |                                                                                                                                                                                                                                            |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>Original Packet</p> <p>Original Source:*<br/> <input type="text" value="boulder-network"/></p> <p>Original Destination:<br/> <input type="text" value="Address"/></p> | <p>Translated Packet</p> <p>Translated Source:<br/> <input type="text" value="Destination Interface IP"/></p> <p><small><b>i</b> The values selected for Destination Interface Objects in 'Interface Objects' tab will be used</small></p> |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

e) Click **Save**.

**Step 4** If you are also managing Firewall2 (San Jose), you can configure similar rules for that device.

- The manual identity NAT rule would be for sanjose-network when the destination is boulder-network. Create new interface objects for the Firewall2 inside and outside networks.
- The manual dynamic interface PAT rule would be for sanjose-network when the destination is "any."

## Rewriting DNS Queries and Responses Using NAT

You might need to configure the threat defense device to modify DNS replies by replacing the address in the reply with an address that matches the NAT configuration. You can configure DNS modification when you configure each translation rule. DNS modification is also known as DNS doctoring.

This feature rewrites the address in DNS queries and replies that match a NAT rule (for example, the A record for IPv4, the AAAA record for IPv6, or the PTR record for reverse DNS queries). For DNS replies traversing from a mapped interface to any other interface, the record is rewritten from the mapped value to the real value. Inversely, for DNS replies traversing from any interface to a mapped interface, the record is rewritten from the real value to the mapped value. This feature works with NAT44, NAT 66, NAT46, and NAT64.

Following are the main circumstances when you would need to configure DNS rewrite on a NAT rule.

- The rule is NAT64 or NAT46, and the DNS server is on the outside network. You need DNS rewrite to convert between DNS A records (for IPv4) and AAAA records (for IPv6).
- The DNS server is on the outside, clients are on the inside, and some of the fully-qualified domain names that the clients use resolve to other inside hosts.
- The DNS server is on the inside and responds with private IP addresses, clients are on the outside, and the clients access fully-qualified domain names that point to servers that are hosted on the inside.

### DNS Rewrite Limitations

Following are some limitations with DNS rewrite:

- DNS rewrite is not applicable for PAT because multiple PAT rules are applicable for each A or AAAA record, and the PAT rule to use is ambiguous.
- If you configure a manual NAT rule, you cannot configure DNS modification if you specify the destination address as well as the source address. These kinds of rules can potentially have a different translation for a single address when going to A vs. B. Therefore, they can not accurately match the IP address inside the DNS reply to the correct NAT rule; the DNS reply does not contain information about which source/destination address combination was in the packet that prompted the DNS request.
- You must enable DNS application inspection with DNS NAT rewrite enabled for NAT rules to rewrite DNS queries and responses. By default, DNS inspection with DNS NAT rewrite enabled is globally applied, so you probably do not need to change the inspection configuration.
- DNS rewrite is actually done on the xlate entry, not the NAT rule. Thus, if there is no xlate for a dynamic rule, rewrite cannot be done correctly. The same problem does not occur for static NAT.
- DNS rewrite does not rewrite DNS Dynamic Update messages (opcode 5).

The following topics provide examples of DNS rewrite in NAT rules.

## DNS64 Reply Modification

The following figure shows an FTP server and DNS server on the outside IPv4 network. The system has a static translation for the outside server. In this case, when an inside IPv6 user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.200.225.

Because you want inside users to use the mapped address for ftp.cisco.com (2001:DB8::D1A5:C8E1, where D1A5:C8E1 is the IPv6 equivalent of 209.165.200.225) you need to configure DNS reply modification for the static translation. This example also includes a static NAT translation for the DNS server, and a PAT rule for the inside IPv6 hosts.

### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

### Procedure

- Step 1** Create the network objects for the FTP server, DNS server, inside network, and PAT pool.
- Choose **Objects > Object Management**.
  - Select **Network** from the table of contents and click **Add Network > Add Object**.
  - Define the real FTP server address.
 

Name the network object (for example, ftp\_server) and enter the host address, 209.165.200.225.

## New Network Object

 Host  Range  Network  FQDN  
 209.165.200.230-209.165.200.235

Allow Overrides

n) Click **Save**.

**Step 2** Configure the static NAT rule with DNS modification for the FTP server.

a) Select **Devices > NAT** and create or edit the threat defense NAT policy.

b) Click **Add Rule**.

c) Configure the following properties:

- **NAT Rule** = Auto NAT Rule.
- **Type** = Static.

d) On **Interface Objects**, configure the following:

- **Source Interface Objects** = outside.
- **Destination Interface Objects** = inside.

e) On **Translation**, configure the following:

- **Original Source** = ftp\_server network object.
- **Translated Source > Address** = ftp\_server\_v6 network object.

## Add NAT Rule

NAT Rule:

Type:

Enable

Interface Objects   Translation   PAT Pool   Advanced

| Original Packet                                                | Translated Packet                                                |
|----------------------------------------------------------------|------------------------------------------------------------------|
| Original Source:*<br><input type="text" value="ftp_server"/> + | Translated Source:<br><input type="text" value="Address"/> +     |
| Original Port:<br><input type="text" value="TCP"/>             | Translated Port:<br><input type="text" value="ftp_server_v6"/> + |
| <input type="text"/>                                           | <input type="text"/>                                             |

- f) On **Advanced**, select the following options:
- **Translate DNS replies that match this rule.**
  - **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

g) Click **OK**.

**Step 3** Configure the static NAT rule for the DNS server.

- a) Click **Add Rule**.
- b) Configure the following properties:
- **NAT Rule** = Auto NAT Rule.
  - **Type** = Static.
- c) On **Interface Objects**, configure the following:
- **Source Interface Objects** = outside.
  - **Destination Interface Objects** = inside.
- d) On **Translation**, configure the following:
- **Original Source** = dns\_server network object.
  - **Translated Source > Address** = dns\_server\_v6 network object.
- e) On **Advanced**, select **Net to Net Mapping**, because this is a one-to-one NAT46 translation.

## Add NAT Rule

NAT Rule:

Type:

Enable

Interface Objects   Translation   PAT Pool   Advanced

| Original Packet                           | Translated Packet                      |
|-------------------------------------------|----------------------------------------|
| Original Source:*                         | Translated Source:                     |
| <input type="text" value="dns_server"/> + | <input type="text" value="Address"/> + |
| Original Port:                            | Translated Port:                       |
| <input type="text" value="TCP"/>          | <input type="text"/>                   |
| <input type="text"/>                      | <input type="text"/>                   |

f) Click **OK**.

**Step 4** Configure the dynamic NAT with a PAT pool rule for the inside IPv6 network.

- a) Click **Add Rule**.
- b) Configure the following properties:
  - **NAT Rule** = Auto NAT Rule.
  - **Type** = Dynamic.
- c) On **Interface Objects**, configure the following:
  - **Source Interface Objects** = inside.
  - **Destination Interface Objects** = outside.
- d) On **Translation**, configure the following:
  - **Original Source** = inside\_v6 network object.
  - **Translated Source > Address** = leave this field empty.

## Add NAT Rule

## DNS Reply Modification, DNS Server on Outside

The following figure shows a DNS server that is accessible from the outside interface. A server, ftp.cisco.com, is on the inside interface. You configure NAT to statically translate the ftp.cisco.com real address (10.1.3.14) to a mapped address (209.165.201.10) that is visible on the outside network.

In this case, you want to enable DNS reply modification on this static rule so that inside users who have access to ftp.cisco.com using the real address receive the real address from the DNS server, and not the mapped address.

When an inside host sends a DNS request for the address of ftp.cisco.com, the DNS server replies with the mapped address (209.165.201.10). The system refers to the static rule for the inside server and translates the address inside the DNS reply to 10.1.3.14. If you do not enable DNS reply modification, then the inside host attempts to send traffic to 209.165.201.10 instead of accessing ftp.cisco.com directly.

### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

### Procedure

- 
- Step 1** Create the network objects for the FTP server.
- Choose **Objects > Object Management**.
  - Select **Network** from the table of contents and click **Add Network > Add Object**.
  - Define the real FTP server address.

Name the network object (for example, ftp\_server) and enter the host address, 10.1.3.14.

### New Network Object

Name

Description

Network  
 Host  Range  Network  FQDN

Allow Overrides

- d) Click **Save**.  
e) Click **Add Network > Add Object** and define the FTP server's translated address.

Name the network object (for example, ftp\_server\_outside) and enter the host address, 209.165.201.10.

### New Network Object

Name

Description

Network  
 Host  Range  Network  FQDN

Allow Overrides

- f) Click **Save**.

**Step 2** Configure the static NAT rule with DNS modification for the FTP server.

- a) Select **Devices > NAT** and create or edit the threat defense NAT policy.  
b) Click **Add Rule**.  
c) Configure the following properties:  
• **NAT Rule** = Auto NAT Rule.

- **Type** = Static.
- d) On **Interface Objects**, configure the following:
- **Source Interface Objects** = inside.
  - **Destination Interface Objects** = outside.
- e) On **Translation**, configure the following:
- **Original Source** = ftp\_server network object.
  - **Translated Source > Address** = ftp\_server\_outside network object.
- f) On **Advanced**, select **Translate DNS replies that match this rule**.

### Add NAT Rule

NAT Rule:

Type:

Enable

Interface Objects   **Translation**   PAT Pool   Advanced

| Original Packet                           | Translated Packet                      |
|-------------------------------------------|----------------------------------------|
| Original Source:*                         | Translated Source:                     |
| <input type="text" value="ftp_server"/> + | <input type="text" value="Address"/> + |
| Original Port:                            | Translated Port:                       |
| <input type="text" value="TCP"/>          | <input type="text"/>                   |
| <input type="text"/>                      | <input type="text"/>                   |

- g) Click **OK**.

## DNS Reply Modification, DNS Server on Host Network

The following figure shows an FTP server and DNS server on the outside. The system has a static translation for the outside server. In this case, when an inside user requests the address for ftp.cisco.com from the DNS server, the DNS server responds with the real address, 209.165.20.10. Because you want inside users to use the mapped address for ftp.cisco.com (10.1.2.56) you need to configure DNS reply modification for the static translation.

### Before you begin

Ensure that you have interface objects (security zones or interface groups) that contain the interfaces for the device. In this example, we will assume the interface objects are security zones named **inside** and **outside**. To configure interface objects, select **Objects > Object Management**, then select **Interface**.

### Procedure

- Step 1** Create the network objects for the FTP server.
- Choose **Objects > Object Management**.
  - Select **Network** from the table of contents and click **Add Network > Add Object**.
  - Define the real FTP server address.  
Name the network object (for example, ftp\_server) and enter the host address, 209.165.201.10.

## New Network Object

Name

ftp\_server

Description

Network

 Host
  Range
  Network

 Allow Overrides

- f) Click **Save**.

**Step 2**

Configure the static NAT rule with DNS modification for the FTP server.

- Select **Devices** > **NAT** and create or edit the threat defense NAT policy.
- Click **Add Rule**.
- Configure the following properties:
  - **NAT Rule** = Auto NAT Rule.
  - **Type** = Static.

- d) On **Interface Objects**, configure the following:
- **Source Interface Objects** = outside.
  - **Destination Interface Objects** = inside.
- e) On **Translation**, configure the following:
- **Original Source** = ftp\_server network object.
  - **Translated Source > Address** = ftp\_server\_translated network object.
- f) On **Advanced**, select **Translate DNS replies that match this rule**.

### Add NAT Rule

## CHAPTER 43

# Alarms for the Cisco ISA 3000

---

You can configure the alarm system on a Cisco ISA 3000 device to alert you when undesirable conditions occur.

- [About Alarms, on page 1249](#)
- [Defaults for Alarms, on page 1251](#)
- [Requirements and Prerequisites for Alarms, on page 1252](#)
- [Configure the Alarms for the ISA 3000, on page 1252](#)
- [Monitoring Alarms, on page 1260](#)

## About Alarms

You can configure the ISA 3000 to issue alarms for a variety of conditions. If any conditions do not match the configured settings, the system triggers an alarm, which is reported by way of LEDs, syslog messages, SNMP traps, and through external devices connected to the alarm output interface. By default, triggered alarms issue syslog messages only.

You can configure the alarm system to monitor the following:

- Power supply.
- Primary and secondary temperature sensors.
- Alarm input interfaces.

The ISA 3000 has internal sensors plus two alarm input interfaces and one alarm output interface. You can connect external sensors, such as door sensors, to the alarm inputs. You can connect external alarm devices, such as buzzers or lights, to the alarm output interface.

The alarm output interface is a relay mechanism. Depending on the alarm conditions, the relay is either energized or de-energized. When it is energized, any device connected to the interface is activated. A de-energized relay results in the inactive state of any connected devices. The relay remains in an energized state as long as alarms are triggered.

For information about connecting external sensors and the alarm relay, see [Cisco ISA 3000 Industrial Security Appliance Hardware Installation Guide](#).

## Alarm Input Interfaces

You can connect the alarm input interfaces (or contacts) to external sensors, such as one that detects if a door is open.

Each alarm input interface has a corresponding LED. These LEDs convey the alarm status of each alarm input. You can configure the trigger and severity for each alarm input. In addition to the LED, you can configure the contact to trigger the output relay (to activate an external alarm), to send syslog messages, and to send SNMP traps.

The following table explains the statuses of the LEDs in response to alarm conditions for the alarm inputs. It also explains the behavior for the output relay, syslog messages, and SNMP traps, if you enable these responses to the alarm input.

| Alarm Status         | LED                                               | Output Relay       | Syslog           | SNMP Trap      |
|----------------------|---------------------------------------------------|--------------------|------------------|----------------|
| Alarm not configured | Off                                               | —                  | —                | —              |
| No alarms triggered  | Solid green                                       | —                  | —                | —              |
| Alarm activated      | Minor alarm—solid red<br>Major alarm—flashing red | Relay energized    | Syslog generated | SNMP trap sent |
| Alarm end            | Solid green                                       | Relay de-energized | Syslog generated | —              |

## Alarm Output Interface

You can connect an external alarm, such as a buzzer or light, to the alarm output interface.

The alarm output interface functions as a relay and also has a corresponding LED, which conveys the alarm status of an external sensor connected to the input interface, and internal sensors such as the dual power supply and temperature sensors. You configure which alarms should activate the output relay, if any.

The following table explains the statuses of the LEDs and output relay in response to alarm conditions. It also explains the behavior for syslog messages, and SNMP traps, if you enable these responses to the alarm.

| Alarm Status         | LED         | Output Relay       | Syslog           | SNMP Trap      |
|----------------------|-------------|--------------------|------------------|----------------|
| Alarm not configured | Off         | —                  | —                | —              |
| No alarms triggered  | Solid green | —                  | —                | —              |
| Alarm activated      | Solid red   | Relay energized    | Syslog generated | SNMP trap sent |
| Alarm end            | Solid green | Relay de-energized | Syslog generated | —              |

## Syslog Alarms

By default, the system sends syslog messages when any alarm is triggered. You can disable syslog messaging if you do not want the messages.

For syslog alarms to work, you must also enable diagnostic logging. Choose **Device > Platform Settings**, add or edit a Threat Defense platform settings policy that is assigned to the device, and configure destinations and settings on the **Syslog** page. For example, you can configure a syslog server, console logging, or internal buffer logging.

Without enabling a destination for diagnostic logging, the alarm system has nowhere to send syslog messages.

## SNMP Alarms

You can optionally configure the alarms to send SNMP traps to your SNMP server. For SNMP trap alarms to work, you must also configure SNMP settings.

Choose **Device > Platform Settings**, add or edit a Threat Defense platform settings policy that is assigned to the device, and enable SNMP and configure settings on the **SNMP** page.

## Defaults for Alarms

The following table specifies the defaults for alarm input interfaces (contacts), redundant power supply, and temperature.

|                                       | Alarm                                                                                                                                                          | Trigger      | Severity | SNMP Trap                             | Output Relay                          | Syslog Message                        |
|---------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|----------|---------------------------------------|---------------------------------------|---------------------------------------|
| Alarm Contact 1                       | Enabled                                                                                                                                                        | Closed State | Minor    | Disabled                              | Disabled                              | Enabled                               |
| Alarm Contact 2                       | Enabled                                                                                                                                                        | Closed State | Minor    | Disabled                              | Disabled                              | Enabled                               |
| Redundant Power Supply (when enabled) | Enabled                                                                                                                                                        | —            | —        | Disabled                              | Disabled                              | Enabled                               |
| Temperature                           | Enabled for the primary temperature alarm (default values of 92°C and -40°C for the high and low thresholds respectively)<br>Disabled for the secondary alarm. | —            | —        | Enabled for primary temperature alarm | Enabled for primary temperature alarm | Enabled for primary temperature alarm |

Admin

# Configure the Alarms for the ISA 3000

You use FlexConfig to configure alarms for the ISA 3000. The following topics explain how to configure the different types of alarms.

## Configure Alarm Input Contacts

If you connect the alarm input contacts (interfaces) to external sensors, you can configure the contacts to issue alarms based on the input from the sensor. In fact, the contacts are enabled by default to send syslog messages if the contact is closed, that is, if the electrical current stops flowing through the contact. You need to configure the contact only if the defaults do not meet your requirements.

The alarm contacts are numbered 1 and 2, so you need to understand how you have wired the physical pins to configure the correct settings. You configure the contacts separately.

### Procedure

#### Step 1

Create the FlexConfig object to configure the alarm input contacts.

- a) Choose **Objects > Object Management**.
- b) Choose **FlexConfig > FlexConfig Object** from the table of contents.
- c) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.
  - **Name**—The object name. For example, `Configure_Alarm_Contacts`.
  - **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
  - **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
  - **Object body**—In the object body, type the commands needed to configure the alarm contacts. The following steps explain the commands.
- d) Configure a description for the alarm contact.

**alarm contact {1 | 2} description *string***

For example, to set the description of contact 1 to "Door Open," enter the following:

```
alarm contact 1 description Door Open
```

- e) Configure the severity for the alarm contact.

**alarm contact {1 | 2 | any} severity {major | minor | none}**

Instead of configuring one contact, you can specify **any** to change the severity for all contacts. The severity controls the behavior of the LED associated with the contact.

- **major**—The LED blinks red.
- **minor**—The LED is solid red. This is the default.
- **none**—The LED is off.

For example, to set the severity of contact 1 to Major, enter the following:

```
alarm contact 1 severity major
```

- f) Configure the trigger for the alarm contact.

**alarm contact {1 | 2 | any} trigger {open | closed}**

Instead of configuring one contact, you can specify **any** to change the trigger for all contacts. The trigger determines the electrical condition that signals an alert.

- **open**—The normal condition for the contact is closed, that is, the electrical current is running through the contact. An alert is triggered if the contact becomes open, that is, the electrical current stops flowing.
- **closed**—The normal condition for the contact is open, that is, the electrical current does not run through the contact. An alert is triggered if the contact becomes closed, that is, the electrical current starts running through the contact. This is the default.

For example, you connect a door sensor to alarm input contact 1, and its normal state has no electrical current flowing through the alarm contact (it is open). If the door is opened, the contact is closed and electrical current flows through the alarm contact. You would set the alarm trigger to closed so that the alarm goes off when the electrical current starts flowing.

```
alarm contact 1 trigger closed
```

- g) Configure the actions to take when the alarm contact is triggered.

**alarm facility input-alarm {1 | 2} {relay | syslog | notifies}**

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message. This option is enabled by default.
- **notifies**—Send an SNMP trap.

For example, to enable all actions for the alarm input contact 1, enter the following:

```
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

- h) Verify that the object body contains the commands you want.

For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
alarm contact 1 description Door Open
alarm contact 1 severity major
alarm contact 1 trigger closed
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

The object body should look similar to the following:

- i) Click **Save**.

**Step 2** Create the FlexConfig policy and assign it to the devices.

- Choose **Devices > FlexConfig**.
- Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

- Select the alarm contact FlexConfig object in the **User Defined** folder in the table of contents and click **>** to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

- Click **Save**.
- If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.
- Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the

preview. Note that you will also see commands generated from other changes you have made to managed features. For the alarm contact commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
alarm contact 1 description Door Open
alarm contact 1 severity major
alarm contact 1 trigger closed
alarm facility input-alarm 1 relay
alarm facility input-alarm 1 syslog
alarm facility input-alarm 1 notifies
```

**Step 3** Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See [Verify the Deployed Configuration, on page 2734](#).

---

## Configure Power Supply Alarms

The ISA 3000 has two power supplies. By default, the system operates in single-power mode. However, you can configure the system to operate in dual mode, where the second power supply automatically provides power if the primary power supply fails. When you enable dual-mode, the power supply alarm is automatically enabled to send syslog alerts, but you can disable the alert altogether, or also enable SNMP traps or the alarm hardware relay.

The following procedure explains how to enable dual mode, and how to configure the power supply alarms.

### Procedure

---

**Step 1** Create the FlexConfig object to configure the power supply alarm.

- a) Choose **Objects > Object Management**.
- b) Choose **FlexConfig > FlexConfig Object** from the table of contents.
- c) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.
  - **Name**—The object name. For example, Power\_Supply\_Alarms.
  - **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
  - **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
  - **Object body**—In the object body, type the commands needed to configure the power supply alarms. The following steps explain the commands.
- d) Enable dual power supply mode.  
**power-supply dual**

For example:

```
power-supply dual
```

- e) Configure the actions to take when the power supply alarm is triggered.

**alarm facility power-supply rps {relay | syslog | notifies | disable}**

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message. This option is enabled by default.
- **notifies**—Send an SNMP trap.
- **disable**—Disable the power supply alarm. Any other actions configured for the power supply alarm are inoperable.

For example, to enable all actions for the power supply alarm, enter the following:

```
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

- f) Verify that the object body contains the commands you want.

For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

The object body should look similar to the following:

- g) Click **Save**.

**Step 2** Create the FlexConfig policy and assign it to the devices.

- a) Choose **Devices > FlexConfig**.
- b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

- c) Select the power supply alarm FlexConfig object in the **User Defined** folder in the table of contents and click **>** to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

| # | Name                |
|---|---------------------|
| 1 | Power_Supply_Alarms |

- d) Click **Save**.
- e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.
- f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the power supply alarm commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
power-supply dual
alarm facility power-supply rps relay
alarm facility power-supply rps syslog
alarm facility power-supply rps notifies
```

### Step 3 Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See [Verify the Deployed Configuration, on page 2734](#).

## Configure Temperature Alarms

You can configure alarms based on the temperature of the CPU card in the device.

You can set a primary and secondary temperature range. If the temperature drops below the low threshold, or exceeds the high threshold, the alarm is triggered.

The primary temperature alarm is enabled by default for all alarm actions: output relay, syslog, and SNMP. The default settings for the primary temperature range is -40°C to 92°C.

The secondary temperature alarm is disabled by default. You can set the secondary temperature within the range -35°C to 85°C.

Because the secondary temperature range is more restrictive than the primary range, if you set either the secondary low or high temperature, that setting disables the corresponding primary setting, even if you configure non-default values for the primary setting. You cannot enable two separate high and two separate low temperature alarms.

Thus, in practice, you should configure the primary only, or the secondary only, setting for high and low.

## Procedure

### Step 1

Create the FlexConfig object to configure the temperature alarms.

- a) Choose **Objects > Object Management**.
- b) Choose **FlexConfig > FlexConfig Object** from the table of contents.
- c) Click **Add FlexConfig Object**, configure the following properties, and click **Save**.
  - **Name**—The object name. For example, `Configure_Temperature_Alarms`.
  - **Deployment**—Select **Everytime**. You want this configuration to be sent in every deployment to ensure it remains configured.
  - **Type**—Keep the default, **Append**. The commands are sent to the device after the commands for directly-supported features.
  - **Object body**—In the object body, type the commands needed to configure the temperature alarms. The following steps explain the commands.
- d) Configure the acceptable temperature range.

**alarm facility temperature {primary | secondary} {low | high} temperature**

The temperature is in Celsius. The allowed range for the primary alarm is -40 to 92, which is also the default range. The allowed range for the secondary alarm is -35 to 85. The low value must be lower than the high value.

For example, to set a more restrictive temperature range of -20 to 80, which falls within the allowed range for the secondary alarm, configure the secondary alarm as follows:

```
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
```

- e) Configure the actions to take when the temperature alarm is triggered.

**alarm facility temperature {primary | secondary} {relay | syslog | notifies}**

You can configure more than one action. For example, you can configure the device to activate the external alarm, send syslog messages, and also send SNMP traps.

- **relay**—Energize the alarm output relay, which activates the external alarm that you attached to it, such as a buzzer or a flashing light. The output LED also goes red.
- **syslog**—Send a syslog message.
- **notifies**—Send an SNMP trap.

For example, to enable all actions for the secondary temperature alarm, enter the following:

```
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

- f) Verify that the object body contains the commands you want.

For example, if your template includes all of the command examples shown in this procedure, the object body would have the following commands:

```
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

The object body should look similar to the following:

- g) Click **Save**.

**Step 2** Create the FlexConfig policy and assign it to the devices.

- a) Choose **Devices > FlexConfig**.  
 b) Either click **New Policy**, or if an existing FlexConfig policy should be assigned to (or is already assigned to) the target devices, simply edit that policy.

When creating a new policy, assign the target devices to the policy in the dialog box where you name the policy.

- c) Select the temperature alarms FlexConfig object in the **User Defined** folder in the table of contents and click > to add it to the policy.

The object should be added to the **Selected Appended FlexConfigs** list.

- d) Click **Save**.  
 e) If you have not yet assigned all the targeted devices to the policy, click the **Policy Assignments** link below Save and make the assignments now.  
 f) Click **Preview Config**, and in the Preview dialog box, select one of the assigned devices.

The system generates a preview of the configuration CLI that will be sent to the device. Verify that the commands generated from the FlexConfig object look correct. These will be shown at the end of the preview. Note that you will also see commands generated from other changes you have made to managed features. For the temperature alarms commands, you should see something similar to the following:

```
###Flex-config Appended CLI ###
alarm facility temperature secondary low -20
alarm facility temperature secondary high 80
alarm facility temperature secondary relay
alarm facility temperature secondary syslog
alarm facility temperature secondary notifies
```

**Step 3** Deploy your changes.

Because you assigned a FlexConfig policy to the devices, you will always get a deployment warning, which is meant to caution you about the use of FlexConfig. Click **Proceed** to continue with the deployment.

After the deployment completes, you can check the deployment history and view the transcript for the deployment. This is especially valuable if the deployment fails. See [Verify the Deployed Configuration, on page 2734](#).

---

## Monitoring Alarms

The following topics explain how to monitor and manage alarms.

### Monitoring Alarm Status

You can use the following commands in the CLI to monitor alarms.

- **show alarm settings**

Shows the current configuration for each possible alarm.

- **show environment alarm-contact**

Shows information about the physical status of the input alarm contacts.

- **show facility-alarm relay**

Shows information about the alarms that have triggered the output relay.

- **show facility-alarm status [info | major | minor]**

Shows information on all alarms that have been triggered. You can limit the view by filtering on **major** or **minor** status. The **info** keyword provides the same output as using no keyword.

### Monitoring Syslog Messages for Alarms

Depending on the type of alarms you configure, you might see the following syslog messages.

#### Dual Power Supply Alarms

- %FTD-1-735005: Power Supply Unit Redundancy OK
- %FTD-1-735006: Power Supply Unit Redundancy Lost

#### Temperature Alarms

In these alarms, *Celsius* is replaced by the temperature detected on the device, in Celsius.

- %FTD-6-806001: Primary alarm CPU temperature is High *Celsius*
- %FTD-6-806002: Primary alarm for CPU high temperature is cleared
- %FTD-6-806003: Primary alarm CPU temperature is Low *Celsius*

- %FTD-6-806004: Primary alarm for CPU Low temperature is cleared
- %FTD-6-806005: Secondary alarm CPU temperature is High *Celsius*
- %FTD-6-806006: Secondary alarm for CPU high temperature is cleared
- %FTD-6-806007: Secondary alarm CPU temperature is Low *Celsius*
- %FTD-6-806008: Secondary alarm for CPU Low temperature is cleared

#### Alarm Input Contact Alarms

In these alarms, *description* is the description for the contact that you configured.

- %FTD-6-806009: Alarm asserted for ALARM\_IN\_1 *alarm\_1\_description*
- %FTD-6-806010: Alarm cleared for ALARM\_IN\_1 *alarm\_1\_description*
- %FTD-6-806011: Alarm asserted for ALARM\_IN\_2 *alarm\_2\_description*
- %FTD-6-806012: Alarm cleared for ALARM\_IN\_2 *alarm\_2\_description*

## Turning Off the External Alarm

If you are using an external alarm that is attached to the alarm output, and the alarm is triggered, you can turn off the external alarm from the device CLI using the **clear facility-alarm output** command. This command de-energizes the output pin and also turns off the output LED.

## CHAPTER 44

# Static and Default Routes

This chapter describes how to configure static and default routes on the threat defense.

- [About Static and Default Routes, on page 1265](#)
- [Requirements and Prerequisites for Static Routes, on page 1267](#)
- [Guidelines for Static and Default Routes, on page 1268](#)
- [Add a Static Route, on page 1268](#)
- [Reference for Routing, on page 1270](#)

## About Static and Default Routes

To route traffic to a non-connected host or network, you must define a route to the host or network, either using static or dynamic routing. Generally, you must configure at least one static route: a default route for all traffic that is not routed by other means to a default network gateway, typically the next hop router.

## Default Route

The simplest option is to configure a default static route to send all traffic to an upstream router, relying on the router to route the traffic for you. A default route identifies the gateway IP address to which the threat defense device sends all IP packets for which it does not have a learned or static route. A default static route is simply a static route with 0.0.0.0/0 (IPv4) or ::/0 (IPv6) as the destination IP address.

You should always define a default route.

The threat defense has separate routing tables for data interfaces and for management-only interfaces (including the special Linux Management interface). You can only add a default route for the data routing table. The threat defense automatically adds a default route in the management-only routing table that sends traffic to the Linux Management interface, where a separate route lookup occurs in the Linux routing table. You can add static routes to the Linux routing table that can be used by Management using the threat defense CLI **configure network static-routes** command.

---

**Note** The *default* Linux route is set with the **configure network ipv4** or **configure network ipv6** command.

---

## Static Routes

You might want to use static routes in the following cases:

- Your networks use an unsupported router discovery protocol.
- Your network is small and you can easily manage static routes.
- You do not want the traffic or CPU overhead associated with routing protocols.
- In some cases, a default route is not enough. The default gateway might not be able to reach the destination network, so you must also configure more specific static routes. For example, if the default gateway is outside, then the default route cannot direct traffic to any inside networks that are not directly connected to the threat defense device.
- You are using a feature that does not support dynamic routing protocols.
- Virtual routers use static routes to create route leaks. Route leaks enable flow of traffic from an interface of a virtual router to another interface in another virtual router. For more information, see [Interconnecting Virtual Routers, on page 1285](#).

## Route to null0 Interface to Drop Unwanted Traffic

Access rules let you filter packets based on the information contained in their headers. A static route to the null0 interface is a complementary solution to access rules. You can use a null0 route to forward unwanted or undesirable traffic so the traffic is dropped.

Static null0 routes have a favorable performance profile. You can also use static null0 routes to prevent routing loops. BGP can leverage the static null0 route for Remotely Triggered Black Hole routing.

## Route Priorities

- Routes that identify a specific destination take precedence over the default route.
- When multiple routes exist to the same destination (either static or dynamic), then the administrative distance for the route determines priority. Static routes are set to 1, so they typically are the highest priority routes.
- When you have multiple static routes to the same destination with the same administrative distance, see [Equal-Cost Multi-Path \(ECMP\) Routing, on page 1277](#).
- For traffic emerging from a tunnel with the Tunneled option, this route overrides any other configured or learned default routes.

## Transparent Firewall Mode and Bridge Group Routes

For traffic that originates on the threat defense device and is destined through a bridge group member interface for a non-directly connected network, you need to configure either a default route or static routes so the threat defense device knows out of which bridge group member interface to send traffic. Traffic that originates on the threat defense device might include communications to a syslog server or SNMP server. If you have servers that cannot all be reached through a single default route, then you must configure static routes. For transparent mode, you cannot specify the BVI as the gateway interface; only member interfaces can be used.

For bridge groups in routed mode, you must specify the BVI in a static route; you cannot specify a member interface. See [#unique\\_1390](#) for more information.

## Static Route Tracking

One of the problems with static routes is that there is no inherent mechanism for determining if the route is up or down. They remain in the routing table even if the next hop gateway becomes unavailable. Static routes are only removed from the routing table if the associated interface on the threat defense device goes down.

The static route tracking feature provides a method for tracking the availability of a static route and installing a backup route if the primary route should fail. For example, you can define a default route to an ISP gateway and a backup default route to a secondary ISP in case the primary ISP becomes unavailable.

The threat defense device implements static route tracking by associating a static route with a monitoring target host on the destination network that the threat defense device monitors using ICMP echo requests. If an echo reply is not received within a specified time period, the host is considered down, and the associated route is removed from the routing table. An untracked backup route with a higher metric is used in place of the removed route.

When selecting a monitoring target, you need to make sure that it can respond to ICMP echo requests. The target can be any network object that you choose, but you should consider using the following:

- The ISP gateway (for dual ISP support) address
- The next hop gateway address (if you are concerned about the availability of the gateway)
- A server on the target network, such as a syslog server, that the threat defense device needs to communicate with
- A persistent network object on the destination network

---

**Note** A PC that may be shut down at night is not a good choice.

---

You can configure static route tracking for statically defined routes or default routes obtained through DHCP or PPPoE. You can only enable PPPoE clients on multiple interfaces with route tracking configured.

## Requirements and Prerequisites for Static Routes

### User Roles

Admin

Network Admin

# Guidelines for Static and Default Routes

## Firewall Mode and Bridge Groups

- In transparent mode, static routes must use the bridge group member interface as the gateway; you cannot specify the BVI.
- In routed mode, you must specify the BVI as the gateway; you cannot specify the member interface.
- Static route tracking is not supported for bridge group member interfaces or on the BVI.

## Supported Network Address

- Static route tracking is not supported for IPv6.
- The threat defense does not support Class E routing, so a Class E network is not routable in static routes.

## Clustering

- In clustering, static route tracking is only supported on the control node.

## Network Object Group

You cannot use a range of network objects or a network object group having a range of IP addresses in a static route.

## ASP and RIB Route Entries

All routes and its distance installed on the device are captured in the ASP routing table. This is common for all static and dynamic routing protocols. Only the best distance route is captured in the RIB table.

# Add a Static Route

A static route defines where to send traffic for specific destination networks. You should at a minimum define a default route. A default route is simply a static route with 0.0.0.0/0 as the destination IP address.

To configure routes for redundant manager access data interfaces, see [Configure a Redundant Manager Access Data Interface, on page 164](#).

## Procedure

---

- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Click **Routing**.
- Step 3** (May be required) From the virtual routers drop-down list, select the virtual router for which you are configuring a static route.
- Step 4** Select **Static Route**.

- Step 5** Click **Add Routes**.
- Step 6** Click **IPv4** or **IPv6** depending on the type of static route that you are adding.
- Step 7** Choose the **Interface** to which this static route applies.
- For transparent mode, choose a bridge group member interface name. For routed mode with bridge groups, you can choose either the bridge group member interface for the BVI name. To “black hole” unwanted traffic, choose the **Null0** interface.
- For a device using virtual routing, you can select an interface that belongs to another virtual router. You can create such a static route if you want to leak traffic from this virtual router into the other virtual router. For more information, see [Interconnecting Virtual Routers, on page 1285](#).
- Step 8** In the **Available Network** list, choose the destination network.
- To define a default route, create an object with the address 0.0.0.0/0 and select it here.
- Note** Although you can create and choose a Network Object Group containing a range of IP addresses, the management center does not support using ranges in static routes.
- Step 9** In the **Gateway** or **IPv6 Gateway** field, enter or choose the gateway router that is the next hop for this route. You can provide an IP address or a Networks/Hosts object.
- When you are using static-route configuration for virtual routers to leak routes, do not specify the next hop gateway.
- Step 10** In the **Metric** field, enter the number of hops to the destination network. Valid values range from 1 to 255; the default value is 1.
- The metric is a measurement of the “expense” of a route, based on the number of hops (hop count) to the network on which a specific host resides. Hop count is the number of networks that a network packet must traverse, including the destination network, before it reaches its final destination. The metric is used to compare routes among different routing protocols. The default administrative distance for static routes is 1, giving it precedence over routes discovered by dynamic routing protocols but not directly connected routes. The default administrative distance for routes discovered by OSPF is 110. If a static route has the same administrative distance as a dynamic route, the static route takes precedence. Connected routes always take precedence over static or dynamically discovered routes.
- Step 11** (Optional) For a default route, click the **Tunneled** checkbox to define a separate default route for VPN traffic.
- You can define a separate default route for VPN traffic if you want your VPN traffic to use a different default route than your non VPN traffic. For example, traffic incoming from VPN connections can be easily directed towards internal networks, while traffic from internal networks can be directed towards the outside. When you create a default route with the tunneled option, all traffic from a tunnel terminating on the device that cannot be routed using learned or static routes, is sent to this route. You can configure only one default tunneled gateway per device. ECMP for tunneled traffic is not supported.
- Step 12** (IPv4 static route only) To monitor route availability, enter or choose the name of an SLA (service level agreement) Monitor object that defines the monitoring policy, in the **Route Tracking** field.
- See [SLA Monitor, on page 1536](#).
- Step 13** Click **Ok**.
-

# Reference for Routing

This section describes underlying concepts of how routing behaves within the threat defense.

## Path Determination

Routing protocols use metrics to evaluate what path will be the best for a packet to travel. A metric is a standard of measurement, such as path bandwidth, that is used by routing algorithms to determine the optimal path to a destination. To aid the process of path determination, routing algorithms initialize and maintain routing tables, which include route information. Route information varies depending on the routing algorithm used.

Routing algorithms fill routing tables with a variety of information. Destination or next hop associations tell a router that a particular destination can be reached optimally by sending the packet to a particular router representing the next hop on the way to the final destination. When a router receives an incoming packet, it checks the destination address and attempts to associate this address with a next hop.

Routing tables also can include other information, such as data about the desirability of a path. Routers compare metrics to determine optimal routes, and these metrics differ depending on the design of the routing algorithm used.

Routers communicate with one another and maintain their routing tables through the transmission of a variety of messages. The routing update message is one such message that generally consists of all or a portion of a routing table. By analyzing routing updates from all other routers, a router can build a detailed picture of network topology. A link-state advertisement, another example of a message sent between routers, informs other routers of the state of the sender links. Link information also can be used to build a complete picture of network topology to enable routers to determine optimal routes to network destinations.

## Supported Route Types

There are several route types that a router can use. The threat defense device uses the following route types:

- Static Versus Dynamic
- Single-Path Versus Multipath
- Flat Versus Hierarchical
- Link-State Versus Distance Vector

## Static Versus Dynamic

Static routing algorithms are actually table mappings established by the network administrator. These mappings do not change unless the network administrator alters them. Algorithms that use static routes are simple to design and work well in environments where network traffic is relatively predictable and where network design is relatively simple.

Because static routing systems cannot react to network changes, they generally are considered unsuitable for large, constantly changing networks. Most of the dominant routing algorithms are dynamic routing algorithms, which adjust to changing network circumstances by analyzing incoming routing update messages. If the message indicates that a network change has occurred, the routing software recalculates routes and sends out new routing update messages. These messages permeate the network, stimulating routers to rerun their algorithms and change their routing tables accordingly.

Dynamic routing algorithms can be supplemented with static routes where appropriate. A router of last resort (a default route for a router to which all unroutable packets are sent), for example, can be designated to act as a repository for all unroutable packets, ensuring that all messages are at least handled in some way.

## Single-Path Versus Multipath

Some sophisticated routing protocols support multiple paths to the same destination. Unlike single-path algorithms, these multipath algorithms permit traffic multiplexing over multiple lines. The advantages of multipath algorithms are substantially better throughput and reliability, which is generally called load sharing.

## Flat Versus Hierarchical

Some routing algorithms operate in a flat space, while others use routing hierarchies. In a flat routing system, the routers are peers of all others. In a hierarchical routing system, some routers form what amounts to a routing backbone. Packets from non-backbone routers travel to the backbone routers, where they are sent through the backbone until they reach the general area of the destination. At this point, they travel from the last backbone router through one or more non-backbone routers to the final destination.

Routing systems often designate logical groups of nodes, called domains, autonomous systems, or areas. In hierarchical systems, some routers in a domain can communicate with routers in other domains, while others can communicate only with routers within their domain. In very large networks, additional hierarchical levels may exist, with routers at the highest hierarchical level forming the routing backbone.

The primary advantage of hierarchical routing is that it mimics the organization of most companies and therefore supports their traffic patterns well. Most network communication occurs within small company groups (domains). Because intradomain routers need to know only about other routers within their domain, their routing algorithms can be simplified, and, depending on the routing algorithm being used, routing update traffic can be reduced accordingly.

## Link-State Versus Distance Vector

Link-state algorithms (also known as shortest path first algorithms) flood routing information to all nodes in the internetwork. Each router, however, sends only the portion of the routing table that describes the state of its own links. In link-state algorithms, each router builds a picture of the entire network in its routing tables. Distance vector algorithms (also known as Bellman-Ford algorithms) call for each router to send all or some portion of its routing table, but only to its neighbors. In essence, link-state algorithms send small updates everywhere, while distance vector algorithms send larger updates only to neighboring routers. Distance vector algorithms know only about their neighbors. Typically, link-state algorithms are used in conjunction with OSPF routing protocols.

## Supported Internet Protocols for Routing

The threat defense device supports several Internet protocols for routing. Each protocol is briefly described in this section.

- Enhanced Interior Gateway Routing Protocol (EIGRP)

EIGRP is a Cisco proprietary protocol that provides compatibility and seamless interoperability with IGRP routers. An automatic-redistribution mechanism allows IGRP routes to be imported into Enhanced IGRP, and vice versa, so it is possible to add Enhanced IGRP gradually into an existing IGRP network.

- Open Shortest Path First (OSPF)

OSPF is a routing protocol developed for Internet Protocol (IP) networks by the interior gateway protocol (IGP) working group of the Internet Engineering Task Force (IETF). OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area includes an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

- Routing Information Protocol (RIP)

RIP is a distance-vector protocol that uses hop count as its metric. RIP is widely used for routing traffic in the global Internet and is an interior gateway protocol (IGP), which means that it performs routing within a single autonomous system.

- Border Gateway Protocol (BGP)

BGP is an interautonomous system routing protocol. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP). Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

## Routing Table

The threat defense uses separate routing tables for data traffic (through-the-device) and for management traffic (from-the-device). This section describes how the routing tables work. For information about the management routing table, see also [Routing Table for Management Traffic, on page 1277](#).

### How the Routing Table Is Populated

The threat defense routing table can be populated by statically defined routes, directly connected routes, and routes discovered by the dynamic routing protocols. Because the threat defense device can run multiple routing protocols in addition to having static and connected routes in the routing table, it is possible that the same route is discovered or entered in more than one manner. When two routes to the same destination are put into the routing table, the one that remains in the routing table is determined as follows:

- If the two routes have different network prefix lengths (network masks), then both routes are considered unique and are entered into the routing table. The packet forwarding logic then determines which of the two to use.

For example, if the RIP and OSPF processes discovered the following routes:

- RIP: 192.168.32.0/24
- OSPF: 192.168.32.0/19

Even though OSPF routes have the better administrative distance, both routes are installed in the routing table because each of these routes has a different prefix length (subnet mask). They are considered different destinations and the packet forwarding logic determines which route to use.

- If the threat defense device learns about multiple paths to the same destination from a single routing protocol, such as RIP, the route with the better metric (as determined by the routing protocol) is entered into the routing table.

Metrics are values associated with specific routes, ranking them from most preferred to least preferred. The parameters used to determine the metrics differ for different routing protocols. The path with the

lowest metric is selected as the optimal path and installed in the routing table. If there are multiple paths to the same destination with equal metrics, load balancing is done on these equal cost paths.

- If the threat defense device learns about a destination from more than one routing protocol, the administrative distances of the routes are compared, and the routes with lower administrative distance are entered into the routing table.

## Administrative Distances for Routes

You can change the administrative distances for routes discovered by or redistributed into a routing protocol. If two routes from two different routing protocols have the same administrative distance, then the route with the lower *default* administrative distance is entered into the routing table. In the case of EIGRP and OSPF routes, if the EIGRP route and the OSPF route have the same administrative distance, then the EIGRP route is chosen by default.

Administrative distance is a route parameter that the threat defense device uses to select the best path when there are two or more different routes to the same destination from two different routing protocols. Because the routing protocols have metrics based on algorithms that are different from the other protocols, it is not always possible to determine the best path for two routes to the same destination that were generated by different routing protocols.

Each routing protocol is prioritized using an administrative distance value. The following table shows the default administrative distance values for the routing protocols supported by the threat defense device.

**Table 90: Default Administrative Distance for Supported Routing Protocols**

| Route Source           | Default Administrative Distance |
|------------------------|---------------------------------|
| Connected interface    | 0                               |
| VPN route              | 1                               |
| Static route           | 1                               |
| EIGRP Summary Route    | 5                               |
| External BGP           | 20                              |
| Internal EIGRP         | 90                              |
| OSPF                   | 110                             |
| IS-IS                  | 115                             |
| RIP                    | 120                             |
| EIGRP external route   | 170                             |
| Internal and local BGP | 200                             |
| Unknown                | 255                             |

The smaller the administrative distance value, the more preference is given to the protocol. For example, if the threat defense device receives a route to a certain network from both an OSPF routing process (default administrative distance - 110) and a RIP routing process (default administrative distance - 120), the threat

defense device chooses the OSPF route because OSPF has a higher preference. In this case, the router adds the OSPF version of the route to the routing table.

A VPN advertised route (V-Route/RRI) is equivalent to a static route with the default administrative distance 1. But it has a higher preference as with the network mask 255.255.255.255.

In this example, if the source of the OSPF-derived route was lost (for example, due to a power shutdown), the threat defense device would then use the RIP-derived route until the OSPF-derived route reappears.

The administrative distance is a local setting. For example, if you change the administrative distance of routes obtained through OSPF, that change would only affect the routing table for the threat defense device on which the command was entered. The administrative distance is not advertised in routing updates.

Administrative distance does not affect the routing process. The routing processes only advertise the routes that have been discovered by the routing process or redistributed into the routing process. For example, the RIP routing process advertises RIP routes, even if routes discovered by the OSPF routing process are used in the routing table.

## Backup Dynamic and Floating Static Routes

A backup route is registered when the initial attempt to install the route in the routing table fails because another route was installed instead. If the route that was installed in the routing table fails, the routing table maintenance process calls each routing protocol process that has registered a backup route and requests them to reinstall the route in the routing table. If there are multiple protocols with registered backup routes for the failed route, the preferred route is chosen based on administrative distance.

Because of this process, you can create floating static routes that are installed in the routing table when the route discovered by a dynamic routing protocol fails. A floating static route is simply a static route configured with a greater administrative distance than the dynamic routing protocols running on the threat defense device. When the corresponding route discovered by a dynamic routing process fails, the static route is installed in the routing table.

## How Forwarding Decisions Are Made

Forwarding decisions are made as follows:

- If the destination does not match an entry in the routing table, the packet is forwarded through the interface specified for the default route. If a default route has not been configured, the packet is discarded.
- If the destination matches a single entry in the routing table, the packet is forwarded through the interface associated with that route.
- If the destination matches more than one entry in the routing table, then the packet is forwarded out of the interface associated with the route that has the longer network prefix length.

For example, a packet destined for 192.168.32.1 arrives on an interface with the following routes in the routing table:

- 192.168.32.0/24 gateway 10.1.1.2
- 192.168.32.0/19 gateway 10.1.1.3

In this case, a packet destined to 192.168.32.1 is directed toward 10.1.1.2, because 192.168.32.1 falls within the 192.168.32.0/24 network. It also falls within the other route in the routing table, but 192.168.32.0/24 has the longest prefix within the routing table (24 bits versus 19 bits). Longer prefixes are always preferred over shorter ones when forwarding a packet.

**Note** Existing connections continue to use their established interfaces even if a new similar connection would result in different behavior due to a change in routes.

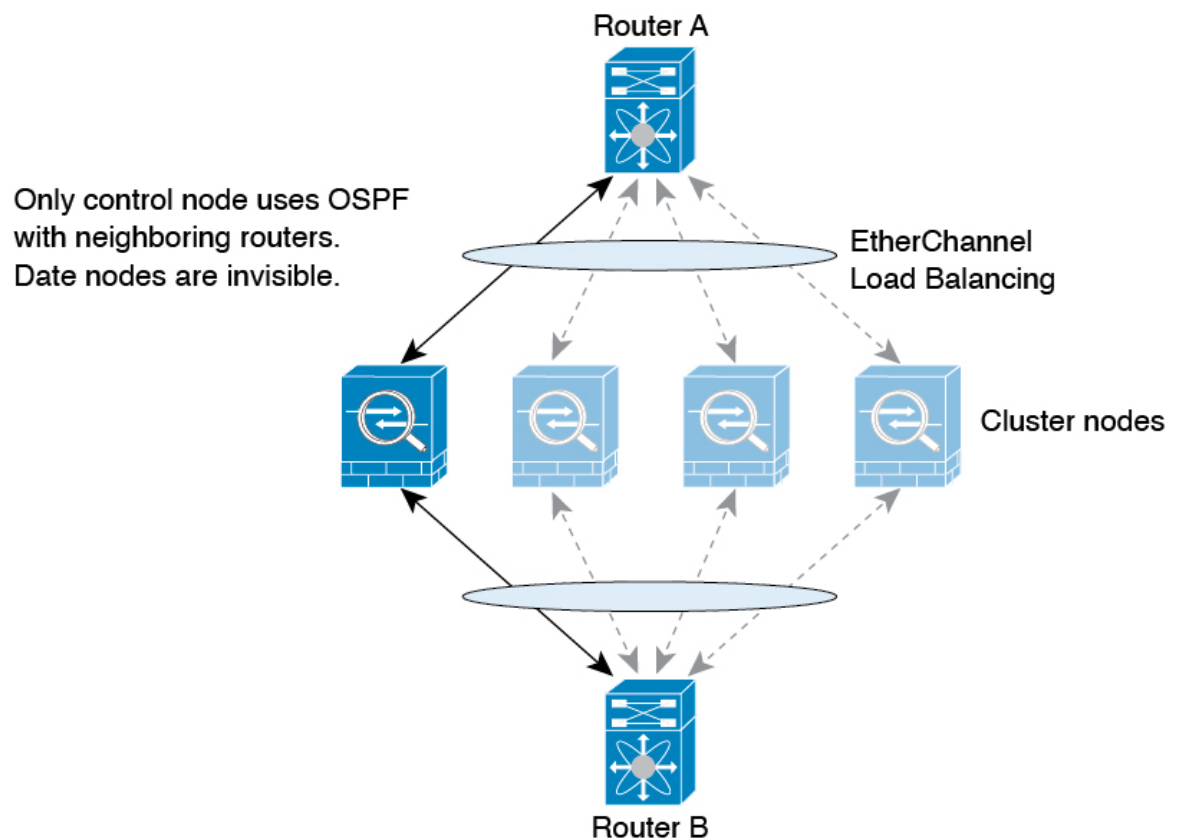

## Dynamic Routing and High Availability

Dynamic routes are synchronized on the standby unit when the routing table changes on the active unit. This means that all additions, deletions, or changes on the active unit are immediately propagated to the standby unit. If the standby unit becomes active in an active/standby ready High Availability pair, it will already have an identical routing table as that of the former active unit because routes are synchronized as a part of the High Availability bulk synchronization and continuous replication processes.

## Dynamic Routing in Clustering

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

*Figure 342: Dynamic Routing in Spanned EtherChannel Mode*

After the data node learn the routes from the control node, each node makes forwarding decisions independently. The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a

consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

## Dynamic Routing in Individual Interface Mode

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

*Figure 343: Dynamic Routing in Individual Interface Mode*

In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

EIGRP does not form neighbor relationships with cluster peers in individual interface mode.

**Note** If the cluster has multiple adjacencies to the same router for redundancy purposes, asymmetric routing can lead to unacceptable traffic loss. To avoid asymmetric routing, group all of these node interfaces into the same traffic zone. See [Create an ECMP Zone, on page 1337](#).

## Routing Table for Management Traffic

The threat defense device includes the following routing tables for from-the-device management traffic:

- Linux Management routing table—Special management traffic sourced from the Management interface such as management center communication, the licensing communication, and database updates always uses the Linux Management routing table.
- Data routing table—All from-the-device traffic (as well as all through traffic) uses the data routing table by default. All regular data interfaces are part of this routing table. Most services let you choose a specific interface, so only routes associated with that interface are used.
- Management-only routing table—The Management interface and all data interfaces that you set to management-only are part of this routing table. To send from-the-device traffic from any of these interfaces, you must choose a specific management-only interface when you configure the service. An exception is for DNS lookups: in some cases, threat defense will use data and then fall back to management automatically if a route is not found. You can add static routes for management-only interfaces, but not for the special Management interface. The threat defense device automatically adds a default route for Management that forwards traffic to Linux, where a separate route lookup occurs in the Linux routing table. You can add static routes to the Linux routing table that can be used by Management using the threat defense CLI **configure network static-routes** command.

---

**Note** The *default* Linux route is set with the **configure network ipv4** or **configure network ipv6** command.

---

---

**Note** For devices that have not yet merged the Management and legacy Diagnostic interfaces, see refer to pre-7.3 versions of this guide.

---

## Equal-Cost Multi-Path (ECMP) Routing

The threat defense device supports Equal-Cost Multi-Path (ECMP) routing.

You can have up to 8 equal cost static or dynamic routes per interface. For example, you can configure multiple default routes on the outside interface that specify different gateways.

```
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.3
route for 0.0.0.0 0.0.0.0 through outside to 10.1.1.4
```

In this case, traffic is load-balanced on the outside interface between 10.1.1.2, 10.1.1.3, and 10.1.1.4. Traffic is distributed among the specified gateways based on an algorithm that hashes the source and destination IP addresses, incoming interface, protocol, source and destination ports.

### ECMP Across Multiple Interfaces Using Traffic Zones

If you configure traffic zones to contain a group of interfaces, you can have up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone. For example, you can configure multiple default routes across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2
route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

Similarly, your dynamic routing protocol can automatically configure equal cost routes. The threat defense device load-balances traffic across the interfaces with a more robust load balancing mechanism.

When a route is lost, the device seamlessly moves the flow to a different route.

## About Route Maps

Route maps are used when redistributing routes into an OSPF, RIP, EIGRP or BGP routing process. They are also used when generating a default route into an OSPF routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process.

Route maps have many features in common with widely known ACLs. These are some of the traits common to both:

- They are an ordered sequence of individual statements, and each has a permit or deny result. Evaluation of an ACL or a route map consists of a list scan, in a predetermined order, and an evaluation of the criteria of each statement that matches. A list scan is aborted once the first statement match is found and an action associated with the statement match is performed.
- They are generic mechanisms. Criteria matches and match interpretation are dictated by the way that they are applied and the feature that uses them. The same route map applied to different features might be interpreted differently.

These are some of the differences between route maps and ACLs:

- Route maps are more flexible than ACLs and can verify routes based on criteria which ACLs can not verify. For example, a route map can verify if the type of route is internal.
- Each ACL ends with an implicit deny statement, by design convention. If the end of a route map is reached during matching attempts, the result depends on the specific application of the route map. Route maps that are applied to *redistribution* behave the same way as ACLs: if the route does not match any clause in a route map then the route redistribution is denied, as if the route map contained a deny statement at the end.

## Permit and Deny Clauses

Route maps can have permit and deny clauses. The deny clause rejects route matches from redistribution. You can use an ACL as the matching criterion in the route map. Because ACLs also have permit and deny clauses, the following rules apply when a packet matches the ACL:

- ACL permit + route map permit: routes are redistributed.
- ACL permit + route map deny: routes are not redistributed.
- ACL deny + route map permit or deny: the route map clause is not matched, and the next route-map clause is evaluated.

## Match and Set Clause Values

Each route map clause has two types of values:

- A match value selects routes to which this clause should be applied.
- A set value modifies information that will be redistributed into the target protocol.

For each route that is being redistributed, the router first evaluates the match criteria of a clause in the route map. If the match criteria succeeds, then the route is redistributed or rejected as dictated by the permit or deny clause, and some of its attributes might be modified by the values set from the set commands. If the match criteria fail, then this clause is not applicable to the route, and the software proceeds to evaluate the route against the next clause in the route map. Scanning of the route map continues until a clause is found that matches the route or until the end of the route map is reached.

A match or set value in each clause can be missed or repeated several times, if one of these conditions exists:

- If several match entries are present in a clause, all must succeed for a given route in order for that route to match the clause (in other words, the logical AND algorithm is applied for multiple match commands).
- If a match entry refers to several objects in one entry, either of them should match (the logical OR algorithm is applied).
- If a match entry is not present, all routes match the clause.
- If a set entry is not present in a route map permit clause, then the route is redistributed without modification of its current attributes.

---

**Note** Do not configure a set entry in a route map deny clause because the deny clause prohibits route redistribution—there is no information to modify.

---

A route map clause without a match or set entry does perform an action. An empty permit clause allows a redistribution of the remaining routes without modification. An empty deny clause does not allow a redistribution of other routes (this is the default action if a route map is completely scanned, but no explicit match is found).

## CHAPTER 45

# Virtual Routers

This chapter describes underlying concepts about virtual routers and on how virtual routing behaves within the Secure Firewall Threat Defense.

- [About Virtual Routers and Virtual Routing and Forwarding \(VRF\), on page 1281](#)
- [Maximum Number of Virtual Routers By Device Model, on page 1288](#)
- [Requirements and Prerequisites for Virtual Routers, on page 1289](#)

- [Modifications to the Management Center Web Interface - Routing Page, on page 1291](#)
- [Manage Virtual Routers, on page 1292](#)
- [Create a Virtual Router, on page 1292](#)
- [Monitoring Virtual Routers, on page 1295](#)
- [Configuration Examples for Virtual Routers, on page 1296](#)

## About Virtual Routers and Virtual Routing and Forwarding (VRF)

You can create multiple virtual routers to maintain separate routing tables for groups of interfaces. Because each virtual router has its own routing table, you can provide clean separation in the traffic flowing through the device.

Thus, you can provide support to two or more distinct customers over a common set of networking equipment. You can also use virtual routers to provide more separation for elements of your own network, for example, by isolating a development network from your general purpose corporate network.

Virtual routers implement the “light” version of Virtual Routing and Forwarding, or VRF-Lite, which does not support Multiprotocol Extensions for BGP (MBGP).

When you create a virtual router, you assign interfaces to the router. You can assign a given interface to one, and only one, virtual router. You would then define static routes, and configure routing protocols such as OSPF or BGP, for each virtual router. You would also configure separate routing processes over your entire network, so that routing tables on all participating devices are using the same per-virtual-router routing process and tables. Using virtual routers, you create logically-separated networks over the same physical network to ensure the privacy of the traffic that runs through each virtual router.

Because the routing tables are separate, you can use the same, or overlapping, address spaces across the virtual routers. For example, you could use the 192.168.1.0/24 address space for two separate virtual routers, supported by two separate physical interfaces.

Note that there are separate management and data routing tables per virtual router. For example, if you assign a management-only interface to a virtual router, then the routing table for that interface is separate from the data interfaces assigned to the virtual router.

## About Virtual Routers and Dynamic VTI

### Virtual Routers and Dynamic VTI

You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. You can assign a dynamic VTI to only one virtual router.

A virtual router associated with:

- A dynamic VTI is called an Indoor VRF (IVRF).
- A tunnel source interface is known as Front Door VRF (FVRF).

A dynamic VTI and its corresponding protected network interface must be part of the same virtual router. You must map the borrow IP interface and the dynamic VTI to the same virtual router. A tunnel source interface can be part of multiple virtual routers.

To configure virtual routers using dynamic VTI for a route-based site-to-site VPN, see [How to Configure a Virtual Router with Dynamic VTI, on page 1282](#).

For more information about a configuration example, see [How to Secure Traffic from Networks with Multiple Virtual Routers over a Site-to-Site VPN with Dynamic VTI, on page 1314](#)

## How to Configure a Virtual Router with Dynamic VTI

To configure a virtual router with dynamic VTI for a route-based site-to-site VPN in the management center:

| Step | Do This                                                                                                          | More Information                                                               |
|------|------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| 1    | Create a route-based site-to-site VPN with a dynamic VTI interface on the hub and static VTI(s) on the spoke(s). | <a href="#">Create a Route-based Site-to-Site VPN, on page 1645</a>            |
| 2    | Create a virtual router.                                                                                         | <a href="#">Create a Virtual Router, on page 1292</a>                          |
| 3    | Assign the interfaces to the virtual router.                                                                     | <a href="#">Configure a Virtual Router, on page 1293</a>                       |
| 4    | Configure routing policies for the hub and spoke.                                                                | <a href="#">Configure Endpoints for a Hub and Spoke Topology, on page 1648</a> |
| 5    | Configure access control policies for the hub and spoke.                                                         | <a href="#">Configure Endpoints for a Hub and Spoke Topology, on page 1648</a> |

## Applications of Virtual Routers

You can use virtual routers to isolate network on shared resources and/or to isolate networks with common security policy. Thus, virtual routers help you to achieve:

- Traffic separation for customers through dedicated routing tables for each customer or for different departments.
- Common security policy management for different departments or networks.
- Shared internet access for different departments or network.

## Global and User-Defined Virtual Routers

### Global Virtual Routers

For a device with virtual routing capability, system creates a global virtual router by default. The system assigns all interfaces in your network to the global virtual router. A routed interface can belong to either a user-defined virtual router or a global virtual router. When you upgrade threat defense to a version which has virtual router capability, all its existing routing configuration becomes part of the global virtual router.

### User-Defined Virtual Routers

A user-defined virtual router is the one defined by you. You can create more than one virtual router on a device. However, anytime, an interface can be assigned to only one user-defined virtual router. While some of the device features are supported on user-defined virtual routers, few of the features are supported only on the global virtual routers. User-defined virtual routers support route-based site-to-site VPN (static VTI) (static and dynamic VTI).

### Supported Features and Monitoring Policies

You can configure the following features on the global virtual router only:

- OSPFv3
- RIP
- EIGRP
- IS-IS
- Multicast Routing
- Policy Based Routing (PBR)

ISIS and PBR are supported through Flex Config in management center (see [Predefined FlexConfig Objects, on page 2714](#)). Configure only global virtual router interfaces for these features.

DHCP server auto-configuration uses WINS/DNS server that is learned from an interface. This interface can only be a global virtual router interface.

You can configure the following features separately for each user-defined virtual router:

- Static routes and their SLA monitors
- OSPFv2
- BGPv4/v6
- Integrated Routing and Bridging (IRB)
- SNMP

Following features are used by the system when querying or communicating with the remote system (from-the-box traffic). These features use interfaces in the global virtual router only. That means, if you configure an interface for the feature, it must belong to the global virtual router. As a rule, anytime, if the system must look up a route to reach an external server for its own management purposes, it does the route lookup in the global virtual router.

- DNS server when used to resolve fully qualified names used in access control rules, or for resolving names for the **ping** command. If you specify **any** as the interface for a DNS server, the system considers interfaces in the global virtual router only.
- AAA server or identity realm when used with VPN. You can configure VPN on interfaces in the global virtual router only. Thus, the external AAA servers that are used for VPN, such as Active Directory, must be reachable through an interface in the global virtual router.
- 

## Configuring Policies to be Virtual-Router-Aware

When you create a virtual router, the routing table for that virtual router is automatically separated from the global virtual router or any other virtual router. However, security policies are not automatically virtual-router-aware.

For example, if you write an access control rule that applies to “any” source or destination security zone, then the rule will apply to all interfaces across all virtual routers. This might in fact be exactly what you want. For example, all of your customers might want to block access to the same list of objectionable URL categories.

But, if you need to apply a policy to one of the virtual routers but not others, you need to create security zones that contain interfaces from that single virtual router only. Then, use the virtual-router-constrained security zones in the source and destination criteria of the security policy.

By using security zones whose memberships are constrained to the interfaces assigned to a single virtual router, you can write virtual-router-aware rules in the following policies:

- Access control policy.
- Intrusion and file policies.
- SSL decryption policy.
- Identity policy and user-to-IP address mappings. If you use overlapping address spaces in virtual routers, ensure that you create separate realms for each virtual router and apply them correctly in the identity policy rules.

If you use overlapping address spaces in your virtual routers, you should use security zones to ensure that the right policies get applied. For example, if you use the 192.168.1.0/24 address space in two separate virtual routers, an access control rule that simply specifies the 192.168.1.0/24 network will apply to traffic in both virtual routers. If that is not the desired outcome, you can limit the application of the rule by also specifying the source/destination security zones for just one of the virtual routers.

# Interconnecting Virtual Routers

## Static and Dynamic Route Leaking

You can configure the device to route traffic between virtual routers. This process of route leaking can be done manually by setting up static routes or dynamically through BGP settings.

### Static Route Leaking

You can configure static routes to route traffic between virtual routers.

For example, if you have the outside interface in the global virtual router, you can set up static default routes in each of the other virtual routers to send traffic to the outside interface. Then, any traffic that cannot be routed within a given virtual router gets sent to the global router for subsequent routing.

Static routes between virtual routers are known as route leaks, because you are leaking traffic to a different virtual router. When you are leaking routes, say, VR1 routes to VR2, you can initiate connections from VR2 to VR1 only. For traffic to flow from VR1 to VR2, you must configure the reverse route. When you create a static route to an interface in another virtual router, you do not need to specify a gateway address. Simply select the destination interface.

For inter-virtual-router routes, the system does destination interface look-up in the source virtual router. Then, it looks up the MAC address of the next hop in the destination virtual router. Thus, the destination virtual router must have either a dynamic (learned) or static route for the selected interface for the destination address.

Configuring NAT rules that use source and destination interfaces in different virtual routers can also allow traffic to route between virtual routers. If you do not select the option for NAT to do a route lookup, the rule will simply send traffic out the destination interface with a NATed address whenever destination translation happens. However, the destination virtual router should have a route for the translated destination IP address so that next-hop lookup can succeed.

Though NAT rule leaks traffic from one virtual router to another, to ensure correct routing, we recommend that you configure a static route leak between these virtual routers for the translated traffic. Without the route leak, sometimes the rule may not match the traffic you expect it to match, and the translation may not be applied.

Virtual routing does not support a cascading or chain of route leaks. For example, assume that your threat defense has VR1, VR2, and VR3 virtual routers; VR3 is directly connected to a network - 10.1.1.0/24. Now, assume you configure a route leak in VR1 for network 10.1.1.0/24 through interface in VR2 and in VR2 define a route leak for 10.1.1.0/24 through VR3. This chain of route leaks will not allow traffic to hop from VR1 to VR2 and then exit from VR3. In case of route leaks, the route lookups first determine egress interface from input Virtual Router's routing table and then looks at the output of Virtual Router's routing table for next hop lookup. From both the lookups, egress interface should match. In our example, the egress interfaces will not be the same and hence the traffic does not pass through.

Use static inter VRF route with caution when the destination network is not a direct-connected subnet of the upstream (outgoing) VR. For example, assume two VRs - VR1 and VR2. While VR1 handles the outgoing traffic which gets the default route from its external peer through BGP or any dynamic routing protocol, and VR2 handles the incoming traffic which is configured with static inter VRF default route with VR1 as the next-hop. When VR1 loses the default route from its peer, VR2 will not be able to detect that its upstream (outgoing) VR lost the default route and the traffic is still sent toward VR1 which will eventually get dropped without notifications. In this scenario, we recommend that you configure VR2 with dynamic route leak through BGP.

### Dynamic Route Leaking Using BGP

You can implement an inter-virtual-router route leak by exporting routes from a source virtual router (say VR1) to the source BGP table using route target extended community and then importing the same route target extended community from the source BGP table into the destination BGP table, which in turn is used by the destination virtual router (say, VR2). You can use the route maps for filtering the routes. The routes of global virtual router can also be leaked to user-defined virtual routers and vice versa. The BGP inter-virtual-router route leaking supports both ipv4 and ipv6 prefixes.

For details on configuring BGP route leaking, see [Configure BGP Route Import/Export Settings, on page 1402](#).

### BGP Route Leaking Guidelines

- Ensure that all the routes required for recursion are imported and present in the routing table of the ingress virtual router.
- ECMP is supported per virtual router. Hence, do not configure an ECMP across different virtual routers. The overlapping prefixes imported from different virtual routers cannot form an ECMP. That is, when you attempt to import routes with overlapping addresses from two different virtual routers to other virtual routers (a global virtual router or an user-defined virtual router), only one route (as per BGP best path algorithm, the first route that was advertised) is imported to the respective virtual routing table. For example, if a network 10.10.0.0/24, connected to VR1 is advertised through BGP to a global virtual router first, and later another network with the same address 10.10.0.0/24, connected to VR2 is also advertised through BGP to global virtual router, only the VR1 network route is imported to the global virtual routing table.
- OSPFv3 is not supported on user-defined virtual routers. Hence, do not configure BGPv6 to leak OSPFv3 user-defined virtual routers to global virtual router. However, you can configure BGPv6 to leak OSPFv3 global virtual router routes to user-defined virtual router through redistribution.
- It is recommended to keep VTI interface, protected internal interfaces (loopback interface if supported for VTI) to be part of same virtual router to prevent the need for route leak.

## Overlapping IP Addresses

Virtual router creates multiple instances of routing tables that are independent, thereby, the same or overlapping IP addresses can be used without conflicts. Threat Defense allows the same network to be part of two or more virtual routers. This involves multiple policies to be applied at the interface or at the virtual router level.

Other than few exceptions, the routing functions and most of the NGFW and IPS capability does not get impacted by the overlapping IP addresses. The following section describes the features that have limitations with overlapping IP addresses and the suggestions or recommendations to overcome them.

### Limitations with Overlapping IP Addresses

When using an overlapping IP address in multiple virtual routers, to ensure proper application of the policy, you have to modify policies or rules for some of the features. Such features require you to use more specific interface either by splitting existing security zone or using new interface group as the need be.

Following features need modification for its proper functioning with an overlapping IP address:

- Network Map—Modify the network discovery policy to exclude some overlapping IP segments to ensure that there is no overlapping IP address being mapped.

- Identity Policy—The identity feed source cannot differentiate among virtual routers; to overcome this limitation, map overlapping address spaces or virtual routers in different realms.

For the following features, you need to apply rules on specific interfaces to ensure that different policies are applied on overlapping IP segments:

- Access Policy
- Prefilter Policy
- QoS/Rate Limit
- SSL Policy

### Unsupported Features with Overlapping IP Addresses

- ISE SGT-based Rule in AC Policy—The static security group tag (SGT) to IP address mappings downloaded from Cisco Identity Services Engine (ISE) are not virtual-router-aware. Set up separate ISE systems per virtual router if you need to create different SGT mappings per virtual router. This is not necessary if you intend to map the same IP addresses to the same SGT number in each virtual router.
- Overlapping DHCP server pools are not supported across virtual routers.
- Events and Analytics—Many of the management center analytics are dependent on network map and identity mappings which cannot differentiate if the same IP address belongs to two different end hosts. Hence, these analytics are not accurate when there are overlapping IP segments existing in same device but different virtual routers.

## Configuring SNMP on User-Defined Virtual Routers

In addition to supporting SNMP on the management interface and Global virtual router data interfaces, Secure Firewall Threat Defense now allows you to configure SNMP host on user-defined virtual routers.

Configuring an SNMP host on user-defined virtual routers includes the following process:

1. [Enable the Physical Interface and Configure Ethernet Settings](#)
2. [Create a Virtual Router](#)
3. [Add SNMP Hosts](#)

---

**Note** SNMP is not virtual router-aware. Hence, while configuring SNMP server on the user-defined virtual router, ensure that the network address is not an [Overlapping IP Addresses](#).

---

4. [Deploy Configuration Changes](#). On successful deployment, the-SNMP polling and traps are sent to the Network Management Station through the virtual router interface.

## Maximum Number of Virtual Routers By Device Model

The maximum number of virtual routers you can create depends on the device model. The following table provides the maximum limits. You can double-check on your system by entering the **show vrf counters** command, which shows the maximum number of user-defined virtual routers for that platform not including the global virtual router. The numbers in the table below include user and global routers. For the Firepower 4100/9300, these numbers apply to native mode.

For platforms that support multi-instance capability, such as the Firepower 4100/9300, determine the maximum number of virtual routers per container instance by dividing the maximum virtual routers by the number of cores on the device, and then multiplying by the number of cores assigned to the instance, rounding down to the nearest whole number. For example, if the platform supports a maximum of 100 virtual routers, and it has 70 cores, then each core would support a maximum of 1.43 virtual routers (rounded). Thus, an instance assigned 6 cores would support 8.58 virtual routers, which rounds down to 8, and an instance assigned 10 cores would support 14.3 virtual routers (rounding down, 14).

| Device Model                  | Maximum Virtual Routers |
|-------------------------------|-------------------------|
| Firepower 1010                | 5                       |
| Firepower 1120                | 5                       |
| Firepower 1140                | 10                      |
| Firepower 1150                | 10                      |
| Secure Firewall 1210CE/1210CP | 5                       |
| Secure Firewall 1220CX        | 10                      |
| Secure Firewall 1230/1240     | 10                      |
| Secure Firewall 1250/1260     | 15                      |
| Firepower 2110                | 10                      |
| Firepower 2120                | 20                      |
| Firepower 2130                | 30                      |
| Firepower 2140                | 40                      |
| Secure Firewall 3105          | 10                      |
| Secure Firewall 3110          | 15                      |
| Secure Firewall 3120          | 25                      |
| Secure Firewall 3130          | 50                      |
| Secure Firewall 3140          | 100                     |
| Firepower 4112                | 60                      |

| Device Model                          | Maximum Virtual Routers |
|---------------------------------------|-------------------------|
| Firepower 4115                        | 80                      |
| Firepower 4125                        | 100                     |
| Firepower 4145                        | 100                     |
| Secure Firewall 4215                  | 100                     |
| Secure Firewall 4225                  | 100                     |
| Secure Firewall 4245                  | 100                     |
| Firepower 9300 appliance, all models  | 100                     |
| Threat Defense Virtual, all platforms | 30                      |
| ISA 3000                              | 10                      |

## Guidelines and Limitations for Virtual Routers

**Firewall Mode Guidelines**

Virtual routers are supported on routed firewall mode only.

### Interface Guidelines

- You can assign an interface to only one virtual router.
- A virtual router can have any number of interfaces that are assigned to it.
- You can assign only routed interfaces with logical names and VTIs to a user-defined virtual router.
- If you want to change a virtual router interface to a non-routed mode, remove the interface from the virtual router, and then change its mode.
- You can assign an interface to a virtual router, either from a global virtual router or from another user-defined virtual router.
- The following interfaces cannot be assigned to an user-defined virtual router:
  - Members of EtherChannel.
  - Members of Redundant interfaces.
  - Members of BVI.
- VTI is a route-based VPN. So, when the tunnel is established, the traffic that uses VTI for encryption must be controlled through routing. Static routing, as well as dynamic routing with BGP, OSPFv2/v3, or EIGRP is supported.
- You cannot use interfaces that belong to user-defined virtual routers in policy-based site-to-site or remote access VPNs.
- A dynamic VTI and its corresponding protected network interface must be part of the same virtual router.
- You must map the borrow IP interface and the dynamic VTI to the same virtual router.
- User-defined virtual routers support only BGPv4/v6 and OSPFv2 routing protocols.
- A tunnel source interface can be in a different user-defined virtual router than that associated with the dynamic VTI.
- If a route using the interface that is being moved or its virtual router is deleted, exist in source or destination virtual router table, remove the routes before the interface movement or virtual router deletion.
- As separate routing tables are maintained for each virtual router, when an interface is moved from one virtual router to another virtual router, be it global or user-defined, the system removes the IP address configured on the interface temporarily. All existing connections on the interface are terminated. Thus, moving interfaces between virtual routers have drastic effect on the network traffic. Hence take precautionary measures before you move interfaces.

### Global Virtual Router Guidelines

- The interfaces which are named and not part of other virtual routers, are part of the global virtual router.
- You cannot remove routed interfaces from global virtual router.
- You cannot modify global virtual router.
- Generally, after configuring interfaces, if you un-register and register back to same or another management center, interface configuration is imported back from device. With virtual router support, there is a restriction—the IP address for only global virtual router interfaces is retained.

### Clustering Guidelines

- When the control unit link fails due to failure of its interfaces, the unit removes all leaked routes of its interfaces from the global routing table and propagates the inactive connected and static routes to other units of the cluster. This results in removal of those leaked routes from the routing table in other units. These removal takes place prior to another unit becoming a new control unit, which takes approximately 500 ms. When another unit becomes the new control unit, these routes are learned and added back to the routing tables through BGP convergence. Thus, till the convergence time, approximately one minute, the leaked routes are not available for the routing events to take place.
- When a control role change occurs in a cluster, the leaked routes learnt through BGP is updated with the best ECMP path. However, the non-best ECMP path is removed from the cluster routing table only after the BGP reconvergence timer elapses, that is 210 seconds. Thus, till the BGP reconvergence timer elapse, the old, non-best ECMP path persist as preferred route for routing events.

### Additional Guidelines

- While configuring BGP for virtual routers, you can redistribute the routes belonging to different protocols within the same virtual routers. For example, OSPF VR2 routes cannot be imported into BGP VR1. You can only redistribute OSPF VR2 into BGP VR2, and then configure a route leak between BGP VR2 and BGP VR1.
- You cannot use IPv6 ACL for filtering the routes in the route map. Only prefix list is supported.
- Security Intelligence Policy—The Security Intelligence policy is not virtual-router-aware. If you add an IP address, URL, or DNS name to the block list, it is blocked for all virtual routers. This limitation is applicable on the interface having security zones.
- NAT Rules—Do not mix interfaces in NAT rules. In virtual routing, if the specified source and destination interface objects (interface groups or security zones) have interfaces that belong to different virtual routers, the NAT rule diverts traffic from one virtual router through another virtual router. The NAT does the route lookup in the virtual router table for the inbound interface only. If necessary, define static routes in the source virtual router for the destination interface. If you leave the interface as **any**, the rule applies to all interfaces regardless of virtual router membership.
- DHCP Relay—Interconnecting virtual routers for DHCP relay is not supported. For example, if DHCP relay client is enabled on VR1 interface and DHCP relay server is enabled on VR2 interface, the DHCP requests will not be forwarded outside of VR2 interface.
- Recreating a deleted virtual router—When you recreate a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to recreate a deleted virtual router successively, use a different name for the new virtual router.

## Modifications to the Management Center Web Interface - Routing Page

Devices earlier to the threat defense 6.6 and few device models are not supported with virtual routing capability. The management center web interface displays the same Routing page of the management center 6.5 or earlier version for such non supported devices. To know the supported devices and platform for virtual routing, see [Maximum Number of Virtual Routers By Device Model](#).

You can configure virtual routers in the routing page of a supported device:

1. Navigate to **Devices** > **Device Management** and edit the virtual-router-aware device.
2. Click **Routing** to enter the virtual routers page.

For devices using virtual routing, the left pane of the Routing page displays the following:

- **Manage Virtual Routers**—allows you to create and manage virtual routers.
- List of virtual routing protocols—lists routing protocols that you can configure for the virtual routers.
- **General Settings**—allows you to configure BGP general settings that are applicable for all the virtual routers. Select the **Enable BGP** check box in order to define other BGP settings. To configure other BGP settings for a virtual router, navigate to **BGP** in the virtual routing protocols .

## Manage Virtual Routers

When you click **Manage Virtual Routers** on the Virtual Routers pane, the Manage Virtual Routers page appears. This page displays the existing virtual routers on the device and the associated interfaces. In this page, you can **Add Virtual Router** (+) to the device. You can also **Edit** (✎) and **Delete** (🗑) user-defined virtual routers. You cannot edit or remove a global virtual router. You can only **View** (👁) the details of a global virtual router.

## Create a Virtual Router

### Procedure

---

**Step 1** Choose **Devices** > **Device Management**, and edit the threat defense device.

**Step 2** Click **Routing**.

**Step 3** Click **Manage Virtual Routers**.

**Step 4** Click **Add Virtual Router** (+).

**Step 5** In the Add Virtual Router box, enter a name and description for the virtual router.

**Note** If you are creating a virtual router that was deleted less than 10 seconds earlier, an error message appears stating that deletion of the virtual router is in progress. If you want to create a deleted virtual router successively, use a different name for the new virtual router.

**Step 6** Click **Ok**.

The Routing page appears, displaying the newly created virtual router page.

---

### What to do next

- [Configure a Virtual Router](#).

## Configure a Virtual Router

You can assign interfaces to a user-defined virtual router and configure the routing policies for the device. Though you cannot manually add or remove interfaces for a global virtual router, you can configure the routing policies for the device interfaces.

### Before you begin

- To configure routing policies for a user-defined virtual router, add a router. See [Create a Virtual Router, on page 1292](#).
- All routing configuration settings of a non-virtual routing capable device are also available for a global virtual router. For information on the settings, see [Reference for Routing](#).
- Only limited routing protocols are supported for a user-defined virtual router.

### Procedure

- 
- Step 1** From the **Devices > Device Management** page, edit the virtual-router supported device. Navigate to **Routing**. For information on the modifications to the routing page, see [Modifications to the Management Center Web Interface - Routing Page, on page 1291](#).
- Step 2** From the drop-down list, select the desired virtual router.
- Step 3** In the **Virtual Router Properties** page, you can modify the description.
- Step 4** To add interfaces, select the interface under the **Available Interfaces** box, and then click **Add**.
- Remember the following:
- Only interfaces with a logical name are listed under the **Available Interfaces** box. You can edit the interface and provide a logical name in **Interfaces**. Remember to save the changes for the settings to take effect.
  - Only interfaces of global virtual routers are available for assigning; the **Available Interfaces** box lists only interfaces that are not assigned to any other user-defined virtual routers. You can assign physical interfaces, subinterfaces, redundant interfaces, bridge groups, VTIs, and EtherChannels to a virtual router, but not their member interfaces. Because the member interfaces cannot be named, they cannot be used in virtual routing.
- You can assign the diagnostic interface to the global virtual router only.
- Step 5** To save the settings, click **Save**.
- Step 6** To configure the routing policy for the virtual router, click the respective names to open the corresponding settings page:
- **OSPF**—Only OSPFv2 is supported on the user-defined virtual router. All other settings for OSPFv2 are as applicable as for a non-virtual-router-aware interface, except that **Interface** allows you to select only the interfaces of the virtual router that you are configuring. You can define the OSPFv3 and OSPFv2 routing policies for a global virtual router. For information on the OSPF settings, see [OSPF, on page 1349](#).
  - **RIP**—You can configure RIP routing policies only for a global virtual router. For information on RIP settings, see [RIP, on page 1405](#).
  - **BGP**—This page displays the BGP general settings that you have configured in **Settings**:

- You cannot modify any of those general settings on this page, except for the router ID settings. You can override the router ID settings that were defined in the **Settings** page by editing them on this page.
- To configure other BGP IPv4 or IPv6 settings, you must enable the BGP option in **BGP** page under **General Settings**.
- BGP configuration for both IPv4 and IPv6 address family are supported for global router and the user-defined virtual router.

For information on configuring BGP settings, see [BGP, on page 1387](#).

- **Static Route**—Use this setting to define where to send traffic for a specific destination network. You can also use this setting to create an inter-virtual-router static route. You can create a leak of connected or static route by using the interfaces of user-defined or global virtual routers. **FMC prefixes** to an interface to indicate that it is belonging to another virtual router and can be used for a route leak. For the route leak to be successful, do not specify next hop gateway.

The Static Route table displays the virtual router whose interface is used for a route leak in the **Leaked from Virtual Router** column. If it is not a route leak, the column displays N/A.

Irrespective of which virtual router the static route belongs, a Null0 interface is listed along with the interfaces of the same virtual router to which the static route belongs.

For information on static route settings, see [Static and Default Routes, on page 1265](#).

- **Multicast**—You can configure multicast routing policies only for a global virtual router. For information on multicast settings, see [Multicast, on page 1411](#).

**Step 7** To save the settings, click **Save**.

---

#### What to do next

- [Modify a Virtual Router](#).
- [Remove Virtual Routers](#).

## Modify a Virtual Router

You can modify the description and other routing policies of a virtual router.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Click **Routing**.

**Step 3** Click **Manage Virtual Routers**.

All virtual routers along with the assigned interfaces are displayed in the **Virtual Routers** page.

**Step 4** To modify a virtual router, click **Edit** (✎) against the desired virtual router.

**Note** You cannot modify the general settings of the global virtual router. Hence, edit is not available for the global router; instead a **View** (👁) is provided to view the settings.

**Step 5** To save the changes, click **Save**.

---

#### What to do next

- [Remove Virtual Routers](#).

## Remove Virtual Routers

#### Before you begin

- You cannot delete the Global virtual router. Hence, the delete option is not available for the Global virtual router.
- You can remove multiple virtual routers at a time.
- All the routing policies of the deleted virtual router are also deleted.
- All the interfaces of the deleted virtual router move to the global virtual router.
- If there are any restrictions on the movement of interfaces, such as overlapping IPs, route conflicts, and so on, you can remove the router only after resolving the conflicts.

#### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Click **Routing**.

**Step 3** Click **Manage Virtual Routers**.

All virtual routers along with the mapped interfaces are displayed in the **Virtual Routers** page.

**Step 4** To remove a virtual router, click **Delete** (🗑) against the desired virtual router.

**Step 5** To remove multiple routers, holding the CTRL key, click the virtual routers that you want to delete. Right-click, and then click **Delete**.

**Step 6** To save the changes, click **Save**.

---

## Monitoring Virtual Routers

To monitor and troubleshoot virtual routers, log into the device CLI and use the following commands:

- **show vrf**: Displays the details of the virtual routers and their associated interfaces.
- **show route vrf <vrf\_name>**: Displays the routing details of a virtual router.

- **show run router bgp all**: Displays the BGP routing details of all virtual router.
- **show run router bgp vrf <vrf\_name>**: Displays the BGP routing details of a virtual router.
- **show crypto ipsec sa/show crypto ikev2 sa**: Displays the details of the tunnel and the associated virtual router.
- You can monitor the tunnels in the Site-to site monitoring dashboard (**Overview > Site to Site VPN**).

In the **Tunnel Status** widget, hover over a topology, click View  and click **Packet Tracer** to view and troubleshoot the threat defense VPN tunnels.

## Configuration Examples for Virtual Routers

### How to Route to a Distant Server through Virtual Routers

In virtual routing, you can create multiple virtual routers to maintain separate routing tables for groups of interfaces, thereby achieve network separation. In some scenarios, you may need to access a server that is reachable only through a separate virtual router. This example provides the procedure that interconnects virtual routers to reach to a host that is multiple hops away.

Consider an example, where a member of the sales department of a garment company wants to look up at the stock maintained by the warehousing department of its factory unit. In a virtual routing environment, you need to leak route between virtual routers where destination (warehousing department) is multiple hops away from sales department. This route leaking is done by adding multihop route leak, where, you configure a static route in Sales virtual router(source) to an interface in Warehouse virtual router (destination). As the destination network is multi-hop away, you also need to configure the Warehouse virtual router with the route to the destination network, namely 10.50.0.0/24.

**Figure 344: Interconnecting Two Virtual Routers - An Example**

### Before you begin

This example assumes that you have already configured Sales\_Router1 to route traffic from 10.20.0.1/30 interface to 10.50.0.5/24.

### Procedure

- 
- Step 1** Configure the inside interface (Gi0/1) of the device to be assigned to Sales virtual router:
- Choose **Devices > Device Management > Interfaces**.
  - Edit the Gi0/1 interface:
    - **Name**—For this example, VR-Sales.
    - Select the **Enabled** checkbox.
    - In **IPV4**, for **IP Type**, choose **Use Static IP**.
    - **IP Address**—Enter 10.30.0.1/24.
  - Click **Ok**.
  - Click **Save**.
- Step 2** Configure the inside interface (Gi0/2) of the device to be assigned to Warehouse virtual router:
- Choose **Devices > Device Management > Interfaces**.
  - Edit the Gi0/2 interface:
    - **Name**—For this example, VR-Warehouse.
    - Select the **Enabled** checkbox.
    - In **IPV4**, for **IP Type**, choose **Use Static IP**.
    - **IP Address**—Leave it blank. The system does not allow you to configure interfaces with same IP address (10.30.0.1/24), as you are yet to create user-defined virtual routers.
  - Click **Ok**.
  - Click **Save**.
- Step 3** Create Sales and Warehouse virtual routers and assign their interfaces:
- Choose **Devices > Device Management**, and edit the threat defense device.
  - Choose **Routing > Manage Virtual Routers**.
  - Click **Add Virtual Router** and create Sales.
  - Click **Add Virtual Router** and create Warehouse.
  - Select Sales from virtual router drop-down, in **Virtual Router Properties**, add VR-Sales as **Selected Interface** and save.
  - Select Warehouse from virtual router drop-down, in **Virtual Router Properties**, add VR-Warehouse as **Selected Interface** and save.
- Step 4** Revisit the VR-Warehouse interface configuration:
- Choose **Devices > Device Management > Interfaces**.

- b) Click **Edit** against VR-Warehouse interface. Specify the IP Address as 10.30.0.1/24. The system now allows you to configure with same IP address of VR-Sales, because the interfaces are separately assigned to two different virtual routers.
- c) Click **Ok**.
- d) Click **Save**.

**Step 5**

Create network objects for the warehouse server—10.50.0.0/24, and for the warehouse gateway— 10.40.0.2/30:

- a) Choose **Object > Object Management**.
- b) Choose **Add Network > Add Object**:
  - **Name**—For this example, Warehouse-Server.
  - **Network**—Click Network and enter 10.50.0.0/24.
- c) Click **Save**.
- d) Choose **Add Network > Add Object**:
  - **Name**—For this example, Warehouse-Gateway.
  - **Network**—Click Host and enter 10.40.0.2.

- e) Click **Save**.

**Step 6**

Define the route leak in Sales that points to the VR-Warehouse interface:

- a) Choose **Devices > Device Management**, and edit the threat defense device.
- b) Choose **Routing**.
- c) Choose Sales virtual router from the drop-down, and then click **Static Route**.
- d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select VR-Warehouse.
  - **Network**—Select the Warehouse-Server object.
  - **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

### Add Static Route Configuration

Type:  IPv4  IPv6

Interface\*  
 VR-Warehouse

Available Network

- any-ipv4
- IPv4-Benchmark-Tests
- IPv4-Link-Local
- IPv4-Multicast
- IPv4-Private-10.0.0.0-8
- IPv4-Private-172.16.0.0-12

Selected Network  
 Warehouse-Server

Gateway\*

Metric:  
  
 (1 - 254)

Tunneled:  (Used only for default Route)

Route Tracking:

- e) Click **Ok**.
- f) Click **Save**.

**Step 7** In the Warehouse virtual router, define the route that points to the Warehouse Router 2 gateway:

- a) Choose Warehouse virtual router from the drop-down, and then click **Static Route**.
- b) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select VR-Warehouse.
  - **Network**—Select the Warehouse-Server object.
  - **Gateway**—Select the Warehouse-Gateway object.

### Add Static Route Configuration

Type:  IPv4  IPv6

Interface\*  
 VR-Warehouse

Available Network

- any-ipv4
- IPv4-Benchmark-Tests
- IPv4-Link-Local
- IPv4-Multicast
- IPv4-Private-10.0.0.0-8
- IPv4-Private-172.16.0.0-12

Selected Network  
 Warehouse-Server

Ensure that egress virtualrouter has route to that destination

Gateway  
 Warehouse-Gateway

Metric:  
 1  
 (1 - 254)

Tunneled:  (Used only for default Route)

Route Tracking:

- c) Click **Ok**.
- d) Click **Save**.

**Step 8** Configure access control rule that allows access to the warehouse server. For creating the access control rule, you need to create security zones. Use **Object > Object Management > Interface**. Choose **Add > Security Zone** and create security zones for VR-Sales and VR-Warehouse; for Warehouse-Server network object, create a Warehouse-Server interface group (Choose **Add > Interface Group**).

**Step 9** Choose **Policies > Access Control** and configure an access control rule to allow traffic from the source interfaces in the Sales virtual router to the destination interfaces in the Warehouse virtual router for the destination Warehouse-Server network object.

For example, if the interfaces in Sales are in the Sales-Zone security zone, and those in Warehouse are in the Warehouse-Zone security zone, the access control rule would look similar to the following:

SalesWarehouse

Enter Description

## How to Provide Internet Access with Overlapping Address Spaces

When using virtual routers, you can have the same network address for interfaces that reside in separate routers. However, because the IP addresses routed in these separate virtual routers are the same, apply NAT/PAT rules for each interface with separate NAT/PAT pools to ensure that return traffic goes to the correct destination. This example provides the procedure to configure the virtual routers and NAT/PAT rules to manage the overlapping address spaces.

For example, interfaces vr1-inside and vr2-inside on threat defense is defined to use the IP address 192.168.1.1/24, managing endpoints on their segment in the 192.168.1.0/24 network. To allow Internet access from two virtual routers that use the same address space, you need to apply NAT rules separately to the interfaces within each virtual router, ideally using separate NAT or PAT pools. You could use PAT to translate the source addresses in VR1 to 10.100.10.1, and for those in VR2, to 10.100.10.2. The following illustration shows this setup, where the Internet-facing outside interface is part of the global router. You must define the NAT/PAT rules with the source interface (vr1-inside and vr2-inside) explicitly selected—using “any” as the source interface makes it impossible for the system to identify the correct source because the same IP address could exist on two different interfaces.

**Note** Even if you have some interfaces within virtual routers that does not use overlapping address spaces, define the NAT rule with the source interface to make troubleshooting easier, and to ensure a cleaner separation between traffic from the virtual routers that is Internet-bound.

### Procedure

#### Step 1

Configure the inside interface of the device for VR1:

- a) Choose **Devices > Device Management > Interfaces**.
- b) Edit the interfaces that you want to assign to VR1:
  - **Name**—For this example, vr1-inside.
  - Select the **Enabled** checkbox.
  - In **IPv4**, for **IP Type**, choose **Use Static IP**.
  - **IP Address**—Enter 192.168.1.1/24.
- c) Click **Ok**.
- d) Click **Save**.

**Step 2**

Configure the inside interface of the device for VR2:

- a) Choose **Devices > Device Management > Interfaces**.
- b) Edit the interfaces that you want to assign to VR2:
  - **Name**—For this example, vr2-inside.
  - Select the **Enabled** checkbox.
  - In **IPV4**, for **IP Type**, choose **Use Static IP**.
  - **IP Address**—Leave it blank. The system does not allow you to configure interfaces with same IP address, as you are yet to create user-defined virtual routers.
- c) Click **Ok**.
- d) Click **Save**.

**Step 3**

Configure VR1 and the static default route leak to the outside interface:

- a) Choose **Devices > Device Management**, and edit the threat defense device.
- b) Choose **Routing > Manage Virtual Routers**. Click **Add Virtual Router** and create VR1.
- c) For VR1, in **Virtual Router Properties**, assign vr1-inside and save.
- d) Click **Static Route**.
- e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select the outside interface of the global router.
  - **Network**—Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR1.
  - **Gateway**—Leave it blank. When leaking a route into another virtual router, do not provide a Gateway.

### Add Static Route Configuration

Type:  IPv4  IPv6

Interface\*

(Interface starting with this icon  signifies it is available for route leak)

Available Network  + Selected Network

- any-ipv4
- IPv4-Benchmark-Tests
- IPv4-Link-Local
- IPv4-Multicast
- IPv4-Private-10.0.0.0-8
- IPv4-Private-172.16.0.0-12

any-ipv4 

Ensure that egress virtualrouter has route to that destination

Gateway

Metric:

(1 - 254)

Tunneled:  (Used only for default Route)

Route Tracking:

- f) Click **Ok**.
- g) Click **Save**.

#### Step 4

Configure VR2 and the static default route leak to the outside interface:

- a) Choose **Devices > Device Management**, and edit the threat defense device.
- b) Choose **Routing > Manage Virtual Routers**. Click **Add Virtual Router** and create VR2.
- c) For VR2, in **Virtual Router Properties**, assign vr2-inside and save.
- d) Click **Static Route**.
- e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select the outside interface of the global router.
  - **Network**—Select the any-ipv4 object. This network is the default route for any traffic that cannot be routed within VR2.
  - **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the Gateway.

### Add Static Route Configuration

Type:  IPv4  IPv6

Interface\*

(Interface starting with this icon  signifies it is available for route leak)

Available Network  +

Selected Network

- any-ipv4
- IPv4-Benchmark-Tests
- IPv4-Link-Local
- IPv4-Multicast
- IPv4-Private-10.0.0.0-8
- IPv4-Private-172.16.0.0-12

any-ipv4

Ensure that egress virtualrouter has route to that destination

Gateway

Metric:  
  
 (1 - 254)

Tunneled:  (Used only for default Route)

Route Tracking:

- f) Click **Ok**.
- g) Click **Save**.

#### Step 5

Configure IPv4 static default route, namely 172.16.1.2 on the outside interface of the global router:

- a) Choose **Devices > Device Management**, and edit the threat defense device.
- b) Choose **Routing** and edit global router properties.
- c) Click **Static Route**.
- d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select the outside interface of the global router.
  - **Network**—Select the any-ipv4 object. This will be the default route for any IPv4 traffic.
  - **Gateway**—If already created, select the host name from the drop-down. If the object is not yet created, click **Add** and define the host object for the IP address of the gateway at the other end of the network link on the outside interface, in this example, 172.16.1.2. After you create the object, select it in the Gateway field.

Add Static Route Configuration ?

Type:  IPv4  IPv6

Interface\*  

  
(Interface starting with this icon  signifies it is available for route leak)

Available Network + Selected Network

Add

- any-ipv4
- IPv4-Benchmark-Tests
- IPv4-Link-Local
- IPv4-Multicast
- IPv4-Private-10.0.0.0-8
- IPv4-Private-172.16.0.0-12

Gateway\*  
 +

Metric:  
  
(1 - 254)

Tunneled:  (Used only for default Route)

Route Tracking:

Cancel OK

- e) Click **Ok**.
- f) Click **Save**.

**Step 6** Revisit the vr2-inside interface configuration:

- a) Choose **Devices > Device Management > Interfaces**.
- b) Click **Edit** against vr2-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with same IP address of vr1-inside, because the interfaces are separately assigned to two different virtual routers.
- c) Click **Ok**.
- d) Click **Save**.

**Step 7** Create the NAT rule to PAT inside to outside traffic of VR1 to 10.100.10.1.

- a) Choose **Devices > NAT**.
- b) Click **New Policy > Threat Defense NAT**.
- c) Enter InsideOutsideNATRule as the NAT policy name, and select the threat defense device. Click **Save**.
- d) In InsideOutsideNATRule page, click **Add Rule** and define the following:
  - **NAT Rule**—Select Manual NAT Rule.

- **Type**—Select Dynamic.
- **Insert**—Above, if any dynamic NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select vr1-interface object and click **Add to Source** (If the object is not available, create one in **Object > Object Management > Interface**), and select outside as **Add to Destination**.
- In **Translation**, for **Original Source**, select any-ipv4. For **Translated Source**, click **Add** and define host object VR1-PAT-Pool with 10.100.10.1. Select VR1-PAT-Pool as shown in the figure below:

NAT Rule:  
Manual NAT Rule

Insert:  
In Category NAT Rules Before

Type:  
Static

Enable  
Description:

Interface Objects Translation PAT Pool Advanced

| Original Packet                    | Translated Packet                         |
|------------------------------------|-------------------------------------------|
| Original Source:*<br>any-ipv4 +    | Translated Source:<br>Address             |
| Original Destination:<br>Address + | Translated Destination:<br>VR1-PAT-Pool + |

| Original Destination Port:<br>+    | Translated Destination Port:<br>+         |

Cancel OK

- Click **Ok**.
- Click **Save**.

### Step 8

Add NAT rule to PAT inside to outside traffic of VR2 to 10.100.10.2.

- Choose **Devices > NAT**.
- Edit InsideOutsideNATRule to define the VR2 NAT rule:
  - **NAT Rule**—Select Manual NAT Rule.
  - **Type**—Select Dynamic.
  - **Insert**—Above, if any dynamic NAT rule exists.
  - Click **Enabled**.
  - In **Interface Objects**, select vr2-interface object and click **Add to Source** (If the object is not available, create one in **Object > Object Management > Interface**), and select outside as **Add to Destination**.

- In **Translation**, for **Original Source**, select any-ipv4. For **Translated Source**, click **Add** and define host object VR2-PAT-Pool with 10.100.10.2. Select VR2-PAT-Pool as shown in the figure below:

NAT Rule:  
Manual NAT Rule

Insert:  
In Category NAT Rules Before

Type:  
Static

Enable

Description:

Interface Objects Translation PAT Pool Advanced

| Original Packet                    | Translated Packet                         |
|------------------------------------|-------------------------------------------|
| Original Source:*<br>any-ipv4 +    | Translated Source:<br>Address +           |
| Original Destination:<br>Address + | Translated Destination:<br>VR2-PAT-Pool + |
| Original Source Port:<br>+         | Translated Source Port:<br>+              |
| Original Destination Port:<br>+    | Translated Destination Port:<br>+         |

Cancel OK

- Click **Ok**.
- Click **Save**.

**Step 9** To configure the access control policy that allows traffic from the vr1-inside and vr2-inside interfaces to the outside interface, you need to create security zones. Use **Object > Object Management > Interface**. Choose **Add > Security Zone** and create security zones for vr1-inside, vr2-inside, and outside interfaces.

**Step 10** Choose **Policies > Access Control** and configure an access control rule to allow traffic from vr1-inside-zone and vr2-inside-zone to outside-zone.

Assuming that you create zones named after the interfaces, a basic rule that allows all traffic to flow to the Internet will look like the following. You can apply other parameters to this access control policy:

### Add Rule

Name:   Enabled Insert:

Action:  Time Range:

Zones Networks VLAN Tags **Users** Applications Ports URLs SGT/ISE Attributes

Available Zones

- outside-zone
- vr1-inside-zone
- vr2-inside-zone

Source Zones (2)

- vr1-inside-zone
- vr2-inside-zone

## How to Allow RA VPN Access to Internal Networks in Virtual Routing

On virtual routing-enabled devices, RA VPN is supported only on global virtual router interfaces. This example provides the procedure that allows your Secure Client user to connect to user-defined virtual router networks.

In the following example, the RA VPN (Secure Client) user connects to the outside interface of threat defense at 172.16.3.1, and is given an IP address within the pool of 192.168.80.0/24. The user can access the inside network of only the global virtual router. To allow traffic flow through the network of the user-defined virtual router VR1, namely 192.168.1.0/24, leak the route by configuring the static routes on global and VR1.

### Before you begin

This example assumes that you have already configured the RA VPN, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.

### Procedure

#### Step 1

Configure route leak from Global virtual router to the user-defined VR1:

- a) Choose **Devices** > **Device Management**, and edit the threat defense device.
- b) Click **Routing**. By default, the Global routing properties page appears.
- c) Click **Static Route**.
- d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select the VR1 inside interface.
  - **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
  - **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.

Add Static Route Configuration

Type:  IPv4  IPv6

Cancel OK

The route leak allows Secure Client assigned IP addresses in the VPN pool to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

**Step 2** Configure the route leak from VR1 to the Global virtual router:

- a) Choose **Devices > Device Management**, and edit the threat defense device.
- b) Click **Routing** and from the drop-down, select VR1.
- c) Click **Static Route**.
- d) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select the outside interface of the global router.
  - **Network**—Select the global virtual router network object.
  - **Gateway**—Leave it blank. When leaking a route into another virtual router, does not select the gateway.

Add Static Route Configuration

Cancel OK

The configured static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections to Secure Client assigned IP addresses in the VPN pool.

e) Click **Ok**.

### What to do next

If RA VPN address pool and the IP addresses in the user-defined virtual router overlap, you must also use static NAT rules on the IP addresses to enable proper routing. Alternatively, you can change your RA VPN address pool so that there is no overlap.

## How to Secure Traffic from Networks in Multiple Virtual Routers over a Site-to-Site VPN

On virtual routing-enabled devices, Site-to-Site VPN is supported only on global virtual router interfaces. You cannot configure it on an interface that belongs to a user-defined virtual router. This example provides the procedure that allows you to secure the connections from or to networks hosted within user-defined virtual routers over the site-to-site VPN. You also need to update the site-to-site VPN connection to include the user-defined virtual routing networks.

Let us consider a scenario, where, a site-to-site VPN is configured between a branch office network to a company headquarters network; the threat defense in the branch office having virtual routers. In this case, the site-to-site VPN is defined on the outside interface of the branch office at 172.16.3.1. This VPN includes the inside network 192.168.2.0/24 without extra configuration, because the inside interface is also part of the global virtual router. But, to provide site-to-site VPN services to the 192.168.1.0/24 network, which is part of the VR1 virtual router, you must leak the route by configuring the static routes on global and VR1, and add the VR1 network to the site-to-site VPN configuration.

### Before you begin

This example assumes that you have already configured the site-to-site VPN between the 192.168.2.0/24 local network and the 172.16.20.0/24 external network, defined the virtual routers, and configured and assigned the interfaces to the appropriate virtual routers.

### Procedure

- Step 1** Configure route leak from the Global virtual router to the user-defined VR1:
- Choose **Devices > Device Management**, and edit the threat defense device.
  - Click **Routing**. By default, the Global routing properties page appears.
  - Click **Static Route**.
  - Click **Add Route**. In **Add Static Route Configuration**, specify the following:
    - **Interface**—Select the VR1 inside interface.
    - **Network**—Select the VR1 virtual router network object. You can create one using the **Add Object** option.
    - **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

Add Static Route Configuration

Type:  IPv4  IPv6

Cancel OK

The route leak allows endpoints protected by the external (remote) end of the site-to-site VPN to access the 192.168.1.0/24 network in the VR1 virtual router.

e) Click **Ok**.

## Step 2

Configure the route leak from VR1 to the Global virtual router:

- Choose **Devices > Device Management**, and edit the threat defense device.
- Click **Routing** and from the drop-down, select VR1.
- Click **Static Route**.
- Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select the outside interface of the global router.
  - **Network**—Select the global virtual router network object.
  - **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select the gateway.

Add Static Route Configuration ?

This static route allows endpoints on the 192.168.1.0/24 network (VR1) to initiate connections that will traverse the site-to-site VPN tunnel. For this example, the remote endpoint that is protecting the 172.16.20.0/24 network.

e) Click **Ok**.

**Step 3** Add the 192.168.1.0/24 network to the site-to-site VPN connection profile:

- a) Choose **Devices > VPN > Site To Site**, and edit the VPN Topology.
- b) In **Endpoints**, edit Node A endpoint.
- c) In **Edit Endpoint**, in the **Protected Networks** field, click **Add New Network Object**.
- d) Add the VR1 network object with 192.168.1.0 network:

- e) Click **Ok** and save the configuration.

---

## How to Secure Traffic from Networks with Multiple Virtual Routers over a Site-to-Site VPN with Dynamic VTI

ISPs have different segmented networks for different customers. You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. A single threat defense device can act as a dynamic VTI hub with a global or one or more user-defined virtual routers. Each user-defined virtual router can be one customer network.

Let us consider an example where route-based site-to-site VPNs are configured between two company headquarter networks and their two branch office networks. The ISP's threat defense, a dynamic VTI hub, manages the two company headquarter networks with two user-defined virtual routers: VRF green and VRF red. The dynamic VTI hub establishes a site-to-site VPN between:

- Customer 1 (VRF green) and Branch 1 (SVTI spoke 1)
- Customer 2 (VRF red) and Branch 2 (SVT2 spoke 2)

Figure 345: Site-to-Site VPNs with Multiple Virtual Routers and Dynamic VTI

This example illustrates how to configure networks with multiple virtual routers over a site-to-site VPN with dynamic VTI.

## Procedure

- 
- Step 1** Configure a dynamic VTI interface on the hub.
- Choose **Devices > Device Management** and edit the threat defense device.
  - Choose **Add Interfaces > Virtual Tunnel Interface**.
  - Select the **Tunnel Type** as **Dynamic**.
  - Specify the interface name as DVTI1 and configure all the parameters for the dynamic VTI.
  - Click **Save**
  - Repeat steps 1a - e to configure the second dynamic VTI on the hub, DVTI2.
- Step 2** Configure static VTI on spoke 1.
- Choose **Devices > Device Management** and edit the threat defense device.
  - Choose **Add Interfaces > Virtual Tunnel Interface**.
  - Select the **Tunnel Type** as **Static**.
  - Specify the interface name as SVTI spoke-1 and configure all the parameters for the static VTI.
  - Click **Save**
  - Repeat steps 2a - e to configure the static VTI on spoke 2: SVTI spoke-2.
- Step 3** Configure a route-based site-to-site VPN between hub and SVTI spoke 1.
- Choose **Devices > Site To Site** and click + **Site To Site VPN**.
  - Enter a name for the VPN topology in the **Topology Name** field.
  - Choose **Route Based (VTI)** and select **Hub and Spoke** as the network topology.
  - Click the **Endpoints** tab.
  - Configure the hub and the spoke (DVTI1 and SVTI spoke-1) and their routing policies.
  - Configure the **IKE**, **IPsec**, and **Advanced** options for the VPN, if required.
  - Click **Save**.

- h) Repeat steps 3a - g to configure the second route-based site-to-site VPN topology between hub (DVTI2) and SVTI spoke 2.

**Step 4** Configure the two virtual routers.

- a) Choose **Devices > Device Management** and edit the threat defense device.
- b) Click **Routing**.
- c) Click **Manage Virtual Routers**.
- d) Click **Add Virtual Router**.

Specify the name as VRF green and provide a description for the virtual router.

- e) Repeat steps 4a - d to configure VRF red.

**Step 5** Assign all the interfaces to the virtual routers.

- a) From the drop-down list, select the virtual router.
- b) In the **Virtual Router Properties** page, select the interfaces listed under the **Available Interfaces** box.

Assign the dynamic VTI interface along with the other interfaces.

- c) Click **Add**.

**Step 6** Repeat steps 5a - c for VRF red.

**Step 7** Configure the routing policy for the virtual router.

- a) From the drop-down list, select the virtual router.
- b) Click **Static Route** or one of the dynamic routing protocols.
- c) Configure the routing parameters.
- d) Click **Save**.

---

### What to do next

Select the hub and spoke devices and click **Deploy**. After the deployment, you can monitor the VPN tunnels in the Site-to site monitoring dashboard (**Overview > Site to Site VPN**).

You can also use the commands listed in [Monitoring Virtual Routers, on page 1295](#) to view and troubleshoot the virtual router.

## How to Route Traffic between Two Overlapping Network Host in Virtual Routing

You can configure hosts on the virtual routers that have same network address. If the hosts want to communicate, you can configure twice NAT. This example provides the procedure to configure the NAT rules to manage the overlapping network host.

In the following example, two hosts Host A and Host B belong to different virtual routers: VRG (interface vrg-inside), VRB (interface vrb-inside) respectively with the same subnet 10.1.1.0/24. For both the hosts to communicate, create a NAT policy where, VRG-Host interface object would use a mapped NAT address - 20.1.1.1, and VRB-Host interface object would use a mapped NAT address - 30.1.1.1. Thus, Host A uses 30.1.1.1 to communicate to Host B; Host B uses 20.1.1.1 to reach Host A.

### Before you begin

This example assumes that you have already configured:

- vrg-inside and vrb-inside interfaces are associated with virtual routers: VRG and VRB respectively and vrg-inside and vrb-inside interfaces configured with same subnet address (say, 10.1.1.0/24).
- Interfaces zones VRG-Inf, VRB-Inf created with vrg-inside and vrb-inside interfaces respectively.
- Host A in VRG with vrg-inside as default gateway; Host B in VRB with vrb-inside as default gateway.

### Procedure

- 
- Step 1** Create the NAT rule to handle traffic from Host A to Host B. Choose **Devices > NAT**.
- Step 2** Click **New Policy > Threat Defense NAT**.
- Step 3** Enter a NAT policy name, and select the threat defense device. Click **Save**.
- Step 4** In the NAT page, click **Add Rule** and define the following:
- **NAT Rule**—Select Manual NAT Rule.
  - **Type**—Select Static.
  - **Insert**—Select Above, if any NAT rule exists.
  - Click **Enabled**.
  - In **Interface Objects**, select VRG-Inf object and click **Add to Source** (If the object isn't available, create one in **Object > Object Management > Interface**), and select VRB-Inf object and click **Add to Destination**.
  - In **Translation**, select the following:
    - **Original Source**, select vrg-inside.
    - **Original Destination**, click **Add** and define object VRB-Mapped-Host with 30.1.1.1. Select VRB-Mapped-Host.

- **Translated Source**, click **Add** and define object, VRG-Mapped-Host with 20.1.1.1. Select VRG-Mapped-Host.
- **Translated Destination**, select vrb-inside as shown in the following figure:

Add NAT Rule ?

NAT Rule:  
Manual NAT Rule

Insert:  
In Category NAT Rules Before

Type:  
Static

Enable  
Description:

Interface Objects Translation PAT Pool Advanced

| Original Packet                    | Translated Packet                            |
|------------------------------------|----------------------------------------------|
| Original Source:*<br>vrg-inside +  | Translated Source:<br>Address +              |
| Original Destination:<br>Address + | Translated Destination:<br>VRG-Mapped-Host + |

| NAT Rules Before |           |        |                          |                               |                  |                       |                   |                    |                         |                     |     |
| 1                |           | Static | VRG-Inf                  | VRB-Inf                       | vrg-inside       | VRB-Mapped-Host       |                   | VRG-Mapped-Host    | vrb-inside              |                     | Dns |
| Auto NAT Rules   |           |        |                          |                               |                  |                       |                   |                    |                         |                     |     |
| NAT Rules After  |           |        |                          |                               |                  |                       |                   |                    |                         |                     |     |

When you deploy the configuration, a warning message appears:

Validation Messages: [Redacted]

1 total | 0 errors | 1 warning | 0 infos

**ManualNat64Rule: Host2Host**

- Warning: [ManualNatRule 1] The NAT rule has source and destination interfaces belonging to different Virtual Routers, the traffic will be able to leak between Virtual Routers without explicit route leak configuration whenever destination translation happens. If you intend to apply this NAT rule even when destination translation is not happening, create a static route leak explicitly. The rule involves interfaces from [VRG] to [VRB]

## How to Manage Overlapping Segments in Routed Firewall Mode with BVI Interfaces

You can deploy single threat defense between multiple overlapping networks transparently and/or deploy the firewall between the hosts of same network. To achieve this deployment, configure BVI per virtual router. The procedure to configure the BVIs in virtual router is explained here.

BVI is a virtual interface within a router that acts like a normal routed interface. It does not support bridging, but represents the comparable bridge group to routed interfaces within the router. All the packets coming in or going out of these bridged interfaces, pass through the BVI interface. The interface number of the BVI is the number of the bridge group that the virtual interface represents.

In the following example, BVI-G is configured in VRG and Bridge Group 1 is the routed interface for interfaces G0/1 and G0/2. Similarly, BVI-B is configured in VRB and Bridge Group 2 is the routed interface for interfaces G0/3 and G0/4. Consider that both BVIs have the same IP subnet address, say 10.10.10.5/24. Because of virtual routers, the network is isolated on the shared resources.

## Procedure

- 
- Step 1** Choose **Devices > Device Management**. Edit the required device.
- Step 2** In **Interfaces**, choose **Add Interfaces > Bridge Group Interface**.
- a) Enter the following details for BVI-G:
- **Name**—For this example, BVI-G.
  - **Bridge Group ID**—For this example, 1.
  - **Available Interface**—Select the interfaces.
  - In **IPV4**, for **IP Type**, choose **Use Static IP**.
  - **IP Address**—Enter 10.10.10.5/24.

Add Bridge Group Interface ?

Interfaces IPv4 IPv6

Name:

Description:

Bridge Group ID \*:

(1 - 250)

Available Interfaces ↻

- GigabitEthernet0/0
- GigabitEthernet0/1
- GigabitEthernet0/2**
- GigabitEthernet0/3
- GigabitEthernet0/4
- GigabitEthernet0/5

Selected Interfaces

- GigabitEthernet0/1 🗑
- GigabitEthernet0/2 🗑

- b) Click **Ok**.
- c) Click **Save**.
- a) Enter the following details for BVI-B:
- **Name**—For this example, BVI-B.
  - **Bridge Group ID**—For this example, 2.
  - **Available Interface**—Select the sub interfaces.
  - In **IPV4**, for **IP Type**, choose **Use Static IP**.
  - **IP Address**—Leave this field empty as the system does not allow two interfaces to have overlapping IP address. You can revisit the Bridge Group and provide the same IP address after aligning it under a virtual router.

- b) Click **Ok**.
- c) Click **Save**.

**Step 3** Create virtual router, say VRG, and select BVI-G as its network:

- a) Choose **Devices > Device Management**.
- b) Edit the device, and choose **Routing > Manage Virtual Routers**.
- c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.
- d) In **Virtual Routing Properties**, select **BVI-G** and click **Add**.

- e) Click **Save**.

**Step 4** Create virtual router, say VRB, and select BVI-B as its network:

- a) Choose **Devices > Device Management**.
- b) Edit the device, and choose **Routing > Manage Virtual Routers**.
- c) Click **Add Virtual Router**. Enter a name for the virtual router and click **Ok**.

- d) In **Virtual Routing Properties**, select **BVI-B** and click **Add**.

The screenshot displays the Cisco Management Center interface for configuring a Virtual Router. The top navigation bar includes 'Device', 'Routing', 'Interfaces', 'Inline Sets', and 'DHCP'. The left sidebar shows a tree view with 'Manage Virtual Routers' selected, containing options for 'Virtual Router Properties', 'OSPF', 'BGP', 'IPv4', and 'Static Route'. The main content area is titled 'Virtual Router Properties' and contains the following fields:

- VRF Name:** VRB
- Description:** (empty text box)
- Select Interface:** (search box with 'Q Search' text)
- Available Interfaces:** A list containing 'BVI-B' (highlighted in blue) and 'vrg-inside'.
- Selected Interfaces:** A list containing 'BVI-B' with a trash icon next to it.

- e) Click **Save**.

### Step 5

Revisit the BVI-B configuration:

- Choose **Devices > Device Management > Interfaces**.
- Click **Edit** against BVI-B interface. Specify the IP Address as 10.10.10.5/24. The system now allows you to configure with same IP address of BVI-G, because the interfaces are separately assigned to two different virtual routers.
- Click **Ok**.
- Click **Save**.

If you want to enable inter-BVI communication, use an external router as default gateway. In overlapping BVI scenarios, as in this example, use twice NAT external router as gateway to establish inter-BVI traffic. When configuring NAT for the members of a bridge group, you specify the member interface. You cannot configure NAT for the bridge group interface (BVI) itself. When doing NAT between bridge group member interfaces, you must specify the real and mapped addresses. You cannot specify “any” as the interface.

## How to Configure User Authentication with Overlapping Networks

In virtual routing, you can configure multiple virtual routers with overlapping IP and overlapping users. In the example, VRG, and VRB are the virtual routers with overlapping IP - 192.168.1.1/24. The users on two different domains are also on overlapping network IP 192.168.1.20. For VRG and VRB users to access the shared server 172.16.10.X, leak routes to the global virtual router. Use source NAT to handle the overlapping IP. For controlling the access from VRG and VRB users, you must set user authentication in management center. Management Center uses realms, Active Directories, Identity source, and Identity rules and policies for authenticating user identity. Because threat defense does not have direct role in authenticating users, user access is managed only through the access control policy. For controlling traffic from the overlapping users, use Identity policy and rules to create access control policy.

### Before you begin

This example assumes that you have:

- Two AD servers for the VRG and VRB users.
- ISE with the two AD servers added.

### Procedure

#### Step 1

Configure the inside interface of the device for VRG:

- Choose **Devices > Device Management > Interfaces**.
- Edit the interfaces that you want to assign to VRG:
  - **Name**—For this example, VRG-inside.
  - Select the **Enabled** checkbox.
  - In **IPV4**, for **IP Type**, choose **Use Static IP**.
  - **IP Address**—Enter 192.168.1/24.

- Click **Ok**.
- Click **Save**.

#### Step 2

Configure the inside interface of the device for VRB:

- Choose **Devices > Device Management > Interfaces**.
- Edit the interfaces that you want to assign to VRB:
  - **Name**—For this example, VRB-inside.

- Select the **Enabled** checkbox.
- In **IPv4**, for **IP Type**, choose **Use Static IP**.
- **IP Address**—Leave it blank. The system doesn't allow you to configure interfaces with same IP address, as you're yet to create user-defined virtual routers.

- Click **Ok**.
- Click **Save**.

**Step 3**

Configure VRG and the static default route leak to the inside interface of the Global router for the VRG users to access the common server 172.16.10.1:

- Choose **Devices > Device Management**, and edit the threat defense device.
- Choose **Routing > Manage Virtual Routers**. Click **Add Virtual Router** and create VRG.
- For VRG, in **Virtual Router Properties**, assign VRG-inside and save.

- Click **Static Route**.
- Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select the inside interface of the global router.
  - **Network**—Select the any-ipv4 object.
  - **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.
- Click **Ok**.
- Click **Save**.

**Step 4**

Configure VRB and the static default route leak to the inside interface of the Global router for the VRB users to access the shared server 172.16.10.x:

- Choose **Devices > Device Management**, and edit the threat defense device.

- b) Choose **Routing > Manage Virtual Routers**. Click **Add Virtual Router** and create VRB.
- c) For VRB, in **Virtual Router Properties**, assign VRB-inside and save.

- d) Click **Static Route**.
- e) Click **Add Route**. In **Add Static Route Configuration**, specify the following:
  - **Interface**—Select the inside interface of the global router.
  - **Network**—Select the any-ipv4 object.
  - **Gateway**—Leave it blank. When leaking a route into another virtual router, do not select a gateway.
- f) Click **Ok**.
- g) Click **Save**.

**Step 5** Revisit the VRB-inside interface configuration:

- a) Choose **Devices > Device Management > Interfaces**.
- b) Click **Edit** against VRB-inside interface. Specify the IP Address as 192.168.1.1/24. The system now allows you to configure with the same IP address as that of VRG-inside, because the interfaces are separately assigned to two different virtual routers.
- c) Click **Ok**.
- d) Click **Save**.

**Step 6** Add NAT rules for the source objects VRG and VRB. Click **Devices > NAT**.

**Step 7** Click **New Policy > Threat Defense NAT**.

**Step 8** Enter a NAT policy name, and select the threat defense device. Click **Save**.

**Step 9** In the NAT page, click **Add Rule** and define the following source NAT for VRG:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.

- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.
- In **Interface Objects**, select VRG-Inside object and click **Add to Source** (If the object is not available, create one in **Object > Object Management > Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRG-Users.
  - **Translated Source**, click **Add** and define object, VRG-NAT with 10.1.1.1. Select VRG-NAT as shown in the following figure:

## Add NAT Rule

NAT Rule:  
Manual NAT Rule

Insert:  
In Category NAT Rules Before

Type:  
Static

Enable

Description:

Interface Objects Translation PAT Pool Advanced

| Original Packet                    | Translated Packet                    |
|------------------------------------|--------------------------------------|
| Original Source:*<br>VRG-Users +   | Translated Source:<br>Address        |
| Original Destination:<br>Address + | Translated Destination:<br>VRG-NAT + |
| Original Source Port:              | Translated Source Port:              |

Cancel OK

**Step 10** Click **Ok**.

**Step 11** In the NAT page, click **Add Rule** and define the following source NAT for VRB:

- **NAT Rule**—Select Manual NAT Rule.
- **Type**—Select Static.
- **Insert**—Select Above, if any NAT rule exists.
- Click **Enabled**.

- In **Interface Objects**, select VRB-Inside object and click **Add to Source** (If the object is not available, create one in **Object > Object Management > Interface**), and select Global-Inside object and click **Add to Destination**.
- In **Translation**, select the following:
  - **Original Source**, select VRB-Users.
  - **Translated Source**, click **Add** and define object, VRB-NAT with 20.1.1.1. Select VRB-NAT as shown in the following figure:

Add NAT Rule ?

NAT Rule:  
Manual NAT Rule

Insert:  
In Category NAT Rules Before

Type:  
Static

Enable

Description:

Interface Objects **Translation** PAT Pool Advanced

| Original Packet                               | Translated Packet                               |
|-----------------------------------------------|-------------------------------------------------|
| Original Source:*<br>VRB-Users +              | Translated Source:<br>Address                   |
| Original Destination:<br>Address +            | Translated Destination:<br>VRB-NAT +            |
| Original Source Port:<br><input type="text"/> | Translated Source Port:<br><input type="text"/> |

**Step 12** Click **Save**.

The NAT rule looks like this:

| Rules            |           |       |                  |                       |                  | Original Packet       |  |
|------------------|-----------|-------|------------------|-----------------------|------------------|-----------------------|--|
| #                | Direction | Type  | Source Interface | Destination Interface | Original Sources | Original Destinations |  |
| NAT Rules Before |           |       |                  |                       |                  |                       |  |
| 1                |           | St... | any              | any                   | VRG-Users        |                       |  |
| 2                |           | St... | any              | any                   | VRB-Users        |                       |  |
| Auto NAT Rules   |           |       |                  |                       |                  |                       |  |

- Step 13** Add the two unique AD servers in management center one for each VRG and VRB users—choose **System > Integration > Realms**.
- Step 14** Click **New Realm** and complete the fields. For detailed information on the fields, see [Realm Fields, on page 2478](#).
- Step 15** For controlling the access from VRG and VRB users, define 2 Active Directories, see [Realm Directory and Synchronize fields, on page 2482](#) see [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#)
- Step 16** Add ISE in management center—choose **System > Integration > Identity Sources**.
- Step 17** Click **Identity Services Engine** and complete the fields. For detailed information on the fields, see [How to Configure ISE/ISE-PIC for User Control Using a Realm, on page 2539](#).
- Step 18** Create Identity policy, rules, and then define access control policy for controlling access of overlapping users from VRG and VRB.

## How to Interconnect Virtual Routers using BGP

You can now configure BGP settings on a device to leak the routes among virtual routers (Global and user-defined virtual routers). The route target of the source virtual router is exported to the BGP table, which, in turn is imported to the destination virtual router. The route map is used to share the Global virtual routes with the user-defined virtual routers and vice versa. Note that all import or export of the routes to the BGP table is configured at the user-defined virtual router, including the Global virtual routes.

Consider the firewall device of a factory is configured with the following virtual routers and interfaces:

- Global virtual router is configured with Inside (10.10.1.4/24) and Outside (10.10.0.5/24)
- VR-S (Sales) virtual router is configured with Inside1 (10.10.10.7/24) and Outside1 (10.10.11.7/24)
- VR-W (Warehouse) virtual router is configured with Inside2 (10.10.12.7/24) and Outside2 (10.10.13.7/24)

Assume that you want the routes of warehouse (VR-W) to be leaked with sales (VR-S) and Global, and the outside interface routes of VR-S to VR-W. Similarly, you want the outside interface routes of the Global router to be leaked to sales (VR-S). This example demonstrates the BGP configuration procedure to achieve interconnecting the routers:

Figure 346: Interconnect Virtual Routers using BGP Settings

**Before you begin**

- Create a Virtual Router—VR-S and VR-W.
- Enable BGP and for each virtual router [Configure BGP Redistribution Settings](#).

**Procedure****Step 1**

Configure VR-W to export its routes tagging them with a route target to VR-S:

- Choose **Devices > Device Management**, edit device, and then click the **Routing** tab.
- From the virtual router drop-down, select VR-W.
- Click **BGP > IPv4 > Route Import/Export**.
- To leak the VR-W routes to VR-S, tag the routes with a route target, so that the VR-W routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, `200:200`. Click **Add**:

- From the virtual router drop-down, select VR-S.
- Click **BGP > IPv4 > Route Import/Export**.
- To receive the leaked routes from VR-W, configure the Import Route Target to import the VR-W routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the same route target value that you had configured for VR-W, `200:200`. Click **Add**.

Manage Virtual Routers

VR-S

Virtual Router Properties

ECMP

OSPF

BGP

IPv4

Enable IPv4:

AS Number 100

General Neighbor Add Aggregate Address Filtering Networks Redistribution Route I

Route Targets Import:

ASN:nn (or) ASN:nn,ASN:nn,ASN:nn Add

200:200

Route Targets Export:

ASN:nn (or) ASN:nn,ASN:nn,ASN:nn Add

**Note** If you want to conditionalize routes to be leaked from VR-W, you can specify the match criteria in the route map object, and choose it in the **User Virtual Router Export Route Map**. Similarly, if you want to conditionalize the routes to be imported to VR-S from the BGP table, you can use the **User Virtual Router Import Route Map**. This procedure is explained in Step 3.

**Step 2** Configure VR-W to export its routes to the Global virtual router:

- You need to create a route map that would allow the VR-W routes to be exported to the Global routing table. Choose **Objects > Object Management > Route Map**.
- Click **Add Route Map**, give a name, say *Export-to-Global*, and then click **Add**.
- Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list:

New Route Map Object

Name

Export-to-Global

Entries (1)

Add

| Sequence No ▲ | Redistribution |
|---------------|----------------|
| 1             | Allow          |

Allow Overrides

Cancel Save

- Click **Save**.

In this example, all the VR-W routes are leaked to the Global routing table. Hence, no match criteria is configured for the route map.

- Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP > IPv4 > Route Import/Export**.
- From the **Global Virtual Router Export Route Map** drop-down list, choose Export-to-Global:

Enable IPv4:

AS Number: 100

General Neighbor Add Aggregate Address Filtering Networks Redistribution Route

Route Targets Import:

ASN:nn (or) ASN:nn,ASN:nn,ASN:nn Add

User Virtual Router

Import Route Map:

Global Virtual Router

Import Route Map:

Route Targets Export:

ASN:nn (or) ASN:nn,ASN:nn,ASN:nn Add

200:200

User Virtual Router

Export Route Map:

Global Virtual Router

Export Route Map:

Export-to-Global

**Step 3**

To leak only the Outside1 routes of VR-S to VR-W:

- a) From the virtual router drop-down, select VR-S.
- b) Click **BGP > IPv4 > Route Import/Export**.
- c) To leak the VR-S routes to VR-W, tag the routes with a route target, so that the VR-S routes are exported to its BGP table with the route target marked on them. In the **Route Targets Export** field, enter a value, say, *100:100*. Click **Add**.
- d) From the virtual router drop-down, select VR-W, and choose **BGP > IPv4 > Route Import/Export**.
- e) To receive the leaked routes from VR-S, configure the Import Route Target to import the VR-S routes that are marked with the route target from the (peer or redistributed) BGP table. In the **Route Targets Import** field, enter the VR-S route target value, *100:100*. Click **Add**.
- f) Now, you need to conditionalize that only the Outside1 routes of VR-S to be leaked to VR-W. Choose **Objects > Object Management > Prefix List > IPv4 Prefix List**.
- g) Click **Add IPv4 Prefix List**, give a name, say *VRS-Outside1-Only*, and then click **Add**.
- h) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.
- i) Enter the IP Address (first two octets) of the VR-S Outside1 interface.
- j) Click **Save**.
- k) Create a route map with the match clause with the prefix list. Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-VRS*, and then click **Add**.
- l) Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.
- m) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**.
- n) Under **Available IPv4 Prefix List**, select *VRS-Outside1-Only*, and then click **Add**.
- o) Click **Save**.
- p) Navigate to the **Routing** tab of the device, and select VR-W. Click **BGP > IPv4 > Route Import/Export**.
- q) From the **Global Virtual Router Import Route Map** drop-down list, choose *Import-from-VRS*:

**Step 4** Configure VR-S to import the Outside routes of Global virtual router:

**Note** To leak routes to or from a Global virtual router, you must configure the source or destination user defined virtual router respectively. Thus, in this example, VR-S is the destination router that imports the routes from Outside interface of the Global virtual router.

- Choose **Objects > Object Management > Prefix List > IPv4 Prefix List**.
- Click **Add IPv4 Prefix List**, give a name, say *Global-Outside-Only*, and then click **Add**.
- Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.
- Enter the IP Address (first two octets) of the Global Outside interface:

Add Prefix List Entry

Action:

Sequence No:   
Range: 1-4294967295

IP Addresses: (Limit 250) Address:   
Format: ipaddr/len (len<=32)

Min Prefix Length:   
Range: 1 - 32

Max Prefix Length:   
Range: 1 - 32

- Click **Save**.
- Click **Route Map**. Click **Add Route Map**, give a name, say *Import-from-Global*, and then click **Add**.
- Specify a **Sequence Number**, say 1, and then choose Allow from the **Redistribution** drop-down list.

- h) In the **Match Clause** tab, click **IPv4**. Under **Address** tab, click **Prefix List**.
- i) Under **Available IPv4 Prefix List**, select Global-Outside-Only, and then click **Add**:

## About ECMP

The threat defense device supports Equal-Cost Multi-Path (ECMP) routing. You can configure traffic zones per virtual router to contain a group of interfaces. You can have up to 8 equal cost static or dynamic routes across up to 8 interfaces within each zone. For example, you can configure multiple default routes across three interfaces in the zone:

```
route for 0.0.0.0 0.0.0.0 through outside1 to 10.1.1.2
route for 0.0.0.0 0.0.0.0 through outside2 to 10.2.1.2
route for 0.0.0.0 0.0.0.0 through outside3 to 10.3.1.2
```

## Guidelines and Limitations for ECMP

### Firewall Mode Guidelines

ECMP zones are supported on routed firewall mode only.

### Interface Guidelines

dVTI and Loopback interfaces are not supported.

### Additional Guidelines

- A device can have a maximum of 256 ECMP zones.
- You can associate only 8 interfaces per ECMP zone.
- An interface can be a member of only one ECMP zone.
- You cannot remove an interface that is associated with an equal cost static route from the ECMP zone.
- You cannot delete an ECMP zone if its interface has equal cost static routes associated with it.
- Only routed interfaces can be associated with an ECMP zone.
- The following interfaces cannot be associated with an ECMP zone:
  - BVI interface.
  - Member interfaces in an EtherChannel.
  - Failover or state link interface.
  - Management-only or management-access interfaces.
  - Cluster control link interface.
  - VNIs.
  - VLAN interfaces.
  - Interfaces in a remote access VPN configuration with SSL enabled.
- DHCP Relay is not supported on interfaces in an ECMP zone.
- Dual ISP/WAN threat defense Deployment—Create a single ECMP zone for the primary and secondary data interfaces. This configuration enables creation of static routes for both the interfaces with same metric values.
- The threat defense does not support ECMP with NAT in IPsec sessions—a standard IPsec virtual private network (VPN) tunnel does not work with NAT points in the delivery path of IPsec packets.

## Manage ECMP Page

When you click **ECMP** on the Routing pane, the ECMP page appears corresponding to the virtual router. This page displays the existing ECMP zones with the associated interfaces of the virtual router. In this page, you can Add an ECMP zone to the virtual router. You can also **Edit** (✎) and **Delete** (🗑) ECMP.

You can perform the following:

- [Create an ECMP Zone, on page 1337](#)
- [Configure an Equal Cost Static Route, on page 1338](#)
- [Modify an ECMP Zone, on page 1339](#)
- [Remove an ECMP Zone, on page 1339](#)

# Create an ECMP Zone

ECMP zones are created per virtual router. Thus, only the interfaces of the virtual router where the ECMP is being created can be associated with the ECMP.

## Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Click **Routing**.
- Step 3** From the virtual router drop-down, select the virtual router in which you want to create the ECMP zone.
- You can create ECMP zones in global virtual router and user-defined virtual routers. For information on creating virtual routers, see [Create a Virtual Router, on page 1292](#).
- Step 4** Click **ECMP**.
- Step 5** Click **Add**.
- Step 6** In the **Add ECMP** box, enter a name for the ECMP zone.
- Note** The ECMP name must be unique for the routed device.
- Step 7** To associate interfaces, select the interface under the **Available Interfaces** box, and then click **Add**.
- Remember the following:
- Only interfaces belonging to the virtual router are available for assigning.
  - Only interfaces with a logical name are listed under the **Available Interfaces** box. You can edit the interface and provide a logical name in **Interfaces**. Remember to save the changes for the settings to take effect.
- Step 8** Click **OK**.
- The ECMP page now displays the newly created ECMP.
- Step 9** Click **Save** and **Deploy** the configuration.

---

You can associate the ECMP zone interfaces with equal cost static route by defining them with same destination and metric value, but with different gateway.

### What to do next

- [Configure an Equal Cost Static Route, on page 1338](#)
- [Modify an ECMP Zone, on page 1339](#)
- [Remove an ECMP Zone, on page 1339](#)

# Configure an Equal Cost Static Route

| Smart License | Classic License | Supported Devices                         | Supported Domains | Access                                   |
|---------------|-----------------|-------------------------------------------|-------------------|------------------------------------------|
| Any           | N/A             | threat defense and threat defense virtual | Any               | Admin/Network<br>Admin/Security Approver |

You can assign interfaces of a virtual router, both global and user-defined, to an ECMP zone for the device.

## Before you begin

- To configure an equal cost static route for an interface, ensure to associate it with an ECMP zone. See [Create an ECMP Zone, on page 1337](#).
- All routing configuration settings of a non-VRF capable device are also available for a global virtual router.
- You cannot define a static route for interfaces with same destination and metric without associating the interfaces with an ECMP zone.

## Procedure

- 
- Step 1** From the **Devices > Device Management** page, edit the threat defense device. Click the **Routing** tab.
  - Step 2** From the drop-down list, select the virtual router whose interfaces are associated with an ECMP zone.
  - Step 3** To configure the equal cost static route for the interfaces, click **Static Route**.
  - Step 4** Either click **Add Route** to add a new route, or click **Edit** (✎) for an existing route.
  - Step 5** From the **Interface** drop-down, select the interface belonging to the virtual router and an ECMP zone.
  - Step 6** Select the destination network from the **Available Networks** box and click **Add**.
  - Step 7** Enter a gateway for the network.
  - Step 8** Enter a metric value. It can be a number that ranges between 1 and 254.
  - Step 9** To save the settings, click **Save**.
  - Step 10** To configure equal cost static routing, repeat the steps to configure the static route for another interface in the same ECMP zone with the same destination network and metric value. Remember to provide a different gateway.
- 

## What to do next

- [Modify an ECMP Zone, on page 1339](#)
- [Remove an ECMP Zone, on page 1339](#)

# Modify an ECMP Zone

## Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Click **Routing**.
- Step 3** Click **ECMP**.
- ECMP zones with its associated interfaces are displayed in the **ECMP** page.
- Step 4** To modify an ECMP, click **Edit** (✎) against the desired ECMP. In the **Edit ECMP** box, you can do the following:
- **ECMP Name**—Ensure that the changed name is unique for the device.
  - **Interfaces**—You can add or remove interfaces. You cannot include an interface that is already associated with another ECMP. In addition, you cannot remove the interface that is associated with an equal cost static route.
- Step 5** Click **OK**.
- Step 6** To save the changes, click **Save**.
- 

### What to do next

- [Configure an Equal Cost Static Route, on page 1338](#)
- [Remove an ECMP Zone, on page 1339](#)

# Remove an ECMP Zone

## Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Click **Routing**.
- Step 3** Click **ECMP**.
- ECMP zones with its associated interfaces are displayed in the **ECMP** page.
- Step 4** To remove an ECMP zone, click **Delete** (🗑) against the ECMP zone.
- You cannot delete the ECMP zone if any of its interfaces are associated with an equal cost static route.
- Step 5** Click **Delete** in the confirmation message.

**Step 6** To save the changes, click **Save**.

## Configuration Example for ECMP

This example demonstrates how to use management center to configure ECMP zones on threat defense such that the traffic flowing through the device is handled efficiently. With ECMP configured, threat defense maintains the routing table per zone basis, and hence it makes it possible to re-route the packets in the best possible routes. Thus, ECMP supports asymmetric routing, load balancing, and handles lost traffic seamlessly. In this example, R4 records the two paths to reach the external file server.

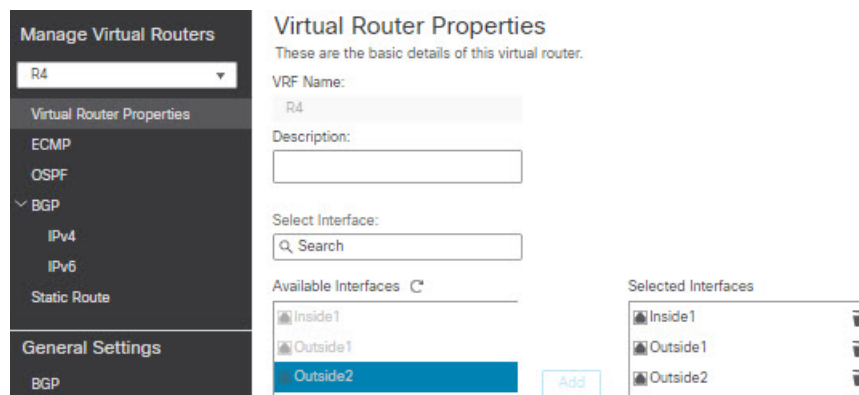

*Figure 347: Configuration Example for ECMP*

### Procedure

**Step 1** [Create a Virtual Router](#)—R4 with *Inside1*, *Outside1*, and *Outside2* interfaces:

*Figure 348: Configuring R4 Virtual Router*

**Step 2** Create ECMP zones:

- a) In the **Routing** tab, choose R4 user defined virtual router, and then click **ECMP**.

- b) Click **Add**.
- c) Enter the ECMP name and from the **Available Interfaces** list, choose *Outside1* and *Outside2*:

**Figure 349: Creating ECMP Zone**

Add ECMP

Name

ECMP-R4

Associate Interfaces with ECMP

You can add interfaces to this ECMP by clicking on Add button. ECMP can have up to 8 interfaces associated with it. All the interfaces in the ECMP must have a name and security level as this ECMP.

Available Interfaces

Selected Interfaces

Inside1

Add

Outside1

Outside2

Cancel OK

- d) Click **Ok**, and then **Save**.

### Step 3

Create static routes for the zone interfaces:

- a) In the **Routing** tab, click **Static Route**.
- b) From the **Interface** drop-down list, select *Outside1*.
- c) Under **Available Network**, choose *any-ipv4* and click **Add**.
- d) Specify the next-hop address in the **Gateway** field, 10.1.1.2:

Figure 350: Configuring Static Route for Outside1

- e) Configure the static route for Outside2, repeating from Step 3b to Step 3d. Ensure to specify same metric, but different gateways for the static routes:

Figure 351: Configured Static Routes of ECMP Zone Interfaces

+ Add Route

| Network       | Interface | Leaked from Virtual Router | Gateway  | Tunneled | Metric | Tracked |
|---------------|-----------|----------------------------|----------|----------|--------|---------|
| ▼ IPv4 Routes |           |                            |          |          |        |         |
| any-ipv4      | Outside1  |                            | 10.1.1.2 | false    | 1      |         |
| any-ipv4      | Outside2  |                            | 10.1.3.2 | false    | 1      |         |
| ▼ IPv6 Routes |           |                            |          |          |        |         |

**Step 4 Save and Deploy.**

The network packets to reach its destination, R3, follows R4>R1>R3 or R4>R2>R3, based on the ECMP algorithm. If R1>R3 route is lost, the traffic flows through R2 without any packet drops. Similarly, the response from R3 can be received by *Outside2* though the packet was sent from *Outside1*. In addition, when the network traffic is heavy, R4 distributes them between the two routes and thus balances the load.

## CHAPTER 47

# Bidirectional Forwarding Detection Routing

This chapter describes how to configure threat defense to use the Bidirectional Forwarding Detection (BFD) routing protocol.

- [About BFD Routing, on page 1343](#)
- [Guidelines for BFD Routing, on page 1343](#)
- [Configure BFD, on page 1344](#)
- [History for BFD Routing, on page 1347](#)

## About BFD Routing

BFD is a detection protocol designed to provide fast forwarding path failure detection times for all media types, encapsulations, topologies, and routing protocols. BFD operates in a unicast, point-to-point mode on top of any data protocol being forwarded between two systems. However, in threat defense, BFD is supported on BGP protocols only. Packets are carried in the payload of the encapsulating protocol appropriate for the media and the network.

BFD provides a consistent failure detection method for network administrators in addition to fast forwarding path failure detection. Because the network administrator can use BFD to detect forwarding path failures at a uniform rate, rather than the variable rates for different routing protocol hello mechanisms, network profiling and planning are easier and reconvergence time is consistent and predictable.

## Guidelines for BFD Routing

### Context Mode Guidelines

BFD is supported on all threat defense platforms. It is supported in multi-instance mode.

### Firewall Mode Guidelines

Supported in routed firewall mode and not in transparent mode.

### Failover and Cluster Guidelines

- BFD is not supported on failover interfaces.
- In clustering, BFD is supported only on the control node.

### Routing and Protocol Guidelines

- OSPFv2, OSPFv3, BGP IPv4, and BGP IPv6 protocol are supported.

---

**Note** For optimal routing, do not configure BFD when BGP graceful restart for NSF is configured on the device.

---

IS-IS and EIGRP protocols are not supported.

- BFD for static routes is not supported. You can configure BFD on interfaces that belong only to virtual routers.
- Only named interfaces are supported.
- BFD on BVI, VTI, and loopback interfaces are not supported.

### Single-hop Guidelines

- Echo mode is disabled by default. You can enable echo mode on single-hop only.
- Echo mode is not supported for IPv6.
- Use only a single-hop template to configure a single-hop policy.
- Authentication of the single-hop template is optional.
- You cannot configure multiple BFDs on the same interface.

### Multi-hop Guidelines

- Do not configure the source IP address also as the destination IP address.
- Source and destination address should have same IP type—IPv4 or IPv6.
- Only network objects of host or network type are allowed.
- Use only a multi-hop template to configure a multi-hop policy.
- Authentication is mandatory for the multi-hop template.

### Upgrade Guidelines

When you upgrade to version 7.3 and when the previous version has any FlexConfig BFD policies, the management center displays a warning message during deployment. However, it does not stop the deployment process. After post-upgrade deployment, to manage the BFD policies from the UI (**Device (Edit) > Routing > BFD**), you must configure BFD policies in the **Device (Edit) > Routing > BFD** page and remove the configuration from the FlexConfig policy for the device.

## Configure BFD

This section describes how to enable and configure the BFD routing policy on your system.

## Procedure

- 
- Step 1** Create [BFD Template, on page 1474](#).
  - Step 2** [Configure BFD Policies, on page 1345](#).
  - Step 3** Configure BFD support in the BGP neighbor settings; see, [Step 12, on page 1396](#)
- 

## Configure BFD Policies

You can bind a BFD template to an interface belonging to a virtual router, or to a source and destination address pair.

### Before you begin

- BFD policy is configurable only on interfaces that belong to virtual routers. See [Configure a Virtual Router](#).

## Procedure

- 
- Step 1** From the **Devices > Device Management** page, edit the virtual-router supported device. Navigate to **Routing**.
  - Step 2** From the drop-down list, select the desired virtual router, and then click **BFD**.
  - Step 3** To configure a BFD on the interface, click the **Single-Hop** tab or **Multi-Hop** tab.

**Note** For a single-hop policy, the BFD template is configured on an interface; for a multi-hop policy, the BFD template is configured on a source and destination address pair.

- Step 4** Click **Add**. To modify the configured BFD policy, click **Edit** (✎).

**Note** When you edit the interface mapping with BFD template to replace it with a new BFD template, the management center uses a **no** command to remove the template mapping from interface and applies the new template to the interface which causes a BFD flap which may also lead to an OSPFv2, OSPFv3, or BGP flap. However, if the BFD intervals are higher, the BFD flap might not occur. Alternatively, to avoid the flapping, you can delete the existing BFD template mapping; deploy the interface, and then add the new BFD template to the interface and deploy the configuration.

- See [Configure Single-Hop BFD Policies, on page 1345](#).
  - See [Configure Multi-Hop BFD Policies, on page 1346](#).
- 

## Configure Single-Hop BFD Policies

You can configure a single-hop BFD policy only on an interface that is belonging to a virtual router.

**Before you begin**

- [BFD Template](#). You cannot configure single-hop BFD policy on interfaces using a multi-hop template.

**Procedure**

- 
- Step 1** In the **Single-Hop** tab, click **Add** or **Edit**.
- Step 2** In the **Add BFD Single-Hop** dialog box, configure the following:
- In the **Interface** drop-down list, interfaces belonging to virtual routers are listed. Select the interface you want to configure with the BFD policy.
  - In the **Template Name** drop-down list, single-hop templates are listed. Select the template that you want to apply.
- If you have not created a single-hop template, use **Add (+)** and [BFD Template](#).
- Step 3** Click **OK** and **Save** the configuration.
- 

**Configure Multi-Hop BFD Policies**

You can configure multi-hop BFD policy on a source and destination address pair.

**Before you begin**

- [BFD Template](#). You cannot configure multi-hop BFD policy using a single-hop template.

**Procedure**

- 
- Step 1** In the **Add BFD Multi-Hop** dialog box, configure the following:
- Click the BFD source address type—**IPv4** or **IPv6** radio button.
  - In the **Source Address** drop-down list, network objects are listed. Select the source address that you want to configure for the BFD policy. You cannot choose *any-ipv4* or *any-ipv6*.
- If you have not created the required network object, use **Add (+)** and create a host/network object.
- Note** The created network object's IP type should match with the selected source IP type.
- In the **Destination Address** drop-down list, network objects are listed. Select the destination address that you want to configure for the BFD. You cannot choose *any-ipv4* or *any-ipv6*.
- If you have not created the required network object, use **Add (+)** and create a host/network object.
- Note** The created network object's IP type should match with the selected source IP type.
- Attention** Do not select the network object that has the same IP address as that of the source address.

- d) In the **Template Name** drop-down list, multi-hop templates are listed. Select the template that you want to apply on the BFD policy.

If you have not created a multi-hop template, use **Add (+)** and [BFD Template](#).

**Step 2** Click **OK** and **Save** the configuration.

The multi-hop map (table view) is displayed on the **Multi-Hop** tab page.

## History for BFD Routing

| Feature              | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------|---------------------------|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BFD support for OSPF | 7.4                       | 7.4                    | You can enable BFD on OSPFv2 and OSPFv3 interfaces.<br>New/modified screens: <ul style="list-style-type: none"> <li>• <b>Configuration &gt; Device Setup &gt; Routing &gt; OSPFv2</b></li> <li>• <b>Configuration &gt; Device Setup &gt; Routing &gt; OSPFv3</b></li> </ul>                                                                                                        |

FlexConfig no longer supports BFD configuration. You can now configure BFD policies for threat defense in the management center UI. In threat defense, BFD is supported only on the BGP protocol.<br>New/modified screens: <b>Devices &gt; Device Management &gt; Routing &gt; BFD</b> . |

## CHAPTER 48

# OSPF

---

This chapter describes how to configure the threat defense to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

- [OSPF, on page 1349](#)
- [Requirements and Prerequisites for OSPF, on page 1352](#)
- [Guidelines for OSPF, on page 1352](#)
- [Configure OSPFv2, on page 1355](#)
- [Configure OSPFv3, on page 1367](#)
- [History for OSPF, on page 1376](#)

## OSPF

This chapter describes how to configure the threat defense to route data, perform authentication, and redistribute routing information using the Open Shortest Path First (OSPF) routing protocol.

## About OSPF

OSPF is an interior gateway routing protocol that uses link states rather than distance vectors for path selection. OSPF propagates link-state advertisements rather than routing table updates. Because only LSAs are exchanged instead of the entire routing tables, OSPF networks converge more quickly than RIP networks.

OSPF uses a link-state algorithm to build and calculate the shortest path to all known destinations. Each router in an OSPF area contains an identical link-state database, which is a list of each of the router usable interfaces and reachable neighbors.

The advantages of OSPF over RIP include the following:

- OSPF link-state database updates are sent less frequently than RIP updates, and the link-state database is updated instantly, rather than gradually, as stale information is timed out.
- Routing decisions are based on cost, which is an indication of the overhead required to send packets across a certain interface. The threat defense device calculates the cost of an interface based on link bandwidth rather than the number of hops to the destination. The cost can be configured to specify preferred paths.

The disadvantage of shortest path first algorithms is that they require a lot of CPU cycles and memory.

The threat defense device can run two processes of OSPF protocol simultaneously on different sets of interfaces. You might want to run two processes if you have interfaces that use the same IP addresses (NAT allows these interfaces to coexist, but OSPF does not allow overlapping addresses). Or you might want to run one process on the inside and another on the outside, and redistribute a subset of routes between the two processes. Similarly, you might need to segregate private addresses from public addresses.

You can redistribute routes into an OSPF routing process from another OSPF routing process, a RIP routing process, or from static and connected routes configured on OSPF-enabled interfaces.

The threat defense device supports the following OSPF features:

- Intra-area, inter-area, and external (Type I and Type II) routes.
- Virtual links.
- LSA flooding.
- Authentication to OSPF packets (both password and MD5 authentication).
- Configuring the threat defense device as a designated router or a designated backup router. The threat defense device also can be set up as an ABR.
- Stub areas and not-so-stubby areas.
- Area boundary router Type 3 LSA filtering.

OSPF supports MD5 and clear text neighbor authentication. Authentication should be used with all routing protocols when possible because route redistribution between OSPF and other protocols (such as RIP) can potentially be used by attackers to subvert routing information.

If NAT is used, if OSPF is operating on public and private areas, and if address filtering is required, then you need to run two OSPF processes—one process for the public areas and one for the private areas.

A router that has interfaces in multiple areas is called an Area Border Router (ABR). A router that acts as a gateway to redistribute traffic between routers using OSPF and routers using other routing protocols is called an Autonomous System Boundary Router (ASBR).

An ABR uses LSAs to send information about available routes to other OSPF routers. Using ABR Type 3 LSA filtering, you can have separate private and public areas with the ASA acting as an ABR. Type 3 LSAs (inter-area routes) can be filtered from one area to other, which allows you to use NAT and OSPF together without advertising private networks.

---

**Note** Only Type 3 LSAs can be filtered. If you configure the threat defense device as an ASBR in a private network, it will send Type 5 LSAs describing private networks, which will get flooded to the entire AS, including public areas.

---

If NAT is employed but OSPF is only running in public areas, then routes to public networks can be redistributed inside the private network, either as default or Type 5 AS external LSAs. However, you need to configure static routes for the private networks protected by the threat defense device. Also, you should not mix public and private networks on the same threat defense device interface.

You can have two OSPF routing processes, one RIP routing process, and one EIGRP routing process running on the threat defense device at the same time.

## OSPF Support for Fast Hello Packets

The OSPF Support for Fast Hello Packets feature provides a way to configure the sending of hello packets in intervals less than one second. Such a configuration would result in faster convergence in an Open Shortest Path First (OSPF) network.

### Prerequisites for OSPF Support for Fast Hello Packets

OSPF must be configured in the network already or configured at the same time as the OSPF Support for Fast Hello Packets feature.

### OSPF Hello Interval and Dead Interval

OSPF hello packets are packets that an OSPF process sends to its OSPF neighbors to maintain connectivity with those neighbors. The hello packets are sent at a configurable interval (in seconds). The defaults are 10 seconds for an Ethernet link and 30 seconds for a non broadcast link. Hello packets include a list of all neighbors for which a hello packet has been received within the dead interval. The dead interval is also a configurable interval (in seconds), and defaults to four times the value of the hello interval. The value of all hello intervals must be the same within a network. Likewise, the value of all dead intervals must be the same within a network.

These two intervals work together to maintain connectivity by indicating that the link is operational. If a router does not receive a hello packet from a neighbor within the dead interval, it will declare that neighbor to be down.

### OSPF Fast Hello Packets

OSPF fast hello packets refer to hello packets being sent at intervals of less than 1 second. To understand fast hello packets, you should already understand the relationship between OSPF hello packets and the dead interval. See [OSPF Hello Interval and Dead Interval, on page 1351](#).

OSPF fast hello packets are achieved by using the `ospf dead-interval` command. The dead interval is set to 1 second, and the `hello-multiplier` value is set to the number of hello packets you want sent during that 1 second, thus providing subsecond or "fast" hello packets.

When fast hello packets are configured on the interface, the hello interval advertised in the hello packets that are sent out this interface is set to 0. The hello interval in the hello packets received over this interface is ignored.

The dead interval must be consistent on a segment, whether it is set to 1 second (for fast hello packets) or set to any other value. The hello multiplier need not be the same for the entire segment as long as at least one hello packet is sent within the dead interval.

### Benefits of OSPF Fast Hello Packets

The benefit of the OSPF Fast Hello Packets feature is that your OSPF network will experience faster convergence time than it would without fast hello packets. This feature allows you to detect lost neighbors within 1 second. It is especially useful in LAN segments, where neighbor loss might not be detected by the Open System Interconnection (OSI) physical layer and data-link layer.

## Implementation Differences Between OSPFv2 and OSPFv3

OSPFv3 is not backward compatible with OSPFv2. To use OSPF to route both IPv4 and IPv6 traffic, you must run both OSPFv2 and OSPFv3 at the same time. They coexist with each other, but do not interact with each other.

The additional features that OSPFv3 provides include the following:

- Protocol processing per link.
- Removal of addressing semantics.
- Addition of flooding scope.
- Support for multiple instances per link.
- Use of the IPv6 link-local address for neighbor discovery and other features.
- LSAs expressed as prefix and prefix length.
- Addition of two LSA types.
- Handling of unknown LSA types.
- Authentication support using the IPsec ESP standard for OSPFv3 routing protocol traffic, as specified by RFC-4552.

## Requirements and Prerequisites for OSPF

### Model Support

Threat Defense

Threat Defense Virtual

### Supported Domains

Any

### User Roles

Admin

Network Admin

## Guidelines for OSPF

### Firewall Mode Guidelines

OSPF supports routed firewall mode only. OSPF does not support transparent firewall mode.

### High Availability Guidelines

OSPFv2 and OSPFv3 support Stateful High Availability.

### IPv6 Guidelines

- OSPFv2 does not support IPv6.
- OSPFv3 supports IPv6.
- OSPFv3 uses IPv6 for authentication.
- The threat defense device installs OSPFv3 routes into the IPv6 RIB, provided it is the best route.

### OSPFv3 Hello Packets and GRE

Typically, OSPF traffic does not pass through GRE tunnel. When OSPFv3 on IPv6 is encapsulated inside GRE, the IPv6 header validation for security check such as Multicast Destination fails. The packet is dropped due to the implicit security check validation, as this packet has destination IPv6 multicast.

You may define a pre-filter rule to bypass GRE traffic. However, with pre-filter rule, inner packets would not be interrogated by the inspection engine.

### Clustering Guidelines

- OSPFv3 encryption is not supported. An error message appears if you try to configure OSPFv3 encryption in a clustering environment.
- In Spanned interface mode, dynamic routing is not supported on management-only interfaces.
- In Individual interface mode, make sure that you establish the control and data units as either OSPFv2 or OSPFv3 neighbors.
- In Individual interface mode, OSPFv2 adjacencies can only be established between two contexts on a shared interface on the control unit. Configuring static neighbors is supported only on point-to-point-links; therefore, only one neighbor statement is allowed on an interface.
- When a control role change occurs in the cluster, the following behavior occurs:
  - In spanned interface mode, the router process is active only on the control unit and is in a suspended state on the data units. Each cluster unit has the same router ID because the configuration has been synchronized from the control unit. As a result, a neighboring router does not notice any change in the router ID of the cluster during a role change.
  - In individual interface mode, the router process is active on all the individual cluster units. Each cluster unit chooses its own distinct router ID from the configured cluster pool. A control role change in the cluster does not change the routing topology in any way.

### Multiprotocol Label Switching (MPLS) and OSPF Guidelines

When a MPLS-configured router sends Link State (LS) update packets containing opaque Type-10 link-state advertisements (LSAs) that include an MPLS header, authentication fails and the appliance silently drops the update packets, rather than acknowledging them. Eventually the peer router will terminate the neighbor relationship because it has not received any acknowledgments.

Make sure that non-stop forwarding (NSF) is disabled on the appliance to ensure that the neighbor relationship remains stable:

- Navigate to the **Non Stop Forwarding** page in management center(**Devices > Device Management (select the desired device) > Routing > OSPF > Advanced > Non Stop Forwarding** ).

Ensure the **Non Stop Forwarding Capability** boxes are not checked.

---

**Note** The Firepower 4100/9300 models may have high latency when using MPLS because they lack load balancing across multiple receiving queues.

---

### **Bidirectional and Forwarding Detection (BFD) and OSPF Guidelines**

- You can enable BFD on OSPFv2 and OSPFv3 interfaces (Physical Interfaces, Sub-Interfaces, and Port-Channels).
- BFD is not supported on VTI Tunnels, DVTI Tunnels, Loopback, Switchport, VNI, VTEP, and IRB interfaces.

### **Route Redistribution Guidelines**

- Redistribution of route maps with IPv4 or IPv6 prefix list on OSPFv2 or OSPFv3 is not supported. Use an access list in the route map on OSPF for redistribution.
- When OSPF is configured on a device that is a part of EIGRP network or vice versa, ensure that OSPF-router is configured to tag the route (EIGRP does not support route tag yet).

When redistributing OSPF into EIGRP and EIGRP into OSPF, a routing loop occurs when there is an outage on one of the links, interfaces, or even when the route originator is down. To prevent the redistribution of routes from one domain back into the same domain, a router can tag a route that belongs to a domain while it is redistributing, and those routes can be filtered on the remote router based on the same tag. Because the routes will not be installed into the routing table, they will not be redistributed back into the same domain.

### **Additional Guidelines**

- OSPFv2 and OSPFv3 support multiple instances on an interface.
- OSPFv3 supports encryption through ESP headers in a non-clustered environment.
- OSPFv3 supports Non-Payload Encryption.
- OSPFv2 supports Cisco NSF Graceful Restart and IETF NSF Graceful Restart mechanisms as defined in RFCs 4811, 4812 & 3623 respectively.
- OSPFv3 supports Graceful Restart mechanism as defined in RFC 5187.
- There is a limit to the number of intra area (type 1) routes that can be distributed. For these routes, a single type-1 LSA contains all prefixes. Because the system has a limit of 35 KB for packet size, 3000 routes result in a packet that exceeds the limit. Consider 2900 type 1 routes to be the maximum number supported.

- For a device using virtual routing, you can configure OSPFv2 and OSPFv3 for a global virtual router. However, you can configure only OSPFv2 for a user-defined virtual router.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.

## Configure OSPFv2

This section describes the tasks involved in configuring an OSPFv2 routing process. For a device using virtual routing, you can configure OSPFv2 for global as well as for user-defined virtual routers.

### Configure OSPF Areas, Ranges, and Virtual Links

You can configure several OSPF area parameters, which include setting authentication, defining stub areas, and assigning specific costs to the default summary route. You can enable up to two OSPF process instances. Each OSPF process has its own associated areas and networks. Authentication provides password-based protection against unauthorized access to an area.

Stub areas are areas into which information on external routes is not sent. Instead, there is a default external route generated by the ABR into the stub area for destinations outside the autonomous system. To take advantage of the OSPF stub area support, default routing must be used in the stub area.

#### Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
  - Step 2** Click **Routing**.
  - Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.
  - Step 4** Click **OSPF**.
  - Step 5** Check the check box of **Process 1**. You can enable up to two OSPF process instances for each context/virtual router. You must choose an OSPF process to be able to configure the Area parameters.  
  
If the device is using virtual routing, the ID fields display the unique process IDs generated for the chosen virtual router.
  - Step 6** Choose the **OSPF Role** from the drop-down list, and enter a description for it in the next field. The options are Internal, ABR, ASBR, and ABR & ASBR. See [About OSPF, on page 1349](#) for a description of the OSPF roles.
  - Step 7** Select **Area > Add**.  
  
You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete areas.
  - Step 8** Configure the following area options for each OSPF process:
    - **OSPF Process**—Choose the process ID. For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
    - **Area ID**—Designation of the area for which routes are to be summarized.

- **Area Type**—Choose one of the following:
  - **Normal**—(Default) Standard OSPF area.
  - **Stub**—A stub area does not have any routers or areas beyond it. Stub areas prevent Autonomous System (AS) External LSAs (Type 5 LSAs) from being flooded into the stub area. When you create a stub area, you can prevent summary LSAs (Types 3 and 4) from being flooded into the area by NOT checking the **Summary Stub** check box.
  - **NSSA**—Makes the area a not-so-stubby area (NSSA). NSSAs accept Type 7 LSAs. You can disable route redistribution by NOT checking the **Redistribute** check box and checking the **Default Information Originate** check box. You can prevent summary LSAs from being flooded into the area by NOT checking the **Summary NSSA** check box.
- **Metric Value**—The metric used for generating the default route. The default value is 10. Valid metric values range from 0 through 16777214.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Available Network**—Choose one of the available networks and click **Add**, or click **Add (+)** to add a new network object. See [Network, on page 1497](#) for the procedure for adding networks.
- **Authentication**—Choose the OSPF authentication:
  - **None**—(Default) Disables OSPF area authentication.
  - **Password**—Provides a clear text password for area authentication, which is not recommended where security is a concern.
  - **MD5**—Allows MD5 authentication.
- **Default Cost**—The default cost for the OSPF area, which is used to determine the shortest paths to the destination. Valid values range from 0 through 65535. The default value is 1.

**Step 9** Click **OK** to save the area configuration.

**Step 10** Select **Range > Add**.

- Choose one of the available networks and whether to advertise, or,
- Click **Add (+)** to add a new network object. See [Network, on page 1497](#) for the procedure for adding networks.

**Step 11** Click **OK** to save the range configuration.

**Step 12** Select **Virtual Link**, click **Add (+)**, and configure the following options for each OSPF process:

- **Peer Router**—Choose the IP address of the peer router. To add a new peer router, click **Add (+)**. See [Network, on page 1497](#) for the procedure for adding networks.
- **Hello Interval**—The time in seconds between the hello packets sent on an interface. The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. Valid values range from 1 through 65535. The default is 10.

The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.

- **Transmit Delay**—The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 through 8192. The default is 1.

LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

- **Retransmit Interval**—The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the attached network. The value must be greater than the expected round-trip delay, and can range from 1 through 65535. The default is 5.

When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.

- **Dead Interval**—The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The dead interval is an unsigned integer. The default is four times the hello interval, or 40 seconds. The value must be the same for all routers and access servers that are attached to a common network. Valid values range from 1 through 65535.

- **Authentication**—Choose the OSPF virtual link authentication from the following:

- **None**—(Default) Disables virtual link area authentication.
- **Area Authentication**—Enables area authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
- **Password**—Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
- **MD5**—Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.

**Note** Ensure to enter only numbers as the MD5 key ID.

- **Key Chain**—Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, see [Creating Key Chain Objects, on page 1496](#). Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.

**Step 13** Click **OK** to save the virtual link configuration.

**Step 14** Click **Save** on the Routing page to save your changes.

---

### What to do next

Continue with [Configure OSPF Redistribution](#).

## Configure OSPF Redistribution

The threat defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by EIGRP, RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

### Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
  - Step 2** Click **Routing**.
  - Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.
  - Step 4** Click **OSPF**.
  - Step 5** From **OSPF Role** drop-down, choose role .
  - Step 6** Click **Redistribution > Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete areas.

- Step 7** Configure the following redistribution options for each OSPF process:
    - **OSPF Process**—Choose the process ID. For a device using virtual routing, this drop-down list displays the unique process IDs generated for the selected virtual router.
    - **Route Type**—Choose one of the following types:
      - **Static**—Redistributes static routes to the OSPF routing process.
      - **Connected**—Redistributes connected routes (routes established automatically by virtue of having the IP address enabled on the interface) to the OSPF routing process. Connected routes are redistributed as external to the device. You can select whether to use subnets under the Optional list.
      - **OSPF**—Redistributes routes from another OSPF routing process, for example, internal, external 1 and 2, NSSA external 1 and 2, or whether to use subnets. You can select these options under the Optional list.
      - **BGP**—Redistribute routes from the BGP routing process. Add the AS number and whether to use subnets.
      - **RIP**—Redistributes routes from the RIP routing process. You can select whether to use subnets under the Optional list.
- Note** As a user-defined virtual router does not support RIP, you cannot redistribute routes from RIP.
- **EIGRP**—Redistribute routes from the EIGRP routing process. Add the AS number and whether to use subnets.
  - **Metric Value**—Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.

- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag Value**—Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.
- **RouteMap**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add (+)**. See [Route Map](#) to add a new route map.

- Step 8** Click **OK** to save the redistribution configuration.
- Step 9** Click **Save** on the Routing page to save your changes.

---

#### What to do next

Continue with [Configure OSPF Inter-Area Filtering, on page 1359](#).

## Configure OSPF Inter-Area Filtering

ABR type 3 LSA filtering extends the capability of an ABR that is running OSPF to filter type 3 LSAs between different OSPF areas. Once a prefix list is configured, only the specified prefixes are sent from one OSPF area to another OSPF area. All other prefixes are restricted to their OSPF area. You can apply this type of area filtering to traffic going into or coming out of an OSPF area, or to both the incoming and outgoing traffic for that area.

When multiple entries of a prefix list match a given prefix, the entry with the lowest sequence number is used. For efficiency, you may want to put the most common matches or denials near the top of the list by manually assigning them a lower sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.

#### Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Click **Routing**.
- Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.
- Step 4** Click **OSPF**.
- Step 5** Select **InterArea > Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete inter-areas.

**Step 6**

Configure the following inter-area filtering options for each OSPF process:

- **OSPF Process**—For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Area ID**—The area for which routes are to be summarized.
- **PrefixList**—The name of the prefix. To add a new prefix list object, see Step 5.
- **Traffic Direction**—Inbound or outbound. Choose Inbound to filter LSAs coming into an OSPF area, or Outbound to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.

**Step 7**

Click **Add** (+), and enter a name for the new prefix list, and whether to allow overrides.

You must configure a prefix list before you can configure a prefix rule.

**Step 8**

Click **Add** to configure prefix rules, and configure the following parameters:

- **Action**—Select **Block** or **Allow** for the redistribution access.
- **Sequence No**—The routing sequence number. By default, sequence numbers are automatically generated in increments of 5, beginning with 5.
- **IP Address**—Specify the prefix number in the format of IP address/mask length.
- **Min Prefix Length**—(Optional) The minimum prefix length.
- **Max Prefix Length**—(Optional) The maximum prefix length.

**Step 9**

Click **OK** to save the inter-area filtering configuration.

**Step 10**

Click **Save** on the Routing page to save your changes.

---

**What to do next**

Continue with [Configure OSPF Filter Rules, on page 1360](#).

## Configure OSPF Filter Rules

You can configure ABR Type 3 LSA filters for each OSPF process. ABR Type 3 LSA filters allow only specified prefixes to be sent from one area to another area and restrict all other prefixes. You can apply this type of area filtering out of a specific OSPF area, into a specific OSPF area, or into and out of the same OSPF area at the same time. OSPF ABR Type 3 LSA filtering improves your control of route distribution between OSPF areas.

### Procedure

---

**Step 1**

Choose **Devices > Device Management**, and edit the threat defense device.

- Step 2** Click **Routing**.
- Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.
- Step 4** Click **OSPF**.
- Step 5** Select **Filter Rule > Add**.
- You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete filter rules.
- Step 6** Configure the following filter rule options for each OSPF process:
- **OSPF Process**—For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
  - **Access List**—The access list for this OSPF process. To add a new standard access list object, click **Add** (+) and see [Configure Standard ACL Objects, on page 1471](#).
  - **Traffic Direction**—Choose In or Out for the traffic direction being filtered. Choose In to filter LSAs coming into an OSPF area, or Out to filter LSAs coming out of an OSPF area. If you are editing an existing filter entry, you cannot modify this setting.
  - **Interface**—The interface for this filter rule.
- Step 7** Click **OK** to save the filter rule configuration.
- Step 8** Click **Save** on the Routing page to save your changes.

---

#### What to do next

Continue with [Configure OSPF Summary Addresses, on page 1361](#).

## Configure OSPF Summary Addresses

When routes from other protocols are redistributed into OSPF, each route is advertised individually in an external LSA. However, you can configure the threat defense device to advertise a single route for all the redistributed routes that are included for a specified network address and mask. This configuration decreases the size of the OSPF link-state database. Routes that match the specified IP address mask pair can be suppressed. The tag value can be used as a match value for controlling redistribution through route maps.

Routes learned from other routing protocols can be summarized. The metric used to advertise the summary is the smallest metric of all the more specific routes. Summary routes help reduce the size of the routing table.

Using summary routes for OSPF causes an OSPF ASBR to advertise one external route as an aggregate for all redistributed routes that are covered by the address. Only routes from other routing protocols that are being redistributed into OSPF can be summarized.

#### Procedure

---

- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Click **Routing**.

**Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

**Step 4** Click **OSPF**.

**Step 5** Select **Summary Address > Add**.

You can click **Edit** (✎) to edit, or use the right-click menu to cut, copy, past, insert, and delete summary addresses.

**Step 6** Configure the following summary address options for each OSPF process:

- **OSPF Process**—For a device using virtual routing, the drop-down lists the unique process IDs generated for the selected virtual router.
- **Available Network**—The IP address of the summary address. Select one from the Available networks list and click **Add**, or to add a new network, click **Add (+)**. See [Network, on page 1497](#) for the procedure for adding networks.
- **Tag**—A 32-bit decimal value that is attached to each external route. This value is not used by OSPF itself, but may be used to communicate information between ASBRs.
- **Advertise—Advertises** the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

**Step 7** Click **OK** to save the summary address configuration.

**Step 8** Click **Save** on the Routing page to save your changes.

---

### What to do next

Continue with [Configure OSPF Interfaces and Neighbors, on page 1362](#).

## Configure OSPF Interfaces and Neighbors

You can change some interface-specific OSPFv2 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval, the dead interval, and the authentication key. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

You need to define static OSPFv2 neighbors to advertise OSPFv2 routes over a point-to-point, non-broadcast network. This feature lets you broadcast OSPFv2 advertisements across an existing VPN connection without having to encapsulate the advertisements in a GRE tunnel.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Click **Routing**.

**Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.

**Step 4** Click **OSPF**.

**Step 5** Select **Interface > Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete areas.

**Step 6** Configure the following Interface options for each OSPF process:

- **Interface**—The interface you are configuring.

**Note** If the device is using virtual routing, this drop-down list displays only those interfaces that belong to the router.

- **Default Cost**—The cost of sending a packet through the interface. The default value is 10.

- **Priority**—The designated router for a network. Valid values range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router.

When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router. This setting does not apply to interfaces that are configured as point-to-point interfaces.

- **MTU Ignore**—OSPF checks whether neighbors are using the same MTU on a common interface. This check is performed when neighbors exchange DBD packets. If the receiving MTU in the DBD packet is higher than the IP MTU configured on the incoming interface, OSPF adjacency is not established.

- **Database Filter**—Use this setting to filter the outgoing LSA interface during synchronization and flooding. By default, OSPF floods new LSAs over all interfaces in the same area, except the interface on which the LSA arrives. In a fully meshed topology, this flooding can waste bandwidth and lead to excessive link and CPU usage. Checking this check box prevents OSPF flooding of the LSA on the selected interface.

- **Hello Interval**—Specifies the interval, in seconds, between hello packets sent on an interface. Valid values range 1–8192 seconds. The default value is 10 seconds.

The smaller the hello interval, the faster topological changes are detected, but more traffic is sent on the interface. This value must be the same for all routers and access servers on a specific interface.

- **Transmit Delay**—Estimated time in seconds to send an LSA packet on the interface. Valid values range 1–65535 seconds. The default is 1 second.

LSAs in the update packet have their ages increased by the amount specified by this field before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

- **Retransmit Interval**—Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.

When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.

- **Dead Interval**—Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range 1–65535.

- **Hello Multiplier**—Specifies the number of Hello packets to be sent per second. Valid values are 3–20.
- **Point-to-Point**—Lets you transmit OSPF routes over VPN tunnels.
- **Authentication**—Choose the OSPF interface authentication from the following:
  - **None**—(Default) Disables interface authentication.
  - **Area Authentication**—Enables interface authentication using MD5. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
  - **Password**—Provides a clear text password for virtual link authentication, which is not recommended where security is a concern.
  - **MD5**—Allows MD5 authentication. Click **Add**, and enter the key ID, key, confirm the key, and then click **OK**.
 

**Note**                      Ensure to enter only numbers as the MD5 key ID.
  - **Key Chain**—Allows key chain authentication. Click **Add**, and create the key chain, and then click **Save**. For detailed procedure, see [Creating Key Chain Objects, on page 1496](#). Use the same authentication type (MD5 or Key Chain) and key ID for the peers to establish a successful adjacency.
- **Enable BFD**—Allows you to enable BFD on this interface.
- **Enter Password**—The password you configure if you choose Password as the type of authentication.
- **Confirm Password**—Confirm the password that you chose.

**Step 7**                      Select **Neighbor > Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete areas.

**Step 8**                      Configure the following parameters for each OSPF process:

- **OSPF Process**—Choose 1 or 2.
- **Neighbor**—Choose one of the neighbors in the drop-down list, or click **Add** (+) to add a new neighbor; enter the name, description, network, whether to allow overrides, and then click **Save**.
- **Interface**—Choose the interface associated with the neighbor.

**Step 9**                      Click **OK** to save the neighbor configuration.

**Step 10**                     Click **Save** on the Routing page to save your changes.

## Configure OSPF Advanced Properties

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, an LSA timer, and graceful restarts.

### Graceful Restarts

The threat defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored.

This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv2 by using either using NSF Cisco (RFC 4811 and RFC 4812) or NSF IETF (RFC 3623).

**Note** NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

## Procedure

- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Click **Routing**.
- Step 3** (For a virtual-router-aware device) From the virtual routers drop-down list, choose the virtual router for which you are configuring OSPF.
- Step 4** Click **OSPF > Advanced**.
- Step 5** Select **General**, and configure the following:
  - **Router ID**—Choose Automatic or IP Address (appears for non-cluster and a cluster in spanned etherchannel mode) or Cluster Pool (appears for a cluster in individual interface mode) for the router ID. If you choose IP address, enter the IP address in the adjacent field. If you choose Cluster Pool, choose the IPv4 cluster pool value in the adjacent drop-down field. For information on creating the cluster pool address, see [Address Pools, on page 1472](#).
  - **Ignore LSA MOSPF**—Suppresses syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.
  - **RFC 1583 Compatible**—Configures RFC 1583 compatibility as the method used to calculate summary route costs. Routing loops can occur with RFC 1583 compatibility enabled. Disable it to prevent routing loops. All OSPF routers in an OSPF routing domain should have RFC compatibility set identically.
  - **Adjacency Changes**—Defines the adjacency changes that cause syslog messages to be sent.

By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.
  - **Log Adjacency Changes**—Causes the threat defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.

- **Log Adjacency Change Details**—Causes the threat defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.
- **Administrative Route Distance**—Allows you to modify the settings that were used to configure administrative route distances for **inter-area**, **intra-area**, and **external** IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **LSA Group Pacing**—Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Enable Default Information Originate**—Check the **Enable** check box to generate a default external route into an OSPF routing domain and configure the following options:
  - **Always advertise the default route**—Ensures that the default route is always advertised.
  - **Metric Value**—Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type**—The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **RouteMap**—Choose the routing process that generates the default route if the route map is satisfied or click **Add (+)** to add a new one. See [Route Map](#) to add a new route map.

**Step 6** Click **OK** to save the general configuration.

**Step 7** Select **Non Stop Forwarding**, and configure Cisco NSF graceful restart for OSPFv2, for an NSF-capable or NSF-aware device:

**Note** There are two graceful restart mechanisms for OSPFv2, Cisco NSF and IETF NSF. Only one of these graceful restart mechanisms can be configured at a time for an OSPF instance. An NSF-aware device can be configured as both Cisco NSF helper and IETF NSF helper but a NSF-capable device can be configured in either Cisco NSF or IETF NSF mode at a time for an OSPF instance.

- a) Check the **Enable Cisco Non Stop Forwarding Capability** check box.
- b) (Optional) Check the **Cancel NSF restart when non-NSF-aware neighboring networking devices are detected** check box if required.
- c) (Optional) Make sure the **Enable Cisco Non Stop Forwarding Helper** mode check box is unchecked to disable the helper mode on an NSF-aware device.

**Step 8** Configure IETF NSF Graceful Restart for OSPFv2, for an NSF-capable or NSF-aware device:

- a) Check the **Enable IETF Non Stop Forwarding Capability** check box.
- b) In the **Length of graceful restart interval (seconds)** field, enter the restart interval in seconds. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.
- c) (Optional) Make sure the **Enable IETF nonstop forwarding (NSF) for helper mode** check box is unchecked to disable the IETF NSF helper mode on an NSF-aware device.
- d) **Enable Strict Link State advertisement checking**—When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.

- e) **Enable IETF Non Stop Forwarding**—Enables non stop forwarding, which allows for the forwarding of data packets to continue along known routes while the routing protocol information is being restored following a switchover. OSPF uses extensions to the OSPF protocol to recover its state from neighboring OSPF devices. For the recovery to work, the neighbors must support the NSF protocol extensions and be willing to act as "helpers" to the device that is restarting. The neighbors must also continue forwarding data traffic to the device that is restarting while protocol state recovery takes place.

---

## Configure OSPFv3

This section describes the tasks involved in configuring an OSPFv3 routing process. For a device using virtual routing, you can configure OSPFv3 only for its global virtual router and not for its user-defined virtual router.

### Configure OSPFv3 Areas, Route Summaries, and Virtual Links

To enable OSPFv3, you need to create an OSPFv3 routing process, create an area for OSPFv3, enable an interface for OSPFv3, and then redistribute the route into the targeted OSPFv3 routing process.

#### Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Select **Routing > OSPFv3**.
- Step 3** By default **Enable Process 1** is selected. You can enable up to two OSPF process instances.
- Step 4** Choose the OSPFv3 role from the drop-down list, and enter a description for it. The options are Internal, ABR, ASBR, and ABR and ASBR. See [About OSPF, on page 1349](#) for descriptions of the OSPFv3 roles.
- Step 5** Select **Area > Add**.
- You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete areas.
- Step 6** Select **General**, and configure the following options for each OSPF process:
- **Area ID**—The area for which routes are to be summarized.
  - **Cost**—The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.
  - **Type**—Specifies Normal, NSSA, or Stub. If you select Normal, there are no other parameters to configure. If you select Stub, you can choose to send summary LSAs in the area. If you select NSSA, you can configure the next three options:
    - **Allow Sending summary LSA into this area**—Allows the sending of summary LSAs into the area.
    - **Imports routes to normal and NSSA area**—Allows redistribution to import routes to normal and not to stubby areas.
    - **Defaults information originate**—Generates a default external route into an OSPFv3 routing domain.

- **Metric**—Metric used for generating the default route. The default value is 10. Valid metric values range from 0 to 16777214.
- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.

**Step 7** Click **OK** to save the general configuration.

**Step 8** (Not applicable for Internal OSPFv3 Role) Select **Route Summary > Add Route Summary**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete route summaries.

**Step 9** Configure the following route summary options for each OSPF process:

- **IPv6 Prefix/Length**—The IPv6 prefix. To add a new network object, click **Add** (+). See [Network, on page 1497](#) for the procedure for adding networks.
- **Cost**—The metric or cost for the summary route, which is used during OSPF SPF calculations to determine the shortest paths to the destination. Valid values range from 0 to 16777215.
- **Advertise**—Advertises the summary route. Uncheck this check box to suppress routes that fall under the summary address. By default, this check box is checked.

**Step 10** Click **OK** to save the route summary configuration.

**Step 11** (Not applicable for Internal OSPFv3 Role) Select **Virtual Link**, click **Add Virtual Link**, and configure the following options for each OSPF process:

- **Peer RouterID**—Choose the IP address of the peer router. To add a new network object, click **Add** (+). See [Network, on page 1497](#) for the procedure for adding networks.
- **TTL Security**—Enables TTL security check. The value for the hop-count is a number from 1 to 254. The default is 1.

OSPF sends outgoing packets with an IP header Time to Live (TTL) value of 255 and discards incoming packets that have TTL values less than a configurable threshold. Because each device that forwards an IP packet decrements the TTL, packets received via a direct (one-hop) connection have a value of 255. Packets that cross two hops have a value of 254, and so on. The receive threshold is configured in terms of the maximum number of hops that a packet may have traveled.

- **Dead Interval**—The time in seconds that hello packets are not seen before a neighbor indicates that the router is down. The default is four times the hello interval, or 40 seconds. Valid values range from 1 to 65535.

The dead interval is an unsigned integer. The value must be the same for all routers and access servers that are attached to a common network.

- **Hello Interval**—The time in seconds between the hello packets sent on an interface. Valid values range from 1 to 65535. The default is 10.

The hello interval is an unsigned integer that is to be advertised in the hello packets. The value must be the same for all routers and access servers on a specific network. The smaller the hello interval, the faster topological changes are detected, but the more traffic is sent on the interface.

- **Retransmit Interval**—The time in seconds between LSA retransmissions for adjacencies that belong to the interface. The retransmit interval is the expected round-trip delay between any two routers on the

attached network. The value must be greater than the expected round-trip delay, and can range from 1 to 65535. The default is 5.

When a router sends an LSA to its neighbor, it keeps the LSA until it receives the acknowledgment message. If the router receives no acknowledgment, it resends the LSA. Be conservative when setting this value, or needless retransmission can result. The value should be larger for serial lines and virtual links.

- **Transmit Delay**—The estimated time in seconds that is required to send an LSA packet on the interface. The integer value must be greater than zero. Valid values range from 1 to 8192. The default is 1.

LSAs in the update packet have their own ages incremented by this amount before transmission. If the delay is not added before transmission over a link, the time in which the LSA propagates over the link is not considered. The value assigned should take into account the transmission and propagation delays for the interface. This setting has more significance on very low-speed links.

**Step 12** Click **OK** to save the virtual link configuration.

**Step 13** Click **Save** on the Router page to save your changes.

---

### What to do next

Continue with [Configure OSPFv3 Redistribution](#).

## Configure OSPFv3 Redistribution

The Secure Firewall Threat Defense device can control the redistribution of routes between the OSPF routing processes. The rules for redistributing routes from one routing process into an OSPF routing process are displayed. You can redistribute routes discovered by EIGRP, RIP and BGP into the OSPF routing process. You can also redistribute static and connected routes into the OSPF routing process.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Select **Routing > OSPF**.

**Step 3** Select **Redistribution**, and click **Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete areas.

**Step 4** Configure the following redistribution options for each OSPF process:

- **Source Protocol**—The source protocol from which routes are being redistributed. The supported protocols are connected, OSPF, Static, EIGRP, and BGP. If you choose OSPF, you must enter the Process ID in the **Process ID** field. If you choose BGP, you must add the AS number in the **AS Number** field.
- **Metric** —Metric value for the routes being distributed. The default value is 10. Valid values range from 0 to 16777214.

When redistributing from one OSPF process to another OSPF process on the same device, the metric will be carried through from one process to the other if no metric value is specified. When redistributing other processes to an OSPF process, the default metric is 20 when no metric value is specified.

- **Metric Type**—The metric type is the external link type that is associated with the default route that is advertised into the OSPF routing domain. The available options are 1 for a Type 1 external route or 2 for a Type 2 external route.
- **Tag**—Tag specifies the 32-bit decimal value attached to each external route that is not used by OSPF itself, but which may be used to communicate information between ASBRs. If none is specified, then the remote autonomous system number is used for routes from BGP and EGP. For other protocols, zero is used. Valid values are from 0 to 4294967295.
- **Route Map**—Checks for filtering the importing of routes from the source routing protocol to the current routing protocol. If this parameter is not specified, all routes are redistributed. If this parameter is specified, but no route map tags are listed, no routes are imported. Or you can add a new route map by clicking **Add (+)**. See [Route Map, on page 1522](#) for the procedure to add a new route map.
- **Process ID**—The OSPF process ID, either 1 or 2.
 

**Note** The Process ID is enabled the OSPFv3 process is redistributing a route learned by another OSPFv3 process.
- **Match**—Enables OSPF routes to be redistributed into other routing domains:
  - **Internal** for routes that are internal to a specific autonomous system.
  - **External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 as Type 1 external routes.
  - **External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 as Type 2 external routes.
  - **NSSA External 1** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 as Type 1 external routes.
  - **NSSA External 2** for routes that are external to the autonomous system, but are imported into OSPFv3 in an NSSA for IPv6 as Type 2 external routes.

**Step 5** Click **OK** to save the redistribution configuration.

**Step 6** Click **Save** on the Routing page to save your changes.

---

### What to do next

Continue with [Configure OSPFv3 Summary Prefixes, on page 1370](#).

## Configure OSPFv3 Summary Prefixes

You can configure the threat defense device to advertise routes that match a specified IPv6 prefix and mask pair.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Select **Routing > OSPFv3**.

**Step 3** Select **Summary Prefix > Add**.

You can click **Edit** (✎), or use the right-click menu to cut, copy, past, insert, and delete summary prefixes.

**Step 4** Configure the following summary prefix options for each OSPF process:

- **IPv6 Prefix/Length**—The IPv6 prefix and prefix length label. Select one from the list or click **Add** (+) to add a new network object. See [Network, on page 1497](#) for the procedure for adding networks.
- **Advertise**— Advertises routes that match the specified prefix and mask pair. Uncheck this check box to suppress routes that match the specified prefix and mask pair.
- (Optional) **Tag**—A value that you can use as a match value for controlling redistribution through route maps.

**Step 5** Click **OK** to save the summary prefix configuration.

**Step 6** Click **Save** on the Routing page to save your changes.

---

#### What to do next

Continue with [Configure OSPFv3 Interfaces, Authentication, and Neighbors, on page 1371](#).

## Configure OSPFv3 Interfaces, Authentication, and Neighbors

You can change certain interface-specific OSPFv3 parameters, if necessary. You are not required to change any of these parameters, but the following interface parameters must be consistent across all routers in an attached network: the hello interval and the dead interval. If you configure any of these parameters, be sure that the configurations for all routers on your network have compatible values.

#### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Select **Routing > OSPFv3**.

**Step 3** Select **Interface > Add**.

You can click **Edit** to edit, or use the right-click menu to cut, copy, past, insert, and delete areas.

**Step 4** Configure the following interface options for each OSPFv3 process:

- **Interface**—The interface you are configuring.
- **Enable OSPFv3**—Enables OSPFv3.
- **OSPF Process**—Choose 1 or 2.
- **Area**—The area ID for this process.

- **Instance**—Specifies the area instance ID to be assigned to the interface. An interface can have only one OSPFv3 area. You can use the same area on multiple interfaces, and each interface can use a different area instance ID.

**Step 5** Select **Properties**, and configuring the following options for each OSPFv3 process:

- **Filter Outgoing Link Status Advertisements**—Filters outgoing LSAs to an OSPFv3 interface. All outgoing LSAs are flooded to the interface by default.
- **Disable MTU mismatch detection**—Disables the OSPF MTU mismatch detection when DBD packets are received. OSPF MTU mismatch detection is enabled by default.
- **Flood Reduction**—Changes normal LSAs into Do Not Age LSAs, so that they don't get flooded every 3600 seconds across areas.

OSPF LSAs are refreshed every 3600 seconds. In large OSPF networks, this can lead to large amounts of unnecessary LSA flooding from area to area.

- **Point-to-Point Network**—Lets you transmit OSPF routes over VPN tunnels. When an interface is configured as point-to-point, non-broadcast, the following restrictions apply:
  - You can define only one neighbor for the interface.
  - You need to manually configure the neighbor.
  - You need to define a static route pointing to the crypto endpoint.
  - If OSPF over a tunnel is running on the interface, regular OSPF with an upstream router cannot be run on the same interface.
  - You should bind the crypto map to the interface before specifying the OSPF neighbor to ensure that the OSPF updates are passed through the VPN tunnel. If you bind the crypto map to the interface after specifying the OSPF neighbor, use the **clear local-host all** command to clear OSPF connections so that the OSPF adjacencies can be established over the VPN tunnel.

- **Broadcast**— Specifies that the interface is a broadcast interface. By default, this check box is checked for Ethernet interfaces. Uncheck this check box to designate the interface as a point-to-point, nonbroadcast interface. Specifying an interface as point-to-point, nonbroadcast lets you transmit OSPF routes over VPN tunnels.

- **Cost**—Specifies the cost of sending a packet on the interface. Valid values for this setting range from 0 to 255. The default value is 1. Entering 0 for this setting makes the router ineligible to become the designated router or backup designated router. This setting does not apply to interfaces that are configured as point-to-point, nonbroadcast interfaces.

When two routers connect to a network, both attempt to become the designated router. The device with the higher router priority becomes the designated router. If there is a tie, the router with the higher router ID becomes the designated router.

- **Priority**—Determines the designated router for a network. Valid values range from 0 to 255.
- **Dead Interval**—Time period in seconds for which hello packets must not be seen before neighbors indicate that the router is down. The value must be the same for all nodes on the network and can range from 1 to 65535.
- **Hello Interval**— Time period in seconds between OSPF packets that the router will send before adjacency is established with a neighbor. Once the routing device detects an active neighbor, the hello packet interval

changes from the time specified in the poll interval to the time specified in the hello interval. Valid values range from 1 to 65535 seconds.

- **Retransmit Interval**—Time in seconds between LSA retransmissions for adjacencies that belong to the interface. The time must be greater than the expected round-trip delay between any two routers on the attached network. Valid values range from 1 to 65535 seconds. The default is 5 seconds.
- **Transmit Delay**—Estimated time in seconds to send a link-state update packet on the interface. Valid values range from 1 to 65535 seconds. The default is 1 second.
- **Enable BFD**—Allows you to enable BFD on this interface.

**Step 6** Click **OK** to save the properties configuration.

**Step 7** Select **Authentication**, and configure the following options for each OSPFv3 process:

- **Type**—Type of authentication. The available options are Area, Interface, and None. The None option indicates that no authentication is used.
- **Security Parameters Index**— A number from 256 to 4294967295. Configure this if you chose Interface as the type.
- **Authentication**—Type of authentication algorithm. Supported values are SHA-1 and MD5. Configure this if you chose Interface as the type.
- **Authentication Key**— When MD5 authentication is used, the key must be 32 hexadecimal digits (16 bytes) long. When SHA-1 authentication is used, the key must be 40 hexadecimal digits (20 bytes) long.
- **Encrypt Authentication Key**—Enables encryption of the authentication key.
- **Include Encryption**— Enables encryption.
- **Encryption Algorithm**—Type of encryption algorithm. Supported value is DES. The NULL entry indicates no encryption. Configure this if you chose **Include Encryption**.
- **Encryption Key**—Enter the encryption key. Configure this if you chose **Include Encryption**.
- **Encrypt Key**—Enables the key to be encrypted.

**Step 8** Click **OK** to save the authentication configuration.

**Step 9** Select **Neighbor**, click **Add**, and configure the following options for each OSPFv3 process:

- **Link Local Address**—The IPv6 address of the static neighbor.
- **Cost**—Enables cost. Enter the cost in the **Cost** field, and check the **Filter Outgoing Link State Advertisements** if you want to advertise.
- (Optional) **Poll Interval**—Enables the poll interval. Enter the **Priority** level and the **Poll Interval** in seconds.

**Step 10** Click **Add** to add the neighbor.

**Step 11** Click **OK** to save the Interface configuration.

---

## Configure OSPFv3 Advanced Properties

The Advanced Properties allows you to configure options, such as syslog message generation, administrative route distances, passive OSPFv3 routing, LSA timers, and graceful restarts.

### Graceful Restarts

The threat defense device may experience some known failure situations that should not affect packet forwarding across the switching platform. The Non-Stop Forwarding (NSF) capability allows data forwarding to continue along known routes, while the routing protocol information is being restored. This capability is useful when there is a scheduled hitless software upgrade. You can configure graceful restart on OSPFv3 using graceful-restart (RFC 5187).

**Note** NSF capability is also useful in HA mode and clustering.

Configuring the NSF graceful-restart feature involves two steps; configuring capabilities and configuring a device as NSF-capable or NSF-aware. A NSF-capable device can indicate its own restart activities to neighbors and a NSF-aware device can help a restarting neighbor.

A device can be configured as NSF-capable or NSF-aware, depending on some conditions:

- A device can be configured as NSF-aware irrespective of the mode in which it is.
- A device has to be in either Failover or Spanned Etherchannel (L2) cluster mode to be configured as NSF-capable.
- For a device to be either NSF-aware or NSF-capable, it should be configured with the capability of handling opaque Link State Advertisements (LSAs)/ Link Local Signaling (LLS) block as required.

### Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Choose **Routing > OSPFv3 > Advanced**.
- Step 3** For **Router ID**, choose Automatic or IP Address (appears for non-cluster and a cluster in spanned etherchannel mode) or Cluster Pool (appears for a cluster in individual interface mode). If you choose IP Address, enter the IPv6 address in the **IP Address** field. If you choose Cluster Pool, choose the IPv6 cluster pool value from the **Cluster Pool** down-down field. For information on creating the cluster pool address, see [Address Pools, on page 1472](#).
- Step 4** Check the **Ignore LSA MOSPF** check box if you want to suppress syslog messages when the route receives unsupported LSA Type 6 multicast OSPF (MOSPF) packets.
- Step 5** Select **General**, and configure the following:
- **Adjacency Changes**—Defines the adjacency changes that cause syslog messages to be sent.  
By default, a syslog message is generated when an OSPF neighbor goes up or down. You can configure the router to send a syslog message when an OSPF neighbor goes down and also a syslog for each state.
  - **Adjacency Changes**—Causes the threat defense device to send a syslog message whenever an OSPF neighbor goes up or down. This setting is checked by default.

- **Include Details**—Causes the threat defense device to send a syslog message whenever any state change occurs, not just when a neighbor goes up or down. This setting is unchecked by default.
- **Administrative Route Distances**—Allows you to modify the settings that were used to configure administrative route distances for inter-area, intra-area, and external IPv6 routes. The administrative route distance is an integer from 1 to 254. The default is 110.
- **Default Information Originate**—Check the **Enable** check box to generate a default external route into an OSPFv3 routing domain and configure the following options:
  - **Always Advertise**—Will always advertise the default route whether or not one exists.
  - **Metric**—Metric used for generating the default route. Valid metric values range from 0 to 16777214. The default value is 10.
  - **Metric Type**—The external link type that is associated with the default route that is advertised into the OSPFv3 routing domain. Valid values are 1 (Type 1 external route) and 2 (Type 2 external route). The default is Type 2 external route.
  - **Route Map**—Choose the routing process that generates the default route if the route map is satisfied or click **Add** (+) to add a new one. See [Route Map, on page 1522](#) to add a new route map.

**Step 6** Click **OK** to save the general configuration.

**Step 7** Select **Passive Interface**, select the interfaces on which you want to enable passive OSPFv3 routing from the Available Interfaces list, and click **Add** to move them to the Selected Interfaces list.

Passive routing assists in controlling the advertisement of OSPFv3 routing information and disables the sending and receiving of OSPFv3 routing updates on an interface.

**Step 8** Click **OK** to save the passive interface configuration.

**Step 9** Select **Timer**, and configure the following LSA pacing and SPF calculation timers:

- **Arrival**—Specifies the minimum delay in milliseconds that must pass between acceptance of the same LSA arriving from neighbors. The range is from 0 to 6000,000 milliseconds. The default is 1000 milliseconds.
- **Flood Pacing**—Specifies the time in milliseconds at which LSAs in the flooding queue are paced in between updates. The configurable range is from 5 to 100 milliseconds. The default value is 33 milliseconds.
- **Group Pacing**—Specifies the interval in seconds at which LSAs are collected into a group and refreshed, check summed, or aged. Valid values range from 10 to 1800. The default value is 240.
- **Retransmission Pacing**—Specifies the time in milliseconds at which LSAs in the retransmission queue are paced. The configurable range is from 5 to 200 milliseconds. The default value is 66 milliseconds.
- **LSA Throttle**—Specifies the delay in milliseconds to generate the first occurrence of the LSA. The default value is 0 millisecond. The minimum specifies the minimum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds. The maximum specifies the maximum delay in milliseconds to originate the same LSA. The default value is 5000 milliseconds.

**Note** For LSA throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

- **SPF Throttle**—Specifies the delay in milliseconds to receive a change to the SPF calculation. The default value is 5000 milliseconds. The minimum specifies the delay in milliseconds between the first and second SPF calculations. The default value is 10000 milliseconds. The maximum specifies the maximum wait time in milliseconds for SPF calculations. The default value is 10000 milliseconds.

**Note** For SPF throttling, if the minimum or maximum time is less than the first occurrence value, then OSPFv3 automatically corrects to the first occurrence value. Similarly, if the maximum delay specified is less than the minimum delay, then OSPFv3 automatically corrects to the minimum delay value.

- Step 10** Click **OK** to save the LSA timer configuration.
- Step 11** Select **Non Stop Forwarding**, and check the **Enable graceful-restart helper** check box. This is checked by default. Uncheck this to disable the graceful-restart helper mode on an NSF-aware device.
- Step 12** Check the **Enable link state advertisement** check box to enable strict link state advertisement checking.
- When enabled, it indicates that the helper router will terminate the process of restarting the router if it detects that there is a change to a LSA that would be flooded to the restarting router, or if there is a changed LSA on the retransmission list of the restarting router when the graceful restart process is initiated.
- Step 13** Check the **Enable graceful-restart (Use when Spanned Cluster or Failover Configured)** and enter the graceful-restart interval in seconds. The range is 1-1800. The default value is 120 seconds. For a restart interval below 30 seconds, graceful restart will be terminated.
- Step 14** Click **OK** to save the graceful restart configuration.
- Step 15** Click **Save** on the Routing page to save your changes.

## History for OSPF

Table 91: Feature History for OSPF

| Feature                        | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                          |

## CHAPTER 49

# EIGRP

This section describes how to configure the threat defense to route data, perform authentication, and redistribute routing information using the Enhanced Interior Gateway Routing Protocol (EIGRP).

- [About EIGRP Routing, on page 1377](#)
- [Requirements and Prerequisites for EIGRP, on page 1378](#)
- [Guidelines and Limitations of EIGRP Routing, on page 1378](#)
- [Configure EIGRP, on page 1380](#)

## About EIGRP Routing

Enhanced Interior Gateway Routing Protocol (EIGRP), developed by Cisco, is an enhanced version of IGRP. Unlike IGRP and RIP, EIGRP does not send out periodic route updates. EIGRP updates are sent out only when the network topology changes. Key capabilities that distinguish EIGRP from other routing protocols include fast convergence, support for variable-length subnet mask, support for partial updates, and support for multiple network layer protocols.

A router running EIGRP stores all the neighbor routing tables so that it can quickly adapt to alternate routes. If no appropriate route exists, EIGRP queries its neighbors to discover an alternate route. These queries are propagated until an alternate route is found. EIGRP support for the variable-length subnet masks allows routes to be automatically summarized on a network boundary. Additionally, EIGRP can be configured to summarize any bit boundary at any interface.

EIGRP does not make periodic updates. Instead, it sends partial updates when the metric for a route changes. Propagation of partial updates is automatically bounded such that only those routers that need the information are updated. As a result of these two capabilities, EIGRP consumes significantly less bandwidth than IGRP.

To dynamically learn of other routers on directly attached networks, threat defense uses neighbor discovery. EIGRP routers send out multicast hello packets to announce their presence on the network. When the EIGRP device receives a hello packet from a new neighbor, it sends its topology table to the neighbor with an initialization bit set. When the neighbor receives the topology update with the initialization bit set, the neighbor sends its topology table back to the device.

The hello packets are sent out as multicast messages. No response is expected for a hello message. Statically defined neighbors is an exception to this rule. If you manually configure a neighbor, hello messages, routing updates, and acknowledgments are sent as unicast messages.

Once this neighbor relationship is established, routing updates are not exchanged unless there is a change in the network topology. The neighbor relationship is maintained through the hello packets. Each hello packet received from a neighbor includes a hold time. Hold time is the time within which threat defense can expect

to receive a hello packet from that neighbor. If the device does not receive a hello packet from that neighbor within the hold time advertised by that neighbor, the device considers that neighbor to be unavailable.

EIGRP uses neighbor discovery/recovery, Reliable Transport Protocol (RTP), and Diffusing Update Algorithm (DUAL) for route computations. DUAL saves all routes to a destination in the topology table, and not just the least-cost route. The least-cost route is inserted into the routing table. The other routes remain in the topology table. If the main route fails, another route is chosen from the feasible successors. A successor is a neighboring router that is used for packet forwarding that has a least-cost path to a destination. A feasibility calculation ensures that the path is not part of a routing loop.

If a feasible successor is not found in the topology table, a route recomputation takes place. During route recomputation, DUAL queries the EIGRP neighbors for a route. The query is propagated to successive neighbors. If a feasible successor is not found, an unreachable message is returned.

During route recomputation, DUAL marks the route as active. By default, threat defense waits for three minutes to receive a response from its neighbors. If the device does not receive a response from a neighbor, the route is marked as stuck-in-active. All routes in the topology table that point to the unresponsive neighbor as a feasibility successor are removed.

## Requirements and Prerequisites for EIGRP

### Model Support

Threat Defense

Threat Defense Virtual

### Supported Domains

Any

### User Roles

Admin

Network Admin

## Guidelines and Limitations of EIGRP Routing

### Firewall Mode Guidelines

Supported on routed firewall mode only.

### Device Guidelines

- Only one EIGRP process is allowed per device.
- EIGRP can be configured through management center UI on threat defense 6.6 and higher versions.

### Interface Guidelines

- Only routed interfaces with logical names and with an IP address can be associated with an EIGRP routing process.
- Only interfaces belonging to the global virtual router can be part of EIGRP. EIGRP can learn, filter, and redistribute routes across routing protocols in global virtual router.
- Supports physical, EtherChannel, redundant, subinterfaces only. However, the members of EtherChannel interfaces are not supported.
- BVI and VNI cannot be part of EIGRP.
- A passive interface cannot be configured as a neighbor interface.

### IP Address and Network Objects Support

- Only IPv4 address is supported.
- Range, FQDN, and wildcard mask are not supported.
- Only Standard access list objects are supported.

### Redistribution Guidelines

- BGP, OSPF, and RIP in the global virtual router can redistribute to EIGRP.
- EIGRP can redistribute to BGP, OSPF, RIP, Static, and Connected in the global virtual router.
- When EIGRP is configured on a device that is a part of OSPF network or vice versa, ensure that OSPF-router is configured to tag the route (EIGRP does not support route tag).

When redistributing EIGRP into OSPF and OSPF into EIGRP, a routing loop occurs when there is an outage on one of the links, interfaces, or even when the route originator is down. To prevent the redistribution of routes from one domain back into the same domain, a router can tag a route that belongs to a domain while it is redistributing, and those routes can be filtered on the remote router based on the same tag. Because the routes will not be installed into the routing table, they will not be redistributed back into the same domain.

### Deployment Process Guidelines

When you want to change the existing AS number of a deployed EIGRP configuration, you must disable the EIGRP and deploy it. This step will clear the deployed EIGRP configuration on the threat defense. Next, recreate the EIGRP configurations with a new AS number and then deploy it. Thus, this process prevents any deployment failures owing to the same EIGRP configuration being deployed on the threat defense.

### Upgrade Guidelines

When you upgrade to version 7.2 and later when the previous version has any FlexConfig EIGRP policies, the management center displays a warning message during deployment. However, it does not stop the deployment process. However, after deployment, to manage the EIGRP policies from the UI (**Device (Edit) > Routing > EIGRP**), you must redo the configuration in the **Device (Edit) > Routing > EIGRP** page and remove the configuration from FlexConfig. To automate creation of the policies in the UI, management center provides an option to migrate the policies from FlexConfig to the UI. For more details, see [Migrating FlexConfig Policies, on page 2744](#).

# Configure EIGRP

You can enable and configure EIGRP on the firewall device in the **Routing** tab.

## Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Click the **Routing** tab.
- Step 3** Under Global, click **EIGRP**.
- Step 4** Check the **Enable EIGRP** check box to enable the EIGRP routing process.
- Step 5** In the **AS Number** field, enter the autonomous system (AS) number for the EIGRP process. The AS number includes multiple autonomous numbers. The AS number can be from 1 to 65535 and is a uniquely assigned value that identifies each network on the Internet.
- Step 6** To configure other EIGRP properties, see the following topics:
- [Configure EIGRP Settings, on page 1380.](#)
  - [Configure EIGRP Neighbors Settings, on page 1381.](#)
  - [Configure EIGRP Filter Rules Settings, on page 1381.](#)
  - [Configure EIGRP Redistribution Settings, on page 1382.](#)
  - [Configure EIGRP Summary Address Settings, on page 1383.](#)
  - [Configure EIGRP Interfaces Settings, on page 1383.](#)
  - [Configure EIGRP Advanced Settings, on page 1384.](#)
- 

## Configure EIGRP Settings

### Procedure

- 
- Step 1** On the **EIGRP** page, click the **Setup** tab.
- Step 2** Check the **Auto Summary** check box to enable EIGRP to summarize network number boundaries.
- Note** Enabling Auto Summary can cause routing problems if you have noncontiguous networks.
- Step 3** In the **Available Networks/Hosts** box, click the networks or hosts that should participate in the EIGRP routing process, and then click **Add**. To add a new network object, click **Add (+)**. See [Network, on page 1497](#) for the procedure for adding networks.
- Step 4** To configure passive interfaces, check the **Passive Interface** check box. In EIGRP, a passive interface does not send or receive routing updates.

- a) To specify selective interfaces as passive, click the **Selected Interface** radio button. In the **Available Interfaces** box, select the interfaces, and click **Add**.
- b) To specify all interfaces as passive, click the **All Interfaces** radio button.

**Step 5** Click **Ok** and **Save** the settings.

---

## Configure EIGRP Neighbors Settings

You can define static neighbors for the EIGRP process. When you define an EIGRP neighbor, hello packets are unicast to that neighbor.

### Procedure

---

- Step 1** On the **EIGRP** page, click the **Neighbors** tab.
  - Step 2** Click **Add**.
  - Step 3** From the **Interface** drop-down, choose the interface through which the neighbor is available.
  - Step 4** From the **Neighbor** drop-down, choose the IP address of the static neighbor. To add the network object, click **Add (+)**. See [Network, on page 1497](#) for the procedure for adding network objects.
  - Step 5** Click **Ok** and **Save** the settings.
- 

## Configure EIGRP Filter Rules Settings

You can configure route filtering rules for the EIGRP routing process. Filter rules allow you to control the routes that are accepted or advertised by the EIGRP routing process.

### Procedure

---

- Step 1** On the **EIGRP** page, click the **Filter Rules** tab.
- Step 2** Click **Add (+)**.
- Step 3** In the **Add Filter Rules** dialog box, from the **Filter Direction** drop-down, choose the direction for the rule:
  - Inbound—The rule filters default route information from incoming EIGRP routing updates.
  - Outbound—The rule filters default route information from outgoing EIGRP routing updates.
- Step 4** To select the interface to which the filtering rule applies, click the **Interface** radio button, and from the drop-down, select the interface.
- Step 5** To select the protocol to which the filtering rule applies, click the **Protocol** radio button and from the drop-down, select the protocol—BGP, RIP, Static, Connected, or OSPF. For BGP and OSPF protocols, you can specify the relevant Process ID.

- Step 6** From the **Access List** drop-down, choose the access list. The list defines the networks that are to be received and that are to be suppressed in routing updates. To add a new standard access list object, click **Add (+)** and see [Configure Standard ACL Objects, on page 1471](#) for the detailed procedure.
- Step 7** Click **Ok** and **Save** the settings.

## Configure EIGRP Redistribution Settings

You can define the rules for redistributing routes from other routing protocols to the EIGRP routing process.

### Procedure

- Step 1** On the **EIGRP** page, click the **Redistribution** tab.
- Step 2** Click **Add (+)**.
- Step 3** In the **Add Redistribution** dialog box, from the **Protocol** drop-down, choose the source protocol from which the routes are being redistributed:
- **BGP**—Redistributes routes discovered by the BGP routing process to EIGRP.
  - **RIP**—Redistributes routes discovered by the RIP routing process to EIGRP.
  - **Static**—Redistributes static routes to the EIGRP routing process. Static routes that fall within the scope of a network statement are automatically redistributed to EIGRP; you do not need to define a redistribution rule for them.
  - **Connected**—Redistributes connected routes (routes established automatically by virtue of having IP address enabled on the interface) to the EIGRP routing process. Connected routes that fall within the scope of a network statement are automatically redistributed to EIGRP; you do not need to define a redistribution rule for them.
  - **OSPF**—Redistributes routes discovered by the OSPF routing process to EIGRP. If you choose this protocol, the Match options on this dialog box become available under **Optional OSPF Redistribution**:
    - **Internal**—Routes that are internal to a specific AS.
    - **External1**—Routes that are external to the AS and imported into OSPF as a Type 1 external route.
    - **External2**—Routes that are external to the AS and imported into the selected process as a Type 2 external route.
    - **Nsaa-External1**—Not-So-Stubby Area (NSSA) routes that are external to the AS and imported into the selected process as Type 1 external routes.
    - **Nsaa-External2**—(NSSA) routes that are external to the AS and imported into the selected process as Type 2 external routes.
- Note** These options are not available when redistributing static, connected, RIP, or BGP routes.
- Step 4** Under **Optional Metrics** enter the relevant values:

- **Bandwidth**—The minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295.
- **Delay Time**—The routing delay in tens of microseconds. Valid values range from 0 to 4294967295.
- **Reliability** —The likelihood of successful packet transmission is expressed as a number 0 through 255. The value 255 indicates 100 percent reliability; 0 means no reliability.
- **Loading**— The effective bandwidth of the route. Valid values range from 1 to 255. 255 indicates 100 percent loading.
- **MTU**—The smallest permissible value for the maximum transmission unit of the path. Valid values range from 1 to 65535.

- Step 5** From the **Route Map** drop-down, choose the route map object to apply to the redistribution entry. To create a new route map object, click **Add** (+). See [Route Map](#) for the procedure to add a new route map.
- Step 6** Click **Ok** and **Save** the settings.
- 

## Configure EIGRP Summary Address Settings

You can configure summary addresses for each interface. You need to manually define summary addresses if you want to create summary addresses that do not occur at a network boundary, or if you want to use summary addresses on threat defense with automatic route summarization disabled. If more specific routes are available in the routing table, EIGRP advertises the summary address with a metric equal to the minimum of all the more specific routes.

### Procedure

---

- Step 1** On the **EIGRP** page, click the **Summary Address** tab.
- Step 2** Click **Add**.
- Step 3** From the **Interface** drop-down, choose the interface from which the summary address is advertised.
- Step 4** From the **Network** drop-down, choose the network object with specific IP address and network mask to be summarized. To add a new network, click **Add** (+). See [Network, on page 1497](#) for the procedure for adding networks.
- Step 5** In the **Administrative Distance** field, enter the administrative distance of the summary route. Valid values range from 1 to 255.
- Step 6** Click **Ok** and **Save** the settings.
- 

## Configure EIGRP Interfaces Settings

You can configure interface-specific EIGRP routing properties in the Interfaces tab.

## Procedure

- 
- Step 1** On the **EIGRP** page, click the **Interfaces** tab.
- Step 2** Click **Add (+)**.
- Step 3** From the **Interface** drop-down, choose the name of the interface to which the configuration applies.
- Step 4** In the **Hello Interval** field, enter the interval, in seconds, between EIGRP hello packets that are sent on an interface. Valid values range from 1 to 65535. The default value is 5 seconds.
- Step 5** In the **Hold Time** field, enter the hold time that is advertised by the device in EIGRP hello packets. Valid values range from 3 to 65535. The default value is 15 seconds.
- Step 6** To enable EIGRP split-horizon on the interface, click the **Split Horizon** check box.
- Step 7** In the **Delay Time** field, enter the delay time in tens of microseconds. Valid values are from 1 to 16777215. This option is not supported for devices in multi-context mode.
- Step 8** Specify values for the Authentication properties:
- **Enable MD5 Authentication**—Check the check box to use MD5 hash algorithm for authentication of EIGRP packets.
  - **Key Type**—From the drop-down, select any one of the following key type:
    - **None**—To indicate that no authentication is required.
    - **Unencrypted**—To indicate that the key string to be used is a clear text password for authentication.
    - **Encrypted**—To indicate that the key string to be used is an encrypted password for authentication.
    - **Auth Key**—To indicate that the key string to be used is an EIGRP authentication key.
  - **Key ID**—The ID of the key that is used to authenticate EIGRP updates. Enter a numerical key identifier. Valid values range from 0 to 255.
  - **Key**—An alphanumeric character string of up to 17 characters. For an encrypted authentication type, this field should have a minimum of 17 characters.
  - **Confirm Key**—Re-enter the key.
- Step 9** Click **Ok** and **Save** the settings.
- 

## Configure EIGRP Advanced Settings

You can configure EIGRP advanced settings such as the router ID, stub routing, and adjacency changes.

## Procedure

- 
- Step 1** On the **EIGRP** page, click the **Advanced** tab.

- Step 2** Under **Default Route Information**, you can specify the sending and receiving of default route information in EIGRP updates.
- (Appears for non-cluster and cluster in spanned etherchannel mode) **Router ID (IP Address)**—Enter the ID used to identify the originating router for external routes. If an external route is received with the local router ID, the route is discarded. To prevent this issue, specify a global address for the router ID. An unique value should be configured for each EIGRP router.
  - (Appears only for a cluster in individual interface mode) **IPv4 Address Pool**—Select the relevant cluster pool value (IPv4 address pool object). To create the address pool, see [Address Pools, on page 1472](#).
  - **Accept Default Route Info**—Check the check box to configure EIGRP to accept exterior default routing information.
    - **Access List**—From the **Access List** drop-down, specify a standard access list that defines the networks that are allowed and the networks that are not when receiving default route information. To add a new standard access list object, click **Add (+)** and see [Configure Standard ACL Objects, on page 1471](#) for the detailed procedure.
  - **Send Default Route Info**—Check the check box to configure EIGRP to advertise exterior default routing information.
    - **Access List**—From the **Access List** drop-down, specify a standard access list that defines the networks that are allowed and the networks that are not when sending default route information. To add a new standard access list object, click **Add (+)** and see [Configure Standard ACL Objects, on page 1471](#) for the detailed procedure.
- Step 3** Under **Administrative Distance**, specify:
- **Internal Distance**—Administrative distance for EIGRP internal routes. Internal routes are those that are learned from another entity within the same autonomous system. Valid values range from 1 to 255. The default value is 90.
  - **External Distance**—Administrative distance for EIGRP external routes. External routes are those for which the best path is learned from a neighbor external to the autonomous system. Valid values range from 1 to 255. The default value is 170.
- Step 4** Under **Adjacency Changes**, specify:
- **Log Neighbor Changes**—Click the check box to enable the logging of EIGRP neighbor adjacency changes.
  - **Log Neighbor Warnings**—Click the check box to enable the logging of EIGRP neighbor warning messages.
  - (Optional) Enter the time interval (in seconds) between repeated neighbor warning messages. Valid values range from 1 to 65535. Repeated warnings are not logged if they occur during this interval.
- Step 5** Under **Stub**, to enable the device as an EIGRP stub routing process, click one or more of the following EIGRP stub routing processes check boxes:
- **Receive only**—Configures the EIGRP stub routing process to receive route information from the neighbor routers but not send route information to the neighbors. If this option is selected, you cannot select any of the other stub routing options.

- **Connected**—Advertises connected routes.
- **Redistributed**—Advertises redistributed routes.
- **Static**—Advertises static routes.
- **Summary**—Advertises summary routes.

**Step 6** Under **Default Metrics**, define the default metrics for routes redistributed to the EIGRP routing process:

- **Bandwidth**—the minimum bandwidth of the route in kilobits per second. Valid values range from 1 to 4294967295.
  - **Delay Time**—the route delay in tens of microseconds. Valid values range from 0 to 4294967295.
  - **Reliability**—the likelihood of successful packet transmission expressed as a number 0 through 255. The value 255 indicates 100 percent reliability; 0 means no reliability.
  - **Loading**—the effective bandwidth of the route. Valid values range from 1 to 255; 255 indicates 100 percent loading.
  - **MTU**—the smallest allowed value for the maximum transmission unit of the path. Valid values range from 1 to 65535.
-

## CHAPTER 50

# BGP

---

This section describes how to configure the threat defense to route data, perform authentication, and redistribute routing information using the Border Gateway Protocol (BGP).

- [About BGP, on page 1387](#)
- [Requirements and Prerequisites for BGP, on page 1390](#)
- [Guidelines for BGP, on page 1390](#)
- [Configure BGP, on page 1391](#)

## About BGP

BGP is an inter and intra autonomous system routing protocol. An autonomous system is a network or group of networks under a common administration and with common routing policies. BGP is used to exchange routing information for the Internet and is the protocol used between Internet service providers (ISP).

## Routing Table Changes

BGP neighbors exchange full routing information when the TCP connection between neighbors is first established. When changes to the routing table are detected, the BGP routers send to their neighbors only those routes that have changed. BGP routers do not send periodic routing updates, and BGP routing updates advertise only the optimal path to a destination network.

---

**Note** AS loop detection is done by scanning the full AS path (as specified in the AS\_PATH attribute), and checking that the AS number of the local system does not appear in the AS path. By default, EBGP advertises the learned routes to the same peer to prevent additional CPU cycles on the ASA in performing loop checks and to avoid delays in the existing outgoing update tasks.

---

Routes learned via BGP have properties that are used to determine the best route to a destination, when multiple paths exist to a particular destination. These properties are referred to as BGP attributes and are used in the route selection process:

- **Weight**—This is a Cisco-defined attribute that is local to a router. The weight attribute is not advertised to neighboring routers. If the router learns about more than one route to the same destination, the route with the highest weight is preferred.

- **Local preference**—The local preference attribute is used to select an exit point from the local AS. Unlike the weight attribute, the local preference attribute is propagated throughout the local AS. If there are multiple exit points from the AS, the exit point with the highest local preference attribute is used as an exit point for a specific route.
- **Multi-exit discriminator**—The multi-exit discriminator (MED) or metric attribute is used as a suggestion to an external AS regarding the preferred route into the AS that is advertising the metric. It is referred to as a suggestion because the external AS that is receiving the MEDs may also be using other BGP attributes for route selection. The route with the lower MED metric is preferred.
- **Origin**—The origin attribute indicates how BGP learned about a particular route. The origin attribute can have one of three possible values and is used in route selection.
  - **IGP**—The route is interior to the originating AS. This value is set when the network router configuration command is used to inject the route into BGP.
  - **EGP**—The route is learned via the Exterior Border Gateway Protocol (EBGP).
  - **Incomplete**—The origin of the route is unknown or learned in some other way. An origin of incomplete occurs when a route is redistributed into BGP.
- **AS\_path**—When a route advertisement passes through an autonomous system, the AS number is added to an ordered list of AS numbers that the route advertisement has traversed. Only the route with the shortest AS\_path list is installed in the IP routing table.
- **Next hop**—The EBGP next-hop attribute is the IP address that is used to reach the advertising router. For EBGP peers, the next-hop address is the IP address of the connection between the peers. For IBGP, the EBGP next-hop address is carried into the local AS. However, when the next hop is in the same subnet as the peering address of the eBGP peer, the next hop is not modified. This behavior is referred to as the third party next hop.

Use the **next-hop-self** command when redistributing VPN-advertised routes to iBGP peers to ensure that the routes are redistributed with the correct next hop IP.

- **Community**—The community attribute provides a way of grouping destinations, called communities, to which routing decisions (such as acceptance, preference, and redistribution) can be applied. Route maps are used to set the community attribute. The predefined community attributes are as follows:
  - **no-export**—Do not advertise this route to EBGP peers.
  - **no-advertise**—Do not advertise this route to any peer.
  - **internet**—Advertise this route to the Internet community; all routers in the network belong to it.

## When to Use BGP

Customer networks, such as universities and corporations, usually employ an Interior Gateway Protocol (IGP) such as OSPF for the exchange of routing information within their networks. Customers connect to ISPs, and ISPs use BGP to exchange customer and ISP routes. When BGP is used between autonomous systems (AS), the protocol is referred to as External BGP (EBGP). If a service provider is using BGP to exchange routes within an AS, then the protocol is referred to as Interior BGP (IBGP).

BGP can also be used for carrying routing information for IPv6 prefix over IPv6 networks.

## BGP Path Selection

BGP may receive multiple advertisements for the same route from different sources. BGP selects only one path as the best path. When this path is selected, BGP puts the selected path in the IP routing table and propagates the path to its neighbors. BGP uses the following criteria, in the order presented, to select a path for a destination:

- If the path specifies a next hop that is inaccessible, drop the update.
- Prefer the path with the largest weight.
- If the weights are the same, prefer the path with the largest local preference.
- If the local preferences are the same, prefer the path that was originated by BGP running on this router.
- If no route was originated, prefer the route that has the shortest AS\_path.
- If all paths have the same AS\_path length, prefer the path with the lowest origin type (where IGP is lower than EGP, and EGP is lower than incomplete).
- If the origin codes are the same, prefer the path with the lowest MED attribute.
- If the paths have the same MED, prefer the external path over the internal path.
- If the paths are still the same, prefer the path through the closest IGP neighbor.
- Determine if multiple paths require installation in the routing table for [BGP Multipath, on page 1389](#).
- If both paths are external, prefer the path that was received first (the oldest one).
- Prefer the path with the lowest IP address, as specified by the BGP router ID.
- If the originator or router ID is the same for multiple paths, prefer the path with the minimum cluster list length.
- Prefer the path that comes from the lowest neighbor address.

## BGP Multipath

BGP Multipath allows installation into the IP routing table of multiple equal-cost BGP paths to the same destination prefix. Traffic to the destination prefix is then shared across all installed paths.

These paths are installed in the table together with the best path for load-sharing. BGP Multipath does not affect best-path selection. For example, a router still designates one of the paths as the best path, according to the algorithm, and advertises this best path to its BGP peers.

In order to be candidates for multipath, paths to the same destination need to have these characteristics equal to the best-path characteristics:

- Weight
- Local preference
- AS-PATH length
- Origin code
- Multi Exit Discriminator (MED)
- One of these:

- Neighboring AS or sub-AS (before the addition of the BGP Multipaths)
- AS-PATH (after the addition of the BGP Multipaths)

Some BGP Multipath features put additional requirements on multipath candidates:

- The path should be learned from an external or confederation-external neighbor (eBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric.

These are the additional requirements for internal BGP (iBGP) multipath candidates:

- The path should be learned from an internal neighbor (iBGP).
- The IGP metric to the BGP next hop should be equal to the best-path IGP metric, unless the router is configured for unequal-cost iBGP multipath.

BGP inserts up to  $n$  most recently received paths from multipath candidates into the IP routing table, where  $n$  is the number of routes to install to the routing table, as specified when you configure BGP Multipath. The default value, when multipath is disabled, is 1.

For unequal-cost load balancing, you can also use BGP Link Bandwidth.

---

**Note** The equivalent next-hop-self is performed on the best path that is selected among eBGP multipaths before it is forwarded to internal peers.

---

## Requirements and Prerequisites for BGP

### Model Support

Threat Defense

Threat Defense Virtual

### Supported Domains

Any

### User Roles

Admin

Network Admin

## Guidelines for BGP

### Firewall Mode Guidelines

Does not support transparent firewall mode. BGP is supported only in routed mode.

### IPv6 Guidelines

Supports IPv6.

### Additional Guidelines

- For BGP, the next hop IP address for the routes is the network IP address and not 0.0.0.0.
- The system does not add route entry for the IP address received over PPPoE in the CP route table. BGP always looks into CP route table for initiating the TCP session, hence BGP does not form TCP session. Thus, BGP over PPPoE is not supported.
- BGP is not supported on management-only or BVI interfaces.
- To avoid adjacency flaps due to route updates being dropped if the route update is larger than the minimum MTU on the link, ensure that you configure the same MTU on the interfaces on both sides of the link.
- BGP with PATH MTU (PMTU) can cause adjacency flaps if MTU discovery fails, especially with ECMP routing. Hence, be cautious while using BGP, PMTU, and ECMP as packet drops can occur if MTU discovery fails due to any reason.
- The BGP table of the member unit is not synchronized with the control unit table. Only its routing table is synchronized with the control unit routing table.
- When you configure a route-based site-to-site VPN using static or dynamic VTI interfaces, ensure that the value of the TTL hop is more than one if you use BGP as the routing protocol.

## Configure BGP

To configure BGP, see the following topics:

### Procedure

- 
- Step 1** [Configure BGP Basic Settings, on page 1392](#)
  - Step 2** [Configure BGP General Settings, on page 1394](#)
  - Step 3** [Configure BGP Neighbor Settings, on page 1395](#)
  - Step 4** [Configure BGP Aggregate Address Settings, on page 1399](#)
  - Step 5** [Configure BGPv4 Filtering Settings, on page 1400](#)
- Note** The Filtering section is applicable only to IPv4 settings
- Step 6** [Configure BGP Network Settings, on page 1400](#)
  - Step 7** [Configure BGP Redistribution Settings, on page 1401](#)
  - Step 8** [Configure BGP Route Injection Settings, on page 1402](#)
  - Step 9** [Configure BGP Route Import/Export Settings, on page 1402](#)
-

## Configure BGP Basic Settings

You can set many basic settings for BGP.

For a device using virtual routing, the basic settings described in this section must be configured in the **BGP** page under **General Settings**. For more information, see [Modifications to the Management Center Web Interface - Routing Page, on page 1291](#).

### Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Select **Routing**.
- Step 3** (For a virtual-router-aware device) Under **General Settings**, click **BGP**.
- Step 4** Check the **Enable BGP** check box to enable the BGP routing process.
- Step 5** In the **AS Number** field, enter the autonomous system (AS) number for the BGP process. The AS number internally includes multiple autonomous numbers. The AS number can be from 1 to 4294967295 or from 1.0 to 65535.65535. The AS number is a uniquely assigned value, that identifies each network on the Internet.
- Step 6** In the **Router ID** drop-down list, choose Automatic or Manual (appears for non-cluster and a cluster in spanned etherchannel mode) or Cluster Pool (appears for a cluster in individual interface mode). If you choose Automatic, the highest-level IP address on the threat defense device is used as the router ID. If you choose Manual, enter the IP address in the **IP Address** field. If you choose Cluster Pool, enter the cluster pool value in the **Cluster Pool** field. For information on creating the cluster pool address, see [Address Pools, on page 1472](#).
- Step 7** To use a fixed router ID, choose Manual and enter an IPv4 address in the **IP Address** field. The default value is Automatic. For a virtual router-aware device, you can override the router ID settings in the **Virtual Routers > BGP** page.
- Step 8** (Optional) Edit the various BGP settings, starting with **General**. The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network. Click **Edit** (✎) to edit the settings in the group:
- Enter a **Scanning Interval** for BGP routers for next-hop validation. Valid values are from 5 to 60 seconds. The default value is 60.
  - Enter the **Number of AS numbers in AS\_PATH attribute**. An AS\_PATH attribute is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Valid values are between 1 and 254. The default value is None.
  - Check the **Log Neighbor Changes** check box to enable logging of BGP neighbor changes (up or down) and resets. This helps in troubleshooting network connectivity problems and measuring network stability. This is enabled by default.
  - Check the **Use TCP Path MTU Discovery** check box to use the Path MTU determining technique to determine the maximum transmission unit (MTU) size on the network path between two IP hosts. This avoids IP fragmentation. This is enabled by default.
  - Check the **Reset session upon Failover** check box to reset the external BGP session immediately upon link failure. This is enabled by default.
  - Check the **Enforce that the first AS is peer's AS for EBGP routes** check box to discard incoming updates received from external BGP peers that do not list their AS number as the first segment in the AS\_PATH attribute. This prevents a mis-configured or unauthorized peer from misdirecting traffic by advertising a route as if it was sourced from another autonomous system. This is enabled by default.

- g) Check the **Use dot notation for AS number** check box to split the full binary 4-byte AS number into two words of 16 bits each, separated by a dot. AS numbers from 0-65535 are represented as decimal numbers and AS numbers larger than 65535 are represented using the dot notation. This is disabled by default.
- h) Click **OK**.

**Step 9** (Optional) Edit the **Best Path Selection** section:

- a) Enter a value for **Default Local Preference** between 0 and 4294967295. The default value is 100. Higher values indicate higher preference. This preference is sent to all routers and access servers in the local autonomous system.
- b) Check the **Allow comparing MED from different neighbors** check box to allow the comparison of Multi Exit Discriminator (MED) for paths from neighbors in different autonomous systems. This is disabled by default.
- c) Check the **Compare Router ID for identical EBGP paths** check box to compare similar paths received from external BGP peers during the best path selection process and switch the best path to the route with the lowest router ID. This is disabled by default.
- d) Check the **Pick the best MED path among paths advertised from the neighboring AS** check box to enable MED comparison among paths learned from confederation peers. The comparison between MEDs is made only if no external autonomous systems are there in the path. This is disabled by default.
- e) Check the **Treat missing MED as the least preferred one** check box to consider the missing MED attribute as having a value of infinity, making the path the least desirable; therefore, a path with a missing MED is least preferred. This is disabled by default.
- f) Click **OK**.

**Step 10** (Optional) Edit the **Neighbor Timers** section:

- a) Enter the time interval for which the BGP neighbor remains active after not sending a keepalive message in the **Keep alive interval** field. At the end of this keepalive interval, the BGP peer is declared dead, if no messages are sent. The default value is 60 seconds.
- b) Enter the time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Hold time** field. The default value is 180 seconds. Specify a value from 0 to 65535.
- c) (Optional) Enter the minimum time interval for which the BGP neighbor remains active while a BGP connection is being initiated and configured in the **Min Hold time** field. Specify a value from 3 to 65535.

**Note** A hold time of less than 20 seconds increases the possibility of peer flapping.

- d) Click **OK**.

**Step 11** In the **Next Hop** section, optionally select the **Enable address tracking** check box to enable BGP next hop address tracking and enter the **Delay Interval** between checks on updated next-hop routes installed in the routing table. Click **OK**.

**Note** The **Next Hop** section is applicable only to IPv4 settings.

**Step 12** (Optional) Edit the **Graceful Restart** section:

**Note** This section is available only when the threat defense device is in failover or spanned cluster mode. This is done so that there is no drop in packets in the traffic flow, when one of the devices in the failover setup fails.

- a) Check the **Enable Graceful Restart** checkbox to enable threat defense peers to avoid a routing flap following a switchover.

- b) Specify the time duration that threat defense peers will wait to delete stale routes before a BGP open message is received in the **Restart Time** field. The default value is 120 seconds. Valid values are between 1 and 3600 seconds.
- c) Enter the time duration that the threat defense will wait before deleting stale routes after an end of record (EOR) message is received from the restarting threat defense in the **Stalepath Time** field. The default value is 360 seconds. Valid values are between 1 and 3600 seconds.
- d) Click **OK**.

**Step 13** Click **Save**.

**Step 14** To view the BGP basic settings, from the virtual routers drop-down, select the desired router, and then click **BGP**.

This page displays the basic settings that are configured in the **Settings** page. You can edit the router ID settings on this page.

**Step 15** To edit the router ID settings, modify the IP address in the **IP Address** fields. The modified value overrides the router ID settings that were configured in the **BGP** page under **General Settings**.

## Configure BGP General Settings

Configure Route maps, Administrative Route Distances, Synchronization, Next-hop, and packet forwarding. The defaults for these settings are appropriate in most cases, but you can adjust them to fit the needs of your network.

### Procedure

**Step 1** On the **Device Management** page, click **Routing**.

**Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, select the virtual router for which you are configuring BGP.

**Step 3** Choose **BGP > IPv4** or **IPv6**.

**Step 4** Click **General**.

**Step 5** In **General**, update the following sections:

- a) In the **Settings** section, enter or select a **Route Map** object and click **OK**.

**Note** The **Route Map** field is applicable only to IPv4 settings.

- b) In the **Administrative Route Distances** section, update the following as required, and click **OK**:

- **External** — Enter the administrative distance for external BGP routes. Routes are external when learned from an external autonomous system. The range of values for this argument are from 1 to 255. The default value is 20.
- **Internal** — Enter administrative distance for internal BGP routes. Routes are internal when learned from peer in the local autonomous system. The range of values for this argument are from 1 to 255. The default value is 200.
- **Local** — Enter administrative distance for local BGP routes. Local routes are those networks listed with a network router show command, often as back doors, for the router or for the networks that is

being redistributed from another process. The range of values for this argument are from 1 to 255. The default value is 200.

- c) In the **Routes and Synchronization** section, update the following as required, and click **OK**:
- (Optional) **Generate default routes** — Check the check box of this option to configure default-information originate.
  - (Optional) **Summarize subnet routes into network-level routes** — Check the check box of this to configure automatic summarization of subnet routes into network-level routes. This check box is applicable only to IPv4 settings.
  - (Optional) **Advertise inactive routes** — Check the check box of this to advertise routes that are not installed in the routing information base (RIB).
  - (Optional) **Synchronize between BGP and IGP system** — Check the check box of this to enable synchronization between BGP and your Interior Gateway Protocol (IGP) system. Usually, a BGP speaker does not advertise a route to an external neighbor unless that route is local or exists in the IGP. This feature allows routers and access servers within an autonomous system to have the route before BGP makes it available to other autonomous systems.
  - (Optional) **Redistribute iBGP into IGP** — Check the check box of this to configure iBGP redistribution into an interior gateway protocol (IGP), such as OSPF.
- d) In the **Forward Packets over Multiple Paths** section, update the following as required and click **OK**:
- (Optional) **Number of Paths** — Enter the maximum number of Border Gateway Protocol routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.
  - (Optional) **iBGP Number of Paths** — Enter the maximum number of parallel internal Border Gateway Protocol (iBGP) routes that can be installed in a routing table. The range of values are from 1 to 8. The default value is 1.

**Step 6** Click **Save**.

---

## Configure BGP Neighbor Settings

A BGP router must connect with each of its peers before exchanging updates. These peers are called BGP neighbors. Use Neighbor to define BGP IPv4 or IPv6 neighbors and neighbor settings.

### Procedure

---

- Step 1** On the Device Management page, click **Routing**.
- Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.
- Step 3** Choose **BGP > IPv4** or **IPv6**.
- Step 4** Click **Neighbor**.
- Step 5** Click **Add** to define BGP neighbors and neighbor settings.

- Step 6** Enter the BGP neighbor **IP address**. This IP address is added to the BGP neighbor table. When you are configuring BGP IPv6 on static VTI, enter the virtual tunnel IP address of the neighbor.
- Step 7** Choose the BGP neighbor **Interface**.
- Note** The **Interface** field is only applicable to IPv6 settings.
- Step 8** Enter the autonomous system to which the BGP neighbor belongs, in the **Remote AS** field.
- Step 9** Check the **Enabled address** check box to enable communication with this BGP neighbor. Further neighbor settings will be configured only if the Enabled address check box is selected.
- Step 10** (Optional) Check the **Shutdown administratively** check box to disable a neighbor or peer group.
- Step 11** (Optional) Check the **Configure graceful restart (failover / spanned mode)** check box to enable configuration of the BGP graceful restart capability for this neighbor. After selecting this option, you must check the **Enable graceful restart** check box to specify whether graceful restart should be enabled or disabled for this neighbor.
- Note**
- The graceful restart is enabled only when the device is in HA mode or when L2 cluster (all nodes from the same network) is configured.
  - The graceful restart option for BGPv6 is enabled only on threat defense Version 7.3+.
  - If you configure graceful restart only at General Settings and not at BGP IPv6, the global General Settings configuration persist.
  - If you configure graceful restart at General Settings and also at BGP IPv6, the global General Settings configuration is overridden by the BGP IPv6 configuration settings.
- Step 12** (Optional) To enable configuration of the BFD support for BGP, from the **BFD Fallover** drop-down list, choose the BFD type—single-hop, multi-hop, or auto-detect-hop. This selection registers the BGP neighbor to receive forwarding path detection failure messages from BFD. Choose None if you do not want to have BFD support.
- Step 13** (Optional) Enter a **Description** for the BGP neighbor.
- Step 14** (Optional) From the **Update Sourced** drop-down list, choose an interface to source the BGP packets.
- You can choose a loopback address as this interface to overcome path failures. You can also choose any physical, port-channel, or a sub-interface.
- Step 15** (Optional) In **Filtering Routes**, use access lists, route maps, prefix lists and AS path filters as required, to distribute BGP Neighbor information. Update the following sections:
- a) Choose or select the appropriate incoming or outgoing **Access List** to distribute BGP neighbor information.
 

**Note** Access lists are only applicable to IPv4 settings.
  - b) Choose or select the appropriate incoming or outgoing **Route Maps** to apply a route map to incoming or outgoing routes.
  - c) Choose or select the appropriate incoming or outgoing **Prefix List** to distribute BGP neighbor information.
  - d) Choose or select the appropriate incoming or outgoing **AS path filter** to distribute BGP neighbor information.
  - e) Check the check box of **Limit the number of prefixes allowed from the neighbor** to control the number of prefixes that can be received from a neighbor.
    - Enter the maximum number of prefixes allowed from a specific neighbor in the **Maximum Prefixes** field.

- Enter the percentage (of maximum) at which the router starts to generate a warning message in the **Threshold Level** field. Valid values are integers between 1 and 100. The default value is 75.
- f) Check the **Control prefixes received from the peer** check box to specify additional controls for the prefixes received from a peer. Do one of the following
- Check the **Terminate peering when prefix limit is exceeded** check box to stop the BGP neighbor when the prefix limit is reached. Specify the interval after which the BGP neighbor will restart in the **Restart interval** field.
  - Check the **Give only warning message when prefix limit is exceeded** check box to generate a log message when the maximum prefix limit is exceeded. Here, the BGP neighbor will not be terminated.
- g) Click **OK**.

**Step 16**

- (Optional) In **Routes**, specify miscellaneous Neighbor route parameter. Proceed to update the following:
- a) Enter the minimum interval (in seconds) between the sending of BGP routing updates in the **Advertisement Interval** field. Valid values are between 1 and 600.
  - b) Check the **Remove private AS numbers from outbound routing updates** check box to exclude the private AS numbers from being advertised on outbound routes.
  - c) Check the **Generate default routes** check box to allow the local router to send the default route 0.0.0.0 to a neighbor to use as a default route. Enter or Select the route map that allows the route 0.0.0.0 to be injected conditionally in the **Route map** field.
  - d) To add conditionally advertised routes, click Add Row +. In the Add Advertised Route dialog box, do the following:
    1. Add or choose a route map in the **Advertise Map** field, that will be advertised if the conditions of the exist map or the non-exist map are met.
    2. Click **Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
    3. Click **Non-Exist Map** and choose a route map from the Route Map Object Selector. This route map is compared with the routes in the BGP table, to determine whether the advertise map route is advertised.
    4. Click **OK**.

**Step 17**

In **Timers**, check the **Set timers for the BGP peer** check box to set the keepalive frequency, hold time and minimum hold time

- **Keep alive interval**—Enter the frequency (in seconds) with which threat defense sends keepalive messages to the neighbor. Valid values are between 0 and 65535. The default value is 60 seconds.
- **Hold time**—Enter the interval (in seconds) after not receiving a keepalive message that threat defense declares a peer dead. Valid values are between 0 and 65535. The default value is 180 seconds.
- **Min hold time**—(Optional) Enter the minimum interval (in seconds) after not receiving a keepalive message that threat defense declares a peer dead. Valid values are between 3 and 65535. The default value is 3 seconds.

**Note** A hold time of less than 20 seconds increases the possibility of peer flapping.

**Step 18**

In **Advanced**, update the following:

- a) (Optional) Check the **Enable Authentication** check box to enable MD5 authentication on a TCP connection between two BGP peers.
1. Choose an encryption type from the **Enable Encryption** drop-down list.
  2. Enter a password in the **Password** field. Reenter the password in the **Confirm Password** field. The password is case-sensitive and can be up to 25 characters long when the service password-encryption command is enabled and up to 81 characters long when the service password-encryption command is not enabled. The string can contain any alphanumeric characters, including spaces.
- Note** You cannot specify a password in the format number-space-anything. The space after the number can cause authentication to fail.
- b) (Optional) Select the **Send Community attribute to this neighbor** check box to specify that communities attributes should be sent to the BGP neighbor
- c) (Optional) Select the **Use FTD as next hop for this neighbor** check box to configure the router as the next-hop for a BGP speaking neighbor or peer group.
- d) Select the **Disable Connection Verification** check box to disable the connection verification process for eBGP peering sessions that are reachable by a single hop but are configured on a loopback interface or otherwise configured with a non-directly connected IP address. When deselected (default), a BGP routing process will verify the connection of single-hop eBGP peering session (TTL=254) to determine if the eBGP peer is directly connected to the same network segment by default. If the peer is not directly connected to same network segment, connection verification will prevent the peering session from being established.
- e) Select **Allow connections with neighbor that is not directly connected** to accept and attempt BGP connections to external peers residing on networks that are not directly connected. (Optional) Enter the time-to-live in the **TTL hops** field. Valid values are between 1 and 255. Alternately, select **Limited number of TTL hops to neighbor**, to secure a BGP peering session. Enter the maximum number of hops that separate eBGP peers in the **TTL hops** field. Valid values are between 1 and 254.
- f) (Optional) Select the **Use TCP MTU path discovery** check box to enable a TCP transport session for a BGP session.
- g) Choose the TCP connection mode from the **TCP Transport Mode** drop-down list. Options are Default, Active, or Passive.
- h) (Optional) Enter a **Weight** for the BGP neighbor connection.
- i) Select the **BGP Version** that threat defense will accept from the drop-down list. The version can be set to 4-Only to force the software to use only Version 4 with the specified neighbor. The default is to use Version 4 and dynamically negotiate down to Version 2 if requested.

**Step 19** Update **Migration**, only if AS migration is considered.

**Note** The AS migration customization should be removed after transition has been completed.

- a) (Optional) Check the **Customize the AS number for routes received from the neighbor** check box to customize the AS\_PATH attribute for routes received from an eBGP neighbor.
- b) Enter the local autonomous system number in the **Local AS number** field. Valid values are any valid autonomous system number from 1 to 4294967295 or 1.0 to 65535.65535.
- c) (Optional) Check the **Do not prepend local AS number to routes received from neighbor** check box to prevent the local AS number from being prepended to any routes received from eBGP peer.
- d) (Optional) Check the **Replace real AS number with local AS number in routes received from neighbor** check box to replace the real autonomous system number with the local autonomous system number in the eBGP updates. The autonomous system number from the local BGP routing process is not prepended.

- e) (Optional) Check the **Accept either real AS number or local AS number in routes received from neighbor** check box to configure the eBGP neighbor to establish a peering session using the real autonomous system number (from the local BGP routing process) or by using the local autonomous system number.

**Step 20** Click **OK**.

**Step 21** Click **Save**.

---

## Configure BGP Aggregate Address Settings

BGP neighbors store and exchange routing information and the amount of routing information increases as more BGP speakers are configured. Route aggregation is the process of combining the attributes of several different routes so that only a single route is advertised. Aggregate prefixes use the classless interdomain routing (CIDR) principle to combine contiguous networks into one classless set of IP addresses that can be summarized in routing tables. As a result fewer routes need to be advertised. Use the Add/Edit Aggregate Address dialog box to define the aggregation of specific routes into one route.

### Procedure

- 
- Step 1** When editing the threat defense device, click **Routing**.
- Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.
- Step 3** Choose **BGP > IPv4** or **IPv6**.
- Step 4** Click **Add Aggregate Address**.
- Step 5** Enter a value for the aggregate timer (in seconds) in the **Aggregate Timer** field. Valid values are 0 or any value between 6 and 60. The default value is 30.
- Step 6** Click **(+)Add** and update the **Add Aggregate Address** dialog box:
- Network** — Enter an IPv4 address or select the desired network/hosts objects.
  - Attribute Map** — (Optional) Enter or select the route map used to set the attribute of the aggregate route.
  - Advertise Map** — (Optional) Enter or select the route map used to select the routes to create AS\_SET origin communities.
  - Suppress Map** — (Optional) Enter or select the route map used to select the routes to be suppressed.
  - Generate AS set path Information** — (Optional) Check the check box to enable generation of autonomous system set path information.
  - Filter all routes from updates** — (Optional) Check the check box to filter all more-specific routes from updates.
  - Click **OK**.

---

### What to do next

- For BGPv4 settings, proceed to [Configure BGPv4 Filtering Settings, on page 1400](#).
- For BGPv6 settings, proceed to [Configure BGP Network Settings, on page 1400](#).

## Configure BGPv4 Filtering Settings

Filtering settings are used to filter routes or networks received in incoming BGP updates. Filtering is used to restrict routing information that the router learns or advertises.

### Before you begin

Filtering is only applicable for a BGP IPv4 routing policy.

### Procedure

- 
- Step 1** On the Device Management page, click **Routing**.
- Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.
- Step 3** Choose **BGP > IPv4**.
- Step 4** Click **Filtering**.
- Note** The **Filtering** field is applicable only to IPV4 settings.
- Step 5** Click (+) **Add** and update the **Add Filter** dialog box:
- Access List**— Choose an access control list that defines which networks are to be received and which are to be suppressed in routing updates.
  - Direction**— (Optional) Choose a direction that specifies if the filter should be applied to inbound updates or outbound updates.
  - Protocol**— (Optional) Choose the routing process for which you want to filter: None, BGP, Connected, OSPF, RIP, or Static.
  - Process ID**— (Optional) Enter the process ID for the OSPF routing protocol.
  - Click **OK**.
- Step 6** Click **Save**.
- 

## Configure BGP Network Settings

Network settings are used to add networks that will be advertised by the BGP routing process and route maps that will be examined to filter the networks to be advertised.

### Procedure

- 
- Step 1** On the **Device Management** page, click **Routing**.
- Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.
- Step 3** Choose **BGP > IPv4** or **IPv6**.
- Step 4** Click **Networks**.

- Step 5** Click **Add** and update the **Add Networks** dialog box:
- Network**— Choose the network to be advertised by the BGP routing processes.  
**Note** For a network prefix to be advertised, a route to the device must exist on the routing table.  
  
To add a new network object, see [Creating Network Objects, on page 1499](#).
  - (Optional) **Route Map**— Enter or choose a route map that should be examined to filter the networks to be advertised. If not specified, all networks are redistributed. To add a new route map object, see [Route Map, on page 1522](#).
  - Click **OK**.
- Step 6** Click **Save**.
- 

## Configure BGP Redistribution Settings

Redistribution settings allow you to define the conditions for redistributing routes from another routing domain into BGP.

### Procedure

---

- Step 1** On the **Device Management** page, click **Routing**.
- Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.
- Step 3** Choose **BGP > IPv4** or **IPv6**.
- Step 4** Click **Redistribution**.
- Step 5** Click **Add** and update the **Add Redistribution** dialog:
- Source Protocol**— Select the protocol from which you want to redistribute routes into the BGP domain from the Source Protocol drop-down list.  
**Note** User-defined virtual routers does not support redistributing traffic from RIP.
  - Process ID**— Enter the identifier for the selected source protocol. Applies to the OSPF protocol. For devices using virtual routing, this drop-down lists the process ID assigned for the virtual router for which you are configuring the BGP settings.
  - Metric**— (Optional) Enter a metric for the redistributed route.
  - Route Map**— Enter or select a route map that should be examined to filter the networks to be redistributed.  
  
If not specified, all networks are redistributed. To create a new route map object, click **Add (+)**. See [Route Map](#) for the procedure to add a new route map.
  - Match**— The conditions used for redistributing routes from one routing protocol to another. The routes must match the selected condition to be redistributed. You can choose one or more of the following match conditions. These options are enabled only when OSPF is chosen as the Source Protocol.
    - Internal
    - External 1

- External 2
  - NSSA External 1
  - NSSA External 2
- f) Click **OK**.
- 

## Configure BGP Route Injection Settings

Route injection settings allow you to define the routes to be conditionally injected into the BGP routing table.

### Procedure

---

- Step 1** On the **Device Management** page, click **Routing**.
- Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.
- Step 3** Choose **BGP > IPv4** or **IPv6**.
- Step 4** Click **Route Injection**.
- Step 5** Click **Add** and update the **Add Route Injection** dialog box:
- a) **Inject Map**— Enter or select the route map that specifies the prefixes to inject into the local BGP routing table. To create a new route map object, click **Add (+)**. For the procedure to add a new route map, see [Route Map](#).
  - b) **Exist Map**— Enter or select the route map containing the prefixes that the BGP speaker will track.
  - c) **Injected routes will inherit the attributes of the aggregate route**— Check this box to configure the injected route to inherit attributes of the aggregate route.
  - d) Click **OK**.
- Step 6** Click **Save**.
- 

## Configure BGP Route Import/Export Settings

In BGP, you can implement an inter-virtual-router route leak by importing or exporting routes using the route target extended community of the destination and source virtual routers respectively. You can use a route map to filter the desired route targets instead of leaking the entire routing table. You can also leak the routes of global virtual router to user-defined virtual routers and vice versa.

- You can configure BGP to leak routes between two user-defined virtual routers using the route target extended communities:
  - Tag the routes with the route targets from the source virtual router using route target export.
  - Import the routes that are matching the route targets in to the destination virtual router using route target import.

- Optionally, you can filter routes from source virtual router or to destination virtual router using export or import route maps respectively. You can configure route map with match extended community list for filtering the routes. Similarly, you can configure route map with set extended community route targets to tag the routes with the route target extended community.
- To import routes from the global virtual router to a user-defined virtual router, specify the IPv4/IPv6 route map in Global Virtual Router Import Route Map to import to the user-defined virtual router.
- To export routes from a user-defined virtual router to the global virtual router, in addition to exporting the route targets, you can also specify the Global Virtual Router Export Route Map to export from the user-defined virtual router.

The BGP inter-virtual-router route leaking supports both ipv4 and ipv6 prefixes.

### Before you begin

- [Create a Virtual Router](#).
- [Configure BGP Basic Settings](#).
- [Configure BGP, on page 1391](#).

### Procedure

- 
- Step 1** On the Device Management page, click **Routing**.
- Step 2** (For a virtual-router-aware device) From the virtual routers drop-down, choose the virtual router for which you are configuring BGP.
- Step 3** Choose **BGP > IPv4** or **IPv6**.
- Step 4** (Supported only for only virtual routers) Click **Route Import/Export**.
- Step 5** In the **Route Targets Import** field, enter the route target extended community that you want to match for the routes to be imported. On deployment, the routes of the destination virtual router that matches this value is imported to the source virtual router's BGP table.
- Note**
- The route target must be in **ASN:nn** format.
  - You can enter multiple route targets as comma separated values.
  - This value can range from 0:1 to 65534:65535.
- Step 6** In the **Route Targets Export** field, enter the route target extended community to tag the source virtual router's routes with the route target value. On deployment, the routes of the source virtual router are tagged with this value.
- Note**
- The route target must be in **ASN:nn** format.
  - You can enter multiple route targets as comma separated values.
  - This value can range from 0:1 to 65534:65535.

- Step 7** Route maps help you to narrow down the routes to be shared instead of leaking the entire routing table. Route map filtering is applied on the list of routes that are obtained with the specified route target values:
- (Optional) Under **User Virtual Router**, choose the route map from the **Import Route Map** drop-down list to filter the routes at the destination virtual router.  
**Note** The user virtual router import route map is effective only when the route targets import is configured.
  - (Optional) Under **User Virtual Router**, choose the route map from the **Export Route Map** drop-down list to filter the routes at the source virtual router before the routes are exported to other virtual routers.  
**Note** You can use the match and set clauses in the route map with the route target extended community lists for filtering based on other criteria or tagging the routes with the route target community values. For more information, see [Route Map, on page 1522](#).
- Step 8** To share the routes between a user-defined virtual router and global virtual router, specify the route map under the **Global Virtual Router**:
- To leak the global virtual router routes to the user-defined virtual router, select the route map from the **Import Route Map** drop-down list. The IPv4 or IPv6 route map is imported to the user-defined virtual router.
  - To leak the user-defined virtual router routes to the global virtual router, select the route map from the **Export Route Map** drop-down list. The IPv4 or IPv6 route map is exported to the global virtual router.  
**Note** You must specify the route targets for export apart from specifying the route map.
- Note** You can use the match clause of the route map object to filter the routes for leaking. For more information, see [Route Map, on page 1522](#).
- Step 9** Follow the procedure ( [Step 3](#) to [Step 8](#) ) to configure relevant BGP route import and export settings for other virtual routers as well.
- Step 10** Click **Save** and **Deploy**.

---

When the packets flow into the ingress virtual router, BGP imports the routes from the destination virtual routers that have the matching route target value and if a route map is also configured, the routes are further filtered and used to identify the best path routes for routing the packets.

# CHAPTER 51

## RIP

This chapter describes how to configure the threat defense to route data, perform authentication, and redistribute routing information, using the Routing Information Protocol (RIP). For a device using virtual routing, you can configure RIP only for its global virtual router and not for its user-defined virtual router.

- [About RIP, on page 1405](#)
- [Requirements and Prerequisites for RIP, on page 1407](#)
- [Guidelines for RIP, on page 1407](#)
- [Configure RIP, on page 1408](#)

## About RIP

The Routing Information Protocol, or RIP, as it is more commonly called, is one of the most enduring of all routing protocols. RIP has four basic components: routing update process, RIP routing metrics, routing stability, and routing timers. Devices that support RIP send routing-update messages at regular intervals and when the network topology changes. These RIP packets include information about the networks that the devices can reach, as well as the number of routers or gateways that a packet must travel through to reach the destination address. RIP generates more traffic than OSPF, but is easier to configure.

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection. When RIP is enabled on an interface, the interface exchanges RIP broadcasts with neighboring devices to dynamically learn about and advertise routes.

The Secure Firewall Threat Defense device supports both RIP Version 1 and RIP Version 2. RIP Version 1 does not send the subnet mask with the routing update. RIP Version 2 sends the subnet mask with the routing update and supports variable-length subnet masks. Additionally, RIP Version 2 supports neighbor authentication when routing updates are exchanged. This authentication ensures that the Secure Firewall Threat Defense device receives reliable routing information from a trusted source.

RIP has advantages over static routes because the initial configuration is simple, and you do not need to update the configuration when the topology changes. The disadvantage to RIP is that there is more network and processing overhead than in static routing.

## Routing Update Process

RIP sends routing-update messages at regular intervals and when the network topology changes. When a router receives a routing update that includes changes to an entry, it updates its routing table to reflect the new route. The metric value for the path is increased by 1, and the sender is indicated as the next hop. RIP

routers maintain only the best route (the route with the lowest metric value) to a destination. After updating its routing table, the router immediately begins transmitting routing updates to inform other network routers of the change. These updates are sent independently of the regularly scheduled updates that RIP routers send.

## RIP Routing Metric

RIP uses a single routing metric (hop count) to measure the distance between the source and a destination network. Each hop in a path from source to destination is assigned a hop count value, which is typically 1. When a router receives a routing update that contains a new or changed destination network entry, the router adds 1 to the metric value indicated in the update and enters the network in the routing table. The IP address of the sender is used as the next hop.

## RIP Stability Features

RIP prevents routing loops from continuing indefinitely by implementing a limit on the number of hops allowed in a path from the source to a destination. The maximum number of hops in a path is 15. If a router receives a routing update that contains a new or changed entry, and if increasing the metric value by 1 causes the metric to be infinity (that is, 16), the network destination is considered unreachable. The downside of this stability feature is that it limits the maximum diameter of a RIP network to less than 16 hops.

RIP includes a number of other stability features that are common to many routing protocols. These features are designed to provide stability despite potentially rapid changes in network topology. For example, RIP implements the split horizon and hold-down mechanisms to prevent incorrect routing information from being propagated.

## RIP Timers

RIP uses numerous timers to regulate its performance. Following are the timer stages for RIP:

- **Update**—The routing-update timer is the interval between periodic routing updates. This is how often the device sends routing updates. Generally, it is set to 30 seconds, with a small random amount of time added whenever the timer is reset. This is done to help prevent congestion, which could result from all routers simultaneously attempting to update their neighbors.
- **Invalid**—Each routing table entry has a route-timeout timer associated with it. This is the number of seconds since the device received the last valid update. When the route-timeout timer expires, the route is marked invalid but is retained in the table until the route-flush timer expires. Once this timer expires, the route goes into holddown. The default is 180 seconds (3 minutes).
- **Holddown**—The holddown period is the number of seconds the system waits before accepting any new updates for the route that is in holddown (that is, routes that have been marked invalid). The default is 180 seconds (3 minutes).
- **Flush**—The route-flush timer is the number of seconds since the system received the last valid update until the route is discarded and removed from the routing table. The default is 240 seconds (4 minutes).

As an example, when the interface on an adjacent router goes down, the system no longer receives routing updates from the adjacent router. At this time, the Invalid and Flush timers start increasing. In the first 180 seconds, nothing will happen. After 180 seconds, the invalid timer expires, making the route invalid, and the Holddown timer starts and holds the route for another 60 seconds. If there is still no update regarding the interface status on the adjacent router (that is, it is still down), then the route enters into the Flush state where in total the system has waited for 240 seconds from the last update (180 seconds for the Invalid timer and 60

seconds for Holddown timer), and the system flushes the route. Even if the adjacent routers interface comes up immediately, the system does not accept a routing update until the Holddown timer completes the remaining 120 seconds.

## Requirements and Prerequisites for RIP

### Model Support

Threat Defense

Threat Defense Virtual

### Supported Domains

Any

### User Roles

Admin

Network Admin

## Guidelines for RIP

### IPv6 Guidelines

Does not support IPv6.

### Additional Guidelines

The following information applies to RIP Version 2 only:

- If using neighbor authentication, the authentication key and key ID must be the same on all neighbor devices that provide RIP Version 2 updates to the interface.
- With RIP Version 2, the Secure Firewall Threat Defense device transmits and receives default route updates using the multicast address 224.0.0.9. In passive mode, it receives route updates at that address.
- When RIP Version 2 is configured on an interface, the multicast address 224.0.0.9 is registered on that interface. When a RIP Version 2 configuration is removed from an interface, that multicast address is unregistered.

### Limitations

- The Secure Firewall Threat Defense device cannot pass RIP updates between interfaces.
- RIP Version 1 does not support variable-length subnet masks.
- RIP has a maximum hop count of 15. A route with a hop count greater than 15 is considered unreachable.
- RIP convergence is relatively slow compared to other routing protocols.

- You can only enable a single RIP process on the Secure Firewall Threat Defense device.

## Configure RIP

RIP is a distance-vector routing protocol that uses hop count as the metric for path selection.

### Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Select **Routing**.
- Step 3** Select **RIP** from the table of contents.
- Step 4** Check the **Enable RIP** check box to configure the RIP settings.
- Step 5** Choose the RIP versions for sending and receiving RIP updates from the **RIP Version** drop-down list.
- Step 6** (Optional) Check the **Generate Default Route** check box to generate a default route for distribution, based on the route map that you specify.
- a) Specify a route map name to use for generating default routes, in the **Route Map** field.  
The default route 0.0.0.0/0 is generated for distribution over a certain interface, when the route map, specified in the **Route Map** field, is present.
- Step 7** When Send and Receive Version 2 is the chosen RIP Version, the **Enable Auto Summary** option is available. When the **Enable Auto Summary** check box is checked, automatic route summarization is enabled. Disable automatic summarization if you must perform routing between disconnected subnets. When automatic summarization is disabled, subnets are advertised.
- Note** RIP Version 1 always uses automatic summarization—you cannot disable it.
- Step 8** Click **Networks**. Define one or more networks for RIP routing. Enter IP address(es), or enter or select the desired Network/Hosts objects. There is no limit to the number of networks you can add to the security appliance configuration. Any interface that belongs to a network defined by this command, will participate in the RIP routing process. The RIP routing updates will be sent and received only through interfaces on the specified networks. Also, if the network of an interface is not specified, the interface will not be advertised in any RIP updates.
- Note** RIP only supports IPv4 objects.
- Step 9** (Optional) Click **Passive Interface**. Use this option to specify passive interfaces on the appliance, and by extension the active interfaces. The device listens for RIP routing broadcasts on passive interfaces, using that information to populate its routing tables, but does not broadcast routing updates on passive interfaces. Interfaces that are not designated as passive, receive and send updates.
- Step 10** Click **Redistribution** to manage redistribution routes. These are the routes that are being redistributed from other routing processes into the RIP routing process.
- a) Click **Add** to specify redistribution routes.
- b) Choose the routing protocol to redistribute into the RIP routing process, in the **Protocol** drop-down list.
- Note** For the OSPF protocol, specify a process ID. Similarly, specify an AS path for BGP. When you choose the Connected option in the **Protocol** drop-down list, you can redistribute, directly connected networks into the RIP routing process.

- c) (Optional) If you are redistributing OSPF routes into the RIP routing process, you can select specific types of OSPF routes to redistribute in the **Match** drop-down list. Ctrl-click to select multiple types:
- **Internal** – Routes internal to the autonomous system (AS) are redistributed.
  - **External 1** – Type 1 routes external to the AS are redistributed.
  - **External 2** – Type 2 routes external to the AS are redistributed.
  - **NSSA External 1** – Type 1 routes external to a not-so-stubby area (NSSA) are redistributed.
  - **NSSA External 2** – Type 2 routes external to an NSSA are redistributed

**Note** The default is match Internal, External 1, and External 2

- d) Select the RIP metric type to apply to the redistributed routes in the **Metric** drop-down list. The two choices are:
- **Transparent** – Use the current route metric
  - **Specified Value** – Assign a specific metric value. Enter a specific value from 0-16, in the **Metric Value** field.
  - **None** – No metric is specified. Do not use any metric value, to apply to redistributed routes.

**Note** None option is applicable only for Static and Connected protocols.

- e) (Optional) Enter the name of a route map that must be satisfied, in the **Route Map** field before the route can be redistributed into the RIP routing process. Routes are redistributed only if IP address matches an allow statement in the route map address list. To create a new route map object, click **Add (+)**. See [Route Map](#) for the procedure to add a new route map.
- f) Click **OK**.

### Step 11

(Optional) Click **Filtering** to manage filters for the RIP policy. In this section, filters are used to prevent routing updates through an interface, control the advertising of routes in routing updates, control the processing of routing updates and filtering sources of routing updates.

- a) Click **Add** to add RIP filters.
- b) Select the type of traffic to be filtered - Inbound or Outbound in the **Traffic Direction** field.

**Note** If traffic direction is inbound, you can only define an Interface filter.

- c) Specify whether the filter is based on an Interface or a Route, by selecting appropriate in the **Filter On** field. If you click **Interface**, enter or choose the name of the interface on which routing updates are to be filtered. If you click **Route**, choose the route type:
- **Static** – Only static routes are filtered.
  - **Connected** – Only connected routes are filtered.
  - **OSPF** – Only OSPFv2 routes discovered by the specified OSPF process are filtered. Enter the Process ID of the OSPF process to be filtered.
  - **BGP** – Only BGPv4 routes discovered by the specified BGP process are filtered. Enter the AS path of the BGP process to be filtered.

- d) In the **Access List** field, enter or choose the name of one or more access control lists (ACLs) that define the networks to be allowed or removed from RIP route advertisements. To add a new standard access list object, click **Add** (+) and see [Configure Standard ACL Objects, on page 1471](#).
- e) Click **OK**.

**Step 12**

(Optional) Click **Broadcast** to add or edit interface configurations. Using Broadcast, you can override the global RIP versions to send or receive per interface. You can also define the authentication parameters per interface if you want to implement authentication to ensure valid RIP updates.

- a) Click **Add** to add interface configurations.
- b) Enter or choose an interface defined on this appliance in the **Interface** field.
- c) In the Send option, select the appropriate boxes to specify sending updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Send versions specified .
- d) In the Receive option, select the appropriate boxes to specify accepting updates using the RIP **Version 1**, **Version 2**, or both. These options let you override, for the specified interface, the global Receive versions specified .
- e) Select the **Authentication** used on this interface for RIP broadcasts.
  - **None** – No authentication
  - **MD5** – Employ MD5
  - **Clear Text** – Employ clear-text authentication

If you choose MD5 or Clear Text, you must also provide the following authentication parameters.

- **Key ID** – The ID of the authentication key. Valid values are from 0 to 255.
  - **Key** – The key used by the chosen authentication method. Can contain up to 16 characters
  - **Confirm** – Enter the authentication key again, to confirm
- f) Click **OK**.
-

## CHAPTER 52

# Multicast

---

This chapter describes how to configure the Secure Firewall Threat Defense device to use the multicast routing protocol.

- [About Multicast Routing, on page 1411](#)
- [Requirements and Prerequisites for Multicast Routing, on page 1415](#)
- [Guidelines for Multicast Routing, on page 1415](#)
- [Configure IGMP Features, on page 1416](#)
- [Configure PIM Features, on page 1421](#)
- [Configure Multicast Routes, on page 1427](#)
- [Configure Multicast Boundary Filters, on page 1428](#)

## About Multicast Routing

Multicast routing is a bandwidth-conserving technology that reduces traffic by simultaneously delivering a single stream of information to thousands of corporate recipients and homes. Applications that take advantage of multicast routing include videoconferencing, corporate communications, distance learning, and distribution of software, stock quotes, and news.

Multicast routing protocols deliver source traffic to multiple receivers without adding any additional burden on the source or the receivers while using the least network bandwidth of any competing technology. Multicast packets are replicated in the network by threat defense device enabled with Protocol Independent Multicast (PIM) and other supporting multicast protocols, which results in the most efficient delivery of data to multiple receivers possible.

The threat defense device supports both stub multicast routing and PIM multicast routing. However, you cannot configure both concurrently on a single threat defense device.

---

**Note** The UDP and non-UDP transports are both supported for multicast routing. However, the non-UDP transport has no FastPath optimization.

---

## IGMP Protocol

IP hosts use the Internet Group Management Protocol (IGMP) to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast

group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

IGMP uses group addresses (Class D IP address) as group identifiers. Host group address can be in the range of 224.0.0.0 to 239.255.255.255. The address 224.0.0.0 is never assigned to any group. The address 224.0.0.1 is assigned to all systems on a subnet. The address 224.0.0.2 is assigned to all routers on a subnet.

---

**Note** When you enable multicast routing on the threat defense device, IGMP Version 2 is automatically enabled on all interfaces.

---

### Query Messages to Multicast Groups

The threat defense device sends query messages to discover which multicast groups have members on the networks attached to the interfaces. Members respond with IGMP report messages indicating that they want to receive multicast packets for specific groups. Query messages are addressed to the all-systems multicast group, which has an address of 224.0.0.1, with a time-to-live value of 1.

These messages are sent periodically to refresh the membership information stored on the threat defense device. If the threat defense device discovers that there are no local members of a multicast group still attached to an interface, it stops forwarding multicast packets for that group to the attached network, and it sends a prune message back to the source of the packets.

By default, the PIM designated router on the subnet is responsible for sending the query messages. By default, they are sent once every 125 seconds.

When changing the query response time, by default, the maximum query response time advertised in IGMP queries is 10 seconds. If the threat defense device does not receive a response to a host query within this amount of time, it deletes the group.

## Stub Multicast Routing

Stub multicast routing provides dynamic host registration and facilitates multicast routing. When configured for stub multicast routing, the threat defense device acts as an IGMP proxy agent. Instead of fully participating in multicast routing, the threat defense device forwards IGMP messages to an upstream multicast router, which sets up delivery of the multicast data. When configured for stub multicast routing, the threat defense device cannot be configured for PIM sparse or bidirectional mode. You must enable PIM on the interfaces participating in IGMP stub multicast routing.

The threat defense device supports both PIM-SM and bidirectional PIM. PIM-SM is a multicast routing protocol that uses the underlying unicast routing information base or a separate multicast-capable routing information base. It builds unidirectional shared trees rooted at a single Rendezvous Point (RP) per multicast group and optionally creates shortest-path trees per multicast source.

## PIM Multicast Routing

Bidirectional PIM is a variant of PIM-SM that builds bidirectional shared trees connecting multicast sources and receivers. Bidirectional trees are built using a Designated Forwarder (DF) election process operating on each link of the multicast topology. With the assistance of the DF, multicast data is forwarded from sources to the Rendezvous Point (RP), and therefore along the shared tree to receivers, without requiring source-specific state. The DF election takes place during RP discovery and provides a default route to the RP.

---

**Note** If the threat defense device is the PIM RP, use the untranslated outside address of the threat defense device as the RP address.

---

## PIM Source Specific Multicast Support

The threat defense device does not support PIM Source Specific Multicast (SSM) functionality and related configuration. However, the threat defense device allows SSM-related packets to pass through unless it is placed as a last-hop router.

SSM is classified as a data delivery mechanism for one-to-many applications such as IPTV. The SSM model uses a concept of "channels" denoted by an (S,G) pair, where S is a source address and G is an SSM destination address. Subscribing to a channel is achieved by using a group management protocol such as IGMPv3. SSM enables a receiving client, once it has learned about a particular multicast source, to receive multicast streams directly from the source rather than receiving it from a shared Rendezvous Point (RP). Access control mechanisms are introduced within SSM providing a security enhancement not available with current sparse or sparse-dense mode implementations.

PIM-SSM differs from PIM-SM in that it does not use an RP or shared trees. Instead, information on source addresses for a multicast group is provided by the receivers through the local receivership protocol (IGMPv3) and is used to directly build source-specific trees.

## Multicast Bidirectional PIM

Multicast bidirectional PIM is useful for networks that have many sources and receivers talking to each other simultaneously and where each participant can become both the source and receiver of multicast traffic, such as in videoconferencing, Webex meetings, and group chat. When PIM bidirectional mode is used, the RP only creates the (\*,G) entry for the shared tree. There is no (S,G) entry. This conserves resources on the RP because state tables for each (S,G) entry are not maintained.

In PIM sparse mode, traffic only flows down the shared tree. In PIM bidirectional mode, traffic flows up and down the shared tree.

PIM bidirectional mode also does not use the PIM register/register-stop mechanism to register sources to the RP. Each source can begin sending to the source at any time. When the multicast packets arrive at the RP, they are forwarded down the shared tree (if there are receivers) or dropped (when there are no receivers). However, there is no way for the RP to tell the source to stop sending multicast traffic.

Design-wise you must think about where to place the RP in your network because it should be somewhere in the middle between the sources and receivers in the network.

PIM bidirectional mode has no Reverse Path Forwarding (RPF) check. Instead it uses the concept of a Designated Forwarder (DF) to prevent loops. This DF is the only router on the segment that is allowed to send multicast traffic to the RP. If there is only one router per segment that forwards multicast traffic, there will be no loops. The DF is chosen using the following mechanism:

- The router with the lowest metric to the RP is the DF.
- If the metric is equal, then the router with the highest IP address becomes the DF.

## PIM Bootstrap Router (BSR)

PIM Bootstrap Router (BSR) is a dynamic Rendezvous Point (RP) selection model that uses candidate routers for RP function and for relaying the RP information for a group. The RP function includes RP discovery and provides a default route to the RP. It does this by configuring a set of devices as candidate BSRs (C-BSR) which participate in a BSR election process to choose a BSR amongst themselves. Once the BSR is chosen, devices that are configured as candidate Rendezvous Points (C-RP) start sending their group mapping to the elected BSR. The BSR then distributes the group-to-RP mapping information to all the other devices down the multicast tree through BSR messages that travel from PIM router to PIM router on a per-hop basis.

This feature provides a means of dynamically learning RPs, which is very essential in large complex networks where an RP can periodically go down and come up.

### PIM Bootstrap Router (BSR) Terminology

The following terms are frequently referenced in the PIM BSR configuration:

- **Bootstrap Router (BSR)** — A BSR advertises Rendezvous Point (RP) information to other routers with PIM on a hop-by-hop basis. Among multiple Candidate-BSRs, a single BSR is chosen after an election process. The primary purpose of this Bootstrap router is to collect all Candidate-RP (C-RP) announcements in to a database called the RP-set and to periodically send this out to all other routers in the network as BSR messages (every 60 seconds).
- **Bootstrap Router (BSR) messages** — BSR messages are multicast to the All-PIM-Routers group with a TTL of 1. All PIM neighbors that receive these messages retransmit them (again with a TTL of 1) out of all interfaces except the one in which the messages were received. BSR messages contain the RP-set and the IP address of the currently active BSR. This is how C-RPs know where to unicast their C-RP messages.
- **Candidate Bootstrap Router (C-BSR)** — A device that is configured as a candidate-BSR participates in the BSR election mechanism. A C-BSR with highest priority is elected as the BSR. The highest IP address of the C-BSR is used as a tiebreaker. The BSR election process is preemptive, for example if a new C-BSR with a higher priority comes up, it triggers a new election process.
- **Candidate Rendezvous Point (C-RP)** — An RP acts as a meeting place for sources and receivers of multicast data. A device that is configured as a C-RP periodically advertises the multicast group mapping information directly to the elected BSR through unicast. These messages contain the Group-range, C-RP address, and a hold time. The IP address of the current BSR is learned from the periodic BSR messages that are received by all routers in the network. In this way, the BSR learns about possible RPs that are currently up and reachable.

---

**Note** The threat defense device does not act as a C-RP, even though the C-RP is a mandatory requirement for BSR traffic. Only routers can act as a C-RP. So, for BSR testing functionality, you must add routers to the topology.

---

- **BSR Election Mechanism** — Each C-BSR originates Bootstrap messages (BSMs) that contain a BSR Priority field. Routers within the domain flood the BSMs throughout the domain. A C-BSR that hears about a higher-priority C-BSR than itself suppresses its sending of further BSMs for some period of time. The single remaining C-BSR becomes the elected BSR, and its BSMs inform all the other routers in the domain that it is the elected BSR.

## Multicast Group Concept

Multicast is based on the concept of a group. An arbitrary group of receivers expresses an interest in receiving a particular data stream. This group does not have any physical or geographical boundaries—the hosts can be located anywhere on the Internet. Hosts that are interested in receiving data flowing to a particular group must join the group using IGMP. Hosts must be a member of the group to receive the data stream.

## Multicast Addresses

Multicast addresses specify an arbitrary group of IP hosts that have joined the group and want to receive traffic sent to this group.

## Clustering

Multicast routing supports clustering. In Spanned EtherChannel clustering, the control unit sends all multicast routing packets and data packets until fast-path forwarding is established. After fast-path forwarding is established, data units may forward multicast data packets. All data flows are full flows. Stub forwarding flows are also supported. Because only one unit receives multicast packets in Spanned EtherChannel clustering, redirection to the control unit is common.

## Requirements and Prerequisites for Multicast Routing

### Model Support

Threat Defense  
Threat Defense Virtual

### Supported Domains

Any

### User Roles

Admin  
Network Admin

## Guidelines for Multicast Routing

### Firewall Mode

Supported only in routed firewall mode. Transparent firewall mode is not supported.

### IPv6

Does not support IPv6.

### Multicast Group

The range of addresses between 224.0.0.0 and 224.0.0.255 is reserved for the use of routing protocols and other topology discovery or maintenance protocols, such as gateway discovery and group membership reporting. Hence, Internet multicast routing from address range 224.0.0/24 is not supported; IGMP group is not created when enabling multicast routing for the reserved addresses.

### Clustering

In clustering, for IGMP and PIM, this feature is only supported on the primary unit.

### Additional Guidelines

- You must configure an access control or prefilter rule on the inbound security zone to allow traffic to the multicast host, such as 224.1.2.3. However, you cannot specify a destination security zone for the rule, or it cannot be applied to multicast connections during initial connection validation.
- You cannot disable an interface with PIM configured on it. If you have configured PIM on the interface (see [Configure PIM Protocol, on page 1421](#)), disabling the multicast routing and PIM does not remove the PIM configuration. You must remove (delete) the PIM configuration to disable the interface.
- PIM/IGMP Multicast routing is not supported on interfaces in a traffic zone.
- Do not configure threat defense to simultaneously be a Rendezvous Point (RP) and a First Hop Router.
- HSRP standby IP address does not participate in PIM neighborship. Thus, if the RP router IP is routed through a HSRP standby IP address, the multicast routing does not work in Threat Defense. Hence for the multicast traffic to pass through successfully, ensure that the route for the RP address is not the HSRP standby IP address, instead, configure the route address to an interface IP address.
- For a device using virtual routing, you can configure multicast only for its global virtual router and not for its user-defined virtual router.

## Configure IGMP Features

IP hosts use IGMP to report their group memberships to directly-connected multicast routers. IGMP is used to dynamically register individual hosts in a multicast group on a particular LAN. Hosts identify group memberships by sending IGMP messages to their local multicast router. Under IGMP, routers listen to IGMP messages and periodically send out queries to discover which groups are active or inactive on a particular subnet.

This section describes how to configure optional IGMP settings on a per-interface basis.

### Procedure

- 
- Step 1** [Enable Multicast Routing, on page 1417.](#)
  - Step 2** [Configure IGMP Protocol, on page 1417.](#)
  - Step 3** [Configure IGMP Access Groups, on page 1419.](#)
  - Step 4** [Configure IGMP Static Groups, on page 1419.](#)

**Step 5** [Configure IGMP Join Groups, on page 1420.](#)

---

## Enable Multicast Routing

Enabling multicast routing on the threat defense device, enables IGMP and PIM on all interfaces by default. IGMP is used to learn whether members of a group are present on directly attached subnets. Hosts join multicast groups by sending IGMP report messages. PIM is used to maintain forwarding tables to forward multicast datagrams.

---

**Note** Only the UDP transport layer is supported for multicast routing.

---

The following list shows the maximum number of entries for specific multicast tables. Once these limits are reached, any new entries are discarded.

- MFIB—30,000
- IGMP Groups—30,000
- PIM Routes—72,000

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Routing > Multicast Routing > IGMP**.

**Step 3** Check the **Enable Multicast Routing** check box.

Checking this check box enables IP multicast routing on the device. Unchecking this check box disables IP multicast routing. By default, multicast is disabled. Enabling multicast routing enables multicast on all interfaces.

You can disable multicast on a per-interface basis. This is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the threat defense device from sending host query messages on that interface.

---

## Configure IGMP Protocol

You can configure IGMP parameters per interface, such as the forward interface, query messages, and time intervals.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Routing > Multicast Routing > IGMP**.

**Step 3** On **Protocol**, click **Add** or **Edit**.

Use the **Add IGMP parameters** dialog box to add new IGMP parameters to the threat defense device. Use the **Edit IGMP parameters** dialog box to change existing parameters.

**Step 4** Configure the following options:

- **Interface**—From the drop-down list, choose the interface for which you want to configure IGMP protocol.
- **Enable IGMP**—Check the check box to enable IGMP.

**Note** Disabling IGMP on specific interfaces is useful if you know that there are no multicast hosts on a specific interface and you want to prevent the device from sending host query messages on that interface.

- **Forward Interface**—From the drop-down list, choose the specific interface from which you want to forward IGMP messages.

This configures the Secure Firewall Threat Defense device to act as an IGMP proxy agent and forward IGMP messages from hosts connected on one interface to an upstream multicast router on another interface.

- **Version**—Choose IGMP Version 1 or 2.

By default, the threat defense device runs IGMP Version 2, which enables several additional features.

**Note** All multicast routers on a subnet must support the same version of IGMP. The threat defense device does not automatically detect Version 1 routers and switch to Version 1. However, you can have a mix of IGMP Version 1 and 2 hosts on the subnet; the threat defense device running IGMP Version 2 works correctly when IGMP Version 1 hosts are present.

- **Query Interval**—The interval in seconds at which the designated router sends IGMP host-query messages. The range is 1 to 3600. The default is 125.

**Note** If the threat defense device does not hear a query message on an interface for the specified timeout value, then the device becomes the designated router and starts sending the query messages.

- **Response Time**—The interval in seconds before the threat defense device deletes the group. The range is 1 to 25. The default is 10.

If the threat defense device does not receive a response to a host query within this amount of time, it deletes the group.

- **Group Limit**—The maximum number of hosts that can join on an interface. The range is 1 to 500. The default is 500.

You can limit the number of IGMP states resulting from IGMP membership reports on a per-interface basis. Membership reports exceeding the configured limits are not entered in the IGMP cache, and traffic for the excess membership reports is not forwarded.

- **Query Timeout**—The period of time in seconds before which the threat defense device takes over as the requester for the interface after the previous requester has stopped. The range is 60 to 300. The default is 255.

**Step 5** Click **OK** to save the IGMP protocol configuration.

---

## Configure IGMP Access Groups

You can control access to multicast groups by using access control lists.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Routing > Multicast Routing > Access Group**.

**Step 3** On **Access Group**, click **Add** or **Edit**.

Use the **Add IGMP Access Group parameters** dialog box to add new IGMP access groups to the Access Group table. Use the **Edit IGMP Access Group parameters** dialog box to change existing parameters.

**Step 4** Configure the following options:

- a) From the **Interface** drop-down list, choose the interface with which the access group is associated. You cannot change the associated interface when you are editing an existing access group.
- b) Click one of the following:
  - **Standard Access List**— From the **Standard Access List** drop-down list, choose the standard ACL or click **Add (+)** to create a new standard ACL. See [Configure Standard ACL Objects, on page 1471](#) for the procedure.
  - **Extended Access List**— From the **Extended Access List** drop-down list, choose the extended ACL or click **Add (+)** to create a new extended ACL. See [Configure Extended ACL Objects, on page 1468](#) for the procedure.

**Step 5** Click **OK** to save the access group configuration.

---

## Configure IGMP Static Groups

Sometimes a group member cannot report its membership in the group or there may be no members of a group on the network segment, but you still want multicast traffic for that group to be sent to that network segment. You can have multicast traffic for that group sent to the segment by configuring a statically joined IGMP group. With this method, the threat defense device does not accept the packets itself, but only forwards them. Therefore, this method allows fast switching. The outgoing interface appears in the IGMP cache, but this interface is not a member of the multicast group.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Routing > Multicast Routing > IGMP**.

**Step 3** On **Static Group**, click **Add** or **Edit**.

Use the **Add IGMP Static Group parameters** dialog box to statically assign a multicast group to an interface. Use the **Edit IGMP Static Group parameters** dialog box to change existing static group assignments.

**Note** The IGMP Static Group enables PIM to send *Join* requests towards the sources or towards the Rendezvous Point (RP), provided, the firewall with this command is the PIM Designated Router (DR) on that interface where the command is applied.

**Step 4** Configure the following options:

- From the **Interface** drop-down list, choose the interface to which you want to statically assign a multicast group. If you are editing an existing entry, you cannot change the value.
- From the **Multicast Groups** drop-down list, choose the multicast group to which you want to assign the interface, or click **Add (+)** to create a new multicast group. See [Creating Network Objects](#) for the procedure.

**Step 5** Click **OK** to save the static group configuration.

## Configure IGMP Join Groups

You can configure an interface to be a member of a multicast group. Configuring the threat defense device to join a multicast group causes upstream routers to maintain multicast routing table information for that group and keep the paths for that group active.

**Note** See [Configure IGMP Static Groups, on page 1419](#) if you want to forward multicast packets for a specific group to an interface without the threat defense device accepting those packets as part of the group.

### Procedure

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Routing > Multicast Routing > IGMP**.

**Step 3** On **Join Group**, click **Add** or **Edit**.

Use the **Add IGMP Join Group parameters** dialog box to configure the threat defense device to be a member of a multicast group. Use the **Edit IGMP Join Group parameters** dialog box to change existing parameters.

**Note** The IGMP Join Group enables PIM to send *Join* requests towards the sources or towards the Rendezvous Point (RP), provided, the firewall with this command is the PIM Designated Router (DR) on that interface where the command is applied.

**Step 4** Configure the following options:

- From the **Interface** drop-down list, choose the interface you want to be a member of a multicast group. If you are editing an existing entry, you cannot change the value.
- From the **Join Group** drop-down list, choose the multicast group to which you want to assign the interface, or click **Plus** to create a new multicast group. See [Creating Network Objects](#) for the procedure.

---

## Configure PIM Features

Routers use PIM to maintain forwarding tables to use for forwarding multicast diagrams. When you enable multicast routing on the Secure Firewall Threat Defense device, PIM and IGMP are automatically enabled on all interfaces.

---

**Note** PIM is not supported with PAT. The PIM protocol does not use ports, and PAT only works with protocols that use ports.

---

This section describes how to configure optional PIM settings.

### Procedure

- 
- Step 1** [Configure PIM Protocol, on page 1421.](#)
  - Step 2** [Configure PIM Neighbor Filters, on page 1422.](#)
  - Step 3** [Configure PIM Bidirectional Neighbor Filters, on page 1423.](#)
  - Step 4** [Configure PIM Rendezvous Points, on page 1424.](#)
  - Step 5** [Configure PIM Route Trees, on page 1425.](#)
  - Step 6** [Configure PIM Request Filters, on page 1425.](#)
  - Step 7** [Configure Multicast Boundary Filters, on page 1428.](#)
- 

## Configure PIM Protocol

You can enable or disable PIM on a specific interface.

You can also configure the Designated Router (DR) priority. The DR is responsible for sending PIM register, join, and prune messages to the RP. When there is more than one multicast router on a network segment, choosing the DR is based on the DR priority. If multiple devices have the same DR priority, then the device with the highest IP address becomes the DR. By default, the threat defense device has a DR priority of 1.

Router query messages are used to choose the PIM DR. The PIM DR is responsible for sending router query messages. By default, router query messages are sent every 30 seconds. Additionally, every 60 seconds, the threat defense device sends PIM join or prune messages.

## Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Choose **Routing > Multicast Routing > PIM**.
- Step 3** On **Protocol**, click **Add** or **Edit**.
- Use the **Add PIM parameters** dialog box to add new PIM parameters to the interface. Use the **Edit PIM parameters** dialog box to change existing parameters.
- Step 4** Configure the following options:
- **Interface**—From the drop-down list, select the interface for which you want to configure PIM protocol.
  - **Enable PIM**—Check the check box to enable PIM.
  - **DR Priority**—The value for the DR for the selected interface. The router with the highest DR priority on the subnet becomes the designated router. Valid values range from 0 to 4294967294. The default DR priority is 1. Setting this value to 0 makes the threat defense device interface ineligible to become the designated router.
  - **Hello Interval**—The interval in seconds at which the interface sends PIM hello messages. The range is 1 to 3600. The default is 30.
  - **Join Prune Interval**—The interval in seconds at which the interface sends PIM join and prune advertisements. The range is 10 to 600. The default is 60.
- Step 5** Click **OK** to save the PIM protocol configuration.
- 

## Configure PIM Neighbor Filters

You can define the routers that can become PIM neighbors. By filtering the routers that can become PIM neighbors, you can do the following:

- Prevent unauthorized routers from becoming PIM neighbors.
- Prevent attached stub routers from participating in PIM.

## Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Choose **Routing > Multicast Routing > PIM**.
- Step 3** On **Neighbor Filter**, click **Add** or **Edit**.
- Use the **Add PIM Neighbor Filter** dialog box to add new PIM neighbor filters to the interface. Use the **Edit PIM Neighbor Filter** dialog box to change existing parameters.
- Step 4** Configure the following options:

- From the **Interface** drop-down list, choose the interface to which you want to add a PIM neighbor filter.
- **Standard Access List**— From the **Standard Access List** drop-down list, choose a standard ACL or click **Add** (+) to create a new standard ACL. See [Configure Standard ACL Objects, on page 1471](#) for the procedure.

**Note** Choosing **Allow** on the **Add Standard Access List Entry** dialog box lets the multicast group advertisements pass through the interface. Choosing **Block** prevents the specified multicast group advertisements from passing through the interface. When a multicast boundary is configured on an interface, all multicast traffic is prevented from passing through the interface unless permitted with a neighbor filter entry.

**Step 5** Click **OK** to save the PIM neighbor filter configuration.

---

## Configure PIM Bidirectional Neighbor Filters

A PIM bidirectional neighbor filter is an ACL that defines the neighbor devices that can participate in the Designated Forwarder (DF) election. If a PIM bidirectional neighbor filter is not configured for an interface, there are no restrictions. If a PIM bidirectional neighbor filter is configured, only those neighbors permitted by the ACL can participate in the DF election process.

Bidirectional PIM allows multicast routers to keep reduced state information. All of the multicast routers in a segment must be bidirectionally enabled to elect a DF.

When a PIM bidirectional neighbor filter is enabled, the routers that are permitted by the ACL are considered to be bidirectionally capable. Therefore, the following is true:

- If a permitted neighbor does not support bidirectional mode, then the DF election does not occur.
- If a denied neighbor supports bidirectional mode, then the DF election does not occur.
- If a denied neighbor does not support bidirectional mode, the DF election can occur.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Multicast Routing > PIM**.

**Step 3** On **Bidirectional Neighbor Filter**, click **Add** or **Edit**.

Use the **Add PIM Bidirectional Neighbor Filter** dialog box to create ACL entries for the PIM bidirectional neighbor filter ACL. Use the **Edit PIM Bidirectional Neighbor Filter** dialog box to change existing parameters.

**Step 4** Configure the following options:

- From the **Interface** drop-down list, select the interface to which you want to configure the PIM bidirectional neighbor filter ACL entry.

- **Standard Access List**— From the **Standard Access List** drop-down list, select a standard ACL or click **Add (+)** to create a new standard ACL. See [Configure Standard ACL Objects, on page 1471](#) for the procedure.

**Note** Choosing **Allow** on the **Add Standard Access List Entry** dialog box lets the specified devices participate in the DR election process. Choosing **Block** prevents the specified devices from participating in the DR election process.

**Step 5** Click **OK** to save the PIM bidirectional neighbor filter configuration.

## Configure PIM Rendezvous Points

You can configure the threat defense device to serve as a RP to more than one group. The group range specified in the ACL determines the PIM RP group mapping. If an ACL is not specified, then the RP for the group is applied to the entire multicast group range (224.0.0.0/4). See [Multicast Bidirectional PIM, on page 1413](#) for more information about bidirectional PIM.

The following restrictions apply to RPs:

- You cannot use the same RP address twice.
- You cannot specify All Groups for more than one RP.

### Procedure

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Routing > Multicast Routing > PIM**.

**Step 3** On **Rendezvous Points**, click **Add** or **Edit**.

Use the **Add Rendezvous Point** dialog box to create a new entry to the Rendezvous Point table. Use the **Edit Rendezvous Point** dialog box to change existing parameters.

**Step 4** Configure the following options:

- From the **Rendezvous Point IP address** drop-down list, choose the IP address that you want to add as an RP or click **Add (+)** to create a new network object. See [Creating Network Objects](#) for the procedure.
- Check the **Use bi-directional forwarding** check box if the specified multicast groups are to operate in bidirectional mode. In bidirectional mode, if the threat defense device receives a multicast packet and has no directly connected members or PIM neighbors present, it sends a prune message back to the source.
- Click **Use this RP for all Multicast Groups** to use the specified RP for all multicast groups on the interface.
- Click the **Use this RP for all Multicast Groups as specified below** to designate the multicast groups to use with the specified RP and then from the **Standard Access List** drop-down list, choose a standard ACL or click **Add (+)** to create a new standard ACL. See [Configure Standard ACL Objects, on page 1471](#) for the procedure.

**Step 5** Click **OK** to save the rendezvous point configuration.

---

## Configure PIM Route Trees

By default, PIM leaf routers join the shortest-path tree immediately after the first packet arrives from a new source. This method reduces delay, but requires more memory than the shared tree. You can configure whether or not the threat defense device should join the shortest-path tree or use the shared tree, either for all multicast groups or only for specific multicast addresses.

The shortest-path tree is used for any group that is not specified in the Multicast Groups table. The Multicast Groups table displays the multicast groups to use with the shared tree. The table entries are processed from the top down. You can create an entry that includes a range of multicast groups, but excludes specific groups within that range by placing deny rules for the specific groups at the top of the table and the permit rule for the range of multicast groups below the deny statements.

**Note** This behavior is known as Shortest Path Switchover (SPT). We recommend that you always use the Shared Tree option.

---

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Routing > Multicast Routing > PIM**.

**Step 3** On **Route Tree**, select the path for the route tree:

- Click **Shortest Path** to use the shortest-path tree for all multicast groups.
- Click **Shared Tree** to use the shared tree for all multicast groups.
- Click **Shared tree for below mentioned group** to designate the groups specified in the Multicast Groups table, and then from the **Standard Access List** drop-down list, select a standard ACL or click **Add (+)** to create a new standard ACL. See [Configure Standard ACL Objects, on page 1471](#) for the procedure.

**Step 4** Click **OK** to save the route tree configuration.

---

## Configure PIM Request Filters

When the threat defense device is acting as an RP, you can restrict specific multicast sources from registering with it to prevent unauthorized sources from registering with the RP. You can define the multicast sources from which the threat defense device will accept PIM register messages.

## Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Choose **Routing > Multicast Routing > PIM**.
- Step 3** On **Request Filter**, define the multicast sources that are allowed to register with the threat defense device when it acts as an RP:
- From the **Filter PIM register messages using:** drop-down list select **None**, **Access List**, or **Route Map**.
  - If you choose **Access List** from the drop-down list, select an extended ACL or click **Add (+)** to create a new extended ACL. See [Configure Extended ACL Objects, on page 1468](#) for the procedure.  
**Note** In the **Add Extended Access List Entry** dialog box, select **Allow** from the drop-down list to create a rule that allows the specified source of the specified multicast traffic to register with the threat defense device, or select **Block** to create a rule that prevents the specified source of the specified multicast traffic from registering with the device.
  - If you choose **Route Map**, select a route map from the **Route Map** drop-down list, or click **Add (+)** to create a new route map. See [Creating Network Objects](#) for the procedure.
- Step 4** Click **OK** to save the request filter configuration.
- 

## Configure the Secure Firewall Threat Defense Device as a Candidate Bootstrap Router

You can configure the threat defense device as a candidate BSR.

## Procedure

- 
- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Choose **Routing > Multicast Routing > PIM**.
- Step 3** On **Bootstrap Router**, check the **Configure this FTD as a Candidate Bootstrap Router (C-BSR)** check box to perform the C-BSR setup.
- a) From the **Interface** drop-down list, select the interface on the threat defense device from which the BSR address is derived to make it a candidate.  
  
This interface must be enabled with PIM.
  - b) In the **Hash mask length** field, enter the length of a mask (32 bits maximum) that is to be ANDed with the group address before the hash function is called. All groups with the same seed hash (correspond) to the same RP. For example, if this value is 24, only the first 24 bits of the group addresses matter. This fact allows you to get one RP for multiple groups. The range is 0 to 32.

- c) In the **Priority** field, enter the priority of the candidate BSR. The BSR with the larger priority is preferred. If the priority values are the same, the router with the larger IP address is the BSR. The range is 0 to 255. The default value is 0.

**Step 4** (Optional) Click **Add (+)** to select an interface on which no PIM BSR messages will be sent or received in the **Configure this FTD as a Border Bootstrap Router (BSR)** section.

- From the **Interface** drop-down list, select the interface on which no PIM BSR messages will be sent or received.  
RP or BSR advertisements are filtered effectively isolating two domains of RP information exchange.
- Check the **Enable Border BSR** check box to enable BSR.

**Step 5** Click **OK** to save the bootstrap router configuration.

---

## Configure Multicast Routes

Configuring static multicast routes lets you separate multicast traffic from unicast traffic. For example, when a path between a source and destination does not support multicast routing, the solution is to configure two multicast devices with a GRE tunnel between them and to send the multicast packets over the tunnel.

When using PIM, the threat defense device expects to receive packets on the same interface where it sends unicast packets back to the source. In some cases, such as bypassing a route that does not support multicast routing, you may want unicast packets to take one path and multicast packets to take another.

Static multicast routes are not advertised or redistributed.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Routing > Multicast Routing > Multicast Routes > Add or Edit**.

Use the **Add Multicast Route Configuration** dialog box to add a new multicast route to the threat defense device. Use the **Edit Multicast Route Configuration** dialog box to change an existing multicast route.

**Step 3** From the **Source Network** drop-down box, choose an existing network or click **Add (+)** to add a new one. See [Creating Network Objects](#) for the procedure.

**Step 4** To configure an interface to forward the route, click **Interface** and configure the following options:

- From the **Source Interface** drop-down list, choose the incoming interface for the multicast route.
- From the **Output Interface/Dense** drop-down list, choose the destination interface that the route is forwarded through.
- In the **Distance** field, enter the distance of the multicast route. The range is 0 to 255.

**Step 5** To configure an RPF address to forward the route, click **Address** and configure the following options:

- In the **RPF Address** field, enter the IP address for the multicast route.

- In the **Distance** field, enter the distance of the multicast route. The range is 0 to 255.

**Step 6** Click **OK** to save the multicast routes configuration.

---

## Configure Multicast Boundary Filters

Address scoping defines domain boundary filters so that domains with RPs that have the same IP address do not leak into each other. Scoping is performed on the subnet boundaries within large domains and on the boundaries between the domain and the Internet.

You can set up an administratively scoped boundary filter on an interface for multicast group addresses. IANA has designated the multicast address range from 239.0.0.0 to 239.255.255.255 as the administratively scoped addresses. This range of addresses can be reused in domains administered by different organizations. The addresses would be considered local, not globally unique.

A standard ACL defines the range of affected addresses. When a boundary filter is set up, no multicast data packets are allowed to flow across the boundary from either direction. The boundary filter allows the same multicast group address to be reused in different administrative domains.

You can configure, examine, and filter Auto-RP discovery and announcement messages at the administratively scoped boundary. Any Auto-RP group range announcements from the Auto-RP packets that are denied by the boundary ACL are removed. An Auto-RP group range announcement is permitted and passed by the boundary filter only if all addresses in the Auto-RP group range are permitted by the boundary ACL. If any address is not permitted, the entire group range is filtered and removed from the Auto-RP message before the Auto-RP message is forwarded.

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Choose **Routing > Multicast Routing > Multicast Boundary Filter**, and then click **Add** or **Edit**.

Use the **Add Multicast Boundary Filter** dialog box to add new multicast boundary filters to the device. Use the **Edit Multicast Boundary Filter** dialog box to change existing parameters.

You can configure a multicast boundary for administratively scoped multicast addresses. A multicast boundary restricts multicast data packet flows and enables reuse of the same multicast group address in different administrative domains. When a multicast boundary is defined on an interface, only the multicast traffic permitted by the filter ACL passes through the interface.

**Step 3** From the **Interface** drop-down list, choose the interface for which you are configuring the multicast boundary filter ACL.

**Step 4** From the **Standard Access List** drop-down list, choose the standard ACL you want to use, or click **Add** (+) to create a new standard ACL. See [Configure Standard ACL Objects, on page 1471](#) for the procedure.

**Step 5** Check the **Remove any Auto-RP group range announcement from the Auto-RP packets that are denied by the boundary** check box to filter Auto-RP messages from sources denied by the boundary ACL. If this check box is not checked, all Auto-RP messages are passed.

**Step 6** Click **OK** to save the multicast boundary filter configuration.

---

## CHAPTER 53

# Policy Based Routing

This chapter describes how to configure Threat Defense to support policy based routing (PBR) through Management Center's Policy based Routing page. The following sections describe policy based routing, guidelines for PBR, and configuration for PBR.

- [About Policy Based Routing, on page 1431](#)
- [Guidelines and Limitations for Policy Based Routing, on page 1433](#)
- [Path Monitoring, on page 1434](#)
- [Configure Policy-Based Routing Policy, on page 1437](#)
- [Configuration Example for Policy Based Routing, on page 1440](#)
- [Configuration Example for PBR with Path Monitoring, on page 1445](#)

## About Policy Based Routing

In traditional routing, packets are routed based on the destination IP address. However, it is difficult to change the routing of specific traffic in a destination-based routing system. Policy Based Routing (PBR) gives you more control over routing by extending and complementing the existing mechanisms provided by routing protocols.

PBR allows you to set the IP precedence. It also allows you to specify a path for certain traffic, such as priority traffic over a high-cost link. With PBR, you can define routing that is based on criteria other than destination network such as source port, destination address, destination port, protocol, applications, or a combination of these objects.

You can use PBR to classify the network traffic based on applications, username, group membership, and security group association. This routing method is applicable in scenarios where, numerous devices access applications and data in a large network deployment. Traditionally, large deployments have topologies that backhaul all the network traffic to a hub as encrypted traffic in a route-based VPN. These topologies often result in issues such as packet latency, reduced bandwidth, and packet drop. Overcoming these issues involves high-cost complex deployments and management.

PBR policy enables you to securely breakout traffic for specified applications. You can configure PBR policy in the Secure Firewall Management Center user interface to allow the applications to be directly accessed.

### Why Use Policy Based Routing

Consider a company that has two links between locations: one a high-bandwidth, low-delay expensive link, and the other a low-bandwidth, higher-delay, less-expensive link. While using traditional routing protocols, the higher-bandwidth link gets most, if not all, of the traffic sent across it based on the metric savings obtained

by the bandwidth, delay, or both (using EIGRP or OSPF) characteristics of the link. With PBR, you can route higher priority traffic over the high-bandwidth/low-delay link, while sending all other traffic over the low-bandwidth/high-delay link.

Following are a few scenarios where you can use Policy Based Routing:

### Direct Internet Access

In this topology, application traffic from the branch office can be routed directly to the internet instead of through the VPN tunnel connecting to the headquarters. The branch threat defense is configured with an internet exit point and the PBR policy is applied on the ingress interface (*Inside 1*) to identify the traffic based on the applications, user identity (username and group membership), and Security Group Tag (security group association) defined in the ACL. Correspondingly, the traffic is forwarded through the egress interfaces directly to the internet or to the IPsec VPN tunnel.

### Equal-Access and Source-Sensitive Routing

In this topology, traffic from the HR and Mgmt networks can be configured to go through ISP1 and traffic from Eng network can be configured to go through ISP2. Thus, policy based routing enables the network administrators to provide equal-access and source-sensitive routing, as shown here.

### Load Sharing

In addition to the dynamic load-sharing capabilities offered by ECMP load balancing, network administrators can now implement policies to distribute traffic among multiple paths based on the traffic characteristics.

As an example, in the topology depicted in the Equal-Access Source Sensitive Routing scenario, an administrator can configure policy based routing to route the traffic from HR network through ISP1 and traffic from Eng network through ISP2 and thus share the load.

# Guidelines and Limitations for Policy Based Routing

## Firewall Mode Guidelines

PBR is supported only on routed firewall mode.

## Device Guidelines

- PBR through management center's Policy Based Routing page is supported only from Version 7.1+ on both the management center and the device.
- When you upgrade management center or threat defense to version 7.1 and higher, the PBR configuration in the device is removed. You must configure PBR again using the Policy Based Routing page. If the managed device is lower than version 7.1, you must configure PBR again using FlexConfig with deploy option set to "every time."
- Configuring application, user identity, and Security Group Tag (SGT) based PBR policy on cluster devices is not supported.

## Interface Guidelines

- Only routed interfaces and non management-only interfaces belonging to the Global virtual router can be configured as ingress or egress interface.
- PBR is not supported on user-defined virtual routers.
- Only interfaces that have a logical name can be defined in the policy.
- Static VTIs can be configured only as egress interfaces.
- Before proceeding with configuration, ensure that the ingress and egress traffic of each session flows through the same ISP-facing interface to avoid unexpected behavior caused by asymmetric routing, specifically when NAT and VPN are in use.

## IPv6 Support

PBR supports IPv6.

## Application-Based PBR and DNS Configuration

- Application-based PBR uses DNS snooping for application detection. Application detection succeeds only if the DNS requests pass through threat defense in a clear-text format; the DNS traffic is not encrypted.
- You must configure trusted DNS servers.

For more information on configuring DNS servers, see [DNS, on page 1075](#).

## PBR Policies Not Applied for Output Route Look-up

Policy Based Routing is an ingress-only feature; that is, it is applied only to the first packet of a new incoming connection, at which time the egress interface for the forward leg of the connection is selected. Note that PBR

will not be triggered if the incoming packet belongs to an existing connection, or if NAT is applied and NAT chooses the egress interface.

### PBR Policies Not Applied for Embryonic Traffic

---

**Note** An embryonic connection is where the necessary handshake between source and destination has not been made.

---

When a new internal interface is added and a new VPN policy is created using a unique address pool, PBR is applied to the outside interface matching the source of the new client pool. Thus, PBR sends traffic from the client to the next hop on the new interface. However, PBR is not involved in the return traffic from a host that has not yet established a connection with the new internal interface routes to the client. Thus, the return traffic from the host to the VPN client, specifically, the VPN client response is dropped as there is no valid route. You must configure a weighted static route with a higher metric on the internal interface.

### HTTP-based Path Monitoring Guidelines

- HTTP-based path monitoring is supported on physical, port-channel, subinterfaces, and static tunnel interfaces. It is not supported on cluster devices.
- HTTP uses only IPv4 to ping the applications. IPv4 metrics are applied for routing and forwarding the IPv4 and IPv6 traffic.
- HTTP-based application monitoring is enabled by default Secure Firewall Management Center. However, when you upgrade from previous versions, this option is not enabled by default. You must manually enable it.

### Additional Guidelines

- All existing configuration restrictions and limitations of route map will be carried forward.
- While defining the ACL for the policy match criteria, you can select multiple applications from a list of predefined applications to form an Access Control Entry (ACE). In threat defense, the predefined applications are stored as Network Service objects and the group of applications as Network Service Groups (NSG). You can create a maximum of 1024 such NSGs. The application or network service group is detected through first-packet classification. Currently, you cannot add to or modify the predefined applications list.
- Unicast Reverse Path Forwarding (uRPF) validates the source IP address of packets received on an interface against the routing table and not against the PBR route map. When uRPF is enabled, packets received on an interface through PBR are dropped as they are without the specific route entry. Hence, when using PBR, ensure to disable uRPF.

## Path Monitoring

PBR uses either static cost or path monitoring (dynamic metrics) to route its traffic.

Path monitoring, when configured on interfaces, derive metrics such as round trip time (RTT), jitter, mean opinion score (MOS), and packet loss per interface. These metrics are used to determine the best path for routing PBR traffic.

### ICMP-based Path Monitoring

The metrics on the interfaces are collected dynamically using ICMP probe messages to the interface's default gateway or a specified remote peer.

### HTTP-based Path Monitoring

Path monitoring computes flexible metrics for multiple remote peers per interface. To monitor and determine best path for multiple applications through a policy on a branch firewall, HTTP is preferred over ICMP for the following reasons:

- HTTP-ping can derive the performance metrics of the path up to the application layer of the server, where the application is hosted.
- The need to change the firewall configuration whenever the application server IP address is changed is removed as the application domain is tracked instead of the IP address.

---

**Note** You can configure both ICMP and HTTP on the same interface. If the destination in the policy matches to any of the domain IP, the corresponding metrics are used. If the destination does not match to any of the configured domains, the metrics from the ICMP are used by PBR to select the outgoing interface.

---

### Default Monitoring Timers

For metric collection and monitoring, the following timers are used:

- The interface monitor average interval is 30 seconds. This interval indicates the frequency to which the probes average.
- The interface monitor update interval is 30 seconds. This interval indicates the frequency at which the average of the collected values are calculated and made available for PBR to determine the best routing path.
- The interface monitor probe interval by ICMP is one second. This interval indicates the frequency at which an ICMP ping is sent.
- The application monitor probe interval by HTTP is 10 seconds. This interval indicates the frequency at which an HTTP ping is sent. Path monitoring uses the last 30 samples of HTTP ping for calculating the average metrics.

---

**Note** You cannot configure or modify the interval for any of these timers.

---

### PBR and Path Monitoring

Typically, in PBR, traffic is forwarded through egress interfaces based on the priority value (interface cost) configured on them. From management center version 7.2, PBR uses IP-based path monitoring to collect the

performance metrics (RTT, jitter, packet-lost, and MOS) of the egress interfaces. PBR uses the metrics to determine the best path (egress interface) for forwarding the traffic. Path monitoring periodically notifies PBR about the monitored interface whose metric got changed. PBR retrieves the latest metric values for the monitored interfaces from the path monitoring database and updates the data path.

Path monitoring functions only with dynamic metrics, and only if the RTT, jitter, packet-lost, or MOS variables are set on the interfaces. Path monitoring does not function with static metrics—interface cost (cost set in interface).

You must enable path monitoring for the interface and configure the monitoring type. The PBR policy page allows you to specify the desired metric for path determination. See [Configure Policy-Based Routing Policy, on page 1437](#).

### PBR and HTTP-based Path Monitoring

From management center version 7.4, PBR can be configured to use HTTP-based path monitoring to collect the performance metrics of the application domains and not just one destination IP address. Path monitoring does not commence monitoring immediately after HTTP-based application monitoring is configured. It starts monitoring only when a DNS entry is snooped for a domain. With the information on the resolved IP for the domain, it sends and receives the HTTP request and response respectively. When DNS resolves multiple IP addresses for a single domain, the first resolved IP address will be used for probing and monitoring the application. It continues to monitor till the IP address changes or the HTTP-based path monitoring is disabled.

Based on the HTTP request and response durations, path monitoring computes the performance metrics for the application. The collected metrics are forwarded to PBR periodically, for making the routing and forwarding decision for the traffic arising from the configured ingress interface. If traffic arrives before the path monitoring could send its metrics to PBR, the traffic flow follows path chosen by the routing table. For the subsequent traffic flows that arrive after path monitoring metrics are available, PBR applies its routing decision based on the metrics and forwards the traffic.

---

**Note** Based on the Network Service Groups in the match ACL of the policy, you can apply PBR for multiple domains having multiple IP addresses.

---

In HTTP-based path monitoring of applications, the management center associates the applications/NSGs to the egress interface only when the PBR configuration meets the following criteria:

- The match ACL contains the monitored applications.
- The PBR policy is configured with any one of the following interface ordering values (metric type):
  - Minimal Jitter
  - Maximum Mean Opinion Score
  - Minimal Round-Trip Time
  - Minimal Packet Loss

## Configure Path Monitoring Settings

The PBR policy relies on flexible metrics, such as round trip time (RTT), jitter, mean opinion score (MOS), and packet loss of the interfaces to identify the best routing path for its traffic. Path monitoring collects these

metrics on the specified interfaces. On the **Interfaces** page, you can configure interfaces with settings for path monitoring to send the ICMP probes or HTTP pings for metrics collection.

## Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Click the **Path Monitoring** tab.
- Step 4** To configure ICMP based monitoring of the interface, click the **Enable IP based Monitoring** check box.
- Step 5** From the **Monitoring Type** drop-down list, select the relevant option:
- **Auto**—Sends ICMP probes to the IPv4 default gateway of the interface. If the IPv4 gateway does not exist, path monitoring sends the probes to the IPv6 default gateway of the interface.
  - **Peer IPv4**—Sends ICMP probes to the specified peer IPv4 address (next-hop IP) for monitoring. If you select this option, enter the IPv4 address in the **Peer IP To Monitor** field.
  - **Peer IPv6**—Sends ICMP probes to the specified peer IPv6 address (next-hop IP) for monitoring. If you select this option, enter the IPv6 address in the **Peer IP To Monitor** field.
  - **Auto IPv4**—Sends ICMP probes to the default IPv4 gateway of the interface.
  - **Auto IPv6**—Send ICMP probes to the default IPv6 gateway of the interface.
- Note**
- The Auto options are not available for VTI interfaces. You must specify the peer address.
  - Only one next-hop is monitored to a destination. That is, you cannot specify more than one peer address to monitor for an interface.
- Step 6** By default, the **Enable HTTP based Application Monitoring** check box is selected. All applications selected for path monitoring in the match ACL of the PBR policy are listed, provided this interface is configured as the egress interface in the policy. To disable the HTTP-based monitoring of the interface, clear the check box.
- Step 7** Click **Ok**, and to save the settings, click **Save**.
- 

# Configure Policy-Based Routing Policy

You can configure the PBR policy on the Policy Based Routing page by specifying the ingress interfaces, match criteria (Extended Access Control List), and egress interfaces.

## Before you begin

To use the path monitoring metrics for configuring the traffic forwarding priority over egress interfaces, you must configure the path monitoring settings for the interfaces. See [Configure Path Monitoring Settings, on page 1436](#).

## Procedure

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Click **Routing**.

**Step 3** Click **Policy Based Routing**.

The Policy Based Routing page displays the configured policy. The grid displays the list of ingress interfaces and a combination of the policy-based route access list, and egress interfaces.

**Step 4** To configure the policy, click **Add**.

**Step 5** In the **Add Policy Based Route** dialog box, select the **Ingress Interface** from the drop-down list.

**Note** Only interfaces that have logical names and that belong to a global virtual router are listed in the drop-down.

**Step 6** To specify the match criteria and the forward action in the policy, click **Add**.

**Step 7** In the **Add Forwarding Actions** dialog box, do the following:

a) From the **Match ACL** drop-down, choose the extended access control list object. You can predefine the ACL object (see [Configure Extended ACL Objects, on page 1468](#)) or click the **Add (+)** icon to create the object. In the **New Extended Access List Object** box, enter a name, click **Add** to open the **Add Extended Access List Entry** dialog box, where you can define the network, port, user identity, SGT, or application match criteria for the PBR policy.

**Note** You can either have destination address or application/user identity/SGT defined in an ACE.

To selectively apply PBR on the incoming interface, you can define *Block* criteria in the ACE. When the traffic matches the block rule of the ACE, the traffic is forwarded to the egress interface based on the routing table.

b) From the **Send To** drop-down list:

- To select the configured interfaces, choose **Egress Interfaces**.
- To specify the IPv4/IPv6 next hop addresses, choose **IP Address**. Proceed to [Step 7.e, on page 1439](#)

c) If you have selected **Egress Interfaces**, from the **Interface Ordering** drop-down, choose the relevant option:

- By **Interface Priority**—The traffic is forwarded based on the priority of the interfaces. Traffic is routed to the interface with the least priority value first. When the interface is not available, the traffic is then forwarded to the interface with the next lowest priority value. For example, let us assume that *Gig0/1*, *Gig0/2*, and *Gig0/3* are configured with priority values *0*, *1*, and *2* respectively. The traffic is forwarded to *Gig0/1*. If *Gig0/1* becomes unavailable, the traffic is then forwarded to *Gig0/2*.

**Note** To configure the priority for the interfaces, click **Configure Interface Priority** on the Policy Based Routing page. In the dialog box, provide the priority number against the interfaces, and then click **Save**. You can also configure the priority for an interface in the [Configure Routed Mode Interfaces](#).

When the priority value is the same for all the interfaces, the traffic is balanced among the interfaces.

- By **Order**—The traffic is forwarded based on the sequence of the interfaces specified here. For example, let us assume that *Gig0/1*, *Gig0/2*, and *Gig0/3* are selected in the following order, *Gig0/2*, *Gig0/3*, *Gig0/1*. The traffic is forwarded to *Gig0/2* first, then to *Gig0/3*, irrespective of their priority values.
- By **Minimal Jitter**—The traffic is forwarded to the interface that has the lowest jitter value. You need to enable Path Monitoring on the interfaces for PBR to obtain the jitter values.
- By **Maximum Mean Opinion Score**—The traffic is forwarded to the interface that has the maximum mean opinion score (MOS). You need to enable Path Monitoring on the interfaces for PBR to obtain the MOS values.
- By **Minimal Round Trip Time**—The traffic is forwarded to the interface that has the minimal round trip time (RTT). You need to enable Path Monitoring on the interfaces for PBR to obtain the RTT values.
- By **Minimal Packet Loss**—The traffic is forwarded to the interface that has the minimal packet loss. You need to enable Path Monitoring on the interfaces for PBR to obtain the packet loss values.

- d) In the **Available Interfaces** box, all the interfaces with their priority values are listed. From the list of interfaces, click the **Add (+)** button to add to the selected egress interfaces. Proceed to [Step 7.k, on page 1440](#)
- e) If you have selected **IP Address**, enter the IP addresses separated by commas in the **IPv4 Addresses** or **IPv6 Addresses** fields.

**Note** When multiple next-hop IP addresses are provided, the traffic is forwarded as per the sequence of the specified IP addresses until a valid routable next-hop IP address is found. The configured next-hops should be directly connected.

- f) From the **Don't Fragment** drop-down list, select Yes, No, or None. If the DF (Don't Fragment) flag is set to *Yes*, the intermediate routers never perform fragmentation of a packet.
- g) To specify the current interface as the default for forwarding, check the **Default Interface** check box.
- h) The **IPv4 Settings** and **IPv6 Settings** tab enables you to specify the recursive and default settings:

**Note** For a route-map, you can only specify either IPv4 or IPv6 next-hop settings.

- **Recursive**—The route map configuration is applied only when the specified next-hop address and the default next-hop address are found on a directly connected subnet. However, you could use the recursive option, where the next-hop address need not be directly connected. Here, a recursive lookup is performed on the next-hop address, and matching traffic is forwarded to the next-hop used by that route entry according to the current routing path of the router.
- **Default**—If the normal route lookup fails to match traffic, the traffic is forwarded to this specified next-hop IP address.

- i) Check the **Peer Address** check box to use the next-hop address as the peer address.

**Note** You cannot configure a route map with both default next-hop address and peer address.

- j) For IPv4 settings, you can check whether the next IPv4 hops of a route map are available under **Verify Availability**—click the **Add (+)** button and add the next-hop IP address entries:

- **IP Address**—Enter the next hop IP address.

- **Sequence**—Entries are assessed in order using the sequence number. Ensure that no duplicate sequence numbers are entered. The valid range is 1 to 65535.
- **Track**—Enter a valid ID. The valid range is 1 to 255.

k) Click **Save**.

**Step 8** To save the policy, click **Save** and **Deploy**.

---

The threat defense uses ACLs to match traffic and perform routing actions on the traffic. Typically, you configure a route map that specifies an ACL against which traffic is matched, and then you specify one or more actions for that traffic. With the use of path monitoring, PBR can now select the best egress interface for routing the traffic. Finally, you associate the route map with an interface on which you want to apply PBR on all incoming traffic.

## Add Path Monitoring Dashboard

To view the path monitoring metrics, you must add the path monitoring dashboard to the Health Monitoring page of the device.

### Procedure

- 
- Step 1** Choose **System > Health > Monitor**.
  - Step 2** Select the device, and click **Add New Dashboard**.
  - Step 3** Enter a name for the custom dashboard.
  - Step 4** In the **Metrics** area, click the **Add from Predefined Correlations** button.
  - Step 5** From the list, click **Interface - Path Metrics**.

By default, all the four metrics are selected for displaying as portlets in the dashboard with an additional metric field. You can exclude any of them by clicking **Delete** (  ).

- Step 6** Click **Add Dashboard**.
- 

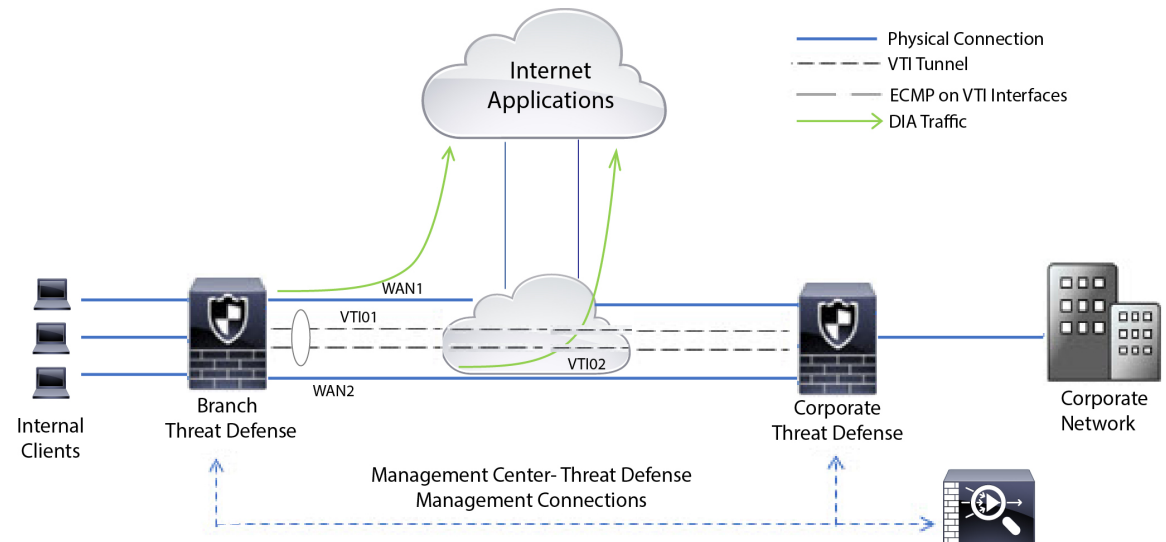

## Configuration Example for Policy Based Routing

Consider a typical corporate network scenario where all the branch network traffic passes through a route-based VPN of the corporate network and diverges to the extranet, when required. Accessing the web-based applications that address day-to-day operations through the corporate network results in huge network expansion and maintenance costs. This example illustrates the PBR configuration procedure for direct internet access.

The following figure depicts the topology of a corporate network. The branch network is connected to the corporate network through a route-based VPN. Traditionally, the corporate threat defense is configured to handle both the internal and external traffic of the branch office. With the PBR policy, the branch threat defense is configured with a policy that routes specific traffic to the WAN network instead of the virtual tunnels. The rest of the traffic flows through the route-based VPN, as usual.

This example also illustrates the configuring of the WAN and the VTI interfaces with ECMP zones to achieve load balancing.

**Figure 352: Configuring Policy Based Routing on Branch Threat Defense in Management Center**

### Before you begin

This example assumes that you have already configured WAN and VTI interfaces for the branch threat defense in management center.

### Procedure

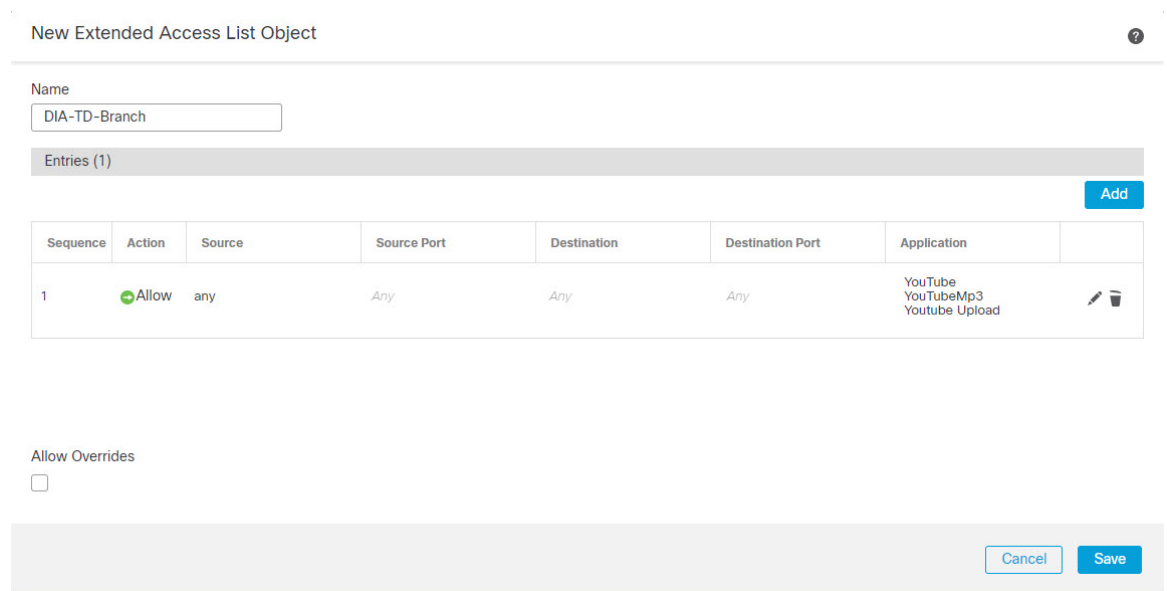

- 
- Step 1** Configure policy based routing for the branch threat defense, select the ingress interfaces:
- Choose **Devices > Device Management**, and edit the threat defense device.
  - Choose **Routing > Policy Based Routing**, and on the **Policy Based Routing** page, click **Add**.
  - In the **Add Policy Based Route** dialog box, select the interfaces (say, *Inside 1*, and *Inside 2*) from the **Ingress Interface** drop-down list.
- Step 2** Specify the match criteria:
- Click **Add**.
  - To define the match criteria, click the **Add (+)** button.
  - In **New Extended Access List Object**, enter the name for the ACL (say, *DIA-FTD-Branch*), and click **Add**.
  - In the **Add Extended Access List Entry** dialog box, choose the required web-based applications from the **Application** tab:

Figure 353: Applications Tab

On the threat defense, the application group in an ACL is configured as a network service group and each of the applications as a network service object.

Figure 354: Extended ACL

e) Click **Save**.

- f) Select *DIA-FTD-Branch* from the **Match ACL** drop-down list.

**Step 3**

Specify the egress interfaces:

- From the **Send To** and **Interface Ordering** drop-down lists, choose Egress Interfaces, and By Priority respectively.
- Under **Available Interfaces**, click the **+** button against the respective interface names to add *WAN1* and *WAN2*:

**Figure 355: Configuring Policy Based Routing**

Add Forwarding Actions

Match ACL:\*  +

Send To:\*

Interface Ordering:\*

Available Interfaces

Search by interface name

| Priority | Interface        |
|----------|------------------|
| 0        | INSIDE1 <b>+</b> |
| 0        | INSIDE2 <b>+</b> |
| 0        | VT101 <b>+</b>   |
| 0        | VT102 <b>+</b>   |

Selected Egress Interfaces\*

| Priority | Interface      |
|----------|----------------|
| 10       | WAN1 <b>🗑️</b> |
| 10       | WAN2 <b>🗑️</b> |

- c) Click **Save**.

**Step 4**

Interface priority configuration:

You can set the priority value for the interfaces either in the **Edit Physical Interface** page, or in the **Policy Based Routing** page (**Configure Interface Priority**). In this example, the Edit Physical Interface method is described.

- Choose **Devices** > **Device Management**, and edit the branch threat defense.
- Set the priority for the interfaces. Click **Edit** against the interface and enter the priority value:

Figure 356: Setting Interface Priority

Edit Physical Interface ?  
 General IPv4 IPv6 Advanced Hardware Configuration FMC Access  
 Name: WAN1  
 Enabled  
 Management Only  
 Description:  
 Mode: None  
 Security Zone: WAN  
 Interface ID: GigabitEthernet0/2  
 MTU: 1500 (64 - 9000)  
 Priority: 10 (0 - 65535)  
 Propagate Security Group Tag:   
Cancel OK

c) Click **Ok** and **Save**.

**Step 5** Create ECMP zones for load balancing:

- a) In the **Routing** page, click **ECMP**.
- b) To associate interfaces to the ECMP zone, click **Add**.
- c) Select *WAN1* and *WAN 2* and create an ECMP zone—*ECMP-WAN*. Similarly, add *VTI01* and *VTI02* and create an ECMP zone—*ECMP-VTI*.

Figure 357: Associating Interfaces with ECMP Zone

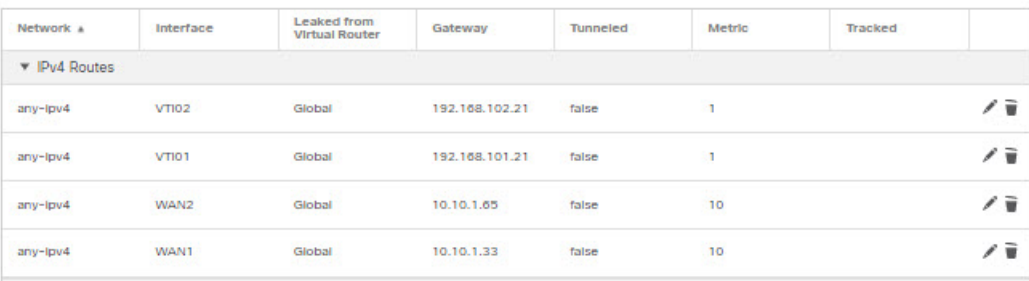

Device Routing Interfaces Inline Sets DHCP  
 Manage Virtual Routers  
 Global  
 Virtual Router Properties  
 ECMP  
 OSPF  
 OSPFv3  
 RIP  
 Policy Based Routing  
 Equal-Cost Multipath Routing (ECMP).  
 All the interfaces belong to the ECMP must apply to the same access policies rules. You can add interfaces to this ECMP by clicking on Add button. ECMP can have up to 8 interfaces associated with it. All the interfaces in the ECMP must have a name and security level as this ECMP.  
 Add  

| Name     | Interfaces   |
|----------|--------------|
| ECMP-WAN | WAN1, WAN2   |
| ECMP-VTI | VTI01, VTI02 |

**Step 6** Configure static routes for the zone interfaces for load balancing:

- a) In the **Routing** page, click **Static Route**.
- b) Click **Add** and specify the static routes for *WAN1*, *WAN2*, *VTI01*, and *VTI02*. Ensure that you specify the same metric value for the interfaces belonging to the same ECMP zones ([Step 5](#)):

Figure 358: Configuring Static Routes for ECMP Zone Interfaces

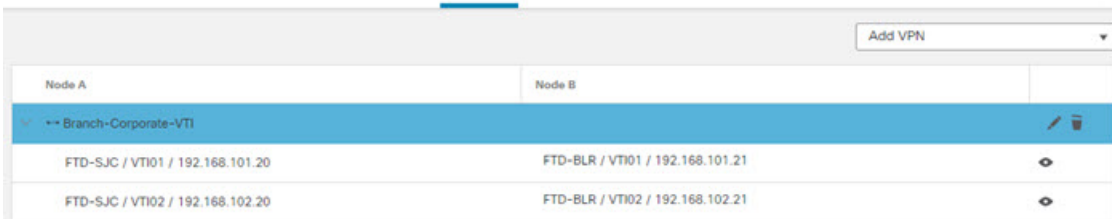

| Network  | Interface | Leaked from Virtual Router | Gateway        | Tunneled | Metric | Tracked |
|----------|-----------|----------------------------|----------------|----------|--------|---------|
| any-ipv4 | VTI02     | Global                     | 192.168.102.21 | false    | 1      |         |
| any-ipv4 | VTI01     | Global                     | 192.168.101.21 | false    | 1      |         |
| any-ipv4 | WAN2      | Global                     | 10.10.1.65     | false    | 10     |         |
| any-ipv4 | WAN1      | Global                     | 10.10.1.33     | false    | 10     |         |

**Note** Ensure that the zone interfaces have the same destination address and metric, but different gateway addresses.

- Step 7** Configure trusted DNS on the WAN objects of the branch threat defense to ensure secured flow of traffic to the internet:
- Choose **Devices > Platform Settings**, and create a DNS policy on the branch threat defense.
  - To specify the trusted DNS, **Edit** the policy and click **DNS**.
  - To specify the DNS servers for the DNS resolution to be used by WAN objects, in the **DNS Settings** tab, provide the DNS server group details and select WAN from the interface objects.
  - Use the **Trusted DNS Servers** tab to provide specific DNS servers that you trust for the DNS resolution.
- Step 8** Save and Deploy.

Any *YouTube* related access requests from the branch inside network *INSIDE1* or *INSIDE2* are routed to *WAN1* or *WAN2* as they would match the *DIA-FTD-Branch* ACL. Any other request, say *google.com*, are routed through *VTI01* or *VTI02* as configured in the Site to Site VPN Settings:

Figure 359: Site to Site VPN Settings

| Node A                           | Node B                           |
|----------------------------------|----------------------------------|
| Branch-Corporate-VTI             |                                  |
| FTD-SJC / VTI01 / 192.168.101.20 | FTD-BLR / VTI01 / 192.168.101.21 |
| FTD-SJC / VTI02 / 192.168.102.20 | FTD-BLR / VTI02 / 192.168.102.21 |

With the ECMP configured, the network traffic is seamlessly balanced.

## Configuration Example for PBR with Path Monitoring

This example details the configuration of PBR with path monitoring for the following applications with flexible metrics:

- Audio or video sensitive applications (example, WebEx Meetings) with Jitter.

- Cloud-based application (example, Office365) with RTT.
- Network-based access control (with a specific source and destination) with Packet Loss.

### Before you begin

1. This example assumes that you are aware of the basic configuration steps for PBR.
2. You have configured ingress and egress interfaces with logical names. In this example, the ingress interface is named *Inside1*, and egress interfaces are named *ISP01*, *ISP02*, and *ISP03*.

## Procedure

- 
- Step 1** Path monitoring configuration on interfaces *ISP01*, *ISP02*, and *ISP03*:
- For the metrics collection on the egress interfaces, you must enable and configure path monitoring on them.
- a) Choose **Devices** > **Device Management**, and edit threat defense.
  - b) Under the **Interfaces** tab, edit the interface (in our example, *ISP01*)
  - c) Click the **Path Monitoring** tab, select the **Enable Path Monitoring** check box, and then specify the monitoring type (see [Configure Path Monitoring Settings, on page 1436](#)).
  - d) Click **Ok** and **Save**.
  - e) Repeat the same steps and configure the path monitoring settings for *ISP02* and *ISP03*.
- Step 2** Configure policy-based routing for a branch in an organization threat defense, select the ingress interfaces:
- a) Choose **Devices** > **Device Management**, and edit the threat defense device.
  - b) Choose **Routing** > **Policy Based Routing**, and on the **Policy Based Routing** page, click **Add**.
  - c) In the **Add Policy Based Route** dialog box, select *Inside 1* from the **Ingress Interface** drop-down list.
- Step 3** Specify the match criteria:
- a) Click **Add**.
  - b) To define the match criteria, click the **Add (+)** button.
  - c) In **New Extended Access List Object**, enter the name for the ACL (example, *PBR-WebEx*), and click **Add**.
  - d) In the **Add Extended Access List Entry** dialog box, choose the required web-based applications (example, WebEx Meetings) from the **Application** tab.
- Remember** On threat defense, the application group in an ACL is configured as a network service group and each of the applications as a network service object.
- e) Click **Save**.
  - f) Select *PBR-WebEx* from the **Match ACL** drop-down list.
- Step 4** Specify the egress interfaces:
- a) From the **Send To** drop-down list, choose Egress Interfaces.
  - b) From the **Interface Ordering** drop-down list, choose By Minimal Jitter.
  - c) Under **Available Interfaces**, click the **Right Arrow (>)** button against the respective interface names to add *ISP01*, *ISP02*, and *ISP03*.
  - d) Click **Save**.

- Step 5** Repeat Step 2 and Step 3 to create PBRs for the same interface (*Inside1*) to route Office365 and network-based access control traffic:
- Create a match criteria object, example *PBR-Office365*, and select the Office365 application from the **Application** tab.
  - From the **Interface Ordering** drop-down list, choose By Minimal Round Trip Time.
  - Specify the egress interfaces *ISP01*, *ISP02*, and *ISP03*, and click **Save**.
  - Now, create a match criteria object, example *PBR-networks*, and specify the source and destination interface in the **Network** tab.
  - From the **Interface Ordering** drop-down list, choose By Minimal Packet Loss.
  - Specify the egress interfaces *ISP01*, *ISP02*, and *ISP03*, and click **Save**.
- Step 6** **Save and Deploy.**
- Step 7** To view path monitoring metrics, choose **Devices > Device Management**, and from **More** (☰) click **Health Monitor**. To view the metric details for the interfaces of the device, you must add the path metrics dashboard. For details, see [Add Path Monitoring Dashboard](#) , on page 1440.
- 

The WebEx, Office365, and networks-based ACL traffic are forwarded through the best route derived from the metrics value collected on *ISP01*, *ISP02*, and *ISP03*.

## Introduction to Objects

For increased flexibility and web interface ease-of-use, the system uses named *objects*, which are reusable configurations that associate a name with a value. When you want to use that value, use the named object instead. The system supports object use in various places in the web interface, including many policies and rules, event searches, reports, dashboards, and so on. The system provides many predefined objects that represent frequently used configurations.

Use the object manager to create and manage objects. Many configurations that use objects also allow you to create objects on the fly, as needed. You can also use the object manager to:

- View the policies, settings, and other objects where a network, port, VLAN, or URL object is used; see [Viewing Objects and Their Usage, on page 1457](#).
- Group objects to reference multiple objects with a single configuration; see [Object Groups, on page 1459](#).
- Override object values for selected devices; see [Object Overrides, on page 1460](#).

After you edit an object used in an active policy, you must redeploy the changed configuration for your changes to take effect. You cannot delete an object that is in use by an active policy.

**Note** An object is configured on a managed device if, and only if, the object is used in a policy that is assigned to that device. If you remove an object from all policies assigned to a given device, the object is also removed from the device configuration on the next deployment, and subsequent changes to the object are not reflected in the device configuration.

### Object Types

The following table lists the objects you can create in the system, and indicates whether each object type can be grouped or configured to allow overrides.

| Object Type                                                                                             | Groupable? | Allows Overrides? |
|---------------------------------------------------------------------------------------------------------|------------|-------------------|
| Network                                                                                                 | yes        | yes               |
| Port                                                                                                    | yes        | yes               |
| Interface: <ul style="list-style-type: none"> <li>• Security Zone</li> <li>• Interface Group</li> </ul> | no         | no                |
| Tunnel Zone                                                                                             | no         | no                |
| Application Filter                                                                                      | no         | no                |

| Object Type                                                                                                                                         | Groupable? | Allows Overrides? |
|-----------------------------------------------------------------------------------------------------------------------------------------------------|------------|-------------------|
| VLAN Tag                                                                                                                                            | yes        | yes               |
| External Attribute: Security Group Tag (SGT) and Dynamic Object                                                                                     | no         | no                |
| URL                                                                                                                                                 | yes        | yes               |
| Geolocation                                                                                                                                         | no         | no                |
| Time Range                                                                                                                                          | no         | no                |
| Variable Set                                                                                                                                        | no         | no                |
| Security Intelligence: Network, DNS, and URL lists and feeds                                                                                        | no         | no                |
| Sinkhole                                                                                                                                            | no         | no                |
| File List                                                                                                                                           | no         | no                |
| Cipher Suite List                                                                                                                                   | no         | no                |
| Distinguished Name                                                                                                                                  | yes        | no                |
| Public Key Infrastructure (PKI): <ul style="list-style-type: none"> <li>• Internal and Trusted CA</li> <li>• Internal and External Certs</li> </ul> | yes        | no                |
| Key Chain                                                                                                                                           | no         | yes               |
| DNS Server Group                                                                                                                                    | no         | no                |
| SLA Monitor                                                                                                                                         | no         | no                |
| Prefix List: IPv4 and IPv6                                                                                                                          | no         | yes               |
| Route Map                                                                                                                                           | no         | yes               |
| Access List: Standard and Extended                                                                                                                  | no         | yes               |
| AS Path                                                                                                                                             | no         | yes               |
| Community List                                                                                                                                      | no         | yes               |
| Policy List                                                                                                                                         | no         | yes               |

# The Object Manager

You can use the object manager to create and manage objects and object groups.

The object manager displays 20 objects or groups per page. If you have more than 20 of any type of object or group, use the navigation links at the bottom of the page to view additional pages. You can also go to a specific page or click **Refresh** (🔄) to refresh your view.

Access the page using **Objects > Object Management**. You can alternatively access the page using **Objects > Other FTD Objects**.

By default, the page lists objects and groups alphabetically by name. You can filter the objects on the page by name or value.

## Importing Objects

Objects can be imported from a comma-separated values file. Up to 1000 objects can be imported in one attempt. The contents of the comma-separated values file should follow a specific format. The format is different for each object type. Only a few types of objects can be imported. See the following table to know the supported object types and the corresponding rules.

| Object Type       | Rules                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Individual object | <ul style="list-style-type: none"><li>• The column header must be mentioned in capital letters.</li><li>• The file must have the following columns headers:<ul style="list-style-type: none"><li>• NAME</li><li>• DN</li></ul></li><li>• Both NAME and DN column entries are mandatory to import an entry.</li><li>• You can import individual objects directly into an existing distinguished name object group.</li></ul> |

| Object Type    | Rules                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Network object | <ul style="list-style-type: none"> <li>• The column header must be mentioned in capital letters.</li> <li>• The file must have the following columns headers: <ul style="list-style-type: none"> <li>• NAME</li> <li>• DESCRIPTION</li> <li>• TYPE</li> <li>• VALUE</li> <li>• LOOKUP</li> </ul> </li> <li>• The NAME and VALUE column entries are mandatory to import an entry of host, range, or network object type.</li> <li>• For an FQDN object, the TYPE column entry must mention 'fqdn,' and the LOOKUP column entry must be specified as 'ipv4,' 'ipv6,' or 'ipv4_ipv6.'</li> <li>• If no content is provided in the LOOKUP column entry for the FQDN object, then the object is saved with the ipv4_ipv6 field value.</li> </ul> |
| Port           | <ul style="list-style-type: none"> <li>• The column header must be mentioned in capital letters.</li> <li>• The file must have the following columns headers: <ul style="list-style-type: none"> <li>• NAME</li> <li>• PROTOCOL</li> <li>• PORT</li> <li>• ICMPCODE</li> <li>• ICMPTYPE</li> </ul> </li> <li>• The NAME column entry is mandatory.</li> <li>• For 'tcp' and 'udp' protocol types, the PORT column entry is mandatory.</li> <li>• For 'icmp' and 'icmp6' protocol types, the ICMPCODE and ICMPTYPE column entries are mandatory.</li> </ul>                                                                                                                                                                                  |

| Object Type | Rules                                                                                                                                                                                                                                                                                                                                                               |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| URL         | <ul style="list-style-type: none"> <li>• The column header must be mentioned in capital letters.</li> <li>• The file must have the following columns headers:               <ul style="list-style-type: none"> <li>• NAME</li> <li>• DESCRIPTION</li> <li>• URL</li> </ul> </li> <li>• The NAME and URL column entries are mandatory to import an entry.</li> </ul> |
| VLAN Tag    | <ul style="list-style-type: none"> <li>• The column header must be mentioned in capital letters.</li> <li>• The file must have the following columns headers:               <ul style="list-style-type: none"> <li>• NAME</li> <li>• DESCRIPTION</li> <li>• TAG</li> </ul> </li> <li>• The NAME and TAG column entries are mandatory to import an entry.</li> </ul> |

## Procedure

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose one of the following object types from the left pane:

- **Distinguished Name > Individual Objects >**
- **Network Object**
- **Port**
- **URL**
- **VLAN Tag**

**Step 3** Choose **Import Object** from the **Add [Object Type]** drop-down list.

**Note** If you have selected **Individual Objects** in the previous step, click **Import**.

**Step 4** Click **Browse**.

**Step 5** Locate and select the comma-separated file on your system.

**Step 6** Click **Open**.

**Note** While importing **Distinguished Name** objects, you can optionally check the **Add imported Distinguished Name objects to the below object group** check box and select the group name from the drop-down box to import the objects directly to an existing distinguished name object group.

**Step 7** Click **Import**.

---

## Editing Objects

See caveats related to network objects and groups at [Network](#), on page 1497.

### Procedure

---

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose an object type from the list; see [Introduction to Objects](#), on page 1452.

**Step 3** Click **Edit** (✎) next to the object you want to edit.

If **View** (👁) appears instead, the object belongs to an ancestor domain and has been configured not to allow overrides, or you do not have permission to modify the object.

**Step 4** Modify the object settings as desired.

**Step 5** If you are editing a variable set, manage the variables in the set; see [Managing Variables](#), on page 1553.

**Step 6** For objects that can be configured to allow overrides:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides](#), on page 1462. You can change this setting only for objects that belong to the current domain.
- If you want to add override values to this object, expand the Override section and click **Add**; see [Adding Object Overrides](#), on page 1462.

**Step 7** Click **Save**.

**Step 8** If you are editing a variable set, and that set is in use by an access control policy, click **Yes** to confirm that you want to save your changes.

---

### What to do next

- If an active policy references your object, deploy configuration changes.

## Viewing Objects and Their Usage

You can view usage details of objects on the Object Management page. Management Center provides this functionality for many object types. However, some object types are not supported.

## Procedure

---

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose one of the following supported object types:

- Access List > Extended
- Access List > Standard
- AS Path
- Community List
- Interface
- Network
- Policy List
- Port
- Prefix List > IPv4 Prefix List
- Prefix List > IPv6 Prefix List
- Route Map
- SLA Monitor
- URL
- VLAN Tag

**Step 3** Click the **Find Usage** () icon next to the object.

The Object Usage window displays a list of all the policies, objects, and other settings where the object is in use. Click any of the listed items to know more about the object usage. For policies and some other settings where the object is used, you can click the corresponding links to visit the respective UI pages.

---

## Filtering Objects or Object Groups

### Procedure

---

**Step 1** Choose **Objects > Object Management**.

**Step 2** Enter your filter criteria in the **Filter** field.

The page updates as you type to display matching items.

You can use the following wildcards:

- The asterisk (\*) matches zero or more occurrences of a character.
- The caret (^) matches content at the beginning of a string.
- The dollar sign (\$) matches content at the end of a string.

**Step 3** Check the **Show Unused Object** check box to view the objects and the object groups that are unused anywhere in the system.

- Note**
- In case an object is a part of an unused object group, the object is considered as used. However, the unused object group is displayed when the **Show Unused Object** check box is checked.
  - The **Show Unused Object** check box is available only for network, port, URL and VLAN tag object types.

---

## Object Groups

Grouping objects allows you to reference multiple objects with a single configuration. The system allows you to use objects and object groups interchangeably in the web interface. For example, anywhere you would use a port object, you can also use a port object group.

You can group network, port, VLAN tag, URL, and PKI objects. Network object groups can be nested, that is, you can add a network object group to another network object group up to 10 levels.

Objects and object groups of the same type cannot have the same name.

When you edit an object group used in a policy (for example, a network object group used in an access control policy), you must re-deploy the changed configuration for your changes to take effect.

Deleting a group does not delete the objects in the group, just their association with each other. Additionally, you cannot delete a group that is in use in an active policy. For example, you cannot delete a VLAN tag group that you are using in a VLAN condition in a saved access control policy.

## Grouping Reusable Objects

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- Step 2** If the object type you want to group is **Network, Port, URL, or VLAN Tag**:
- Choose the object type from the list of object types.
  - Choose **Add Group** from the **Add [Object Type]** drop-down list.
- Step 3** If the object type you want to group is **Distinguished Name**:
- Expand the **Distinguished Name** node.
  - Choose **Object Groups**.
  - Click **Add Distinguished Name Group**.
- Step 4** If the object type you want to group is **PKI**:
- Expand the **PKI** node.

b) Choose one of the following:

- **Internal CA Groups**
- **Trusted CA Groups**
- **Internal Cert Groups**
- **External Cert Groups**

c) Click **Add [Object Type] Group**.

**Step 5** Enter a unique **Name**.

**Step 6** Choose one or more objects from the list, and click **Add**.

You can also:

- Use the filter field **Search** (🔍) to search for existing objects to include, which updates as you type to display matching items. Click **Reload** (🔄) above the search field or click **Clear** (✕) in the search field to clear the search string.
- Click **Add** (+) to create objects on the fly if no existing objects meet your needs.

**Step 7** Optionally for **Network**, **Port**, **URL**, and **VLAN Tag** groups:

- Enter a **Description**.
- Check the **Allow Overrides** check box to allow overrides for this object group; see [Allowing Object Overrides, on page 1462](#).

**Step 8** Click **Save**.

---

### What to do next

- If an active policy references your object group, deploy configuration changes; see [Deploy Configuration Changes, on page 240](#).

## Object Overrides

An object override allows you to define an alternate value for an object, which the system uses for the devices you specify.

You can create an object whose definition works for most devices, and then use overrides to specify modifications to the object for the few devices that need different definitions. You can also create an object that needs to be overridden for all devices, but its use allows you to create a single policy for all devices. Object overrides allow you to create a smaller set of shared policies for use across devices without giving up the ability to alter policies when needed for individual devices.

For example, you might want to deny ICMP traffic to the different departments in your company, each of which is connected to a different network. You can do this by defining an access control policy with a rule that includes a network object called Departmental Network. By allowing overrides for this object, you can then create overrides on each relevant device that specifies the actual network where that device is connected.

You can target an object override to a specific domain. In this case, the system uses the object override value for all devices in the targeted domain unless you override it at the device level.

From the object manager, you can choose an object that can be overridden and define a list of device-level or domain-level overrides for that object.

You can use object overrides with the following object types only:

- Network
- Port
- VLAN tag
- URL
- SLA Monitor
- Prefix List
- Route Map
- Access List
- AS Path
- Community List
- Policy List
- Cert Enrollment (PKI)
- Key Chain

If you can override an object, the **Override** column appears for the object type in the object manager. Possible values for this column include:

- Green checkmark — indicates that you can create overrides for the object and no overrides have been added yet
- Red X — indicates that you cannot create overrides for the object
- Number — represents a count of the overrides that have been added to that object (for example, "2" indicates two overrides have been added)

## Managing Object Overrides

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Choose from the list of object types; see [Introduction to Objects, on page 1452](#).
  - Step 3** Click **Edit** () next to the object you want to edit.

If **View** () appears instead, the object belongs to an ancestor domain and has been configured not to allow overrides, or you do not have permission to modify the object.

- Step 4** Manage the object overrides:
- Add—Add object overrides; see [Adding Object Overrides, on page 1462](#).
  - Allow—Allow object overrides; see [Allowing Object Overrides, on page 1462](#).
  - Delete—In the object editor, click **Delete** (  ) next to the override you want to remove.
  - Edit—Edit object overrides; see [Editing Object Overrides, on page 1463](#).
- 

## Allowing Object Overrides

### Procedure

---

- Step 1** In the object editor, check the **Allow Overrides** check box.
- Step 2** Click **Save**.
- 

#### What to do next

Add object override values; see [Adding Object Overrides, on page 1462](#).

## Adding Object Overrides

For caveats when working with network objects or groups, see [Network, on page 1497](#).

#### Before you begin

Allow object overrides; see [Allowing Object Overrides, on page 1462](#).

### Procedure

---

- Step 1** In the object editor, expand the **Override** section.
- Step 2** Click **Add**.
- Step 3** On **Targets**, choose domains or devices in the **Available Devices and Domains** list and click **Add**.
- Step 4** On the **Override** tab, enter a **Name**.
- Step 5** Optionally, enter a **Description**.
- Step 6** Enter an override value.

#### Example:

For a network object, enter a network value.

- Step 7** Click **Add**.
- Step 8** Click **Save**.
-

**What to do next**

- If an active policy references your object, deploy configuration changes.

## Editing Object Overrides

You can modify the description and the value of an existing override, but you cannot modify the existing target list. Instead, you must add a new override with new targets, which replaces the existing override.

For caveats when working with network objects or groups, see [Network, on page 1497](#)..

**Procedure**

- 
- Step 1** In the object editor, expand the **Override** section.
  - Step 2** Click **Edit** () next to the override you want to modify.
  - Step 3** Optionally, modify the **Description**.
  - Step 4** Modify the override value.
  - Step 5** Click **Save** to save the override.
  - Step 6** Click **Save** to save the object.
- 

**What to do next**

- If an active policy references your object, deploy configuration changes.

## AAA Server

Add reusable AAA server objects.

### Add a RADIUS Server Group

RADIUS Server Group objects contain one or more references to RADIUS servers. These servers are used to authenticate users logging in through Remote Access VPN connections.

You can use this object with threat defense devices.

**Before you begin**

---

**Note** You cannot override RADIUS Server Group Objects.

---

## Procedure

- 
- Step 1** Select **Objects > Object Management > AAA Server > RADIUS Server Group**.  
All currently configured RADIUS Server Group objects will be listed. Use the filter to narrow down the list.
- Step 2** Choose and edit a listed RADIUS Server Group object, or add a new one.  
See [RADIUS Server Options, on page 1465](#) and [RADIUS Server Group Options, on page 1464](#) to configure this object.
- Step 3** Click **Save**
- 

## RADIUS Server Group Options

### Navigation Path

**Objects > Object Management > AAA Server > RADIUS Server Group**. Choose and edit a configured RADIUS Server Group object or add a new one.

### Fields

- **Name** and **Description**—Enter a name and optionally, a description to identify this RADIUS Server Group object.
- **Group Accounting Mode**—The method for sending accounting messages to the RADIUS servers in the group. Choose **Single**, accounting messages are sent to a single server in the group, this is the default. Or, **Multiple**, accounting messages are sent to all servers in the group simultaneously.
- **Retry Interval**—The interval between attempts to contact the RADIUS servers. Values range from 1 to 10 seconds.
- **Realms**(Optional)—Specify or select the Active Directory (AD) realm this RADIUS server group is associated with. This realm is then selected in identity policies to access the associated RADIUS server group when determining the VPN authentication identity source for a traffic flow. This realm effectively provides a bridge from the identity policy to this Radius server group. If no realm is associated with this RADIUS server group, the RADIUS server group cannot be reached to determine the VPN authentication identity source for a traffic flow in an identity policy.

---

**Note** This field is mandatory if you use remote access VPN with User Identity and RADIUS as the identity source.

---

- **Enable authorize only**—If this RADIUS server group is not being used for authentication, but is being used for authorization or accounting, check this field to enable authorize-only mode for the RADIUS server group.

Authorize only mode eliminates the need of including the RADIUS server password in the Access-Request. Thus, the password, configured for the individual RADIUS servers, is ignored.

- **Enable interim account update and Interval**—Enables the generation of RADIUS interim-accounting-update messages in order to inform the RADIUS server of newly assigned IP addresses. Set the length, in hours, of the interval between periodic accounting updates in the Interval field. The valid range is 1 to 120 and the default value is 24.
- **Enable Dynamic Authorization and Port**— Enables the RADIUS dynamic authorization or change of authorization (CoA) services for this RADIUS server group. Specify the listening port for RADIUS CoA requests in the Port field. The valid range is 1024 to 65535 and the default value is 1700. Once defined, the corresponding RADIUS server group will be registered for CoA notification and it listens to the port for the CoA policy updates from the Cisco Identity Services Engine (ISE).
- **Merge Downloadable ACL with Cisco AV Pair ACL**—Enables merging a downloadable access control list (dACL) with a Cisco attribute-value (AV) pair ACL.

A downloadable ACL defines and updates access control lists in CiscoISE and allows ACL download to all the applicable controllers. For more information about using dACLs in Cisco ISE, see the chapter on Segmentation, section on authorization policies, in the *Cisco ISE Administrator Guide*.

A Cisco AV pair ACL can be utilized to define specific authentication, authorization, and accounting elements for each individual session. For more information about using dACLs in Cisco ISE, see the chapter on Segmentation, section on authorization profile settings, in the *Cisco ISE Administrator Guide*.

If you select **Merge Downloadable ACL with Cisco AV Pair ACL**, you can choose the following options:

- **After Cisco AV Pair ACL** means the downloadable ACL entries should be placed after the Cisco AV pair entries.
  - **Before Cisco AV Pair ACL** means the downloadable ACL entries should be placed before the Cisco AV pair entries.
- **RADIUS Servers**—See [RADIUS Server Options](#), on page 1465.

### Related Topics

[Add a RADIUS Server Group](#), on page 1463

## RADIUS Server Options

### Navigation Path

**Objects > Object Management > AAA Server > RADIUS Server Group.** Choose and edit a listed RADIUS Server Group object or add a new one. Then, in the RADIUS Server Group dialog, choose and edit a listed RADIUS Server or add a new one.

### Fields

- **IP Address/Hostname**—The network object that identifies the hostname or IP address of the RADIUS server to which authentication requests will be sent. You may only select one, to add additional servers, add additional RADIUS Server to the RADIUS Server Group list.

---

**Note** The device now supports IPv6 IP addresses for RADIUS authentication.

---

- **Authentication Port**—The port on which RADIUS authentication and authorization are performed. The default is 1812.
- **Key and Confirm Key**— The shared secret that is used to encrypt data between the managed device (client) and the RADIUS server.  
The key is a case-sensitive, alphanumeric string of up to 127 characters. Special characters are permitted.  
The key you define in this field must match the key on the RADIUS server. Enter the key again in the Confirm field.
- **Accounting Port**—The port on which RADIUS accounting is performed. The default is 1813.
- **Timeout**— Session timeout for authentication.

---

**Note** The timeout value must be 60 seconds or more for RADIUS two factor authentication. The default timeout value is 10 seconds.

---

- **Connect Using** —Establishes connectivity from the device to a RADIUS server using a route lookup or using a specific interface.
  - Click the **Routing** radio button to use the routing table.
  - Click the **Specific Interface** radio button and choose a security zone/interface group or the Management interface (the default) from the drop-down list. If you want to use Management, you must choose it specifically; it is not available when using a route lookup. You cannot specify any other management-only interface as the RADIUS source. You can also choose a loopback interface group.
- **Redirect ACL**—Select the redirect ACL from the list or add a new one.

---

**Note** This is the name of the ACL defined in the device to decide the traffic to be redirected. The Redirect ACL name here must be the same as the *redirect-acl* name in ISE server. When you configure the ACL object, ensure that you select Block action for ISE and DNS servers, and Allow action for the rest of the servers.

---

- [RADIUS Server Group Options](#), on page 1464

## Add a Single Sign-on Server

### Before you begin

Obtain the following from your SAML identity provider:

- Identity Provider Entity ID URL
- Sign-in URL

- Sign-out URL
- Identity provider certificate and enroll the certificate in threat defense using the management center web interface (**Devices > Certificates**)

For more information, see [Configuring a SAML Single Sign-On Authentication, on page 1763](#).

## Procedure

**Step 1** Choose **Object > Object Management > AAA Server > Single Sign-on Server**.

**Step 2** Click **Add Single Sign-on Server** and provide the following details:

- **Name**—The name of the SAML single sign-on server object.
- **Identity Provider Entity ID**—The URL that is defined in SAML IdP to identify a service provider uniquely.  
The URL for a page that serves a metadata XML that describes how the SAML Issuer is going to respond to requests.
- **SSO URL**—The URL for signing into the SAML identity provider server.
- **Logout URL**—The URL for signing out of the SAML identity provider server.
- **Base URL**—URL that will redirect the user back to threat defense once the identity provider authentication is done. This is the URL of the access interface configured for the threat defense remote access VPN.
- **Identity Provider Certificate**—Certificate of the IdP enrolled into the threat defense to verify the messages signed by the IdP.

Select an identify provider certificate from the list or click Add to create a new certificate enrollment object.

For more information, see [Managing Threat Defense Certificates, on page 1576](#).

You must enroll all of the Microsoft Azure registered application CA certificates as Trustpoints on the threat defense. The Microsoft Azure SAML identity provider is configured on threat defense for the initial application. All connection profiles are mapped to the configured MS Azure SAML identity provider. For each of the MS Azure applications (other than the default), you can choose the required trustpoint(CA certificate) in the connection profile configuration of the remote access VPN.

For details, see [Configure AAA Settings for Remote Access VPN, on page 1698](#).

- **Service Provider Certificate**—threat defense certificate, which will be used to sign the requests and build circle of trust with IdP.  
If you have not enrolled internal threat defense certificates, click + to add and enroll a certificate. For more information, see [Managing Threat Defense Certificates, on page 1576](#).
- **Request Signature**—Select the encryption algorithm to sign the SAML single sign-on requests.  
The signatures are listed from weakest to strongest: SHA1,SHA256, SHA384, SHA512. Select None to disable encryption.
- **Request Timeout**—Specify the SAML assertion validity duration for the users to complete the single sign-on request. The SAML IdP has two time outs: *NotBefore* and *NotOnOrAfter*. The threat defense validates if its current time is within the time range of (lower limit) *NotBefore* and (upper limit) the

smaller of *NotBefore* plus *timeout* and *NotOnOrAfter*. Thus, if you set a timeout longer than the IdP's *NotOnOrAfter* timeout, the specified timeout is ignored and the *NotOnOrAfter* timeout is selected. If the sum of the specified timeout and the *NotBefore* timeout is less than the *NotOnOrAfter* time, threat defense timeout overrides the timeout.

The timeout range is 1-7200 seconds; the default is 300 seconds.

- **Enable IdP only accessible on Internal Network**—Select this option if the SAML IdP resides on the internal network. Threat Defense acts as a gateway and establishes communication between the users and IdP using an anonymous webvpn session.
- **Request IdP re-authentication on Login**—Select this option to authenticate user at each login even if the previous IdP session is valid.
- **Allow Overrides**—Select this check box to allow overrides for this single sign-on server object.

**Step 3** Click **Save**.

---

[Configure AAA Settings for Remote Access VPN](#), on page 1698

## Access List

An access list object, also known as an access control list (ACL), selects the traffic to which a service will apply. You use these objects when configuring particular features, such as route maps, for threat defense devices. Traffic identified as allowed by the ACL is provided the service, whereas “blocked” traffic is excluded from the service. Excluding traffic from a service does not necessarily mean that it is dropped altogether.

You can configure the following types of ACL:

- **Extended**—Identifies traffic based on source and destination address and ports. Supports IPv4 and IPv6 addresses, which you can mix in a given rule.
- **Standard**—Identifies traffic based on destination address only. Supports IPv4 only.

An ACL is composed of one or more access control entry (ACE), or rule. The order of ACEs is important. When the ACL is evaluated to determine if a packet matches an “allowed” ACE, the packet is tested against each ACE in the order in which the entries are listed. After a match is found, no more ACEs are checked. For example, if you want to “allow” 10.100.10.1, but “block” the rest of 10.100.10.0/24, the allow entry must come before the block entry. In general, place more specific rules at the top of an ACL.

Packets that do not match an “allow” entry are considered to be blocked.

The following topics explain how to configure ACL objects.

## Configure Extended ACL Objects

Use extended ACL objects when you want to match traffic based on source and destination addresses, protocol and port, application group or if the traffic is IPv6.

## Procedure

- 
- Step 1** Select **Objects > Object Management** and choose **Access List > Extended** from the table of contents.
- Step 2** Do one of the following:
- Click **Add Extended Access List** to create a new object.
  - Click **Edit** (✎) to edit an existing object.
- Step 3** In the New Extended Access List Object dialog box, enter a name for the object (no spaces allowed), and configure the access control entries:
- Do one of the following:
    - Click **Add** to create a new entry.
    - Click **Edit** (✎) to edit an existing entry.
  - Select the **Action**, whether to Allow (match) or Block (not match) the traffic criteria.

**Note** The **Logging**, **Log Level**, and **Log Interval** options are used for access rules only (ACLs attached to interfaces or applied globally). Because ACL objects are not used for access rules, leave these values at their defaults.
  - Configure the source and destination addresses on the **Network** tab using any of the following techniques:
    - Select the desired network objects or groups from the Available list and click **Add to Source** or **Add to Destination**. You can create new objects by clicking the + button above the list. You can mix IPv4 and IPv6 addresses.
    - Type an address in the edit box below the source or destination list and click **Add**. You can specify a single host address (such as 10.100.10.5 or 2001:DB8::0DB8:800:200C:417A), or a subnet (in 10.100.10.0/24 or 10.100.10.0 255.255.255.0 format, or for IPv6, 2001:DB8:0:CD30::/60).
  - Click the **Port** tab and configure the service using any of the following techniques.
    - Select the desired port objects from the Available list and click **Add to Source** or **Add to Destination**. You can create new objects by clicking the + button above the list. The object can specify TCP/UDP ports, ICMP/ICMPv6 message types, or other protocols (including “any”). However, the source port, which you typically would leave empty, accepts TCP/UDP only. You cannot select port groups.

For TCP/UDP, note that you must use the same protocol in both the source and destination fields, if you specify both. For example, you cannot specify a UDP source port and a TCP destination port.
    - Type or select a port or protocol in the edit box below the source or destination list and click **Add**.

**Note** To get an entry that applies to all IP traffic, select a destination port object that specifies “all” protocols.
  - Click the **Application** tab and choose the applications that are to be grouped for the direct internet access policy.

- Important**
- You cannot configure applications for cluster devices. Hence, this tab is not applicable for cluster devices.
  - Use extended ACL with applications only in Policy Based Routing. Do not use it in other policies as its behavior is unknown and not supported.

- Note**
- The **Available Applications** list displays a fixed set of pre-defined applications. This list is a subset of the applications that are available on the Access Control policy as only they can be detected by their first packet (FQDN end-points resolved to IP addresses and port). The application definitions are updated through the VDB updates and are pushed to threat defense during subsequent deployments.
  - User-defined custom applications or group of applications are not supported.
  - Currently, management center neither supports user-defined custom applications or group of applications nor allows you to modify the pre-defined applications list.
  - You can use the filter options provided under the **Application Filters** to refine this list.

- f) Click the **Users** tab and choose the users, user groups, or both that are to be classified for the Policy Based Routing (PBR).

- Important** Use extended ACL with users, user groups, or both only for Policy Based Routing. Do not use it in other policies as its behavior is unknown and not supported.

- Note**
- The **Available Realms** list displays the configured active directory/LDAP realms. For information on creation of realm and managing them, see [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#) and [Manage a Realm, on page 2497](#) respectively.

**Note** Local realms and Azure AD realms are not supported.

- The **Available Users** list displays the downloaded users and user groups of the selected AD/LDAP realms. To download the users, user groups, or both, navigate to **Integrations > Other Integrations > Realms**, and then click **Download** against the relevant active directory/LDAP realms.

**Note** Threat defense can support a maximum of 512 user groups and 64000 user-IP mappings.

- The user to IP mapping and user group membership information are updated and pushed to the threat defense from the management center during the user login or logouts, and changes in the group memberships.

- g) Click the **Security Group Tag** tab and choose the source SGT tags to be classified for the direct internet access policy.

- Important** Use extended ACL with SGTs only for Policy Based Routing. Do not use it in other policies as its behavior is unknown and not supported.

**Note** • The **Available Security Group Tags** list displays the configured security group tags. You can choose to use the ISE SGTs or create custom SGTs.

• To use ISE SGTs, ensure that ISE is integrated with management center with **Session Directory Topic** and SXP Topic subscribed. For information on ISE integration, see [Configure ISE for User Control, on page 2547](#).

**Note** The supported ISE versions are 3.2, 3.1, 3.0, and 2.7 patch 2+.

• For information on creating custom SGTs, see [Creating Security Group Tag Objects, on page 1488](#).

**Important** You can configure **Users** and **Security Group Tag** for Secure Firewall 4200 devices only.

h) Select the required application, and click **Add to Rule**.

**Note** • Do not configure destination networks and applications in the extended ACL object.

• The selected applications (Network Service objects) in each of the access control entries, form a Network Service Group (NSG) and this group is deployed on the threat defense. The NSG is used in direct internet access to classify traffic based on the match with the selected application group.

i) Click **Add** to add the entry to the object.

j) If necessary, click and drag the entry to move it up or down in the rule order to the desired location.

Repeat the process to create or edit additional entries in the object.

**Step 4** If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).

**Step 5** Click **Save**.

---

## Configure Standard ACL Objects

Use standard ACL objects when you want to match traffic based on destination IPv4 address only. Otherwise, use extended ACLs.

### Procedure

---

**Step 1** Select **Objects > Object Management** and choose **Access List > Standard** from the table of contents.

**Step 2** Do one of the following:

• Click **Add Standard Access List** to create a new object.

• Click **Edit** (✎) to edit an existing object.

- Step 3** In the New Standard Access List Object dialog box, enter a name for the object (no spaces allowed), and configure the access control entries:
- a) Do one of the following:
    - Click **Add** to create a new entry.
    - Click **Edit** (✎) to edit an existing entry.
  - b) For each access control entry, configure the following properties:
    - **Action**—Whether to Allow (match) or Block (not match) the traffic criteria.
    - **Network**—Add the IPv4 network objects or groups that identify the destination of the traffic.
  - c) Click **Add** to add the entry to the object.
  - d) If necessary, click and drag the entry to move it up or down in the rule order to the desired location.
- Repeat the process to create or edit additional entries in the object.
- Step 4** If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
- Step 5** Click **Save**.
- 

## Address Pools

You can configure IP address pools for both IPv4 and IPv6 that can be used for clustering or for VPN remote access profiles. For clustering in Individual interface mode, you can also configure MAC address pools.

### Procedure

---

- Step 1** Select **Objects > Object Management > Address Pools**.
- Step 2** Click **IPv4 Pools** and then **Add IPv4 Pools**, and configure the following fields.
- **Name**—Enter the name of the address pool. It can be up to 64 characters
  - **Description**—Add an optional description for this pool.
  - **IP Address**—Enter a range of addresses available in the pool. Use dotted decimal notation and a dash between the beginning and the end address, for example: 10.10.147.100-10.10.147.177.
  - **Mask**—Identifies the subnet on which this IP address pool resides.
  - **Allow Overrides**—Check this check box to enable object overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See [Object Overrides, on page 1460](#) for more information.
- Step 3** Click **Save**.
- Step 4** Click **IPv6 Pools** and then **Add IPv6 Pools**, and configure the following fields.

- **Name**—Enter the name of the address pool. It can be up to 64 characters
- **Description**—Add an optional description for this pool.
- **IPv6 Address**—Enter the first IP address available in the configured pool and the prefix length in bits. For example: 2001:DB8::1/64.
- **Number of Addresses**—Identifies the number of IPv6 addresses, starting at the Starting IP Address, that are in the pool.
- **Allow Overrides**—Check this check box to enable overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See [Object Overrides, on page 1460](#) for more information.

**Step 5** Click **Save**.

**Step 6** Click **MAC Address Pool** and then **Add MAC Address Pool**, and configure the following fields.

For clustering in Individual interface mode, you can configure a MAC address pool for the interface. It is not common to manually configure MAC addresses for an interface, but if you have special needs to do so, then this pool is used to assign a unique MAC address to each interface. See [Configure the MAC Address, on page 1011](#).

- **Name**—Enter the name of the address pool. It can be up to 64 characters
- **Description**—Add an optional description for this pool.
- **MAC Address Range**—Enter a range of MAC addresses available in the pool. Use a dash between the beginning and the end address, for example: 000C.F142.4CD1-000C.F142.4CD7.
- **Allow Overrides**—Check this check box to enable overrides. Click the expand arrow to show the **Overrides** table. You can add a new override by clicking **Add**. See [Object Overrides, on page 1460](#) for more information.

---

## Application Filters

System-provided application filters help you perform application control by organizing applications according to basic characteristics: type, risk, business relevance, category, and tags. In the object manager, you can create and manage reusable user-defined application filters based on combinations of the system-provided filters, or on custom combinations of applications. For detailed information, see [Application Rule Conditions, on page 1065](#).

## AS Path

An AS Path is a mandatory attribute to set up BGP. It is a sequence of AS numbers through which a network can be accessed. An AS-PATH is a sequence of intermediate AS numbers between source and destination routers that form a directed route for packets to travel. Neighboring autonomous systems (ASes) use BGP to exchange and update messages about how to reach different AS prefixes. After each router makes a new local decision on the best route to a destination, it will send that route, or path information, along with the accompanying distance metrics and path attributes, to each of its peers. As this information travels through

the network, each router along the path prepends its unique AS number to a list of ASes in the BGP message. This list is the route's AS-PATH. An AS-PATH along with an AS prefix, provides a specific handle for a one-way transit route through the network. Use the [Configure AS Path](#) page to create, copy and edit autonomous system (AS) path policy objects. You can create AS path objects to use when you are configuring route maps, policy maps, or BGP Neighbor Filtering. An AS path filter allows you to filter the routing update message by using regular expressions.

You can use this object with threat defense devices.

## Procedure

- 
- Step 1** Select **Objects > Object Management** and choose **AS Path** from the table of contents.
- Step 2** Click **Add AS Path**.
- Step 3** Enter a name for the AS Path object in the **Name** field. Valid values are between 1 and 500.
- Step 4** Click **Add** on the **New AS Path Object** window.
- Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
  - Specify the regular expression that defines the AS path filter in the **Regular Expression** field.
  - Click **Add**.
- Step 5** If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
- Step 6** Click **Save**.
- 

## BFD Template

The BFD template specifies a set of BFD interval values. BFD interval values as configured in the BFD template are not specific to a single interface. You can also configure authentication for single-hop and multi-hop sessions. Echo mode is disabled by default. You can enable Echo mode on single-hop only.

## Procedure

- 
- Step 1** Choose **Objects > Object Management > BFD Template**.
- Step 2** Click **Add BFD Template** or **Edit**.
- Note** If you are editing a template, you cannot modify its name and type.
- Step 3** On the **Template** tab, configure the following:
- **Template Name**—The name of this BFD template. You must assign a name in order to configure the rest of the parameters in the template. The template name cannot have spaces and cannot have only numbers.
  - **Type**—Click the **Single-Hop** or **Multi-Hop** radio button.
  - **Enable Echo**—(Optional) Enables Echo for the single-hop template.

If the Echo function is not negotiated, BFD control packets are sent at a high rate to meet the detection time. If the Echo function is negotiated, BFD control packets are sent at a slower, negotiated rate and self-directed echo packets are sent at a high rate. We recommend that you use Echo mode, if possible.

- Step 4** On the **Interval** tab, configure the following:
- From the **Interval Type** drop-down list, select **Microseconds** or **Milliseconds**.
  - In the **Multiplier** field, enter the value to be used for computing the hold down time. This value indicates the number of consecutive BFD control packets that must be missed from a BFD peer before BFD declares that the peer is unavailable and the Layer 3 BFD peer is informed of the failure. The range is 3 to 50. The default is 3.
  - In the **Minimum Transmit** field, enter the minimum transmit interval capability. The range is 50 to 999 milliseconds or 50000 to 999000 microseconds.
  - In the **Minimum Receive** field, enter the minimum receive interval capability. The range is 50 to 999 milliseconds or 50000 to 999000 microseconds.
- Step 5** On the **Authentication** tab, configure the following:
- **Authentication Type**—Select **NONE**, **md5**, **meticulous-sha-1**, **meticulous-md5**, or **sha-1** from the drop-down list.
  - **Encrypted Password**—(Optional) Enables encryption of the authentication password.
  - **Password**—The authentication password that must be sent and received in the packets using the routing protocol being authenticated. The valid value is a string containing 1 to 29 uppercase and lowercase alphanumeric characters, except that the first character CANNOT be a digit or a digit followed by a whitespace. For example, '1password' or '0 password' is invalid.
  - **Key ID**—The shared key ID that matches the key value. The range is 0 to 255.
- Step 6** Click **OK**.
- Step 7** Click **Apply** to save the BFD template configuration.

## Cipher Suite List

A cipher suite list is an object comprised of several cipher suites. Each predefined cipher suite value represents a cipher suite used to negotiate an SSL- or TLS-encrypted session. You can use cipher suites and cipher suite lists in SSL rules to control encrypted traffic based on whether the client and server negotiated the SSL session using that cipher suite. If you add a cipher suite list to an SSL rule, SSL sessions negotiated with any of the cipher suites in the list match the rule.

**Note** Although you can use cipher suites in the web interface in the same places as cipher suite lists, you cannot add, modify, or delete cipher suites.

## Creating Cipher Suite Lists

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Choose **Cipher Suite List** from the list of object types.
  - Step 3** Click **Add Cipher Suites**.
  - Step 4** Enter a **Name**.
  - Step 5** Choose one or more cipher suites from the **Available Ciphers** list.
  - Step 6** Click **Add**.
  - Step 7** Optionally, click **Delete** (  ) next to any cipher suites in the **Selected Ciphers** list that you want to remove.
  - Step 8** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes.

## Community List

A Community is an optional transitive BGP attribute. A community is a group of destinations that share some common attribute. It is used for route tagging. The BGP community attribute is a numerical value that can be assigned to a specific prefix and advertised to other neighbors. Communities can be used to mark a set of prefixes that share a common attribute. Upstream providers can use these markers to apply a common routing policy such as filtering or assigning a specific local preference or modifying other attributes. Use the [Configure Community Lists](#) page to create, copy and edit community list policy objects. You can create community list objects to use when you are configuring route maps or policy maps. You can use community lists to create groups of communities to use in a match clause of a route map. The community list is an ordered list of matching statements. Destinations are matched against the rules until a match is found.

You can use this object with threat defense devices.

### Procedure

- 
- Step 1** Select **Objects > Object Management** and choose **Community List** from the table of contents.
  - Step 2** Click **Add Community List**.
  - Step 3** In the **Name** field, specify a name for the community list object.
  - Step 4** Click **Add** on the **New Community List Object** window.
  - Step 5** Select the **Standard** radio button to indicate the community rule type.  
Standard community lists are used to specify well-known communities and community numbers.

- Note** You cannot have entries using Standard and entries using Expanded community rule types in the same Community List object.
- a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
  - b) In the **Communities** field, specify a community number. Valid values can be from 1 to 4294967295 or from 0:1 to 65534:65535.
  - c) Select the appropriate **Route Type**.
    - **Internet** — Select to specify the Internet well-known community. Routes with this community are advertised to all peers (internal and external).
    - **No Advertise** — Select to specify the no-advertise well-known community. Routes with this community are not advertised to any peer (internal or external).
    - **No Export** — Select to specify the no-export well-known community. Routes with this community are advertised to only peers in the same autonomous system or to only other sub-autonomous systems within a confederation. These routes are not advertised to external peers.

- Step 6** Select the **Expanded** radio button to indicate the community rule type.  
Expanded community lists are used to filter communities using a regular expression. Regular expressions are used to specify patterns to match COMMUNITIES attributes.
- a) Select the Allow or Block options from the **Action** drop-down list to indicate redistribution access.
  - b) Specify the regular expression in the **Expressions** field.
- Step 7** Click **Add**.
- Step 8** If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
- Step 9** Click **Save**.

## Extended Community

An extended community is a larger group of destinations that share some common attribute. The BGP extended community list has attributes that can be used to mark a set of prefixes that share a common attribute. These markers are used in the match clause of a route map to filter the routes for implementing route leaks among virtual routers. You can also define policy list objects with the extended community list for filtering. The extended community list is an ordered list of matching statements. Routes are matched against the rules until a match is found with the specified route target (standard) or regular expression (expanded). Use the Extended Community page to create and edit extended community list policy objects.

---

**Note** The extended community lists are applicable only for configuring import or export of routes.

---

You can use this object with threat defense devices.

### Procedure

- 
- Step 1** Select **Objects > Object Management** and choose **Community List > Extended Community** from the table of contents.

**Step 2** Click **Add Extended Community List**.

**Step 3** In the **Name** field, specify a name for the extended community list object. The length of the name cannot exceed 80 characters.

**Step 4** Select the extended community rule type:

- Click the **Standard** radio button to specify one or more route targets.
- Click the **Expanded** radio button to specify regular expressions.

**Note** You cannot have entries using Standard and Expanded extended community rule type in the same Extended Community List object.

**Step 5** Click **Add**.

**Step 6** If you have selected **Standard** as the extended community rule type, specify the following:

- a) In the **Sequence No** field, enter the order in which you want the rule to be executed.  
The sequence number must be unique in the list.
- b) From the **Action** drop-down list, if you want to permit routes that have matching route target that is specified here, select **Allow**; if you want to deny routes that have matching route target that is specified here, select **Block**.
- c) In the **Route Target** field, specify a route target.
  - You can add a single route target or a set of route targets separated by commas in a single entry. For example, *1:2,1:4,1:6*.
  - Valid values can be from 1:1 to 65534:65535.
  - You can have a maximum of 8 route targets in an entry.
  - You cannot have redundant route target set across multiple entries. For example, say you want to configure *seq1* with *1:200,100:100,1:300* route targets, and *seq2* with *1:300,100:100,1:200* route targets. This results in redundant route target set and cannot be deployed.

**Step 7** If you have selected **Expanded** as the extended community rule type, specify the following:

- a) In the **Sequence No** field, enter the order in which you want the rule to be executed.  
The sequence number must be unique in the list.
- b) From the **Action** drop-down list, if you want to permit routes that have matching regular expression that is specified here, select **Allow**; if you want to deny routes that have matching regular expression that is specified here, select **Block**.
- c) Specify the regular expression in the **Expressions** field.
  - You can add a single route target or a set of route targets separated by a space in a single entry. For example, *^(16) / (18):(.)\$*.
  - You can add a maximum of 16 regular expressions to an entry.
  - You cannot have redundant regular expression set across multiple entries. For example, say you want to configure *seq1* with *^(16) / (18):(.)\$ ^4\_[0-9]\*\$* route targets, and *seq2* with *^4\_[0-9]\*\$ ^(16) / (18):(.)\$* route targets. This results in redundant regular expression set and cannot be deployed.

For details on BGP regular expressions, see [here](#).

- Step 8** If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
- Step 9** Click **Save**.

---

The extended community list can be referenced in the match clause of the Route Map object or Policy List object:

- In the Route Map object, the name of the extended community list is displayed in the **Add Route Map Entry > Match Clause > BGP > Community List > Add Extended Community List** dialog. For more details on configuring BGP settings in a route map, see [Route Map, on page 1522](#).
- In the Policy List object, the name of the extended community list is displayed in the **Add Policy List > Community Rule > Add Extended Community List** dialog. For more details on configuring BGP settings in a policy list, see [Policy List, on page 1517](#).

## DHCP IPv6 Pool

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature ([Enable the IPv6 Prefix Delegation Client, on page 997](#)), you can configure the threat defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the threat defense by defining a DHCP IPv6 Pool and assigning it to the DHCPv6 server. The threat defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the threat defense received using Prefix Delegation.

To add a pool, see [Create the DHCP IPv6 Pool, on page 1040](#).

## Distinguished Name

Each distinguished name object represents the [distinguished name](#) for a public key certificate's subject or issuer. You can use distinguished name objects and groups in TLS/SSL rules to control encrypted traffic based on whether the client and server negotiated the TLS/SSL session using a server certificate with the distinguished name as subject or issuer.

(A *distinguished name group* is a named collection of existing distinguished name objects.)

The distinguished name can consist of country code, common name, organization, and organizational unit, but typically consists of a common name only. For example, the common name in the certificate for `https://www.cisco.com` is `cisco.com`. (However, it's not always this simple; [Distinguished Name \(DN\) Rule Conditions, on page 2378](#) shows how to find common names.) The certificate can contain multiple Subject Alternative Names (SANs) you can use as DNS in a rule condition. For detailed information about SANs, see [RFC 5280, section 4.2.1.6](#).

The format of a distinguished name object that references a common name is `CN=name`. If you add a DN rule condition without `CN=`, the system prepends `CN=` before saving the object.

As discussed further in [Distinguished Name \(DN\) Rule Conditions, on page 2378](#), the system uses [Server Name Indication \(SNI\)](#) to match the DN in the TLS/SSL rule whenever possible.

You can also add a distinguished name with one of each of the attributes listed in the following table, separated by commas.

**Table 92: Distinguished name attributes**

| Attribute | Description         | Allowed Values                                                                                         |
|-----------|---------------------|--------------------------------------------------------------------------------------------------------|
| C         | Country Code        | two alphabetic characters                                                                              |
| CN        | Common Name         | up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces |
| O         | Organization        | up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces |
| OU        | Organizational Unit | up to 64 alphanumeric, backslash (/), hyphen (-), quotation ("), or asterisk (*) characters, or spaces |

### Important notes about DN rule conditions

- The first time the system detects an encrypted session to a new server, DN data is not available for ClientHello processing, which *might* result in an undecrypted first session.

If the server requests TLS 1.3, the setting for TLS server identity discovery can help by making sure the server certificate is known before making decryption policy decisions. For more information, see [Access Control Policy Advanced Settings, on page 1840](#).

- You *cannot* configure a distinguished name condition if you also choose the **Decrypt - Known Key** action. Because that action requires you to choose a server certificate to decrypt traffic, the certificate already matches the traffic.

### Wildcard examples

You can define one or more asterisks (\*) as wildcards in an attribute. In a common name attribute, you can define one or more asterisks per domain name label. wildcards match only in that label, but you can define multiple labels with wildcards. See the following table for examples.

**Table 93: Common Name attribute wildcard examples**

| Attribute     | Matches     | Does Not Match                                        |
|---------------|-------------|-------------------------------------------------------|
| CN=*ample.com | example.com | mail.example.com<br>example.text.com<br>ampleexam.com |
| CN=exam*.com  | example.com | mail.example.com<br>example.text.com<br>ampleexam.com |

| Attribute        | Matches          | Does Not Match                                                             |
|------------------|------------------|----------------------------------------------------------------------------|
| CN=*xamp*.com    | example.com      | mail.example.com<br>example.text.com<br>ampleexam.com                      |
| CN=*.example.com | mail.example.com | www.myhost.example.com<br>example.com<br>example.text.com<br>ampleexam.com |

**Note** The DN object `CN=amp.cisco.com` would *not* match a CN like `CN=auth.amp.cisco.com`, which is why we recommend wildcards in these cases.

For more information and examples, see [Distinguished Name \(DN\) Rule Conditions, on page 2378](#).

#### Related Topics

[Distinguished Name \(DN\) Rule Conditions, on page 2378](#)

## Creating Distinguished Name Objects

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Expand the **Distinguished Name** node, and choose **Individual Objects**.
  - Step 3** Click **Add Distinguished Name**.
  - Step 4** Enter a **Name**.
  - Step 5** In the **DN** field, enter a value for the distinguished name or common name. You have the following options:
    - If you add a distinguished name, you can include one of each attribute listed in [Distinguished Name, on page 1479](#) separated by commas.
    - If you add a common name, you can include multiple labels and wild cards.
  - Step 6** Click **Save**.
- 

#### What to do next

- If an active policy references your object, deploy configuration changes.

# DNS Server Group

Domain Name System (DNS) servers resolve fully-qualified domain names (FQDN), such as `www.example.com`, to IP addresses.

## Creating DNS Server Group Objects

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Click **DNS Server Group** from the network objects list.
  - Step 3** Click **Add DNS Server Group**.
  - Step 4** Enter a **Name**.
  - Step 5** Optionally, enter the **Default Domain** that will be used to append to the host names that are not fully-qualified. This setting is only used for the default server group.
  - Step 6** The default **Timeout** and **Retries** values are pre-populated. Change these values if necessary.
    - Retries—The number of times, from 0 to 10, to retry the list of DNS servers when the system does not receive a response. The default is 2.
    - Timeout—The number of seconds, from 1 to 30, to wait before trying the next DNS server. The default is 2 seconds. Each time the system retries the list of servers, this timeout doubles.
  - Step 7** Enter the **DNS Servers** that will be a part of this group, either in IPv4 or IPv6 format as comma separated entries.

A maximum of 6 DNS servers can belong to one group.
  - Step 8** Click **Save**.
- 

### What to do next

The DNS servers configured in the DNS server group should be assigned to interface objects in the DNS platform settings. For more information, see [DNS, on page 1075](#).

## External Attributes

### Dynamic Objects

A *dynamic object* is an object that specifies one or many IP addresses retrieved either using REST API calls or using the Cisco Secure Dynamic Attributes Connector, which is capable of updating IP addresses from

cloud sources. These dynamic objects can be used in access control rules without the need to deploy the access control policy afterward.

---

**Note** Unlike most other objects, dynamic objects do not have to be deployed to managed devices to take effect. Just add dynamic objects to the **Dynamic Attributes** tab page of your access control rule; the object values are automatically updated on the managed device as soon as possible after being pushed by the Cisco Secure Dynamic Attributes Connector.

---

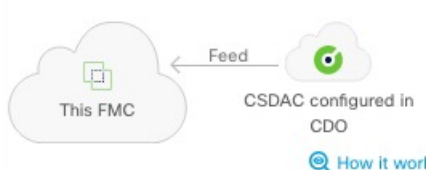

There are the following kinds of dynamic objects:

- Dynamic objects created using the dynamic attributes connector are pushed to the management center as soon as they're created and are updated at a regular interval.
- API-created dynamic objects:
  - Are IP addresses, with or without or classless inter-domain routing (CIDR), that can be used in access control rules much like a network object.
  - Do not support fully-qualified domain names or address ranges.
  - Must be updated using an API.

For more information about API-created dynamic objects, see [About API-Created Dynamic Objects, on page 1487](#).

## Create Dynamic Objects with Cloud-delivered Firewall Management Center

The following page is displayed if you indicated you're configuring the Cisco Secure Dynamic Attributes Connector with cloud-delivered Firewall Management Center in Cisco Security Cloud Control.

**Cloud Delivered FMC with CSDAC embedded in CDO**

**You'll need to take following steps:**  
*Prerequisite: On-board this FMC to CDO*

- 1 Go to Dynamic Attributes Connector in CDO  
Tools and Services / Dynamic Attributes Connector
- 2 Create at least one connector  
Source of dynamic objects
- 3 Create at least one filter  
Condition to target range of objects
- 4 Create at least one adapter  
FMC to which to send dynamic objects

Have questions? Refer to our [Help](#)

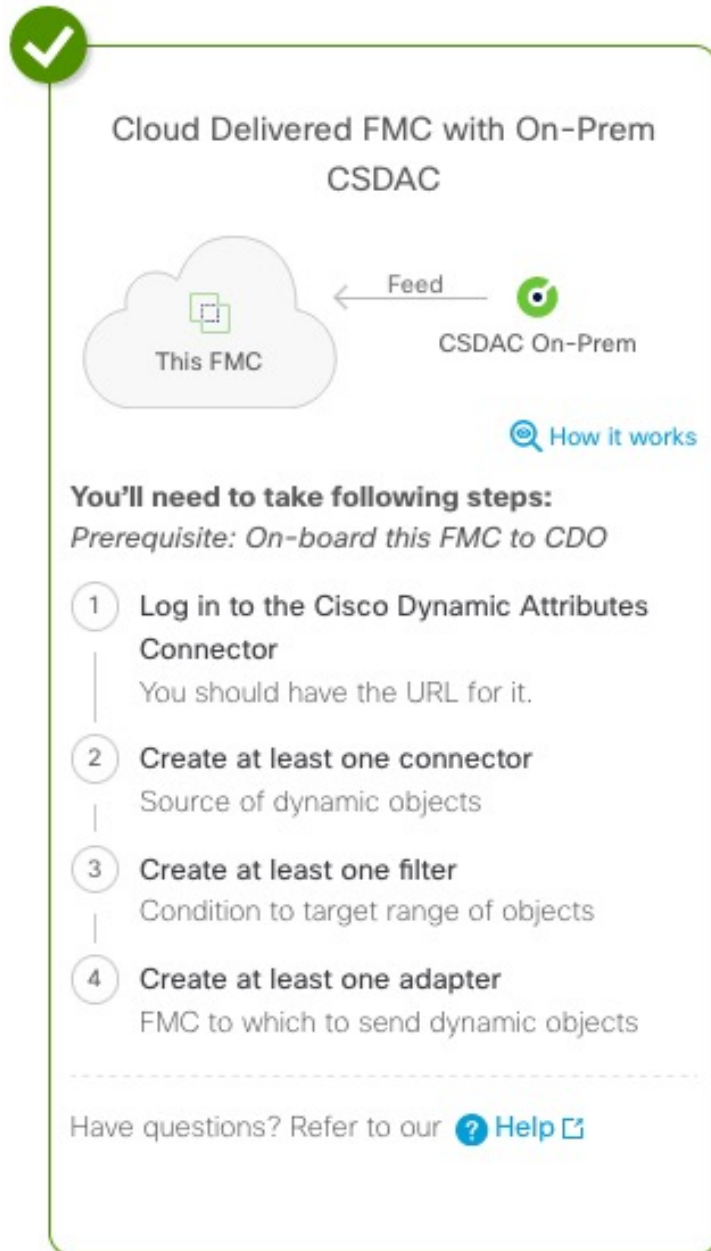

To use this type of deployment:

1. Configure connectors, which retrieve IP addresses from cloud services.  
For more information, see [Create a Connector, on page 1894](#).
2. Configure dynamic attributes filters, which determine what IP addresses to send to the management center.  
For more information, see [Create Dynamic Attributes Filters, on page 1913](#).
3. Configure a cloud-delivered Firewall Management Center adapter, which sends IP addresses to that device.
4. Click **Administration > Integrations & Migration > Cloud Services** and choose **Cloud-Delivered FMC**.
5. View your dynamic objects at **Objects > Object Management > External Attributes > Dynamic Object**.
6. Use dynamic objects in access control rules (**Policies > Access Control**, then click the **Dynamic Attributes** tab).

You do not have to deploy access control rules with dynamic objects; they are updated on all targeted devices automatically.

## Create Dynamic Objects with Cloud-delivered Firewall Management Center and On-Premises Cisco Secure Dynamic Attributes Connector

The following page is displayed if you indicated you're configuring an on-premises Cisco Secure Dynamic Attributes Connector with cloud-delivered Firewall Management Center in Cisco Security Cloud Control.

The screenshot shows a configuration page titled "Cloud Delivered FMC with On-Prem CSDAC". It features a diagram where a cloud icon labeled "This FMC" is connected to a server icon labeled "CSDAC On-Prem" via an arrow labeled "Feed". Below the diagram is a "How it works" link. The page lists four steps: 1. Log in to the Cisco Dynamic Attributes Connector (with a note: "You should have the URL for it."), 2. Create at least one connector (with a note: "Source of dynamic objects"), 3. Create at least one filter (with a note: "Condition to target range of objects"), and 4. Create at least one adapter (with a note: "FMC to which to send dynamic objects"). At the bottom, there is a "Have questions? Refer to our Help" link.

**Cloud Delivered FMC with On-Prem CSDAC**

[How it works](#)

**You'll need to take following steps:**  
*Prerequisite: On-board this FMC to CDO*

- 1 Log in to the Cisco Dynamic Attributes Connector**  
You should have the URL for it.
- 2 Create at least one connector**  
Source of dynamic objects
- 3 Create at least one filter**  
Condition to target range of objects
- 4 Create at least one adapter**  
FMC to which to send dynamic objects

Have questions? Refer to our [Help](#)

To use this type of deployment:

1. Install the Cisco Secure Dynamic Attributes Connector on a supported Linux virtual machine.
2. Configure connectors, which retrieve IP addresses from cloud services.

3. Configure adapters, which send IP addresses to your cloud-delivered Firewall Management Center.
4. Configure dynamic attributes filters, which determine what IP addresses to send to the management center.
5. Click **Administration > Integrations & Migration > Cloud Services** and choose **Cloud-Delivered FMC**.
6. View your dynamic objects at **Objects > Object Management > External Attributes > Dynamic Object**.
7. Use dynamic objects in access control rules (**Policies > Access Control**, then click the **Dynamic Attributes** tab).

You do not have to deploy access control rules with dynamic objects; they are updated on all targeted devices automatically.

## Work With Dynamic Objects

The page available at **Objects > Object Management > External Attributes > Dynamic Object** is displayed similar to the following if you have already configured some dynamic objects.

| Name            | Description | Last Updated       | Number of Mapped IPs |
|-----------------|-------------|--------------------|----------------------|
| o365_Common     |             | 21 Jun 23 09:44 AM | 34                   |
| o365_Exchange   |             | 21 Jun 23 09:44 AM | 34                   |
| o365_SharePoint |             | 21 Jun 23 09:44 AM | 9                    |
| o365_Skype      |             | 21 Jun 23 09:44 AM | 12                   |

This page displays information about each dynamic object and enables you to view or download IP addresses associated with that object. For more information, see [Dynamic Object Mappings, on page 1486](#).

## Dynamic Object Mappings

If you configured dynamic objects either using the API or using the dynamic attributes connector, your connectors send IPs matching dynamic attributes filters to the management center at regular intervals.

To view or download a current list of these IP addresses, click **Show Mapped IDs** as the following figure shows.

| Name            | Description | Last Updated      | Number of Mapp... |
|-----------------|-------------|-------------------|-------------------|
| o365_Common     |             | 06 Mar 23 08:2... | 50                |
| o365_Exchange   |             | 06 Mar 23 08:2... | 34                |
| o365_SharePoint |             | 06 Mar 23 08:2... | 9                 |
| o365_Skype      |             | 06 Mar 23 08:2... | 12                |

IP addresses are added dynamically with time so you should consider doing this on a regular basis, especially if your access control rules are not behaving as expected.

### Related topics

- [About API-Created Dynamic Objects, on page 1487](#)
- [About the Cisco Secure Dynamic Attributes Connector, on page 1885](#)

## About API-Created Dynamic Objects

A *dynamic object* is an object that specifies one or many IP addresses retrieved either using REST API calls or using the Cisco Secure Dynamic Attributes Connector, which is capable of updating IP addresses from cloud sources. These dynamic objects can be used in access control rules without the need to deploy the access control policy afterward.

For more information about the dynamic attributes connector, see the information later in this guide.

Differences between dynamic objects and network objects follow:

- Dynamic objects created using the dynamic attributes connector are pushed to the management center as soon as they're created and are updated at a regular interval.
- API-created dynamic objects:
  - Are IP addresses, with or without or classless inter-domain routing (CIDR), that can be used in access control rules much like a network object.
  - Do not support fully-qualified domain names or address ranges.
  - Must be updated using an API.

### Related Topics

[Add or Edit an API-Created Dynamic Object](#), on page 1487

### Add or Edit an API-Created Dynamic Object

This procedure discusses how to add or edit a *dynamic object*, which is a group of IP addresses using the API, with or without or classless inter-domain routing (CIDR), that can be used in access control rules much like a network object.

---

**Note** This procedure is not necessary if you use the Cisco Secure Dynamic Attributes Connector because it automatically creates dynamic objects for you.

---

### Before you begin

Consult the *Firepower Management Center REST API Quick Start Guide* for information about using the object services REST API to populate the IP object with an address. Dynamic objects do not require deployment.

### Procedure

- 
- Step 1** Click **Objects > Object Management**.
  - Step 2** Click **External Attributes > Dynamic Objects**.
  - Step 3** Click **Add Dynamic Object** or **Edit** (✎).
  - Step 4** Enter a **Name** for the object and an optional **Description**.
  - Step 5** From the **Type** list, click **IP**.
-

**What to do next**

If necessary, update the dynamic object using the API. Deployment is not required.

## Security Group Tag

A Security Group Tag (SGT) object specifies a single SGT value. You can use SGT objects in rules to control traffic with SGT attributes that were **not** assigned by Cisco ISE. You cannot group or override SGT objects.

**Related Topics**

[Autotransition from Custom SGTs to ISE SGTs](#)

[Custom SGT Conditions](#)

[ISE SGT vs Custom SGT Rule Conditions](#)

## Creating Security Group Tag Objects

You can create these objects in the global domain only. To use the object on Classic devices, you must have the Control license. For Smart Licensed devices, any license will do.

**Before you begin**

- Disable ISE/ISE-PIC connections. You cannot create custom SGT objects if you use ISE/ISE-PIC as an identity source.

**Procedure**

- 
- Step 1** Click **Objects > Object Management**.
  - Step 2** Click **External Attributes > Security Group Tag**.
  - Step 3** Click **Add Security Group Tag**.
  - Step 4** Enter a **Name**.
  - Step 5** Optionally, enter a **Description**.
  - Step 6** In the **Tag** field, enter a single SGT.
  - Step 7** Click **Save**.
- 

**What to do next**

- If an active policy references your object, deploy configuration changes.

## File List

If you use malware defense, and the AMP cloud incorrectly identifies a file's disposition, you can add the file to a *file list* to better detect the file in the future. These files are specified using SHA-256 hash values. Each file list can contain up to 10000 unique SHA-256 values.

There are two predefined categories of file lists:

### Clean List

If you add a file to this list, the system treats it as if the AMP cloud assigned a clean disposition.

### Custom Detection List

If you add a file to this list, the system treats it as if the AMP cloud assigned a malware disposition.

Because you manually specify the blocking behavior for the files included in these lists, the system does not query the AMP cloud for these files' dispositions. You must configure a rule in the file policy with either a **Malware Cloud Lookup** or **Block Malware** action and a matching file type to calculate a file's SHA value.

---

**Caution** Do **not** include malware on the clean list. The clean list overrides both the AMP cloud and the custom detection list.

---

## Source Files for File Lists

You can add multiple SHA-256 values to a file list by uploading a comma-separated value (CSV) source file containing a list of SHA-256 values and descriptions. The management center validates the contents and populates the file list with valid SHA-256 values.

The source file must be a simple text file with a .csv file name extension. Any header must start with a pound sign (#); it is treated as a comment and not uploaded. Each entry should contain a single SHA-256 value followed by a description and end with either the LF or CR+LF Newline character. The system ignores any additional information in the entry.

Note the following:

- Deleting a source file from the file list also removes all associated SHA-256 hashes from the file list.
- You cannot upload multiple files to a file list if the successful source file upload results in the file list containing more than 10000 distinct SHA-256 values.
- The system truncates descriptions exceeding 256 characters to the first 256 characters on upload. If the description contains commas, you must use an escape character (\,). If no description is included, the source file name is used instead.
- All non-duplicate SHA-256 values are added to the file list. If a file list contains a SHA-256 value, and you upload a source file containing that value, the newly uploaded value does not modify the existing SHA-256 value. When viewing captured files, file events, or malware events related to the SHA-256 value, any threat name or description is derived from the individual SHA-256 value.
- The system does not upload invalid SHA-256 values in a source file.
- If multiple uploaded source files contain an entry for the same SHA-256 value, the system uses the most recent value.
- If a source file contains multiple entries for the same SHA-256 value, the system uses the last one.
- You cannot directly edit a source file within the object manager. To make changes, you must first modify your source file directly, delete the copy on the system, then upload the modified source file.
- The number of entries associated with a source file refers to the number of distinct SHA-256 values. If you delete a source file from a file list, the total number of SHA-256 entries the file list contains decreases by the number of valid entries in the source file.

## Adding Individual SHA-256 Values to File Lists

You must have the Malware Defense license for this procedure.

You can submit a file's SHA-256 value to add it to a file list. You cannot add duplicate SHA-256 values.

### Before you begin

- Right-click a file or malware event from the event view, choose **Show Full Text** in the context menu, and copy the full SHA-256 value for pasting into the file list.

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Choose **File List** from the list of object types.
  - Step 3** Click **Edit** (✎) next to the clean list or custom detection list where you want to add a file.  
If **View** (👁) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.
  - Step 4** Choose `Enter SHA Value` from the **Add by** drop-down list.
  - Step 5** Enter a description of the source file in the **Description** field.
  - Step 6** Enter or paste the file's entire value in the **SHA-256** field. The system does not support matching partial values.
  - Step 7** Click **Add**.
  - Step 8** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes.

---

**Note** After configuration changes are deployed, the system no longer queries the AMP cloud for files on the list.

---

## Uploading Individual Files to File Lists

You must have the Malware Defense license for this procedure.

If you have a copy of the file you want to add to a file list, you can upload the file to the Secure Firewall Management Center for analysis; the system calculates the file's SHA-256 value and adds the file to the list. The system does not enforce a limit on the size of files for SHA-256 calculation.

## Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- Step 2** Choose **File List** from the list of object types.
- Step 3** Click **Edit** (✎) next to the clean list or custom detection list where you want to add a file.
- If **View** (👁) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.
- Step 4** From the **Add by** drop-down list, choose **Calculate SHA**.
- Step 5** Optionally, enter a description of the file in the **Description** field. If you do not enter a description, the file name is used for the description on upload.
- Step 6** Click **Browse**, and choose a file to upload.
- Step 7** Click **Calculate and Add SHA**.
- Step 8** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes.

---

**Note** After you deploy configuration changes, the system no longer queries the AMP cloud for files on the list.

---

## Uploading Source Files to File Lists

You must have the Malware Defense license for this procedure.

## Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- Step 2** Click **File List**.
- Step 3** Click **Edit** (✎) next to the file list where you want to add values from a source file.
- If **View** (👁) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.
- Step 4** In the **Add by** drop-down list, choose `List of SHAs`.
- Step 5** Optionally, enter a description of the source file in the **Description** field. If you do not enter a description, the system uses the file name.
- Step 6** Click **Browse** to browse to the source file, then click **Upload and Add List**.

**Step 7** Click **Save**.

---

**What to do next**

- If an active policy references your object, deploy configuration changes.

**Note** After you deploy the policies, the system no longer queries the AMP cloud for files on the list.

---

## Editing SHA-256 Values in File Lists

You must have the Malware Defense license for this procedure.

You can edit or delete individual SHA-256 values on a file list. Note that you cannot directly edit a source file within the object manager. To make changes, you must first modify your source file directly, delete the copy on the system, then upload the modified source file.

### Procedure

---

**Step 1** Choose **Objects > Object Management**.

**Step 2** Click **File List**.

**Step 3** Click **Edit** (✎) next to the clean list or custom detection list where you want to modify a file.

If **View** (👁) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.

**Step 4** You can:

- Click **Edit** (✎) next to the SHA-256 value you want to change, and modify the **SHA-256** or **Description** values as desired.
- Click **Delete** (🗑) next to the SHA-256 value you want to delete.

**Step 5** Click **Save** to update the file entry in the list.

**Step 6** Click **Save** to save the file list.

---

**What to do next**

- If an active policy references your object, deploy configuration changes.

**Note** After configuration changes are deployed, the system no longer queries the AMP cloud for files on the list.

---

## Downloading Source Files from File Lists

You must have the Malware Defense license for this procedure.

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- Step 2** Choose **File List** from the list of object types.
- Step 3** Click **Edit** (✎) next to the clean list or custom detection list where you want to download a source file.
- If **View** (👁) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.
- Step 4** Next to the source file you want to download, click **View** (👁).
- Step 5** Click **Download SHA List** and follow the prompts to save the source file.
- Step 6** Click **Close**.
- 

## FlexConfig

Use FlexConfig policy objects in FlexConfig policies to provide customized configuration of features on threat defense devices that you cannot otherwise configure using Secure Firewall Management Center. For more information on FlexConfig policies, see [FlexConfig Policy Overview, on page 2703](#).

You can configure the following types of objects for FlexConfig.

### Text Objects

Text objects define free-form text strings that you use as variables in a FlexConfig object. These objects can have single values or be a list of multiple values.

There are several predefined text objects that are used in the predefined FlexConfig objects. If you use the associated FlexConfig object, you simply need to edit the contents of the text object to customize how the FlexConfig object configures a given device. When editing a predefined object, it is in general a better option to create device overrides for each device you are configuring, rather than directly change the default values of these objects. This helps avoid unintended consequences if another user wants to use the same FlexConfig object for a different set of devices.

For information on configuring text objects, see [Configure FlexConfig Text Objects, on page 2730](#).

### FlexConfig Objects

FlexConfig Objects include device configuration commands, variables, and scripting language instructions. During configuration deployment, these instructions are processed to create a sequence of configuration commands with customized parameters to configure specific features on the target devices.

These instructions are either configured before (prepended) the system configures features defined in regular management center policies and settings, or after (appended). Any FlexConfig that depends on Secure Firewall Management Center-configured objects (for example, a network object) must be appended

to the configuration deployment, or the needed objects would not be configured before the FlexConfig needed to refer to the objects.

For more information on configuring FlexConfig objects, see [Configure FlexConfig Objects, on page 2726](#).

## Geolocation

Each geolocation object you configure represents one or more countries or continents that the system has identified as the source or destination of traffic on your monitored network. You can use geolocation objects in various places in the system's web interface, including access control policies, SSL policies, remote access VPN, and event searches. For example, you could write an access control rule that blocks traffic to or from certain countries.

To ensure that you are using up-to-date information to filter your network traffic, Cisco strongly recommends that you regularly update your Geolocation Database (GeoDB).

## Creating Geolocation Objects

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Choose **Geolocation** from the list of object types.
  - Step 3** Click **Add Geolocation**.
  - Step 4** Enter a **Name**.
  - Step 5** Check the check boxes for the countries and continents you want to include in your geolocation object. Checking a continent chooses all countries within that continent, as well as any countries that GeoDB updates may add under that continent in the future. Unchecking any country under a continent unchecks the continent. You can choose any combination of countries and continents.
  - Step 6** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes.

## Interface

Each interface can be assigned to a *security zone* and/or *interface group*. You then apply your security policy based on zones or groups. For example, you can assign the "inside" interface to the "inside" zone; and the "outside" interface to the "outside" zone. You can configure your access control policy to enable traffic to go from inside to outside, but not from outside to inside, for example. Some policies only support security zones, while other policies support zones and groups.

For more information about interface objects, see [Security Zones and Interface Groups, on page 908](#).

To add interface objects, see [Create Security Zone and Interface Group Objects](#), on page 910.

## Key Chain

To enhance data security and protection of devices, rotating keys for authenticating IGP peers that have a duration of 180 days or less is introduced. The rotating keys prevent any malicious user from guessing the keys used for routing protocol authentication and thereby protecting the network from advertising incorrect routes and redirecting traffic. Changing the keys frequently reduces the risk of them eventually being guessed. When configuring authentication for routing protocols that provide key chains, configure the keys in a key chain to have overlapping lifetimes. This helps to prevent loss of key-secured communication due to absence of an active key. The rotating keys are applicable only for OSPFv2 protocol. If the key lifetime expires and no active keys are found, OSPF uses the last valid key to maintain the adjacency with peers.

---

**Note** Only MD5 cryptographic algorithm is used for authentication.

---

### Lifetime of a Key

To maintain stable communications, each device stores key chain authentication keys and uses more than one key for a feature at the same time. Based on the send and accept lifetimes of a key, key chain management provides a secured mechanism to handle key rollover. The device uses the lifetimes of keys to determine which keys in a key chain are active.

Each key in a key chain has two lifetimes:

- Accept lifetime—The time interval within which the device accepts the key during key exchange with another device.
- Send lifetime—The time interval within which the device sends the key during key exchange with another device.

During a key send lifetime, the device sends routing update packets with the key. The device does not accept communication from other devices when the key sent is not within the accept lifetime of the key on the device. If lifetimes are not configured then it is equivalent to configuring MD5 authentication key without timelines.

### Key Selection

- When key chain has more than one valid key, OSPF selects the key that has the maximum life time.
- Key having an infinite lifetime is preferred.
- If keys have the same lifetime, then key with the higher key ID is preferred.

# Creating Key Chain Objects

## Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- Step 2** Choose **Key Chain** from the list of object types.
- Step 3** Click **Add Key Chain**.
- Step 4** In the Add Key Chain Object dialog box, enter a name for the key chain in the **Name** field.  
The name must start with an underscore or alphabet, followed by alphanumeric characters or special characters (-, \_, +, .).
- Step 5** To add a key to the key chain, click **Add**.
- Step 6** Specify the key identifier in the **Key ID** field.  
The key id value can be between 0 and 255. Use the value 0 only when you want to signal an invalid key.
- Step 7** The **Algorithm** field and the **Crypto Encryption Type** field displays the supported algorithm and the encryption type, namely MD5 and Plain Text respectively.
- Step 8** Enter the password in the **Crypto Key String** field, and re-enter the password in the **Confirm Crypto Key String** field.
- The password can be of a maximum length of 80 characters.
  - The passwords cannot be a single digit nor those starting with a digit followed by a white space. For example, "0 pass" or "1" are invalid.
- Step 9** To set the time interval for a device to accept/send the key during key exchange with another device, provide the lifetime values in the **Accept Lifetime** and **Send Lifetime** fields:
- Note** The Date Time values default to UTC timezones.
- The end time can be the duration, the absolute time when the accept/send lifetime ends, or never expires. The default end time is DateTime.
- Following are the validation rules for the start and end values:
- Start lifetime cannot be null when the end lifetime is specified.
  - The start lifetime for accept or send lifetime must be earlier than the respective end lifetime.
- Step 10** Click **Add**.
- Repeat steps 5 to 10 to create keys. Create a minimum of two keys for a key chain with overlapping lifetimes. This helps to prevent loss of key-secured communication due to absence of an active key.
- Step 11** Manage overrides for the object:
- If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
  - If you want to add override values to this object, expand the Override section and click **Add**; see [Adding Object Overrides, on page 1462](#).

**Step 12** Click **Save**.

---

#### What to do next

- If an active policy references your object, deploy configuration changes.

## Network

A network object represents one or more IP addresses. You can use network objects and groups in various places, including access control policies, network variables, identity rules, network discovery rules, event searches, reports, identity policies, and so on.

When you configure an option that requires a network object, the list is automatically filtered to show only those objects that are valid for the option. For example, some options require host objects, while other options require subnets.

A network object can be one of the following types:

#### Host

A single IP address.

IPv4 example:

209.165.200.225

IPv6 example:

2001:DB8::0DB8:800:200C:417A **OR** 2001:DB8:0:0:0DB8:800:200C:417A

#### Range

A range of IP addresses.

IPv4 example:

209.165.200.225–209.165.200.250

IPv6 example:

2001:db8:0:cd30::1–2001:db8:0:cd30::1000

#### Network

An address block, also known as a subnet.

IPv4 example:

209.165.200.224/27

IPv6 example:

2001:DB8:0:CD30::/60

---

**Note** Security Intelligence ignores IP address blocks using a /0 netmask.

---

## FQDN

A single fully-qualified domain name (FQDN). You can limit FQDN resolution to IPv4 address only, IPv6 address only, or both IPv4 and IPv6 addresses. FQDNs must begin and end with a digit or letter. Only letters, digits, and hyphens are allowed as internal characters in an FQDN.

For example:

```
www.example.com
```

---

**Note** You can use FQDN objects in access control rules and prefilter rules, or manual NAT rules, only. The rules match the IP address obtained for the FQDN through a DNS lookup. To use an FQDN network object, ensure you have configured the DNS server settings in [DNS Server Group, on page 1482](#) and the DNS platform settings in [DNS, on page 1075](#).

You *cannot* use FQDN network objects in identity rules.

---

## Group

A group of network objects or other network object groups. You can create nested groups by adding one network object group to another network object group. You can nest up to 10 levels of groups.

---

**Note** You can add up to 100 network literals in a network object. Additionally, each nested network object group can contain a maximum of 100 network literals.

---

### If you are using Cloud-delivered Firewall Management Center

When you create a network object or group, the object is replicated in the **Objects > FTD Network Objects** page in Cisco Security Cloud Control and vice-versa.

You can use the objects on the **Objects > FTD Network Objects** page when specifying networks while configuring other Security Cloud Control-managed products, such as ASA or FDM.

Changes you make to network objects or groups in either list are reflected in the object or group instance in both lists. Deleting an object or group from either list also deletes its corresponding object or group from the other list.

Exception: If an object created on the Security Cloud Control list has the same name as an existing object on the Cloud-delivered Firewall Management Center list, the object will not be replicated on the Cloud-delivered Firewall Management Center list.

## Network Wildcard Mask

You can create and manage wildcard mask objects from the Object Management page.

You can create network objects with expanded subnet IP address. The existing network object is extended to support both Network and Network Wildcard object. The network object using wildcard mask is listed as **Network Wildcard** against the **Type** column in the network object listing page.

A wildcard mask is an IP address that is a discontinuous mask of bits. You can use contiguous masks to create standard network objects and discontinuous masks for wildcard network objects.

| Example IP Address          | Network Wildcard? | Object Type      |
|-----------------------------|-------------------|------------------|
| 192.0.0.0/8                 | No                | Network          |
| 10.10.0.0/255.255.0.0       | No                | Network          |
| 10.10.0.10/255.255.0.255    | Yes               | Network Wildcard |
| 72.0.240.10/255.255.240.255 | Yes               | Network Wildcard |

**Note** Network wildcard object and object group, which contains network wildcard objects, are allowed only while configuring the following policies:

- Prefilter policy
- Access control policy
- NAT policy

#### Guidelines and Limitations

- To create network wildcard objects, in the management center UI, choose **Objects > Object Management > Network** and click **Add Network** and then **Add Object**. Select the **Network** option and enter the value as expanded subnet mask. Example: 10.0.10.10/255.255.0.255.
- Object override, group object support, group object override, wildcard literals, and wildcard object import are supported.
- The network wildcard object is supported only for IPv4 addresses.
- The network wildcard object is supported from management center and Threat Defense 7.1 version onwards.
- Network wildcard objects are supported only for Snort-3.

## Creating Network Objects

### Procedure

- Step 1** If you are accessing network objects from Security Cloud Control, choose **Objects > Other FTD Objects**.
- Step 2** Choose **Objects > Object Management**.
- Step 3** Choose **Network** from the list of object types.
- Step 4** Choose **Add Object** from the **Add Network** drop-down menu.
- Step 5** Alternatively, you can clone an existing network object and edit the parameters to create a new network object. Click the **Clone** icon on the existing network object that you want to clone.
- Step 6** Enter a **Name**.

- Step 7** Optionally, enter a **Description**.
- Step 8** In the **Network** field, select the required option and enter an appropriate value; see [Network, on page 1497](#).
- Note** You can add up to 100 network literals in a network object. Additionally, each nested network object group can contain a maximum of 100 network literals.
- Step 9** (FQDN objects only) Select the DNS resolution from the **Lookup** drop-down menu to determine whether you want the IPv4, IPv6, or both IPv4 and IPv6 addresses associated with the FQDN.
- Step 10** Manage overrides for the object:
- If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
  - If you want to add override values to this object, expand the Override section and click **Add**; see [Adding Object Overrides, on page 1462](#).
- Step 11** Click **Save**.

---

#### What to do next

- If an active policy references your object, deploy configuration changes.

## Importing Network Objects

For details on importing network objects, see [Importing Objects, on page 1454](#).

## Editing and Deleting Network Objects and Groups

**Caution** When you edit or delete a network object or group from the Object Management page in Cloud-delivered Firewall Management Center, this change also modifies or deletes the corresponding network object or group replicated on the Objects page in Cisco Security Cloud Control. Similarly, changes you make to these objects on the Security Cloud Control objects page are reflected for the corresponding objects in Cloud-delivered Firewall Management Center.

## PKI

### PKI Objects for SSL Application

PKI objects represent the public key certificates and paired private keys required to support your deployment. Internal and trusted CA objects consist of certificate authority (CA) certificates; internal CA objects also contain the private key paired with the certificate. Internal and external certificate objects consist of server certificates; internal certificate objects also contain the private key paired with the certificate.

If you use trusted certificate authority objects and internal certificate objects to configure a connection to ISE/ISE-PIC, you can use ISE/ISE-PIC as an identity source.

If you use internal certificate objects to configure captive portal, the system can authenticate the identity of your captive portal device when connecting to users' web browsers.

If you use trusted certificate authority objects to configure realms, you can configure secure connections to LDAP or AD servers.

If you use PKI objects in SSL rules, you can match traffic encrypted with:

- the certificate in an external certificate object
- a certificate either signed by the CA in a trusted CA object, or within the CA's chain of trust

If you use PKI objects in SSL rules, you can decrypt:

- outgoing traffic by re-signing the server certificate with an internal CA object
- incoming traffic using the known private key in an internal certificate object

You can manually input certificate and key information, upload a file containing that information, or in some cases, generate a new CA certificate and private key.

When you view a list of PKI objects in the object manager, the system displays the certificate's Subject distinguished name as the object value. Hover your pointer over the value to view the full certificate Subject distinguished name. To view other certificate details, edit the PKI object.

---

**Note** The management center and managed devices encrypt all private keys stored in internal CA objects and internal certificate objects with a randomly generated key before saving them. If you upload private keys that are password protected, the appliance decrypts the key using the user-supplied password, then reencrypts it with the randomly generated key before saving it.

---

### PKI Objects for Certificate Enrollment

A certificate enrollment object contains the Certification Authority (CA) server information and enrollment parameters that are required for creating Certificate Signing Requests (CSRs) and obtaining Identity Certificates from the specified CA. These activities occur in your Private Key Infrastructure (PKI).

The certificate enrollment object may also include certificate revocation information. For more information on PKI, digital certificates, and certificate enrollment see [PKI Infrastructure and Digital Certificates](#), on page 1612.

## Internal Certificate Authority Objects

Each internal certificate authority (CA) object you configure represents the CA public key certificate of a CA your organization controls. The object consists of the object name, CA certificate, and paired private key.

You can use internal CA objects and groups in SSL rules to decrypt outgoing encrypted traffic by re-signing the server certificate with the internal CA.

---

**Note** If you reference an internal CA object in a **Decrypt - Resign** SSL rule and the rule matches an encrypted session, the user's browser may warn that the certificate is not trusted while negotiating the SSL handshake. To avoid this, add the internal CA object certificate to either the client or domain list of trusted root certificates.

---

You can create an internal CA object in the following ways:

- import an existing RSA-based or elliptic curve-based CA certificate and private key
- generate a new self-signed RSA-based CA certificate and private key
- generate an unsigned RSA-based CA certificate and private key. You must submit a certificate signing request (CSR) to another CA to sign the certificate before using the internal CA object.

After you create an internal CA object containing a signed certificate, you can download the CA certificate and private key. The system encrypts downloaded certificates and private keys with a user-provided password.

Whether system-generated or user-created, you can modify the internal CA object name, but cannot modify other object properties.

You cannot delete an internal CA object that is in use. Additionally, after you edit an internal CA object used in an SSL policy, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

## CA Certificate and Private Key Import

You can configure an internal CA object by importing an X.509 v3 CA certificate and private key. You can upload files encoded in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the private key file is password-protected, you can supply the decryption password. If the certificate and key are encoded in the PEM format, you can also copy and paste the information.

You can upload only files that contain proper certificate or key information, and that are paired with each other. The system validates the pair before saving the object.

---

**Note** If you configure a rule with the **Decrypt - Resign** action, the rule matches traffic based on the referenced internal CA certificate's encryption algorithm type, in addition to any configured rule conditions. You must upload an elliptic curve-based CA certificate to decrypt outgoing traffic encrypted with an elliptic curve-based algorithm, for example.

---

## Importing a CA Certificate and Private Key

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Expand the **PKI** node, and choose **Internal CAs**.
  - Step 3** Click **Import CA**.
  - Step 4** Enter a **Name**.
  - Step 5** Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.

- Step 6** Above the **Key** field, click **Browse** to upload a DER or PEM-encoded paired private key file.
- Step 7** If the uploaded file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.
- Step 8** Click **Save**.
- 

#### What to do next

- If an active policy references your object, deploy configuration changes.

## Generating a New CA Certificate and Private Key

You can configure an internal CA object by providing identification information to generate a self-signed RSA-based CA certificate and private key.

The generated CA certificate is valid for ten years. The Valid From date is a week before generation.

#### Procedure

---

- Step 1** Choose **Objects > Object Management**.
- Step 2** Expand the **PKI** node, and choose **Internal CAs**.
- Step 3** Click **Generate CA**.
- Step 4** Enter a **Name**.
- Step 5** Enter the identification attributes.
- Step 6** Click **Generate self-signed CA**.
- 

## New Signed Certificates

You can configure an internal CA object by obtaining a signed certificate from a CA. This involves two steps:

- Provide identification information to configure the internal CA object. This generates an unsigned certificate and paired private key, and creates a certificate signing request (CSR) to a CA you specify.
- After the CA issues the signed certificate, upload it to the internal CA object, replacing the unsigned certificate.

You can only reference an internal CA object in an SSL rule if it contains a signed certificate.

## Creating an Unsigned CA Certificate and CSR

#### Procedure

---

- Step 1** Choose **Objects > Object Management**.
- Step 2** Expand the **PKI** node, and choose **Internal CAs**.

- Step 3** Click **Generate CA**.
  - Step 4** Enter a **Name**.
  - Step 5** Enter the identification attributes.
  - Step 6** Click **Generate CSR**.
  - Step 7** Copy the CSR to submit to a CA.
  - Step 8** Click **OK**.
- 

#### What to do next

- You must upload a signed certificate issued by a CA as described in [Uploading a Signed Certificate Issued in Response to a CSR, on page 1504](#)

## Uploading a Signed Certificate Issued in Response to a CSR

Once uploaded, the signed certificate can be referenced in SSL rules.

### Procedure

---

- Step 1** Choose **Objects > Object Management**.
  - Step 2** Expand the **PKI** node, and choose **Internal CAs**.
  - Step 3** Click **Edit** (✎) next to the CA object containing the unsigned certificate awaiting the CSR.
  - Step 4** Click **Install Certificate**.
  - Step 5** Click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.
  - Step 6** If the uploaded file is password protected, check the **Encrypted, and the password is:** check box, and enter the password.
  - Step 7** Click **Save** to upload a signed certificate to the CA object.
- 

#### What to do next

- If an active policy references your object, deploy configuration changes.

## CA Certificate and Private Key Downloads

You can back up or transfer a CA certificate and paired private key by downloading a file containing the certificate and key information from an internal CA object.

---

**Caution** Always store downloaded key information in a secure location.

---

The system encrypts the private key stored in an internal CA object with a randomly generated key before saving it to disk. If you download a certificate and private key from an internal CA object, the system first decrypts the information before creating a file containing the certificate and private key information. You must then provide a password the system uses to encrypt the downloaded file.

---

**Caution** Private keys downloaded as part of a system backup are decrypted, then stored in the unencrypted backup file.

---

## Downloading a CA Certificate and Private Key

You can download CA certificates for both the current domain and ancestor domains.

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Expand the **PKI** node, and choose **Internal CAs**.
  - Step 3** Next to the internal CA object whose certificate and private key you want to download, click **Edit** (✎).
  - Step 4** Click **Download**.
  - Step 5** Enter an encryption password in the **Password** and **Confirm Password** fields.
  - Step 6** Click **OK**.
- 

## Trusted Certificate Authority Objects

Each trusted certificate authority (CA) object you configure represents a CA public key certificate belonging to a trusted CA. The object consists of the object name and CA public key certificate. You can use external CA objects and groups in:

- your SSL policy to control traffic encrypted with a certificate signed either by the trusted CA, or any CA within the chain of trust.
- your realm configurations to establish secure connections to LDAP or AD servers.
- your ISE/ISE-PIC connection. Select trusted certificate authority objects for the **pxGrid Server CA** and **MNT Server CA** fields.

After you create the trusted CA object, you can modify the name and add certificate revocation lists (CRL), but cannot modify other object properties. There is no limit on the number of CRLs you can add to an object. If you want to modify a CRL you have uploaded to an object, you must delete the object and recreate it.

---

**Note** Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

---

You cannot delete a trusted CA object that is in use. Additionally, after you edit a trusted CA object that is in use, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

## Trusted CA Object

You can configure an external CA object by uploading an X.509 v3 CA certificate. You can upload a file encoded in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the file is password-protected, you must supply the decryption password. If the certificate is encoded in the PEM format, you can also copy and paste the information.

You can upload a CA certificate only if the file contains proper certificate information; the system validates the certificate before saving the object.

## Adding a Trusted CA Object

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Expand the **PKI** node, and choose **Trusted CAs**.
  - Step 3** Click **Add Trusted CAs**.
  - Step 4** Enter a **Name**.
  - Step 5** Click **Browse** to upload a DER or PEM-encoded X.509 v3 CA certificate file.
  - Step 6** If the file is password-protected, check the **Encrypted, and the password is:** check box, and enter the password.
  - Step 7** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes.

## Certificate Revocation Lists in Trusted CA Objects

You can upload CRLs to a trusted CA object. If you reference that trusted CA object in an SSL policy, you can control encrypted traffic based on whether the CA that issued the session encryption certificate subsequently revoked the certificate. You can upload files encoded in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

After you add the CRL, you can view the list of revoked certificates. If you want to modify a CRL you have uploaded to an object, you must delete the object and recreate it.

You can upload only files that contain a proper CRL. There is no limit to the number of CRLs you can add to a trusted CA object. However, you must save the object each time you upload a CRL, before adding another CRL.

---

**Note** Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

---

## Adding a Certificate Revocation List to a Trusted CA Object

---

**Note** Adding a CRL to an object has no effect when the object is used in your ISE/ISE-PIC integration configuration.

---

### Procedure

---

**Step 1** Choose **Objects > Object Management**.

**Step 2** Expand the **PKI** node, and choose **Trusted CAs**.

**Step 3** Click **Edit** (✎) next to a trusted CA object.

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 4** Click **Add CRL** to upload a DER or PEM-encoded CRL file.

**Step 5** Click **OK**.

---

#### What to do next

- If an active policy references your object, deploy configuration changes.

## External Certificate Objects

Each external certificate object you configure represents a server public key certificate that does not belong to your organization. The object consists of the object name and certificate. You can use external certificate objects and groups in SSL rules to control traffic encrypted with the server certificate. For example, you can upload a self-signed server certificate that you trust, but cannot verify with a trusted CA certificate.

You can configure an external certificate object by uploading an X.509 v3 server certificate. You can upload a file in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

You can upload only files that contains proper server certificate information; the system validates the file before saving the object. If the certificate is encoded in the PEM format, you can also copy and paste the information.

## Adding External Certificate Objects

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Expand the **PKI** node, and choose **External Certs**.
  - Step 3** Click **Add External Cert**.
  - Step 4** Enter a **Name**.
  - Step 5** Above the **Certificate Data** field, click **Browse** to upload a DER or PEM-encoded X.509 v3 server certificate file.
  - Step 6** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes.

## Internal Certificate Objects

Each internal certificate object you configure represents a server public key certificate belonging to your organization. The object consists of the object name, public key certificate, and paired private key. You can use internal certificate objects and groups in:

- your SSL rules to decrypt traffic incoming to one of your organization's servers using the known private key.
- your ISE/ISE-PIC connection. Select an internal certificate object for the **MC Server Certificate** field.
- your captive portal configuration to authenticate the identity of your captive portal device when connecting to users' web browsers. Select an internal certificate object for the **Server Certificate** field.

You can configure an internal certificate object by uploading an X.509 v3 RSA-based or elliptic curve-based server certificate and paired private key. You can upload a file in one of the following supported formats:

- Distinguished Encoding Rules (DER)
- Privacy-enhanced Electronic Mail (PEM)

If the file is password-protected, you must supply the decryption password. If the certificate and key are encoded in the PEM format, you can also copy and paste the information.

You can upload only files that contain proper certificate or key information, and that are paired with each other. The system validates the pair before saving the object.

After you create the internal certificate object, you can modify the name, but cannot modify other object properties.

You cannot delete an internal certificate object that is in use. Additionally, after you edit an internal certificate object that is in use, the associated access control policy goes out-of-date. You must re-deploy the access control policy for your changes to take effect.

## Adding Internal Certificate Objects

### Procedure

- 
- |               |                                                                                                                                             |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Step 1</b> | Choose <b>Objects &gt; Object Management</b> .                                                                                              |
| <b>Step 2</b> | Expand the <b>PKI</b> node, and choose <b>Internal Certs</b> .                                                                              |
| <b>Step 3</b> | Click <b>Add Internal Cert</b> .                                                                                                            |
| <b>Step 4</b> | Enter a <b>Name</b> .                                                                                                                       |
| <b>Step 5</b> | Above the <b>Certificate Data</b> field, click <b>Browse</b> to upload a DER or PEM-encoded X.509 v3 server certificate file.               |
| <b>Step 6</b> | Above the <b>Key</b> field, or click <b>Browse</b> to upload a DER or PEM-encoded paired private key file.                                  |
| <b>Step 7</b> | If the uploaded private key file is password-protected, check the <b>Encrypted, and the password is:</b> check box, and enter the password. |
| <b>Step 8</b> | Click <b>Save</b> .                                                                                                                         |
- 

## Certificate Enrollment Objects

Trustpoints let you manage and track CAs and certificates. A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one, enrolled identity certificate.

A certificate enrollment object contains the Certification Authority (CA) server information and enrollment parameters that are required for creating Certificate Signing Requests (CSRs) and obtaining Identity Certificates from the specified CA. These activities occur in your Private Key Infrastructure (PKI).

The certificate enrollment object may also include certificate revocation information. For more information on PKI, digital certificates, and certificate enrollment see [PKI Infrastructure and Digital Certificates](#), on page 1612.

### How to Use Certificate Enrollment Objects

Certificate Enrollment Objects are used to enroll your managed devices into your PKI infrastructure, and create trustpoints (CA objects) on devices that support VPN connections by doing the following:

1. Define parameters for CA authentication and enrollment in a Certificate Enrollment Object. Specify shared parameters and use the override facility to specify unique object setting for different devices.
2. Associate and install this object on each managed device that requires the identity certificate. On the device, it becomes a *trustpoint*.

When a certificate enrollment object is associated with and then installed on a device, the process of certificate enrollment starts immediately. The process is automatic for self-signed, SCEP, EST, and PKCS12 file enrollment types, meaning it does not require any additional administrator action. Manual certificate enrollment requires extra administrator action.

3. Specify the created trustpoint in your VPN configuration.

## Managing Certificate Enrollment Objects

To manage certificate enrollment objects, go to **Objects > Object Management**, then from the navigation pane choose **PKI > Cert Enrollment**. The following information is shown:

- Existing certificate enrollment objects are listed in the **Name** column.  
Use the search field (the magnifying glass) to filter the list.
- The enrollment type of each object is shown in the **Type** column. The following enrollment methods can be used:
  - **Self Signed**—The managed device generates its own self signed root certificate.
  - **EST**—Enrollment over Secure Transport is used by the device to obtain an identity certificate from the CA.
  - **SCEP**—(Default) Simple Certificate Enrollment Protocol is used by the device to obtain an identity certificate from the CA.
  - **Manual**—The process of enrolling is carried out manually by the administrator.
  - **PKCS12 File**—Import a PKCS12 file on a threat defense managed device that supports VPN connectivity. A PKCS#12, or PFX or P12 file holds the server certificate, any intermediate certificates, and the private key in one encrypted file. Enter the **Passphrase** value for decryption.

- The **Override** column indicates whether the object allows overrides (a green check mark) or not (a red X). If a number is displayed, it is the number of overrides in place.

Use the Override option to customize the object settings for each device that is part of the VPN configuration. Overriding makes each device's trustpoint details unique. Typically the Common Name or Subject is overridden for each device in the VPN configuration.

See [Object Overrides, on page 1460](#) for details and procedures on overriding objects of any type.

- **Edit** a previously created certificate enrollment object by clicking on the edit icon (a pencil). Editing can only be done if the enrollment object is not associated with any managed devices. Refer to the adding instructions for editing a certificate enrollment object. Failed enrollment objects can be edited.
- **Delete** a previously created certificate enrollment object by clicking on the delete icon (a trash can). You cannot delete a certificate enrollment object if it is associated with any managed device.

Press **(+)** **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog and configure a Certificate Enrollment Object, see [Adding Certificate Enrollment Objects, on page 1511](#). Then install the certificate on each managed, headend device.

### Related Topics

- [Installing a Certificate Using Self-Signed Enrollment](#), on page 1579
- [Installing a Certificate using EST Enrollment](#), on page 1580
- [Installing a Certificate Using SCEP Enrollment](#), on page 1581
- [Installing a Certificate Using Manual Enrollment](#), on page 1581
- [Installing a Certificate Using a PKCS12 File](#), on page 1582

## Adding Certificate Enrollment Objects

You can use these objects with threat defense devices. You must have Admin or Network Admin privileges to do this task.

### Procedure

- 
- Step 1** Open the **Add Cert Enrollment** dialog:
- Directly from Object Management: In the **Objects > Object Management** screen, choose **PKI > Cert Enrollment** from the navigation pane, and press **Add Cert Enrollment**.
  - While configuring a managed device: In the **Devices > Certificates** screen, choose **Add > Add New Certificate** and click ( **+** ) for the **Certificate Enrollment** field.
- Step 2** Enter the **Name**, and optionally, a **Description** of this enrollment object.
- When enrollment is complete, this name is the name of the trustpoint on the managed devices with which it is associated.
- Step 3** Open the **CA Information** tab and choose the **Enrollment Type**.
- **Self-Signed Certificate**—The managed device, acting as a CA, generates its own self-signed root certificate. No other information is needed in this pane.
    - Note** When enrolling a self-signed certificate you must specify the Common Name (CN) in the certificate parameters.
  - **EST**—Enrollment over Secure Transport protocol. Specify the EST information. See [Certificate Enrollment Object EST Options, on page 1512](#).
  - **SCEP**—(Default) Simple Certificate Enrollment Protocol. Specify the SCEP information. See [Certificate Enrollment Object SCEP Options, on page 1513](#).
  - **Manual**
    - **CA Only**—Check this check box to create only the CA certificate from the selected CA. An identity certificate will not be created for this certificate.

If you do not select this check box, a CA certificate is not mandatory. You can generate the CSR without having a CA certificate and obtain the identity certificate.
    - **CA Certificate**—Paste the CA certificate in the PEM format in the box. You can also obtain a CA certificate by copying it from another device.

You can leave this box empty if you choose to generate a CSR without the CA certificate.
  - **PKCS12 File**—Import a PKCS12 file on a threat defense managed device that supports VPN connectivity. A PKCS#12, or PFX, file holds a server certificate, intermediate certificates, and a private key in one encrypted file. Enter the **Passphrase** value for decryption.
  - **Skip Check for CA flag in basic constraints of the CA Certificate**—Check this check box if you want to skip checking the basic constraints extension and the CA flag in a trustpoint certificate.
  - **Validation Usage**—Choose from the options to validate the certificate during a VPN connection:
    - **IPsec Client**—Validate an IPsec client certificate for a site-to-site VPN connection.
    - **SSL Client**—Validate an SSL client certificate during a remote access VPN connection attempt.

- **SSL Server**—Select to validate an SSL server certificate, like as a Cisco Umbrella server certificate.

- Step 4** (Optional) Open the **Certificate Parameters** tab and specify the certificate contents. See [Certificate Enrollment Object Certificate Parameters, on page 1514](#).
- This information is placed in the certificate and is readable by any party who receives the certificate from the router.
- Step 5** (Optional) Open the **Key** tab and specify the Key information. See [Certificate Enrollment Object Key Options, on page 1515](#).
- Step 6** (Optional) Click the **Revocation** tab, and specify the revocation options: See [Certificate Enrollment Object Revocation Options, on page 1517](#).
- Step 7** **Allow Overrides** of this object if desired. See [Object Overrides, on page 1460](#) for a full description of object overrides.
- Step 8** Click **Save**.

---

### What to do next

Associate and install the enrollment object on a device to create a trustpoint on that device.

### Related Topics

- [Installing a Certificate Using Self-Signed Enrollment](#) , on page 1579
- [Installing a Certificate using EST Enrollment](#), on page 1580
- [Installing a Certificate Using SCEP Enrollment](#), on page 1581
- [Installing a Certificate Using Manual Enrollment](#), on page 1581
- [Installing a Certificate Using a PKCS12 File](#), on page 1582

## Add Certificate Enrollment

### Procedure

- 
- Step 1** Enter the **Name**.
- Step 2** Paste the certificate information in the **IdP Certificate** field in PEM format.
- Note** If the certificate is dependent on a root or intermediate certificate, you must install the dependant certificates. See [Certificates, on page 1575](#).
- Step 3** Click **Save**.
- 

## Certificate Enrollment Object EST Options

### Secure Firewall Management Center Navigation Path

**Objects** > **Object Management**, then from the navigation pane choose **PKI** > **Cert Enrollment**. Click (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **CA Information** tab.

**Fields**

**Enrollment Type**—set to **EST**.

- 
- Note**
- EST enrollment type does not support EdDSA key.
  - EST's ability to auto-enroll a device when its certificate expires is not supported.
- 

**Enrollment URL**—The URL of the CA server to which devices should attempt to enroll.

Use an HTTPS URL in the form of **https://CA\_name:port**, where *CA\_name* is the host DNS name or IP address of the CA server. The *port* number is mandatory.

**Username**—The username to access the CA server.

**Password / Confirm Password**—The password to access the CA server.

**Fingerprint**—When retrieving the CA certificate using EST, you may enter the fingerprint for the CA server. Using the fingerprint to verify the authenticity of the CA server's certificate helps prevent an unauthorized party from substituting a fake certificate in place of the real one. Enter the **Fingerprint** for the CA server in hexadecimal format. If the value you enter does not match the fingerprint on the certificate, the certificate is rejected. Obtain the CA's fingerprint by contacting the server directly.

**Source Interface**—The interface that interacts with the CA server. By default, the diagnostic interface is displayed. To configure a data interface as the source interface, choose the respective security zone or interface group object.

**Ignore EST Server Certificate Validations**—The EST server certificate validation is done by default. Check the check box if you want to ignore threat defense validating EST server certificate.

## Certificate Enrollment Object SCEP Options

### Secure Firewall Management Center Navigation Path

**Objects > Object Management**, then from the navigation pane choose **PKI > Cert Enrollment**. Click (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **CA Information** tab.

**Fields**

**Enrollment Type**—set to **SCEP**.

**Enrollment URL**—The URL of the CA server to which devices should attempt to enroll.

Use an HTTP URL in the form of **http://CA\_name:port**, where *CA\_name* is the host DNS name or IP address of the CA server. The port number is mandatory.

- 
- Note** If the SCEP Server is referred with hostname/FQDN, configure DNS Server using FlexConfig object.
- 

If the CA cgi-bin script location at the CA is not the default (/cgi-bin/pkclient.exe), you must also include the nonstandard script location in the URL, in the form of **http://CA\_name:port/script\_location**, where *script\_location* is the full path to the CA scripts.

**Challenge Password / Confirm Password**—The password used by the CA server to validate the identity of the device. You can obtain the password by contacting the CA server directly or by entering the following address in a web browser: `http://URLHostName/certsrv/mscep/mscep.dll`. The password is good for 60 minutes from the time you obtain it from the CA server. Therefore, it is important that you deploy the password as soon as possible after you create it.

**Retry Period**—The interval between certificate request attempts, in minutes. Value can be 1 to 60 minutes. The default is 1 minute.

**Retry Count**—The number of retries that should be made if no certificate is issued upon the first request. Value can be 1 to 100. The default is 10.

**CA Certificate Source**—Specify how the CA certificate will be obtained.

- **Retrieve Using SCEP** (Default, and only supported option)—Retrieve the certificate from the CA server using the Simple Certificate Enrollment Process (SCEP). Using SCEP requires a connection between your device and the CA server. Ensure there is a route from your device to the CA server before beginning the enrollment process.

**Fingerprint**—When retrieving the CA certificate using SCEP, you may enter the fingerprint for the CA server. Using the fingerprint to verify the authenticity of the CA server's certificate helps prevent an unauthorized party from substituting a fake certificate in place of the real one. Enter the **Fingerprint** for the CA server in hexadecimal format. If the value you enter does not match the fingerprint on the certificate, the certificate is rejected. Obtain the CA's fingerprint by contacting the server directly, or by entering the following address in a web browser: `http://<URLHostName>/certsrv/mscep/mscep.dll`.

## Certificate Enrollment Object Certificate Parameters

Specify additional information in certificate requests sent to the CA server. This information is placed in the certificate and can be viewed by any party who receives the certificate from the router.

### Secure Firewall Management Center Navigation Path

**Objects > Object Management**, then from the navigation pane choose **PKI > Cert Enrollment**. Press (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **Certificate Parameters** tab.

### Fields

Enter all information using the standard LDAP X.500 format.

- **Include FQDN**—Whether to include the device's fully qualified domain name (FQDN) in the certificate request. Choices are:
  - **Use Device Hostname as FQDN**
  - **Don't use FQDN in certificate**
  - **Custom FQDN**—Select this and then specify it in the **Custom FQDN** field that displays.
- **Include Device's IP Address**—The interface whose IP address is included in the certificate request.
- **Common Name (CN)**—The X.500 common name to include in the certificate.

---

**Note** When enrolling a self-signed certificate you must specify the Common Name (CN) in the certificate parameters.

---

- **Organization Unit (OU)**—The name of the organization unit (for example, a department name) to include in the certificate.
- **Organization (O)**—The organization or company name to include in the certificate.
- **Locality (L)**—The locality to include in the certificate.
- **State (ST)**—The state or province to include in the certificate.
- **County Code (C)**—The country to include in the certificate. These codes conform to ISO 3166 country abbreviations, for example "US" for the United States of America.
- **Email (E)**—The email address to include in the certificate.
- **Include Device's Serial Number**—Whether to include the serial number of the device in the certificate. The CA uses the serial number to either authenticate certificates or to later associate a certificate with a particular device. If you are in doubt, include the serial number, as it is useful for debugging purposes.

## Certificate Enrollment Object Key Options

### Secure Firewall Management Center Navigation Path

**Objects > Object Management**, then from the navigation pane choose **PKI > Cert Enrollment**. Press (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **Key** tab.

### Fields

- **Key Type**—RSA, ECDSA, EdDSA.

---

**Note**

- For EST enrollment type, do not select EdDSA key as it is not supported.
- EdDSA is supported only in Site-to-Site VPN topologies.
- EdDSA is not supported as an identity certificate for the Remote Access VPN.

---

- **Key Name**—If the key pair you want to associate with the certificate already exists, this field specifies the name of that key pair. If the key pair does not exist, this field specifies the name to assign to the key pair that will be generated during enrollment. If you do not specify a name, the fully qualified domain name (FQDN) key pair is used instead.
- **Key Size**—If the key pair does not exist, defines the desired key size (modulus), in bits. The recommended size is 2048 bits. The larger the modulus size, the more secure the key. However, keys with larger modulus sizes take longer to generate (a minute or more when larger than 512 bits) and longer to process when exchanged.

**Important**

- On management center and threat defense Versions 7.0 and higher, you cannot enroll certificates with RSA key sizes smaller than 2048 bits and keys using SHA-1 with the RSA Encryption algorithm. However, you can use [PKI Enrollment of Certificates with Weak-Crypto](#) to allow certificates that use SHA-1 with RSA Encryption algorithm and smaller key size.
- You cannot generate RSA keys with sizes smaller than 2048 bits for threat defense 7.0, even when you enable the weak-crypto option.

- **Advanced Settings**—Select **Ignore IPsec Key Usage** if you do not want to validate values in the key usage and extended key usage extensions of IPsec remote client certificates. You can suppress key usage checking on IPsec client certificates. By default this option is not enabled.

**Note**

For site-to-site VPN connection, if you use a Windows Certificate Authority (CA), the default Application Policies extension is **IP security IKE intermediate**. If you are using this default setting, you must select the **Ignore IPsec Key Usage** option for the object you select. Otherwise, the endpoints cannot complete the site-to-site VPN connection.

**PKI Enrollment of Certificates with Weak-Crypto**

SHA-1 hashing signature algorithm, and RSA key sizes that are smaller than 2048 bits for certification are not supported on management center and threat defense Version 7.0 and higher. You cannot enroll certificates with RSA key sizes that are smaller than 2048 bits.

To override these restrictions on management center 7.0 managing threat defenses running Versions lesser than 7.0, you can use the enable weak-crypto option on the threat defense. We do not recommend you to permit weak-crypto keys, because, such keys are not as secure as the ones with higher key sizes.

**Note**

Threat Defense 7.0 or higher does not support generating RSA keys with sizes smaller than 2048 bits even when you permit weak-crypto.

To enable weak-crypto on the device, navigate to the **Devices > Certificates** page. Click the **Enable Weak-Crypto** (🔒) button provided against the threat defense device. When the weak-crypto option is enabled, the button changes to (🔓). By default, the weak-crypto option is disabled.

**Note**

When a certificate enrollment fails due to weak cipher usage, the management center displays a warning message prompting you to enable the weak-crypto option. Similarly, when you turn on the enable weak-crypto button, the management center displays a warning message before enabling weak-crypto configuration on the device.

### Upgrading Earlier Versions to Threat Defense 7.0

When you are upgrading to threat defense 7.0, the existing certificate configurations are retained. However, if those certificates have RSA keys smaller than 2048 bits and use SHA-1 encryption algorithm, they cannot be used to establish VPN connections. You must either procure a certificate with RSA key sizes bigger than 2048 bits or enable the permit weak-crypto option for VPN connections.

## Certificate Enrollment Object Revocation Options

Specify whether to check the revocation status of a certificate by choosing and configuring the method. Revocation checking is off by default, neither method (CRL or OCSP) is checked.

### Secure Firewall Management Center Navigation Path

**Objects > Object Management**, then from the navigation pane choose **PKI > Cert Enrollment**. Press (+) **Add Cert Enrollment** to open the **Add Cert Enrollment** dialog, and select the **Revocation** tab.

### Fields

- **Enable Certificate Revocation Lists**—Check to enable CRL checking.
  - **Use CRL distribution point from the certificate**—Check to obtain the revocation lists distribution URL from the certificate.
  - **Use static URL configured**—Check this to add a static, pre-defined distribution URL for revocation lists. Then add the URLs.

**CRL Server URLs**—The URL of the LDAP server from which the CRL can be downloaded.

URLs must start with **http://**. Include a port number in the URL. Enclose IPv6 addresses in square brackets, for example: *http://[0:0:0:0:18:0a01:7c16]*.

- **Enable Online Certificate Status Protocol (OCSP)**—Check to enable OCSP checking.

**OCSP Server URL**—The URL of the OCSP server checking for revocation if you require OCSP checks.

URLs must start with **http://**. Enclose IPv6 addresses in square brackets, for example: *http://[0:0:0:0:18:0a01:7c16]*.
- **Consider the certificate valid if revocation information cannot be reached**—Checked by default. Uncheck if you do not want to allow this.

## Policy List

Use the Configure Policy List page to create, copy, and edit policy list policy objects. You can create policy list objects to use when you are configuring route maps. When a policy list is referenced within a route map, all of the match statements within the policy list are evaluated and processed. Two or more policy lists can be configured with a route map. A policy list can also coexist with any other preexisting match and set statements that are configured within the same route map but outside of the policy list. When multiple policy lists perform matching within a route map entry, all policy lists match on the incoming attribute only.

You can use this object with threat defense devices.

## Procedure

- 
- Step 1** Select **Objects > Object Management** and choose **Policy List** from the table of contents.
- Step 2** Click **Add Policy List**.
- Step 3** Enter a name for the policy list object in the **Name** field. Object names are not case-sensitive.
- Step 4** Select whether to allow or block access for matching conditions from the **Action** drop-down list.
- Step 5** Click the **Interface** tab to distribute routes that have their next hop out of one of the interfaces specified.
- In the **Zones/Interfaces** list, add the zones that contain the interfaces through which the device communicates with the management station. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. The host will be configured on a device only if the device includes the selected interfaces or zones.
- Step 6** Click the **Address** tab to redistribute any routes that have a destination address that is permitted by a standard access list or prefix list.
- Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.
- Step 7** Click the **Next Hop** tab to redistribute any routes that have a next hop router address passed by one of the access lists or prefix lists specified.
- Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.
- Step 8** Click the **Route Source** tab to redistribute routes that have been advertised by routers and access servers at the address specified by the access lists or prefix list.
- Choose whether to use an **Access List** or **Prefix List** for matching and then enter or select the Standard Access List Objects or Prefix list objects you want to use for matching.
- Step 9** Click the **AS Path** tab to match a BGP autonomous system path. If you specify more than one AS path, then the route can match either AS path.
- Step 10** Click the **Community Rule** tab to enable matching of the BGP community or extended community with the specified community list objects or the extended community list objects respectively. If you specify more than one rule, the routes are verified against the rules until a matching permit or deny is met.
- a) To specify a community list to the rule, click **Edit** (✎) given in the **Selected Community List** field. The community lists appear under **Available Community List**. Select the required list, click **Add**, and then click **Ok**.
- To enable matching the BGP community exactly with the specified community, check the **Match the specified community exactly** check box.
- b) To add the extended community list, click **Edit** (✎) given in the **Selected Extended Community List** field. The extended community lists appear under the **Available Extended Community List**. Select the required list, click **Add**, and then click **Ok**.
- Note** The extended community lists are applicable only for configuring import or export of routes.
- Step 11** Click the **Metric & tag** tab to match the metric and security group tag of a route.

- a) Enter the metric values to use for matching in the **Metric** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295.
- b) Enter the tag values to use for matching in the **Tag** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.

**Step 12** If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).

**Step 13** Click **Save**.

---

## Port

Port objects represent different protocols in slightly different ways:

### TCP and UDP

A port object represents the transport layer protocol, with the protocol number in parentheses, plus an optional associated port or port range. For example: `TCP (6) /22`.

### ICMP and ICMPv6 (IPv6-ICMP)

A port object represents the Internet layer protocol plus an optional type and code. For example:  
`ICMP (1) : 3 : 3`.

You can restrict an ICMP or IPV6-ICMP port object by type and, if applicable, code. For more information on ICMP types and codes, see:

- <http://www.iana.org/assignments/icmp-parameters/icmp-parameters.xml>
- <http://www.iana.org/assignments/icmpv6-parameters/icmpv6-parameters.xml>

### Other

A port object can represent other protocols that do not use ports.

The system provides default port objects for well-known ports. You cannot modify or delete these default objects. You can create custom port objects in addition to the default objects.

You can use port objects and groups in various places in the system's web interface, including access control policies, identity rules, network discovery rules, port variables, and event searches. For example, if your organization uses a custom client that uses a specific range of ports and causes the system to generate excessive and misleading events, you can configure your network discovery policy to exclude monitoring those ports.

When using port objects, observe the following guidelines:

- You cannot add any protocol other than TCP or UDP for source port conditions in access control rules. Also, you cannot mix transport protocols when setting both source and destination port conditions in a rule.
- If you add an unsupported protocol to a port object group used in a source port condition, the rule where it is used does not take effect on the managed device when the configuration is deployed.
- If you create a port object containing both TCP and UDP ports, then add it as a source port condition in a rule, you cannot add a destination port, and vice versa.

# Creating Port Objects

## Procedure

---

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose **Port** from the list of object types.

**Step 3** Choose **Add Object** from the **Add Port** drop-down list.

Alternatively, you can clone an existing port object and edit the parameters to create a new port object. Click the **Clone** icon on the existing port object that you want to clone.

**Step 4** Enter a **Name**.

**Step 5** Choose a **Protocol**.

**Step 6** Depending on the protocol you chose, constrain by **Port**, or choose an ICMP **Type** and **Code**.

You can enter ports from **1** to **65535**. Use a hyphen to specify a port range. You must constrain the object by port if you chose to match **All** protocols, using the **Other** drop-down list.

**Step 7** Manage overrides for the object:

- If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
- If you want to add override values to this object, expand the Override section and click **Add**; see [Adding Object Overrides, on page 1462](#).

**Step 8** Click **Save**.

---

### What to do next

- If an active policy references your object, deploy configuration changes.

## Importing Port Objects

For details on importing port objects, see [Importing Objects, on page 1454](#).

## Prefix List

You can create prefix list objects for IPv4 and IPv6 to use when you are configuring route maps, policy maps, OSPF Filtering, or BGP Neighbor Filtering.

## Configure IPv6 Prefix List

Use the Configure IPv6 Prefix list page to create, copy and edit prefix list objects. You can create prefix list objects to use when you are configuring route maps, policy maps, OSPF Filtering, or BGP Neighbor Filtering.

You can use this object with threat defense devices.

## Procedure

- 
- Step 1** Select **Objects > Object Management** and choose **Prefix Lists > IPv6 Prefix List** from the table of contents.
  - Step 2** Click **Add Prefix List**.
  - Step 3** Enter a name for the prefix list object in the **Name** field on the **New Prefix List Object** window.
  - Step 4** Click **Add** on the **New Prefix List Object** window.
  - Step 5** Select the appropriate action, Allow or Block from the **Action** drop-down list, to indicate the redistribution access.
  - Step 6** Enter a unique number that indicates the position a new prefix list entry will have in the list of prefix list entries already configured for this object, in the **Sequence No.** field. If left blank, the sequence number will default to five more than the largest sequence number currently in use.
  - Step 7** Specify the IPv6 address in the IP address/mask length format in the **IP address** field. The mask length must be a valid value between 1-128.
  - Step 8** Enter the minimum prefix length in the **Minimum Prefix Length** field. The value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.
  - Step 9** Enter the maximum prefix length in the **Maximum Prefix Length** field. The value must be greater than or equal to the Minimum Prefix Length, if present, or greater than the mask length if the Minimum Prefix Length is not specified.
  - Step 10** Click **Add**.
  - Step 11** If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
  - Step 12** Click **Save**.
- 

## Configure IPv4 Prefix List

Use the Configure IPv4 Prefix list page to create, copy and edit prefix list objects. You can create prefix list objects to use when you are configuring route maps, policy maps, OSPF Filtering, or BGP Neighbor Filtering. You can use this object with threat defense devices.

## Procedure

- 
- Step 1** Select **Objects > Object Management** and choose **Prefix Lists > IPv4 Prefix List** from the table of contents.
  - Step 2** Click **Add Prefix List**.
  - Step 3** Enter a name for the prefix list object in the **Name** field on the **New Prefix List Object** window.
  - Step 4** Click **Add**.
  - Step 5** Select the appropriate action, Allow or Block from the **Action** drop-down list, to indicate the redistribution access.
  - Step 6** Enter a unique number that indicates the position a new prefix list entry will have in the list of prefix list entries already configured for this object, in the **Sequence No.** field. If left blank, the sequence number will default to five more than the largest sequence number currently in use.

- Step 7** Specify the IPv4 address in the IP address/mask length format in the **IP address** field. The mask length must be a valid value between 1- 32.
- Step 8** Enter the minimum prefix length in the **Minimum Prefix Length** field. The value must be greater than the mask length and less than or equal to the Maximum Prefix Length, if specified.
- Step 9** Enter the maximum prefix length in the **Maximum Prefix Length** field. The value must be greater than or equal to the Minimum Prefix Length, if present, or greater than the mask length if the Minimum Prefix Length is not specified.
- Step 10** Click **Add**.
- Step 11** If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
- Step 12** Click **Save**.
- 

## Route Map

Route maps are used when redistributing routes into any routing process. They are also used when generating a default route into routing process. A route map defines which of the routes from the specified routing protocol are allowed to be redistributed into the target routing process. Configure a route map, to create a new route map entry for a Route Map object or to edit an existing one.

You can use this object with threat defense devices.

### Before you begin

A Route Map may use one or mores of these objects; it is not mandatory to add all these objects. Create and use any of these objects as required, to configure your route map.

- Add ACLs.
- Add Prefix Lists.
- Add AS Path.
- Add Community Lists.
- Add Extended Community Lists.

---

**Note** The extended community lists are applicable only for configuring import or export of routes.

---

- Add Policy Lists.

### Procedure

---

- Step 1** Select **Objects > Object Management** and choose **Route Map** from the table of contents.
- Step 2** Click **Add Route Map**.

**Step 3** Click **Add** on the **New Route Map Object** window.

**Step 4** In the **Sequence No.** field, enter a number, from 0 through 65535, that indicates the position a new route map entry has in the list of route maps entries already configured for this route map object.

**Note** We recommend that you number clauses in intervals of at least 10 to reserve numbering space in case you want to insert clauses in the future.

**Step 5** Select the appropriate action, Allow or Block, from the **Redistribution** drop-down list, to indicate the redistribution access.

**Step 6** Click the **Match Clauses** tab to match (routes/traffic) based on the following criteria, which you select in the table of contents:

- **Security Zones** —Match traffic based on the (ingress/egress) interfaces. You can select zones and add them, or type in interface names and add them.
- **IPv4** — Match IPv4 (routes/traffic) based on the following criteria; select the tab to define the criteria.
  - a. Click the **Address** tab to match routes based on the route address. For IPv4 addresses, choose whether to use an Access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
  - b. Click the **Next Hop** tab to match routes based on the next hop address of a route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
  - c. Click the **Route Source** tab to match routes based on the advertising source address of the route. For IPv4 addresses, choose whether to use an access list or Prefix list for matching from the drop-down list and then enter or select the ACL objects or Prefix list objects you want to use for matching.
- **IPv6** —Match IPv6 (routes/traffic) based on the route address, next-hop address or advertising source address of route.
- **BGP** —Match BGP (routes/traffic) based on the following criteria; select the tab to define the criteria.
  - a. Click the **AS Path** tab to enable matching the BGP autonomous system path access list with the specified path access list. If you specify more than one path access list, then the route can match either path access list.
  - b. Click the **Community List** tab to enable matching of the BGP community or extended community with the specified community list objects or the extended community list objects respectively.
    - To specify a community list to the rule, click **Edit** (✎) given in the **Selected Community List** field. The community lists appears under **Available Community List**. Select the required list, click **Add**, and then click **Ok**. For information on how to create community list objects, see [Community List, on page 1476](#)
    - To add the extended community list, click **Edit** (✎) given in the **Selected Extended Community List** field. The extended community lists appears under the **Available Extended Community List**. Select the required list, click **Add**, and then click **Ok**. For information on how to create extended community list objects, see [Extended Community, on page 1477](#).

To enable matching the BGP community exactly with the specified community list objects, check the **Match the specified community exactly** check box. This option is not applicable for the extended community list.

**Note** If you specify more than one rule, the routes are verified against the rules until a matching permit or deny condition is met. Any route that does not match at least one Match community will not be advertised for outbound route maps.

- c. Click the **Policy List** tab to configure a route map to evaluate and process a BGP policy. When multiple policy lists perform matching within a route map entry, all policy lists match on the incoming attribute only.
- **Others**—Match routes or traffic based on the following criteria.
  - a. Enter the metric values to use for matching in the **Metric Route Value** field, to enable matching the metric of a route. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified metric. The metric values can range from 0 to 4294967295.
  - b. Enter the tag values to use for matching in the **Tag Values** field. You can enter multiple values separated by commas. This setting allows you to match any routes that have a specified security group tag. The tag values can range from 0 to 4294967295.
  - c. Check the appropriate **Route Type** option to enable matching of the route type. Valid route types are External1, External2, Internal, Local, NSSA-External1, and NSSA-External2. You can choose more than one route type from the list.

### Step 7

Click the **Set Clauses** tab to set routes/traffic based on the following criteria, which you select in the table of contents:

- **Metric Values**—Set either Bandwidth, all of the values or none of the values.
  - a. Enter a metric value or bandwidth in Kbits per second in the **Bandwidth** field. Valid values are an integer value in the range from 0 to 4294967295.
  - b. Select to specify the type of metric for the destination routing protocol, from the **Metric Type** drop-down list. Valid values are : internal, type-1, or type-2.
- **BGP Clauses**—Set BGP routes based on the following criteria; select the tab to define the criteria.
  - a. Click the **AS Path** tab to modify an autonomous system path for BGP routes.
    - 1. Enter an AS path number in the **Prepend AS Path** field to prepend an arbitrary autonomous system path string to BGP routes. Usually the local AS number is prepended multiple times, increasing the autonomous system path length. If you specify more than one AS path number then the route can prepend either AS number.
    - 2. Enter an AS path number in the **Prepend Last AS to AS Path** field to prepend the AS path with the last AS number. Enter a value for the AS number from 1 to 10.
    - 3. Check the **Convert route tag into AS path** check box to convert the tag of a route into an autonomous system path.
  - b. Click the **Community List** tab to set the community attributes:
 

Under **Specific Community**:

    - 1. Click the **None** radio button, to remove the community attribute from the prefixes that pass the route map.

2. Click the **Specific Community** radio button, to enter a community number, if applicable. Valid values are from 1 to 4294967295.
3. Check the **Add to existing communities** check box, to add the community to the already existing communities.
4. Select the **Internet**, **No-Advertise**, or **No-Export** check-boxes to use one of the well-known communities.

Under **Specific Extended Community**, in the **Route Target** field, enter the route target number in *ASN:nn* format:

- You can enter values that ranges from 1:1 to 65534:65535.  
You can add a single route target or a set of route targets separated by commas in a single entry. For example, *1:2,1:4,1:6*.
  - You can have a maximum of 8 route targets in an entry.
  - You cannot have redundant route target entries across route maps.
- c. Click the **Others** tab to set additional attributes.
    1. Check the **Set Automatic Tag** check-box to automatically compute the tag value.
    2. Enter a preference value for the autonomous system path in the **Set Local Preference** field. Enter a value between 0 and 4294967295.
    3. Enter a BGP weight for the routing table in the **Set Weight** field. Enter a value between 0 and 65535.
    4. Select to specify the BGP origin code. Valid values are **Local IGP** Local IGP and **Incomplete**.
    5. In the IPv4 Settings section, specify a next hop IPv4 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv4 address then the packets can output at either IP address.  
Select to specify an IPv4 prefix list in the **Prefix List** drop-down list.
    6. In the IPv6 Settings section, specify a next hop IPv6 address of the next hop to which packets are output. It need not be an adjacent router. If you specify more than one IPv6 address, then the packets can output at any of the IP addresses.  
Select to specify an IPv6 prefix in the **Prefix List** drop-down list.

**Step 8** Click **Add**.

**Step 9** If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).

**Step 10** Click **Save**.

---

# Security Intelligence

Security Intelligence functionality requires the IPS license (for threat defense devices) or the Protection license (all other device types).

Security Intelligence *lists* and *feeds* are collections of IP addresses, domain names, and URLs that you can use to quickly filter traffic that matches an entry on a list or feed.

- A list is a static collection that you manage manually.
- A feed is a dynamic collection that updates on an interval over HTTP or HTTPS.

Security Intelligence lists/feeds are grouped into:

- DNS (Domain names )
- Network (IP addresses)
- URLs

## System-Provided Feeds

Cisco provides the following feeds as Security Intelligence objects:

- Security Intelligence feeds updated regularly with the latest threat intelligence from Talos:
  - Cisco-DNS-and-URL-Intelligence-Feed (under DNS Lists and Feeds)
  - Cisco-Intelligence-Feed (for IP addresses, under Network Lists and Feeds)

You cannot delete the system-provided feeds, but you can change the frequency of (or disable) their updates.

- Cisco-TID-Feed (under Network Lists and Feeds)

This feed is not used in the Security Intelligence tab of the access control policy.

Instead, you must enable and configure Secure Firewall threat intelligence director to use this feed, which is a collection of TID observables data.

Use this object to set how frequently this data is published to TID elements.

## Predefined Lists: Global Block Lists and Global Do Not Block Lists

The system ships with predefined global Block lists and Do Not Block lists for domains (DNS), IP addresses (Networks), and URLs.

These lists are empty until you populate them. To build these lists, see [Global and Domain Security Intelligence Lists, on page 1527](#).

By default, access control and DNS policies use these lists as part of Security Intelligence.

## Custom Feeds

You can use third-party feeds, or use a custom internal feed to easily maintain an enterprise-wide Block list in a large deployment with multiple Secure Firewall Management Center appliances.

See [Custom Security Intelligence Feeds, on page 1532](#).

### Custom Lists

Custom lists can augment and fine-tune feeds and the Global lists.

See [Custom Security Intelligence Lists, on page 1533](#).

### Where Security Intelligence Lists and Feeds Are Used

- IP address and address blocks—Use Block and Do Not Block lists in access control policies, as part of Security Intelligence.
- Domain Names—Use Block and Do Not Block lists in DNS policies, as part of Security Intelligence.
- URLs—Use Block and Do Not Block lists in access control policies, as part of Security Intelligence. You can also use URL lists in access control and QoS rules, whose analysis and traffic handling phases occur after Security Intelligence.

## How to Modify Security Intelligence Objects

To add or delete entries on a Block list, Do Not Block list, feed, or sinkhole object:

| Object Type                                                                                                | Edit Capabilities                                                              | Requires Redeploy After Edit? |
|------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|-------------------------------|
| Custom Block and Do Not Block lists                                                                        | Upload new and replacement lists using the object manager.                     | No                            |
| Default (but custom-populated) Block lists and Do Not Block lists: Global, descendant, and domain-specific | Add entries using the context menu or delete entries using the object manager. | No                            |
| System-provided Intelligence Feeds                                                                         | Disable or change update frequency using the object manager.                   | No                            |
| Custom feeds                                                                                               | Fully modify using the object manager.                                         | No                            |
| Sinkhole                                                                                                   | Fully modify using the object manager.                                         | Yes                           |

## Global and Domain Security Intelligence Lists

The management center includes Global Block and Do-Not-Block lists, which enable you to use Security Intelligence to consistently block specific connections or exempt certain connections from being blocked, allowing them to be evaluated by other threat detection processes you have configured.

For example, if you notice a set of routable IP addresses in intrusion events associated with exploit attempts, you can immediately block those IP addresses. Although it may take a few minutes for your changes to propagate, you do not have to redeploy.

By default, Access control and DNS policies use these Global lists, which apply to all security zones. You can opt not to use these lists on a per-policy basis.

---

**Note** These options apply to Security Intelligence only. Security Intelligence cannot block traffic that has already been fastpathed. Similarly, adding an item to a Security Intelligence Do Not Block list does not automatically trust or fastpath matching traffic. For more information, see [About Security Intelligence, on page 1945](#).

---

## Security Intelligence Lists and Multitenancy

Multitenancy adds:

- Domain lists—Block or Do Not Block lists whose contents apply to a particular subdomain only. The Global lists are Domain lists for the Global domain.
- Descendant Domain lists—Block or Do Not Block lists that aggregate the Domain lists of the current domain's descendants.

### Domain Lists

In addition to being able to access (but not edit) the Global lists, each subdomain has its own named lists, the contents of which apply only to that subdomain. For example, a subdomain named Company A owns:

- Domain Block list - Company A and Domain Do Not Block list - Company A
- Domain Block list for DNS - Company A, Domain Do Not Block list for DNS - Company A
- Domain Block list for URL - Company A, Domain Do Not Block list for URL - Company A

Any administrator at or above the current domain can populate these lists. You can use the context menu to add an item to the Block or Do Not Block list in the current and all descendant domains. However, only an administrator in the associated domain can remove an item from a Domain list.

For example, a Global administrator could choose to add the same IP address to the Block list in the Global domain and Company A's domain, but not add it to the Block list in Company B's domain. This action would add the same IP address to:

- Global Block list (where it can be removed only by Global administrators)
- Domain Block list - Company A (where it can be removed only by Company A administrators)

### Descendant Domain Lists

A Descendant Domain list is a Do Not Block list or Block list that aggregates the Domain lists of the current domain's descendants. Leaf domains do not have Descendant Domain lists.

Descendant Domain lists are useful because a higher-level domain administrator can enforce general Security Intelligence settings, while still allowing subdomain users to add items to a Block or Do Not Block list in their own deployment.

For example, the Global domain has the following Descendant Domain lists:

- Descendant Block lists - Global, Descendant Do Not Block lists - Global
- Descendant Block lists for DNS - Global, Descendant Do Not Block lists for DNS - Global

- Descendant Block lists for URL - Global, Descendant Do Not Block lists for URL - Global

**Note** Descendant Domain lists do not appear in the object manager because they are symbolic aggregations, not hand-populated lists. They appear where you can use them: in access control and DNS policies.

## Delete Entries from Global Security Intelligence Lists

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- Step 2** Click **Security Intelligence**.
- Step 3** Click the appropriate option:
- **Network Lists and Feeds** (for IP addresses)
  - **DNS Lists and Feeds** (for domain names)
  - **URL Lists and Feeds**
- Step 4** Click the pencil beside the Global Block or Global Do-Not-Block list.
- Step 5** Click the trash button beside the entry to delete.
- 

## List and Feed Updates for Security Intelligence

List and feed updates replace the existing list or feed file with the contents of the new file. Contents of existing and new files are not merged.

If the system downloads a corrupt feed or a feed with no recognizable entries, the system continues using the old feed data (unless it is the first download). However, if the system can recognize even one entry in the feed, it uses the entries it can recognize.

By default, each feed updates the Management Center every two hours; you can modify this frequency. Any updates the Management Center receives are passed immediately to managed devices. In addition, managed devices poll the management center every 30 minutes for changes. You cannot modify this frequency.

To modify feed update intervals, see [Changing the Update Frequency for Security Intelligence Feeds, on page 1529](#).

## Changing the Update Frequency for Security Intelligence Feeds

You can specify the intervals at which the management center updates Security Intelligence Feeds.

For details about feed updates, see [List and Feed Updates for Security Intelligence, on page 1529](#).

## Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- Step 2** Expand the **Security Intelligence** node, then choose the feed type whose frequency you want to change. The system-provided URL feed is combined with the domain feed under **DNS Lists and Feeds**.
- Step 3** Next to the feed you want to update, click **Edit** (✎).  
If **View** (👁) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.
- Step 4** Edit the **Update Frequency**.
- Step 5** Click **Save**.
- 

# Custom Security Intelligence Lists and Feeds

## Custom Lists and Feeds: Requirements

### List and Feed Formatting

Each list or feed must be a simple text file no larger than 500MB. List files must have the .txt extension. Include one entry or comment per line: one IP address, one URL, one domain name.

---

**Tip** The number of entries you can include is limited by the maximum size of the file. For example, a URL list with no comments and an average URL length of 100 characters (including Punycode or percent Unicode representations and newlines) can contain more than 5.24 million entries.

---

In a DNS list entry, you can specify an asterisk (\*) wildcard character for a domain label. All labels match the wildcard. For example, an entry of `www.example.*` matches both `www.example.com` and `www.example.co`.

If you add comment lines within the source file, they must start with the pound (#) character. If you upload a source file with comments, the system removes your comments during upload. Source files you download contain all your entries without your comments.

### Feed Requirements

When you configure a feed, you specify its location using a URL; the URL cannot be Punycode-encoded.

For feed update intervals of 30 minutes or less, you must specify an MD5 URL. This prevents frequent downloads of unchanged feeds. If your feed server does not provide an MD5 URL, you must use a download interval of at least 30 minutes.

If you use an MD5 checksum, the checksum must be stored in a simple text file with only the checksum. Comments are not supported.

## URL Lists and Feeds: URL Syntax and Matching Criteria

Security Intelligence URL lists and feeds, including custom lists and feeds and entries in the global Block list and Do Not Block list, can include the following, which have the matching behavior as described:

- Hostnames

For example, **www.example.com**.

- URLs

**example.com** matches **example.com** and all subdomains, including **www.example.com**, **eu.example.com**, **example.com/abc**, and **www.example.com/def** -- but NOT **example.co.uk** or **examplexyz.com** or **example.com.malicious-site.com**

You can also include an entire URL path, such as

**https://www.cisco.com/c/en/us/products/security/firewalls/index.html**

---

**Note** You can create a custom URL, Network, and DNS feeds, wherein, you can add the username and password inside the URL itself, for example:

**https://admin:password@server.domain.com/list.txt**

However, if your password contain special characters such as a colon (:) or an at sign (@), the transmission would fail. Ensure that your password does not have any special characters. Alternatively, you could use an encoded password in the URL.

---

- A slash at the end of a URL to specify an exact match

**example.com/** matches ONLY **example.com**; it does NOT match **www.example.com** or any other URL.

- A wildcard (\*) to represent any domain in a URL

An asterisk can represent a complete domain string separated by dots, but not a partial domain string, and not any part of the URL following the first slash.

Valid examples:

- **\*.example.com**
- **www.\*.com**
- **example.\***

(This will match **example.com** and **example.org** and **example.de**, for example, but NOT **example.co.uk**)

- **\*.example.\***
- **example.\*/**

Invalid examples:

- **example\*.com**
- **example.com/\***

- IP addresses (IPv4)

For IPv6 addresses, or to use ranges or CIDR notation, use the Security Intelligence Network object.

You can include one or more wildcards representing an octet, for example 10.10.10.\* or 10.10.\*.\*.

See also [Custom Security Intelligence Lists, on page 1533](#).

## Custom Security Intelligence Feeds

Custom or third-party Security Intelligence feeds allow you to augment the system-provided Intelligence Feeds with other regularly-updated reputable Block lists and Do Not Block lists on the Internet. You can also set up an internal feed, which is useful if you want to update multiple Secure Firewall Management Center appliances in your deployment using one source list.

---

**Note** You cannot add address blocks to Block or Do Not Block lists using a /0 netmask in a Security Intelligence feed. If you want to monitor or block all traffic targeted by a policy, use an access control rule with the **Monitor** or **Block** rule action, respectively, and a default value of `any` for the **Source Networks** and **Destination Networks**.

---

You also can configure the system to use an MD5 checksum to determine whether to download an updated feed. If the checksum has not changed since the last time the system downloaded the feed, the system does not need to re-download it. You may want to use MD5 checksums for internal feeds, especially if they are large.

---

**Note** The system does **not** perform peer SSL certificate verification when downloading custom feeds, nor does the system support the use of certificate bundles or self-signed certificates to verify the remote peer.

---

If you want strict control over when the system updates a feed from the Internet, you can disable automatic updates for that feed. However, automatic updates ensure the most up-to-date, relevant data.

Manually updating Security Intelligence feeds updates all feeds, including the Intelligence Feeds.

See complete requirements at [Custom Lists and Feeds: Requirements, on page 1530](#).

## Creating Security Intelligence Feeds

You must have the IPS license (for threat defense devices) or the Protection license (all other device types).

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Expand the **Security Intelligence** node, then choose a feed type you want to add.
  - Step 3** Click the option appropriate to the feed type you chose above:
    - **Add Network Lists and Feeds** (for IP addresses)
    - **Add DNS Lists and Feeds**
    - **Add URL Lists and Feeds**

- Step 4** Enter a **Name** for the feed.
- Step 5** Choose **Feed** from the **Type** drop-down list.
- Step 6** Enter a **Feed URL**.
- Step 7** Enter an **MD5 URL**.

This is used to determine whether the feed contents have changed since the last update, so the system does not download unchanged feeds.

MD5 URL is required for update intervals shorter than 30 minutes.

If your feed server does not provide an MD5 URL, you must choose an interval of at least 30 minutes.

- Step 8** Choose an **Update Frequency**.
- Step 9** Click **Save**.

Unless you disabled feed updates, the system attempts to download and verify the feed.

---

## Manually Updating Security Intelligence Feeds

You must have the IPS license (for threat defense devices) or the Protection license (all other device types).

### Before you begin

At least one device must already be added to the management center.

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- Step 2** Expand the **Security Intelligence** node, then choose a feed type.
- Step 3** Click **Update Feeds**, then confirm.
- Step 4** Click **OK**.

---

After the Secure Firewall Management Center downloads and verifies the feed updates, it communicates any changes to its managed devices. Your deployment begins filtering traffic using the updated feeds.

## Custom Security Intelligence Lists

Security Intelligence lists are simple static lists of IP addresses and address blocks, URLs, or domain names that you manually upload to the system. Custom lists are useful if you want to augment and fine-tune feeds or one of the global lists, for a single Secure Firewall Management Center's managed devices.

For example, if a reputable feed improperly blocks your access to vital resources but is overall useful to your organization, you can create a custom Do Not Block list that contains only the improperly classified IP addresses, rather than removing the IP address feed object from the access control policy's Block list.

---

**Note** You cannot add address blocks to a Block or Do Not Block list using a /0 netmask in a Security Intelligence list. If you want to monitor or block all traffic targeted by a policy, use an access control rule with the **Monitor** or **Block** rule action, respectively, and a default value of `any` for the **Source Networks** and **Destination Networks**.

---

Regarding list entry formatting, note the following:

- Netmasks for address blocks can be integers from 0 to 32 or 0 to 128, for IPv4 and IPv6, respectively.
- Unicode in domain names must be encoded in Punycode format, and are case insensitive.
- Characters in domain names are case-insensitive.
- Unicode in URLs should be encoded in percent-encoding format.
- Characters in URL subdirectories are case-sensitive.
- List entries that start with the pound sign (#) are treated as comments.
- See additional formatting requirements at [Custom Lists and Feeds: Requirements, on page 1530](#).

Regarding matching list entries, note the following:

- The system matches sub-level domains if a higher-level domain exists in a URL or DNS list. For example, if you add `example.com` to a DNS list, the system matches both `www.example.com` and `test.example.com`.
- The system does not perform DNS lookups (forward or reverse) on DNS or URL list entries. For example, if you add `http://192.168.0.2` to a URL list, and it resolves to `http://www.example.com`, the system only matches `http://192.168.0.2`, not `http://www.example.com`.

## Uploading New Security Intelligence Lists to the Secure Firewall Management Center

To modify a Security Intelligence list, you must make your changes to the source file and upload a new copy. You cannot modify the file's contents using the web interface. If you do not have access to the source file, download a copy from the system.

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Expand the **Security Intelligence** node, then choose a list type.
  - Step 3** Click the option appropriate to the list you chose above:
    - **Add Network Lists and Feeds** (for IP addresses)
    - **Add DNS Lists and Feeds**
    - **Add URL Lists and Feeds**
  - Step 4** Enter a **Name**.
  - Step 5** From the **Type** drop-down list, choose **List**.
  - Step 6** Click **Browse** to browse to the list `.txt` file, then click **Upload**.

**Step 7** Click **Save**.

---

#### What to do next

You do not need to redeploy these changes to take effect. If you want to delete an entry from the list, see [Delete Entries from Global Security Intelligence Lists, on page 1529](#).

## Updating Security Intelligence Lists

### Procedure

---

**Step 1** Choose **Objects > Object Management**.

**Step 2** Expand the **Security Intelligence** node, then choose a list type.

**Step 3** Next to the list you want to update, click **Edit** (✎).

If **View** (👁) appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

**Step 4** If you need a copy of the list to edit, click **Download**, then follow your browser's prompts to save the list as a text file.

**Step 5** Make changes to the list as necessary.

**Step 6** On the Security Intelligence pop-up window, click **Browse** to browse to the modified list, then click **Upload**.

**Step 7** Click **Save**.

---

#### What to do next

You do not need to redeploy these changes to take effect. If you want to delete an entry from the list, see [Delete Entries from Global Security Intelligence Lists, on page 1529](#).

## Sinkhole

A sinkhole object represents either a DNS server that gives non-routable addresses for all domain names within the sinkhole, or an IP address that does not resolve to a server. You can reference the sinkhole object within a DNS policy rule to redirect matching traffic to the sinkhole. You must assign the object both an IPv4 address and an IPv6 address.

## Creating Sinkhole Objects

You must have the IPS license (for threat defense devices) or the Protection license (all other device types).

### Procedure

---

**Step 1** Choose **Objects > Object Management**.

- Step 2** Choose **Sinkhole** from the list of object types.
- Step 3** Click **Add Sinkhole**.
- Step 4** Enter a **Name**.
- Step 5** Enter the **IPv4 Address** and **IPv6 Address** of your sinkhole.
- Step 6** You have the following options:
- If you want to redirect traffic to a sinkhole server, choose **Log Connections to Sinkhole**.
  - If you want to redirect traffic to a non-resolving IP address, choose **Block and Log Connections to Sinkhole**.
- Step 7** If you want to assign an Indication of Compromise (IoC) type to your sinkhole, choose one from the **Type** drop-down.
- Step 8** Click **Save**.
- 

## SLA Monitor

Each Internet Protocol Service Level Agreement (SLA) monitor defines a connectivity policy to a monitored address and tracks the availability of a route to the address. The route is periodically checked for availability by sending ICMP echo requests and waiting for the response. If the requests time out, the route is removed from the routing table and replaced with a backup route. SLA monitoring jobs start immediately after deployment and continue to run unless you remove the SLA monitor from the device configuration (that is, they do not age out). The Internet Protocol Service Level Agreement (SLA) Monitor Object is used in the Route Tracking field of an IPv4 Static Route Policy. IPv6 routes do not have the option to use SLA monitor via route tracking.

You can use these objects with threat defense devices.

### Procedure

---

- Step 1** Select **Objects > Object Management** and choose **SLA Monitor** from the table of contents.
- Step 2** Click **Add SLA Monitor**.
- Step 3** Enter a name for the object in the **Name** field.
- Step 4** (Optional) Enter a description for the object in the **Description** field.
- Step 5** Enter the frequency of ICMP echo request transmissions, in seconds, in the **Frequency** field. Valid values range from 1 to 604800 seconds (7 days). The default is 60 seconds.
- Note** The frequency cannot be less than the timeout value; you must convert frequency to milliseconds to compare the values.
- Step 6** Enter the ID number of the SLA operation in the **SLA Monitor ID** field. Values range from 1 to 2147483647. You can create a maximum of 2000 SLA operations on a device. Each ID number must be unique to the policy and the device configuration.
- Step 7** Enter the amount of time that must pass after an ICMP echo request before a rising threshold is declared, in milliseconds, in the **Threshold** field. Valid values range from 0 to 2147483647 milliseconds. The default is 5000 milliseconds. The threshold value is used only to indicate events that exceed the defined value. You can

use these events to evaluate the proper timeout value. It is not a direct indicator of the reachability of the monitored address.

**Note** The threshold value should not exceed the timeout value.

**Step 8** Enter the amount of time that the SLA operation waits for a response to the ICMP echo requests, in milliseconds, in the **Timeout** field. Values range from 0 to 604800000 milliseconds (7 days). The default is 5000 milliseconds. If a response is not received from the monitored address within the amount of time defined in this field, the static route is removed from the routing table and replaced by the backup route.

**Note** The timeout value cannot exceed the frequency value (adjust the frequency value to milliseconds to compare the numbers).

**Step 9** Enter the size of the ICMP request packet payload, in bytes, in the **Data Size** field. Values range from 0 to 16384 bytes. The default is 28 bytes, which creates a total ICMP packet of 64 bytes. Do not set this value higher than the maximum allowed by the protocol or the Path Maximum Transmission Unit (PMTU). For purposes of reachability, you might need to increase the default data size to detect PMTU changes between the source and the target. A low PMTU can affect session performance and, if detected, might indicate that the secondary path should be used.

**Step 10** Enter a value for type of service (ToS) defined in the IP header of the ICMP request packet in the **ToS** field. Values range from 0 to 255. The default is 0. This field contains information such as delay, precedence, reliability, and so on. It can be used by other devices on the network for policy routing and features such as committed access rate.

**Step 11** Enter the number of packets that are sent in the **Number of Packets** field. Values range from 1 to 100. The default is 1 packet.

**Note** Increase the default number of packets if you are concerned that packet loss might falsely cause the Secure Firewall Threat Defense device to believe that the monitored address cannot be reached.

**Step 12** Enter the IP address that is being monitored for availability by the SLA operation, in the **Monitored Address** field.

**Step 13** The **Available Zones** list displays both zones and interface groups. In the **Zones/Interfaces** list, add the zones or interface groups that contain the interfaces through which the device communicates with the management station. To specify a single interface, you need to create a zone or the interface groups for the interface; see [Create Security Zone and Interface Group Objects, on page 910](#). The host will be configured on a device only if the device includes the selected interfaces or zones.

**Step 14** Click **Save**.

---

## Time Range

Use time range objects to define time periods that you will use to determine when rules apply.

---

**Note** Time-based ACLs is supported in Snort 3 also from management center 7.0 onwards.

---

## Creating Time Range Objects

If you want a policy to apply only during a specified time range, create a time range object, then specify that object in the policy. Note that this object works on threat defense devices only.

You can specify time range objects only in policy types listed at the bottom of this topic.

---

**Note** The timezone represents the device's local time and is used ONLY for applying the time ranges in rules in the policies that support the time ranges. The timezone does not change the configured time of the device. To verify the configuration, in the threat defense CLI, use the **show time-range timezone** and **show time** commands (see the [Cisco Secure Firewall Threat Defense Command Reference](#) guide). In addition, the timezone of a chassis overrides the management center timezone.

---

### Before you begin

Time ranges are applied based on the time zone associated with the device that processes the traffic. By default, this is UTC. To change the time zone associated with a device, go to **Device > Platform Settings**.

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Choose **Time Range** from the list of object types.
  - Step 3** Click **Add Time Range**.
  - Step 4** Enter values.

Observe the following guidelines:

- If you see a red error box around the object name you have entered, mouse over the **Name** field to see naming restrictions.
- All times are in UTC, unless you specify a time zone for the device in **Device > Platform Settings**.
- Enter times using a 24-hour clock. For example, enter 1:30 PM as 13:30.
- To specify a single continuous range, such as typical weekend hours (Fridays at 5pm through Mondays at 8am, including evenings and nights), choose Range Type **Range**.
- To specify part of multiple days, such as Monday through Friday from 8am to 5pm (excluding evenings, nights, and early mornings every day), choose Range Type **Daily Interval**.
- You can specify up to 28 time periods in a single object.
- To specify multiple noncontiguous times of day or different hours for different days, create multiple recurring intervals. For example, to apply a policy at all times other than standard working hours, create a single time range object with the following two recurring intervals:
  - A Daily Interval for Monday through Friday from 5pm through 8am, and
  - A Range recurring interval for Friday at 5pm through Monday at 8am.

**Step 5** Click **Save**.

---

### What to do next

Configure time ranges in any of the following:

- Access control rules
- Prefilter rules
- Tunnel rules
- VPN group policy

In a VPN group policy object, specify the time range object using the **Access Hours** field. For details, see [Configure Group Policy Objects, on page 1561](#) and [Group Policy Advanced Options, on page 1567](#).

## Time Zone

To specify a local time zone for a managed device, create a time zone object and specify it in the device platform settings policy assigned to the device.

This device local time is used **ONLY** for applying time ranges in rules in policies that support time ranges, such as access control, prefilter, and VPN Group policies. If you do not assign a time zone to a device, UTC is used by default when applying time ranges in these policies. No other functionality in the system uses the time zone specified in a time zone object.

Time zone objects are supported only for threat defense devices.

---

**Note** Time-based ACLs is supported in Snort 3 also from management center 7.0 onwards.

---

## Tunnel Zone

A *tunnel zone* represents certain types of plaintext, passthrough tunnels that you explicitly tag for special analysis. A tunnel zone is not an interface object, even though you can use it as an interface constraint in some configurations.

For detailed information, see [Tunnel Zones and Prefiltering, on page 1988](#).

## URL

---

**Important** For best practices for using this and similar options in Security Intelligence configurations and for URL rules in access control and QoS policies, see [Manual URL Filtering Options, on page 1934](#).

---

A URL object defines a single URL or IP address, whereas a URL group object can define more than one URL or address. You can use URL objects and groups in various places in the system's web interface, including access control policies and event searches.

When creating URL objects, keep the following points in mind:

- If you do not include a path (that is, there are no / characters in the URL), the match is based on the server's hostname only. If you include one or more / character, the entire URL string is used for a substring match. Then, a URL is considered a match if any of the following are true:
  - The string is at the beginning of the URL.
  - The string follows a dot.
  - The string contains a dot in the beginning.
  - The string follows the `://` characters.

For example, `ign.com` matches `ign.com` or `www.ign.com`, but not `versign.com`.

---

**Note** We recommend that you do not use manual URL filtering to block or allow individual web pages or parts of sites (that is, URL strings with / characters), as servers can be reorganized and pages moved to new paths.

---

- The system disregards the encryption protocol (HTTP vs HTTPS). In other words, if you block a website, both HTTP and HTTPS traffic to that website is blocked, unless you use an application condition to target a specific protocol. When creating a URL object, you do not need to specify the protocol when creating an object. For example, use `example.com` rather than `http://example.com`.
- If you plan to use a URL object to match HTTPS traffic in an access control rule, create the object using the subject common name in the public key certificate used to encrypt the traffic. Also, the system disregards subdomains within the subject common name, so do not include subdomain information. For example, use `example.com` rather than `www.example.com`.

However, please understand that the subject common name in the certificate might be completely unrelated to a web site's domain name. For example, the subject common name in the certificate for `youtube.com` is `*.google.com` (this of course might change at any time). You will get more consistent results if you use the SSL Decryption policy to decrypt HTTPS traffic so that URL filtering rules work on decrypted traffic.

---

**Note** URL objects will not match HTTPS traffic if the browser resumes a TLS session because the certificate information is no longer available. Thus, even if you carefully configure the URL object, you might get inconsistent results for HTTPS connections.

---

## Creating URL Objects

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
- Step 2** Choose **URL** from the list of object types.
- Step 3** Choose **Add Object** from the **Add URL** drop-down list.
- Step 4** Enter a **Name**.
- Step 5** Optionally, enter a **Description**.
- Step 6** Enter the **URL** or IP address.
- Step 7** Manage overrides for the object:
- If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
  - If you want to add override values to this object, expand the Override section and click **Add**; see [Adding Object Overrides, on page 1462](#).
- Step 8** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes.

## Variable Set

Variables represent values commonly used in intrusion rules to identify source and destination IP addresses and ports. You can also use variables in intrusion policies to represent IP addresses in rule suppressions, adaptive profile updates, and dynamic rule states.

---

**Tip** Preprocessor rules can trigger events regardless of the hosts defined by network variables used in intrusion rules.

---

You use variable sets to manage, customize, and group your variables. You can use the default variable set provided by the system or create your own custom sets. Within any set you can modify predefined default variables and add and modify user-defined variables.

Most of the shared object rules and standard text rules that the system provides use predefined default variables to define networks and port numbers. For example, the majority of the rules use the variable `$HOME_NET` to specify the protected network and the variable `$EXTERNAL_NET` to specify the unprotected (or outside) network. In addition, specialized rules often use other predefined variables. For example, rules that detect exploits against web servers use the `$HTTP_SERVERS` and `$HTTP_PORTS` variables.

Rules are more effective when variables more accurately reflect your network environment. At a minimum, you should modify default variables in the default set. By ensuring that a variable such as `$HOME_NET` correctly

defines your network and `$HTTP_SERVERS` includes all web servers on your network, processing is optimized and all relevant systems are monitored for suspicious activity.

To use your variables, you link variable sets to intrusion policies associated with access control rules or with the default action of an access control policy. By default, the default variable set is linked to all intrusion policies used by access control policies.

Adding a variable to any set adds it to all sets; that is, each variable set is a collection of all variables currently configured on your system. Within any variable set, you can add user-defined variables and customize the value of any variable.

Initially, the system provides a single, default variable set comprised of predefined default values. Each variable in the default set is initially set to its default value, which for a predefined variable is the value set by the Talos Intelligence Group and provided in rule updates.

Although you can leave predefined default variables configured to their default values, Cisco recommends that you modify a subset of predefined variables.

You could work with variables only in the default set, but in many cases you can benefit most by adding one or more custom sets, configuring different variable values in different sets, and perhaps even adding new variables.

When using multiple sets, it is important to remember that the *current value* of any variable in the default set determines the *default value* of the variable in all other sets.

When you select **Variable Sets** on the Object Manager page, the object manager lists the default variable set and any custom sets you created.

On a freshly installed system, the default variable set is comprised only of the default variables predefined by Cisco.

Each variable set includes the default variables provided by the system and all custom variables you have added from any variable set. Note that you can edit the default set, but you cannot rename or delete the default set.

---

**Caution** Importing an access control or an intrusion policy overwrites existing default variables in the default variable set with the imported default variables. If your existing default variable set contains a custom variable not present in the imported default variable set, the unique variable is preserved.

---

## Variable Sets in Intrusion Policies

By default, the system links the default variable set to all intrusion policies used in an access control policy. When you deploy an access control policy that uses an intrusion policy, intrusion rules that you have enabled in the intrusion policy use the variable values in the linked variable set.

When you modify a custom variable set used by an intrusion policy in an access control policy, the system reflects the status for that policy as out-of-date on the Access Control Policy page. You must re-deploy the access control policy to implement changes in your variable set. When you modify the default set, the system reflects the status of all access control policies that use intrusion policies as out-of-date, and you must re-deploy all access control policies to implement your changes.

# Variables

Variables belong to one of the following categories:

## Default Variables

Variables provided by the system. You cannot rename or delete a default variable, and you cannot change its default value. However, you can create a customized version of a default variable.

## Customized Variables

Variables you create. These variables can include:

- *customized default variables*

When you edit the value for a default variable, the system moves the variable from the Default Variables area to the Customized Variables area. Because variable values in the default set determine the default values of variables in custom sets, customizing a default variable in the default set modifies the default value of the variable in all other sets.

- *user-defined variables*

You can add and delete your own variables, customize their values within different variable sets, and reset customized variables to their default values. When you reset a user-defined variable, it remains in the Customized Variables area.

User-defined variables can be one of the following types:

- *network* variables specify the IP addresses of hosts in your network traffic.
- *port* variables specify TCP or UDP ports in network traffic, including the value `any` for either type.

For example, if you create custom standard text rules, you might also want to add your own user-defined variables to more accurately reflect your traffic or as shortcuts to simplify the rule creation process. Alternatively, if you create a rule that you want to inspect traffic in the “demilitarized zone” (or DMZ) only, you can create a variable named `$DMZ` whose value lists the server IP addresses that are exposed. You can then use the `$DMZ` variable in any rule written for this zone.

## Advanced Variables

Variables provided by the system under specific conditions. These variables have a very limited deployment.

## Predefined Default Variables

By default, the system provides a single default variable set, which is comprised of predefined default variables. The Talos Intelligence Group uses rule updates to provide new and updated intrusion rules and other intrusion policy elements, including default variables.

Because many intrusion rules provided by the system use predefined default variables, you should set appropriate values for these variables. Depending on how you use variable sets to identify traffic on your network, you can modify the values for these default variables in any or all variable sets.

**Caution** Importing an access control or an intrusion policy overwrites existing default variables in the default variable set with the imported default variables. If your existing default variable set contains a custom variable not present in the imported default variable set, the unique variable is preserved.

The following table describes the variables provided by the system and indicates which variables you typically would modify. For assistance determining how to tailor variables to your network, contact Professional Services or Support.

**Table 94: System-Provided Variables**

| Variable Name     | Description                                                                                                                                                                          | Modify?                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------|
| \$AIM_SERVERS     | Defines known AOL Instant Messenger (AIM) servers, and is used in chat-based rules and rules that look for AIM exploits.                                                             | Not required.                                                                                                          |
| \$DNS_SERVERS     | Defines Domain Name Service (DNS) servers. If you create a rule that affects DNS servers specifically, you can use the \$DNS_SERVERS variable as a destination or source IP address. | Not required in current rule set.                                                                                      |
| \$EXTERNAL_NET    | Defines the network that the system views as the unprotected network, and is used in many rules to define the external network.                                                      | Yes, you should adequately define \$HOME_NET and then exclude \$HOME_NET as the value for \$EXTERNAL_NET.              |
| \$FILE_DATA_PORTS | Defines non-encrypted ports used in intrusion rules that detect files in a network stream.                                                                                           | Not required.                                                                                                          |
| \$FTP_PORTS       | Defines the ports of FTP servers on your network, and is used for FTP server exploit rules.                                                                                          | Yes, if your FTP servers use ports other than the default ports (you can view the default ports in the web interface). |
| \$GTP_PORTS       | Defines the data channel ports where the packet decoder extracts the payload inside a GTP (General Packet Radio Service [GPRS] Tunneling Protocol) PDU.                              | Not required.                                                                                                          |
| \$HOME_NET        | Defines the network that the associated intrusion policy monitors, and is used in many rules to define the internal network.                                                         | Yes, to include the IP addresses for your internal network.                                                            |
| \$HTTP_PORTS      | Defines the ports of web servers on your network, and is used for web server exploit rules.                                                                                          | Yes, if your web servers use ports other than the default ports (you can view the default ports in the web interface). |
| \$HTTP_SERVERS    | Defines the web servers on your network. Used in web server exploit rules.                                                                                                           | Yes, if you run HTTP servers.                                                                                          |
| \$ORACLE_PORTS    | Defines Oracle database server ports on your network, and is used in rules that scan for attacks on Oracle databases.                                                                | Yes, if you run Oracle servers.                                                                                        |
| \$SHELLCODE_PORTS | Defines the ports you want the system to scan for shell code exploits, and is used in rules that detect exploits that use shell code.                                                | Not required.                                                                                                          |

| Variable Name                   | Description                                                                                                                                                                                                              | Modify?                                                                                                                                                                        |
|---------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>\$\$SIP_PORTS</code>      | Defines the ports of SIP servers on your network, and is used for SIP exploit rules.                                                                                                                                     | Not required.                                                                                                                                                                  |
| <code>\$\$SIP_SERVERS</code>    | Defines SIP servers on your network, and is used in rules that address SIP-targeted exploits.                                                                                                                            | Yes, if you run SIP servers, you should adequately define <code>\$\$HOME_NET</code> and then include <code>\$\$HOME_NET</code> as the value for <code>\$\$SIP_SERVERS</code> . |
| <code>\$\$SMTP_SERVERS</code>   | Defines SMTP servers on your network, and is used in rules that address exploits that target mail servers.                                                                                                               | Yes, if you run SMTP servers.                                                                                                                                                  |
| <code>\$\$SNMP_SERVERS</code>   | Defines SNMP servers on your network, and is used in rules that scan for attacks on SNMP servers.                                                                                                                        | Yes, if you run SNMP servers.                                                                                                                                                  |
| <code>\$\$SNORT_BPF</code>      | Identifies a legacy advanced variable that appears only when it existed on your system in a software release before Version 5.3.0 that you subsequently upgraded to Version 5.3.0 or greater.                            | No, you can only view or delete this variable. You cannot edit it or recover it after deleting it.                                                                             |
| <code>\$\$SQL_SERVERS</code>    | Defines database servers on your network, and is used in rules that address database-targeted exploits.                                                                                                                  | Yes, if you run SQL servers.                                                                                                                                                   |
| <code>\$\$SSH_PORTS</code>      | Defines the ports of SSH servers on your network, and is used for SSH server exploit rules.                                                                                                                              | Yes, if your SSH servers use ports other than the default port (you can view the default ports in the web interface).                                                          |
| <code>\$\$SSH_SERVERS</code>    | Defines SSH servers on your network, and is used in rules that address SSH-targeted exploits.                                                                                                                            | Yes, if you run SSH servers, you should adequately define <code>\$\$HOME_NET</code> and then include <code>\$\$HOME_NET</code> as the value for <code>\$\$SSH_SERVERS</code> . |
| <code>\$\$TELNET_SERVERS</code> | Defines known Telnet servers on your network, and is used in rules that address Telnet server-targeted exploits.                                                                                                         | Yes, if you run Telnet servers.                                                                                                                                                |
| <code>\$\$USER_CONF</code>      | Provides a general tool that allows you to configure one or more features not otherwise available via the web interface.<br><br>Conflicting or duplicate <code>\$\$USER_CONF</code> configurations will halt the system. | No, only as instructed in a feature description or with the guidance of Support.                                                                                               |

## Network Variables

Network variables represent IP addresses you can use in intrusion rules that you enable in an intrusion policy and in intrusion policy rule suppressions, dynamic rule states, and adaptive profile updates. Network variables differ from network objects and network object groups in that network variables are specific to intrusion policies and intrusion rules, whereas you can use network objects and groups to represent IP addresses in various places in the system's web interface, including access control policies, network variables, intrusion rules, network discovery rules, event searches, reports, and so on.

You can use network variables in the following configurations to specify the IP addresses of hosts on your network:

- intrusion rules—Intrusion rule **Source IPs** and **Destination IPs** header fields allow you to restrict packet inspection to the packets originating from or destined to specific IP addresses.
- suppressions—The **Network** field in source or destination intrusion rule suppressions allows you to suppress intrusion event notifications when a specific IP address or range of IP addresses triggers an intrusion rule or preprocessor.
- dynamic rule states—The **Network** field in source or destination dynamic rule states allows you to detect when too many matches for an intrusion rule or preprocessor rule occur in a given time period.
- adaptive profile updates—When you enable adaptive profile updates, the adaptive profiles **Networks** field identifies hosts where you want to improve reassembly of packet fragments and TCP streams in passive deployments.

When you use variables in the fields identified in this section, the variable set you link to an intrusion policy determines the variable values in the network traffic handled by an access control policy that uses the intrusion policy.

You can add any combination of the following network configurations to a variable:

- any combination of network variables, network objects, and network object groups that you select from the list of available networks
- individual network objects that you add from the New Variable or Edit Variable page, and can then add to your variable and to other existing and future variables
- literal, single IP addresses or address blocks

You can list multiple literal IP addresses and address blocks by adding each individually. You can list IPv4 and IPv6 addresses and address blocks alone or in any combination. When specifying IPv6 addresses, you can use any addressing convention defined in RFC 4291.

The default value for included networks in any variable you add is the word `any`, which indicates any IPv4 or IPv6 address. The default value for excluded networks is `none`, which indicates no network. You can also specify the address `::` in a literal value to indicate any IPv6 address in the list of included networks, or no IPv6 addresses in the list of exclusions.

Adding networks to the excluded list negates the specified addresses and address blocks. That is, you can match any IP address with the exception of the excluded IP address or address blocks.

For example, excluding the literal address `192.168.1.1` specifies any IP address other than `192.168.1.1`, and excluding `2001:db8:ca2e::fa4c` specifies any IP address other than `2001:db8:ca2e::fa4c`.

You can exclude any combination of networks using literal or available networks. For example, excluding the literal values `192.168.1.1` and `192.168.1.5` *includes* any IP address other than `192.168.1.1` or `192.168.1.5`. That is, the system interprets this as “**not** `192.168.1.1` **and not** `192.168.1.5`,” which matches any IP address other than those listed between brackets.

Note the following points when adding or editing network variables:

- You cannot logically exclude the value `any` which, if excluded, would indicate no address. For example, you cannot add a variable with the value `any` to the list of excluded networks.

- Network variables identify traffic for the specified intrusion rule and intrusion policy features. Note that preprocessor rules can trigger events regardless of the hosts defined by network variables used in intrusion rules.
- Excluded values must resolve to a subset of included values. For example, you cannot include the address block 192.168.5.0/24 and exclude 192.168.6.0/24.

## Port Variables

Port variables represent TCP and UDP ports you can use in the **Source Port** and **Destination Port** header fields in intrusion rules that you enable in an intrusion policy. Port variables differ from port objects and port object groups in that port variables are specific to intrusion rules. You can create port objects for protocols other than TCP and UDP, and you can use port objects in various places in the system's web interface, including port variables, access control policies, network discovery rules, and event searches.

You can use port variables in the intrusion rule **Source Port** and **Destination Port** header fields to restrict packet inspection to packets originating from or destined to specific TCP or UDP ports.

When you use variables in these fields, the variable set you link to the intrusion policy associated with an access control rule or policy determines the values for these variables in the network traffic where you deploy the access control policy.

You can add any combination of the following port configurations to a variable:

- any combination of port variables and port objects that you select from the list of available ports

Note that the list of available ports does not display port object groups, and you cannot add these to variables.

- individual port objects that you add from the New Variable or Edit Variable page, and can then add to your variable and to other existing and future variables

Only TCP and UDP ports, including the value `any` for either type, are valid variable values. If you use the new or edit variables page to add a valid port object that is not a valid variable value, the object is added to the system but is not displayed in the list of available objects. When you use the object manager to edit a port object that is used in a variable, you can only change its value to a valid variable value.

- single, literal port values and port ranges

You must separate port ranges with a dash (-). Port ranges indicated with a colon (:) are supported for backward compatibility, but you cannot use a colon in port variables that you create.

You can list multiple literal port values and ranges by adding each individually in any combination.

Note the following points when adding or editing port variables:

- The default value for included ports in any variable you add is the word `any`, which indicates any port or port range. The default value for excluded ports is `none`, which indicates no ports.

---

**Tip** To create a variable with the value `any`, name and save the variable without adding a specific value.

---

- You cannot logically exclude the value `any` which, if excluded, would indicate no ports. For example, you cannot save a variable set when you add a variable with the value `any` to the list of excluded ports.

- Adding ports to the excluded list negates the specified ports and port ranges. That is, you can match any port with the exception of the excluded ports or port ranges.
- Excluded values must resolve to a subset of included values. For example, you cannot include the port range 10-50 and exclude port 60.

## Advanced Variables

Advanced variables allow you to configure features that you cannot otherwise configure via the web interface. The system currently provides only one advanced variable, the `USER_CONF` variable.

### USER\_CONF

`USER_CONF` provides a general tool that allows you to configure one or more features not otherwise available via the web interface.

---

**Caution** Do **not** use the advanced variable `USER_CONF` to configure an intrusion policy feature unless you are instructed to do so in the feature description or by Support. Conflicting or duplicate configurations will halt the system.

---

When editing `USER_CONF`, you can type up to 4096 total characters on a single line; the line wraps automatically. You can include any number of valid instructions or lines until you reach the 8192 maximum character length for a variable or a physical limit such as disk space. Use the backslash (\) line continuation character after any complete argument in a command directive.

Resetting `USER_CONF` empties it.

## Variable Reset

You can reset a variable to its default value on the variable set new or edit variables page. The following table summarizes the basic principles of resetting variables.

*Table 95: Variable Reset Values*

| Resetting this variable type... | In this set type... | Resets it to...                                        |
|---------------------------------|---------------------|--------------------------------------------------------|
| default                         | default             | the rule update value                                  |
| user-defined                    | default             | any                                                    |
| default or user-defined         | custom              | the current default set value (modified or unmodified) |

Resetting a variable in a custom set simply resets it to the current value for that variable in the default set.

Conversely, resetting or modifying the value of a variable in the default set always updates the default value of that variable in all custom sets. When the reset icon is grayed out, indicating that you cannot reset the variable, this means that the variable has no customized value in that set. Unless you have customized the value for a variable in a custom set, a change to the variable in the default set updates the value used in any intrusion policy where you have linked the variable set.

**Note** It is good practice when you modify a variable in the default set to assess how the change affects any intrusion policy that uses the variable in a linked custom set, especially when you have not customized the variable value in the custom set.

You can hover your pointer over the **Reset icon** in a variable set to see the reset value. When the customized value and the reset value are the same, this indicates one of the following:

- you are in the custom or default set where you added the variable with the value `any`
- you are in the custom set where you added the variable with an explicit value and elected to use the configured value as the default value

## Adding Variables to Sets

Adding a variable to a variable set adds it to all other sets. When you add a variable from a custom set, you must choose whether to use the configured value as the customized value in the default set:

- **If you use the configured value** (for example, 192.168.0.0/16), the variable is added to the default set using the configured value as a customized value with a default value of `any`. Because the current value in the default set determines the default value in other sets, the initial, default value in other custom sets is the configured value (which in the example is 192.168.0.0/16).
- **If you do not use the configured value**, the variable is added to the default set using only the default value `any` and, consequently, the initial, default value in other custom sets is `any`.

### Example: Adding User-Defined Variables to Default Sets

The following diagram illustrates set interactions when you add the user-defined variable `var1` to the default set with the value 192.168.1.0/24.

You can customize the value of `var1` in any set. In Custom Set 2 where `var1` has not been customized, its value is 192.168.1.0/24. In Custom Set 1 the customized value 192.168.2.0/24 of `var1` overrides the default value. Resetting a user-defined variable in the default set resets its default value to `any` in all sets.

It is important to note in this example that, if you do not update `var1` in Custom Set 2, further customizing or resetting `var1` in the default set consequently updates the current, default value of `var1` in Custom Set 2, thereby affecting any intrusion policy linked to the variable set.

Although not shown in the example, note that interactions between sets are the same for user-defined variables and default variables except that resetting a default variable in the default set resets it to the value configured by Cisco in the current rule update.

### Example: Adding User-Defined Variables to Custom Sets

The next two examples illustrate variable set interactions when you add a user-defined variable to a custom set. When you save the new variable, you are prompted whether to use the configured value as the default value for other sets. In the following example, you elect **to use** the configured value.

Note that, except for the origin of `var1` from Custom Set 1, this example is identical to the example above where you added `var1` to the default set. Adding the customized value `192.168.1.0/24` for `var1` to Custom Set 1 copies the value to the default set as a customized value with a default value of `any`. Thereafter, `var1` values and interactions are the same as if you had added `var1` to the default set. As with the previous example, keep in mind that further customizing or resetting `var1` in the default set consequently updates the current, default value of `var1` in Custom Set 2, thereby affecting any intrusion policy linked to the variable set.

In the next example, you add `var1` with the value `192.168.1.0/24` to Custom Set 1 as in the previous example, but you elect **not to use** the configured value of `var1` as the default value in other sets.

This approach adds `var1` to all sets with a default value of `any`. After adding `var1`, you can customize its value in any set. An advantage of this approach is that, by not initially customizing `var1` in the default set, you decrease your risk of customizing the value in the default set and thus inadvertently changing the current value in a set such as Custom Set 2 where you have not customized `var1`.

## Nesting Variables

You can nest variables so long as the nesting is not circular. Nested, negated variables are not supported.

### Valid Nested Variables

In this example, `SMTP_SERVERS`, `HTTP_SERVERS`, and `OTHER_SERVERS` are valid nested variables.

| Variable      | Type               | Included Networks | Excluded Networks |
|---------------|--------------------|-------------------|-------------------|
| SMTP_SERVERS  | customized default | 10.1.1.1          | —                 |
| HTTP_SERVERS  | customized default | 10.1.1.2          | —                 |
| OTHER_SERVERS | user-defined       | 10.2.2.0/24       | —                 |

| Variable | Type               | Included Networks            | Excluded Networks            |
|----------|--------------------|------------------------------|------------------------------|
| HOME_NET | customized default | 10.1.1.0/24<br>OTHER_SERVERS | SMTP_SERVERS<br>HTTP_SERVERS |

### An Invalid Nested Variable

In this example, HOME\_NET is an invalid nested variable because the nesting of HOME\_NET is circular; that is, the definition of OTHER\_SERVERS includes HOME\_NET, so you would be nesting HOME\_NET in itself.

| Variable      | Type               | Included Networks            | Excluded Networks            |
|---------------|--------------------|------------------------------|------------------------------|
| SMTP_SERVERS  | customized default | 10.1.1.1                     | —                            |
| HTTP_SERVERS  | customized default | 10.1.1.2                     | —                            |
| OTHER_SERVERS | user-defined       | 10.2.2.0/24<br>HOME_NET      | —                            |
| HOME_NET      | customized default | 10.1.1.0/24<br>OTHER_SERVERS | SMTP_SERVERS<br>HTTP_SERVERS |

### An Unsupported Nested, Negated Variable

Because nested, negated variables are not supported, you cannot use the variable NONCORE\_NET as shown in this example to represent IP addresses that are outside of your protected networks.

| Variable     | Type               | Included Networks                         | Excluded Networks |
|--------------|--------------------|-------------------------------------------|-------------------|
| HOME_NET     | customized default | 10.1.0.0/16<br>10.2.0.0/16<br>10.3.0.0/16 | —                 |
| EXTERNAL_NET | customized default | —                                         | HOME_NET          |
| DMZ_NET      | user-defined       | 10.4.0.0/16                               | —                 |
| NOT_DMZ_NET  | user-defined       | —                                         | DMZ_NET           |
| NONCORE_NET  | user-defined       | EXTERNAL_NET<br>NOT_DMZ_NET               | —                 |

### Alternative to an Unsupported Nested, Negated Variable

As an alternative to the example above, you could represent IP addresses that are outside of your protected networks by creating the variable NONCORE\_NET as shown in this example.

| Variable    | Type               | Included Networks                         | Excluded Networks   |
|-------------|--------------------|-------------------------------------------|---------------------|
| HOME_NET    | customized default | 10.1.0.0/16<br>10.2.0.0/16<br>10.3.0.0/16 | —                   |
| DMZ_NET     | user-defined       | 10.4.0.0/16                               | —                   |
| NONCORE_NET | user-defined       | —                                         | HOME_NET<br>DMZ_NET |

## Managing Variable Sets

To use variable sets, you must have the IPS license (for threat defense devices) or the Protection license (all other device types).

### Procedure

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose **Variable Set** from the list of object types.

**Step 3** Manage your variable sets:

- Add — If you want to add a custom variable set, click **Add Variable Set**; see [Creating Variable Sets, on page 1553](#).
- Delete — If you want to delete a custom variable set, click **Delete** (  ) next to the variable set, then click **Yes**. You cannot delete the default variable set or variable sets belonging to ancestor domains.

**Note** Variables created in a variable set you delete are not deleted or otherwise affected in other sets.

- Edit — If you want to edit a variable set, click **Edit** (  ) next to the variable set you want to modify; see [Editing Objects, on page 1457](#).
- Filter — If you want to filter variable sets by name, begin entering a name; as you type, the page refreshes to display matching names. If you want to clear name filtering, click **Clear** (  ) in the filter field.
- Manage Variables — To manage the variables included in variable sets, see [Managing Variables, on page 1553](#).

## Creating Variable Sets

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Choose **Variable Set** from the list of object types.
  - Step 3** Click **Add Variable Set**.
  - Step 4** Enter a **Name**.
  - Step 5** Optionally, enter a **Description**.
  - Step 6** Manage the variables in the set; see [Managing Variables, on page 1553](#).
  - Step 7** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes.

## Managing Variables

You must have the IPS license (for threat defense devices) or the Protection license (all other device types).

### Procedure

- 
- Step 1** Choose **Objects > Object Management**.
  - Step 2** Choose **Variable Set** from the list of object types.
  - Step 3** Click **Edit** () next to the variable set you want to edit.  
If **View** () appears instead, the configuration belongs to an ancestor domain, or you do not have permission to modify the configuration.

- Step 4** Manage your variables:
  - **Display** — If you want to display the complete value for a variable, hover your pointer over the value in the **Value** column next to the variable.
  - **Add** — If you want to add a variable, click **Add**; see [Adding Variables, on page 1554](#).
  - **Delete** — Click **Delete** () next to the variable. If you have saved the variable set since adding the variable, click **Yes** to confirm that you want to delete the variable.

You *cannot* delete the following:

- default variables
- user-defined variables that are used by intrusion rules or other variables
- variables belonging to ancestor domains

- **Edit** — Click **Edit** (✎) next to the variable you want to edit; see [Editing Variables, on page 1555](#).
- **Reset** — If you want to reset a modified variable to its default value, click **Reset** next to a modified variable. If reset is dimmed, one of the following is true:
  - The current value is already the default value.
  - The configuration belongs to an ancestor domain.

**Tip** Hover your pointer over an active reset to display the default value.

**Step 5** Click **Save** to save the variable set. If the variable set is in use by an access control policy, click **Yes** to confirm that you want to save your changes.

Because the current value in the default set determines the default value in all other sets, modifying or resetting a variable in the default set changes the current value in other sets where you have not customized the default value.

---

### What to do next

- If an active policy references your object, deploy configuration changes.

## Adding Variables

You must have the IPS license (for threat defense devices) or the Protection license (all other device types).

### Procedure

---

**Step 1** In the variable set editor, click **Add**.

**Step 2** Enter a unique variable **Name**.

**Step 3** From the **Type** drop-down list, choose either **Network** or **Port**.

**Step 4** Specify values for the variable:

- If you want to move items from the list of available networks or ports to the list of included or excluded items, you can choose one or more items and then drag and drop, or click **Include** or **Exclude**.

**Tip** If addresses or ports in the included and excluded lists for a network or port variable overlap, excluded addresses or ports take precedence.

- Enter a single literal value, then click **Add**. For network variables, you can enter a single IP address or address block. For port variables you can add a single port or port range, separating the upper and lower values with a hyphen (-). Repeat this step as needed to enter multiple literal values.

- If you want to remove an item from the included or excluded lists, click **Delete** (■) next to the item.

**Note** The list of items to include or exclude can be comprised of any combination of literal strings and existing variables, objects, and network object groups in the case of network variables.

- Step 5** Click **Save** to save the variable. If you are adding a new variable from a custom set, you have the following options:
- Click **Yes** to add the variable using the configured value as the customized value in the default set and, consequently, the default value in other custom sets.
  - Click **No** to add the variable as the default value of `any` in the default set and, consequently, in other custom sets.
- Step 6** Click **Save** to save the variable set. Your changes are saved, and any access control policy the variable set is linked to displays an out-of-date status.
- 

#### What to do next

- If an active policy references your object, deploy configuration changes.

## Editing Variables

You must have the IPS license (for threat defense devices) or the Protection license (all other device types).

You can edit both custom and default variables.

You cannot change the **Name** or **Type** values in an existing variable.

### Procedure

---

- Step 1** In the variable set editor, click **Edit** (✎) next to the variable you want to modify.
- If **View** (👁) appears instead, the object belongs to an ancestor domain, or you do not have permission to modify the object.
- Step 2** Modify the variable:
- If you want to move items from the list of available networks or ports to the list of included or excluded items, you can select one or more items and then drag and drop, or click **Include** or **Exclude**.
- Tip** If addresses or ports in the included and excluded lists for a network or port variable overlap, excluded addresses or ports take precedence.
- Enter a single literal value, then click **Add**. For network variables, you can enter a single IP address or address block. For port variables you can add a single port or port range, separating the upper and lower values with a hyphen (-). Repeat this step as needed to enter multiple literal values.
  - If you want to remove an item from the included or excluded lists, click **Delete** (🗑) next to the item.
- Note** The list of items to include or exclude can be comprised of any combination of literal strings and existing variables, objects, and network object groups in the case of network variables.
- Step 3** Click **Save** to save the variable.

- Step 4** Click **Save** to save the variable set. If the variable set is in use by an access control policy, click **Yes** to confirm that you want to save your changes. Your changes are saved, and any access control policy the variable set is linked to displays an out-of-date status.
- 

#### What to do next

- If an active policy references your object, deploy configuration changes.

## VLAN Tag

Each VLAN tag object you configure represents a VLAN tag or range of tags.

You can group VLAN tag objects. Groups represent multiple objects; using a range of VLAN tags in a single object is not considered a group in this sense.

You can use VLAN tag objects and groups in various places in the system's web interface, including rules and event searches. For example, you could write an access control rule that applies only to a specific VLAN.

## Creating VLAN Tag Objects

### Procedure

---

- Step 1** Choose **Objects > Object Management**.
- Step 2** Choose **VLAN Tag** from the list of object types.
- Step 3** Choose **Add Object** from the **Add VLAN Tag** drop-down list.
- Step 4** Enter a **Name**.
- Step 5** Enter a **Description**.
- Step 6** Enter a value in the **VLAN Tag** field. Use a hyphen to specify a range of VLAN tags.
- Step 7** Manage overrides for the object:
- If you want to allow overrides for this object, check the **Allow Overrides** check box; see [Allowing Object Overrides, on page 1462](#).
  - If you want to add override values to this object, expand the Override section and click **Add**; see [Adding Object Overrides, on page 1462](#).
- Step 8** Click **Save**.
- 

#### What to do next

- If an active policy references your object, deploy configuration changes.

# VPN

You can use the following VPN objects on threat defense devices. To use these objects, you must have Admin privileges, and your Smart License account must satisfy export controls. You can configure these objects in leaf domains only.

## Certificate Map Objects

Certificate Map objects are a named set of certificate matching rules. These objects are used to provide an association between a received certificate and a Remote Access VPN connection profile. Connection Profiles and Certificate Map objects are both part of a remote access VPN policy. If a received certificate matches the rules contained in the certificate map, the connection is "mapped", or associated with the specified connection profile. The rules are in priority order, they are matched in the order they are shown in the UI. The matching ends when the first rule within the Certificate Map object results in a match.

### Navigation

Objects > Object Management > VPN > Certificate Map

### Fields

- **Name**—Identify this object so it can be referred to from other configurations, such as Remote Access VPN.
- **Mapping Criteria**—Specify the contents of the certificate to evaluate. If the certificate satisfies these rules, the user will be mapped to the connection profile containing this object.
  - **Field**—Select the field for the matching rule according to the Subject or the Issuer of the client certificate.  
  
If the **Field** is set to *Alternative Subject* or *Extended Key Usage* the Component will be frozen as *Whole Field*
  - **Component**—Select the component of the client certificate to use for the matching rule.

---

**Note** **SER (Serial Number) component** - Ensure you specify the serial number for the Subject field. The certificate map only matches with a serial number attribute in the subject name.

---

- **Operator**—Select the operator for the matching rule as follows:
  - **Equals**—The certificate component must match the entered value. If they do not match exactly, the connection is denied.
  - **Contains**—The certificate component must contain the entered value. If the component does not contain the value, the connection is denied.
  - **Does Not Equal**—The certificate component cannot equal the entered value. For example, for a selected certificate component of Country, and an entered value of US, if the client country value equals US, then the connection is denied.

- **Does Not Contain**—The certificate component cannot contain the entered value. For example, for a selected certificate component of Country, and an entered value of US, if the client country value contains US, the connection is denied.
- **Value**—The value of the matching rule. The value entered is associated with the selected component and operator.

## Secure Client Custom Attributes Objects

Custom attributes are used by the Secure Client to configure features such as Per App VPN, Allow or defer upgrade, and Dynamic split tunneling. A custom attribute has a type and a named value. The type of the attribute is defined first, then one or more named values of this type can be defined. You can create the Secure Client custom attributes objects using the management center, add the objects to a group policy and associate the group policy with a remote access VPN to enable the features for the VPN clients.

Threat Defense supports the following features using the custom attribute objects:

- **Per App VPN**—The Per App VPN feature helps identify an app and tunnel only applications allowed by the threat defense administrator over the VPN.
- **Allow or defer upgrade**— Deferred Upgrade allows the Secure Client user to delay download of the Secure Client upgrade. When a client update is available, you can configure the attributes for Secure Client to open a dialog asking the user if they would like to update, or to defer the upgrade.
- **Dynamic Split Tunneling**— With dynamic split tunneling, you can provision policies that either include or exclude IP addresses or networks from the VPN tunnel. Dynamic split tunneling is configured by creating a custom attribute and adding it to a group policy.

For step-by-step instructions to configure Secure Client custom attributes, see [Add Secure Client Custom Attributes Objects](#), on page 1558 and

For details about the specific custom attributes to configure for a feature, see the *Cisco Secure Client (including AnyConnect) Administrator Guide* for the Secure Client release you are using.

## Add Secure Client Custom Attributes Objects

### Before you begin

Ensure that you have done the following before adding a custom attribute object for Per App VPN:

- Per App VPN must be properly configured via MDM and each device must be enrolled to the MDM server
- Create a base64 encoded string for each app using the Cisco Secure Client Enterprise Application Selector Tool.
  1. Download the Cisco Secure Client Enterprise Application Selector Tool from [here](#).

2. Open the Application Selection Tool and select the mobile platform from the drop-down menu located on the upper left.
3. Add rule by entering Friendly name and App ID; rest of the fields are optional.
4. On the menu bar, click on **Policy**. The encoded base65 rule is displayed in its encoded format.
5. Select and copy the policy string, and save it to use later when you create the Secure Client Custom Attributes object.

## Procedure

- 
- Step 1** Choose **Objects > Object Management > VPN > Custom Attribute**.
- Step 2** Click **Secure Client Custom Attribute**.
- Step 3** Enter a **Name** and optionally a **Description** for the attribute.
- Step 4** Select an attribute from the **Secure Client Attribute** drop-down list:
- **Per App VPN** — Select this option and specify the base64 encoded string in the **Attribute Value** box.
  - **Allow Defer Update**—Select one of the following options and specify the required information to allow or defer Secure Client update:
    - **Show the prompt until user takes action**—Display the prompt to the VPN user until the user chooses to allow or defer the VPN client update.
    - **Show the prompt until times out**—Choose this option to display the prompt for a specified duration and specify the duration in the **Timeout** box.
    - **Do not show the prompt and take automatic action**—Choose this option to automatically allow or defer the VPN update.
    - **Default Action**—Select the default action to be taken when the user does not respond, or when you want to configure an automatic action without the user's intervention. You can choose to update the Secure Client or postpone the update.
    - **Minimum Version**—Specify the minimum Secure Client version to be present on the client system to allow or defer the update.
  - **Dynamic Split Tunneling**—Select this option to include or exclude IP addresses or networks from the VPN tunnel.
    - **Include domains**—Specify domain names that will be included in the remote access VPN tunnel.
    - **Exclude domains**—Specify domain names that will be excluded from the remote access VPN tunnel.
- Step 5** Select the **Allow Overrides** check box to allow object overrides.
- Step 6** Click **Save**.  
The custom attributes object is added to the list.
-

**What to do next**

Associate the custom attributes with a group policy. See [Add Custom Attributes to a Group Policy, on page 1560](#).

**Add Custom Attributes to a Group Policy**

You must associate Secure Client custom attributes with a group policy to use them for remote access VPN connections. You

**Procedure**

---

**Step 1** Select **Objects > Object Management > VPN > Group Policy**.

**Step 2** Add a new group policy or edit an existing group policy.

**Step 3** Click **Secure Client > Custom Attributes**.

**Step 4** Click **Add**.

**Step 5** Select the **Secure Client Attribute**: Per App VPN, Allow Defer Update, or Dynamic Split Tunneling.

**Step 6** Select a **Custom Attribute Object** from the list.

**Note** Click Add (+) to create a new custom attribute object for the selected Secure Client attribute. You can also create a custom attribute object at **Objects > Object Management > VPN > Custom Attribute**. See [Add Secure Client Custom Attributes Objects, on page 1558](#).

**Step 7** Click **Add** to save the attributes to the group policy and then click **Save** to save the changes to the group policy.

**Related Topics**

[Group Policy Secure Client Options, on page 1563](#)

**Threat Defense Group Policy Objects**

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience. For example, in the group policy object, you configure general attributes such as addresses, protocols, and connection settings.

The group policy applied to a user is determined when the VPN tunnel is being established. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile.

---

**Note** There is no group policy attribute inheritance on the threat defense. A group policy object is used, in its entirety, for a user. The group policy object identified by the AAA server upon login is used, or, if that is not specified, the default group policy configured for the VPN connection is used. The provided default group policy can be set to your default values, but will only be used if it is assigned to a connection profile and no other group policy has been identified for the user.

---

To use group objects, you must have one of these Secure Client licenses associated with your Smart License account with Export-Controlled Features enabled:

- Secure Client VPN Only
- Secure Client Advantage
- Secure Client Premier

## Configure Group Policy Objects

See [Threat Defense Group Policy Objects](#), on page 1560.

### Procedure

- 
- Step 1** Choose **Objects > Object Management > VPN > Group Policy**.
- Previously configured policies are listed including the system default. Depending on your level of access, you may edit, view, or delete a group policy.
- Step 2** Click **Add Group Policy** or choose a current policy to edit.
- Step 3** Enter a **Name** and optionally a **Description** for this policy.
- The name can be up to 64 characters, spaces are allowed. The description can be up to 1,024 characters.
- Step 4** Specify the **General** parameters for this Group Policy as described in [Group Policy General Options, on page 1561](#).
- Step 5** Specify the **Secure Client** parameters for this Group Policy as described in [Group Policy Secure Client Options, on page 1563](#).
- Step 6** Specify the **Advanced** parameters for this Group Policy as described in [Group Policy Advanced Options, on page 1567](#).
- Step 7** Click **Save**.
- The new Group Policy is added to the list.
- 

**What to do next**

Add the group policy object to a remote access VPN connection profile.

## Group Policy General Options

**Navigation Path**

**Objects > Object Management > VPN > Group Policy**, Click **Add Group Policy** or choose a current policy to edit., then select the **General** tab.

**VPN Protocols Fields**

Specify the types of Remote Access VPN tunnels that can be used when applying this group policy. **SSL** or **IPsec IKEv2**.

## IP Address Pools

Specifies the IPv4 address assignment that is applied based on address pools that are specific to user-groups in Remote Access VPN. For Remote Access VPN, you can assign IP address from specific address pools for identified user groups using RADIUS/ISE for authorization. You can seamlessly perform policy enforcement for user or user groups in systems which are not identity-aware, by configuring particular Group Policy as RADIUS Authorization attribute (GroupPolicy/Class), for a particular user group. For example, you have to select a specific address pool for contractors and policy enforcement using those addresses to allow restricted access to internal network.

The order of preference that threat defense device assigns the IPv4 Address Pools to the clients:

1. RADIUS attribute for IPv4Address Pool
2. RADIUS attribute for Group Policy
3. Address Pool in Group Policy mapped to a Connection Profile
4. IPv4Address Pool in Connection Profile

Some limitations around using IP address pools in Group Policy:

- IPv6 address pool is not supported.
- Maximum of six IPv4 address pools can be configured in a Group Policy.
- Deployment failures are seen when address pools in use are modified. You must logoff all the users before making any changes to the address pools.
- When address pools are renamed or overlapping address pools are configured, deployment could fail. You must deploy the changes by removing the old address pool and later deploying the changed address pool.

Some troubleshooting commands :

- `show ip local pool <address-pool-name>`
- `show vpn-sessiondb detail anyconnect`
- `vpn-sessiondb loggoff all noconfirm`

## Banner Fields

Specifies the banner text to present to users at login. The length can be up to 491 characters. There is no default value. The IPsec VPN client supports full HTML for the banner, however, the Secure Client supports only partial HTML. To ensure that the banner displays properly to remote users, use the /n tag for IPsec clients, and the <BR> tag for SSL clients.

## DNS/WINS Fields

Domain Naming System (DNS) and Windows Internet Naming System (WINS) servers. Used for Secure Client name resolution.

- **Primary DNS Server** and **Secondary DNS Server**—Choose or create a Network Object which defines the IPv4 or IPv6 addresses of the DNS servers you want this group to use.
- **Primary WINS Server** and **Secondary WINS Server**—Choose or create a Network Object containing the IP addresses of the WINS servers you want this group to use.

- **DHCP Network Scope**—Choose or create a Network Object containing a routable IPv4 address on the same subnet as the desired pool, but not within the pool. The DHCP server determines which subnet this IP address belongs to and assigns an IP address from that pool. If not set properly, deployment of the VPN policy fails.

If you configure DHCP servers for the address pool in the connection profile, the DHCP scope identifies the subnets to use for the pool for this group. The DHCP server must also have addresses in the same subnet identified by the scope. The scope allows you to select a subset of the address pools defined in the DHCP server to use for this specific group.

If you do not define a network scope, the DHCP server assigns IP addresses in the order of the address pools configured. It goes through the pools until it identifies an unassigned address.

We recommend using the IP address of an interface whenever possible for routing purposes. For example, if the pool is 10.100.10.2-10.100.10.254, and the interface address is 10.100.10.1/24, use 10.100.10.1 as the DHCP scope. Do not use the network number. You can use DHCP for IPv4 addressing only. If the address you choose is not an interface address, you might need to create a static route for the scope address.

LINK-SELECTION (RFC 3527) and SUBNET-SELECTION (RFC 3011) are currently not supported.

- **Default Domain**—Name of the default domain. Specify a top-level domain, for example, example.com.

### Split Tunneling Fields

Split tunneling directs some network traffic through the VPN tunnel (encrypted) and the remaining network traffic outside the VPN tunnel (unencrypted or “in the clear”).

- **IPv4 Split Tunneling / IPv6 Split Tunneling**—By default, split tunneling is not enabled. For both IPv4 and IPv6 it is set to **Allow all traffic over tunnel**. Left as is, all traffic from the endpoint goes over the VPN connection.

To configure split tunneling, choose the **Tunnel networks specified below** or **Exclude networks specified below** policy. Then configure an access control list for that policy.

- **Split Tunnel Network List Type**—Choose the type of Access List you are using. Then choose or create a **Standard Access List** or **Extended Access List**. See [Access List, on page 1468](#) for details.
- **DNS Request Split Tunneling**—Also known as Split DNS. Configure the DNS behavior expected in your environment.

By default, split DNS is not enabled and set to **Send DNS request as per split tunnel policy**. Choosing **Always send DNS request over tunnel** forces all DNS requests to be sent over the tunnel to the private network.

To configure split DNS, choose **Send only specified domains over tunnel**, and enter the list of domain names in the **Domain List** field. These requests are resolved through the split tunnel to the private network. All other names are resolved using the public DNS server. Enter up to ten entries in the list of domains, separated by commas. The entire string can be no longer than 255 characters.

### Related Topics

[Configure Group Policy Objects](#), on page 1561

## Group Policy Secure Client Options

These specifications apply to the operation of the Secure Client VPN.

## Navigation

**Objects > Object Management > VPN > Group Policy.** Click **Add Group Policy** or choose a current policy to edit. Then select the **Secure Client** tab.

## Profile Fields

**Profile**—Choose or create a file object containing the Secure Client Profile. See [File Objects, on page 1573](#) for object creation details.

The Secure Client Profile is a group of configuration parameters stored in an XML file. The Secure Client software uses it to configure the connection entries that appear in the client's user interface. These parameters (XML tags) also configure settings to enable more Secure Client features.

Use the GUI-based Secure Client Profile Editor, an independent configuration tool, to create the Secure Client Profile. See the *Secure Client Profile Editor* chapter in the appropriate release of the [Cisco Secure Client \(including AnyConnect\) Administrator Guide](#) for details.

## Management Profile Fields

A Management VPN Tunnel provides connectivity to the corporate network whenever the endpoint is powered up, even if end-user does not connect over VPN.

**Management VPN Profile**—The Management Profile file contains settings for enabling and establishing Management VPN Tunnel on endpoint.

The Standalone Management VPN Tunnel profile editor can be used to create a new profile file or modify an existing file. You can download the profile editor from [Cisco Software Download Center](#).

For more information about adding a profile file, see [File Objects, on page 1573](#).

## Client Modules Fields

Cisco Secure Client VPN Only offers enhanced security through various built-in modules. These modules provide services such as web security, network visibility into endpoint flows, and off-network roaming protection. Each client module includes a client profile that includes a group of custom configurations as per your requirement.

The following Secure Client modules are optional and you can configure these modules to be downloaded when a VPN user downloads Secure Client:

- **AMP Enabler**—Deploys advanced malware protection (AMP) for endpoints.
- **DART**—Captures a snapshot of system logs and other diagnostic information, which can be sent to the Cisco TAC for troubleshooting.
- **ISE Posture**—Uses the OPSWAT library to perform posture checks to assess an endpoint's compliance.
- **Network Access Manager**—Provides 802.1X (Layer 2) and device authentication for access to both wired and wireless networks.
- **Network Visibility**—Enhances the enterprise administrator's ability to do capacity and service planning, auditing, compliance, and security analytics.
- **Start Before Login**—Forces the user to connect to the enterprise infrastructure over a VPN connection before logging on to Windows by starting Secure Client before the Windows login dialog box appears.
- **Umbrella Roaming Security**—Provides DNS-layer security when no VPN is active.

- **Web Security**—Analyzes the elements of a web page, allows acceptable content, and blocks malicious or unacceptable content based on a defined security policy.

Click **Add** and select the following for each client module:

- **Client Module**—Select the Secure Client module from the list.
- **Profile to download**—Choose or create a file object containing the Secure Client Profile. See [File Objects, on page 1573](#) for object creation details.
- **Enable module download**—Select to enable endpoints to download the client module along with the profile. If not selected, the endpoints can download only the client profile.

Use the GUI-based Secure Client Profile Editor, an independent configuration tool to create a client profile for each module. Download the Secure Client Profile Editor from [Cisco Software Download Center](#). See the *Secure Client Profile Editor* chapter in the appropriate release of the [Cisco Secure Client \(including AnyConnect\)](#) for details.

### SSL Settings Fields

- **SSL Compression**—Whether to enable data compression, and if so, the method of data compression to use, Deflate, or LZS. SSL Compression is Disabled by default.  
Data compression speeds up transmission rates, but also increases the memory requirement and CPU usage for each user session. Therefore, decreasing the overall throughput of the security appliance.
- **DTLS Compression**—Whether to compress Datagram Transport Layer Security (DTLS) connections for this group using LZS or not. DTLS Compression is Disabled by default.
- **MTU Size**—The maximum transmission unit (MTU) size for SSL VPN connections established by the Cisco Secure Client VPN Only. Default is 1406 Bytes, valid range is 576 to 1462 Bytes.
  - **Ignore DF Bit**—Whether to ignore the Don't Fragment (DF) bit in packets that need fragmentation. Allows the forced fragmentation of packets that have the DF bit set, allowing them to pass through the tunnel.

### Connection Settings Fields

- **Enable Keepalive Messages between Secure Client and VPN gateway.** And its **Interval** setting.—Whether to exchange keepalive messages between peers to demonstrate that they are available to send and receive data in the tunnel. Default is enabled. Keepalive messages transmit at set intervals. If enabled, enter the time interval (in seconds) that the remote client waits between sending IKE keepalive packets. The default interval is 20 seconds, the valid range is 15 to 600 seconds.
- **Enable Dead Peer Detection on ...** And their **Interval** settings.—Dead Peer Detection (DPD) ensures that the VPN secure gateway or the VPN client quickly detects when the peer is no longer responding, and the connection has failed. Default is enabled for both the gateway and the client. DPD messages transmit at set intervals. If enabled, enter the time interval (in seconds) that the remote client waits between sending DPD messages. The default interval is 30 seconds, the valid range is 5 to 3600 seconds.
- **Enable Client Bypass Protocol**—Allows you to configure how the secure gateway manages IPv4 traffic (when it is expecting only IPv6 traffic), or how it manages IPv6 traffic (when it is expecting only IPv4 traffic).

When the Secure Client makes a VPN connection to the headend, the headend assigns it an IPv4, IPv6, or both an IPv4 and IPv6 address. If the headend assigns the Secure Client connection only an IPv4 address or only an IPv6 address, you can configure the Client Bypass Protocol to drop network traffic for which the headend did not assign an IP address (default, disabled, not checked), or allow that traffic to bypass the headend and be sent from the client unencrypted or “in the clear” (enabled, checked).

For example, assume that the secure gateway assigns only an IPv4 address to the Secure Client connection and the endpoint is dual-stacked. When the endpoint attempts to reach an IPv6 address, if Client Bypass Protocol is disabled, the IPv6 traffic is dropped; however, if Client Bypass Protocol is enabled, the IPv6 traffic is sent from the client in the clear.

- **SSL rekey**—Enables the client to rekey the connection, renegotiating the crypto keys and initialization vectors, increasing the security of the connection. This is disabled by default. When enabled, the renegotiation can be done at a specified interval and rekey the existing tunnel or create a new tunnel by setting the following fields:
  - **Method**—Available when SSL rekey is enabled. Create a **New Tunnel** (default), or renegotiate, the **Existing Tunnel**'s specifications.
  - **Interval**—Available when SSL rekey is enabled. Set to a default of 4 minutes with a range of 4-10080 minutes (1 week).
- **Client Firewall Rules**—Use the Client Firewall Rules to configure firewall settings for the VPN client's platform. Rules are based on criteria such as source address, destination address, and protocol. Extended Access Control List building block objects are used to define the traffic filter criteria. Choose or create an Extended ACL for this group policy. Define a **Private Network Rule** to control data flowing to the private network, a **Public Network Rule** to control data flowing "in the clear", outside of the established VPN tunnel, or both.

---

**Note** Ensure that the ACL contains only TCP/UDP/ICMP/IP ports and source network as any, any-ipv4 or any-ipv6.

Only VPN clients running Microsoft Windows can use these firewall settings.

---

### Custom Attributes Fields

This section lists the Secure Client Custom attributes that are used by the Secure Client to configure features such as Per App VPN, Allow or defer upgrade, and Dynamic split tunneling. Click **Add** to add custom attributes to the group policy.

1. Select the **Secure Client Attribute**: Per App VPN, Allow Defer Update, or Dynamic Split Tunneling.
2. Select a **Custom Attribute Object** from the list.

---

**Note** Click Add (+) to create a new custom attribute object for the selected Secure Client attribute. You can also create a custom attribute object at **Objects > Object Management > VPN > Custom Attribute**. See [Add Secure Client Custom Attributes Objects, on page 1558](#).

---

3. Click **Add** to save the attributes to the group policy and then click **Save** to save the changes to the group policy.

### Related Topics

[Configure Group Policy Objects](#), on page 1561

## Group Policy Advanced Options

### Navigation Path

**Objects > Object Management > VPN > Group Policy**, Click **Add Group Policy** or choose a current policy to edit., then select the **Advanced** tab.

### Traffic Filter Fields

- **Access List Filter**—Filters consist of rules that determine whether to allow or block tunneled data packets coming through the VPN connection. Rules are based on criteria such as source address, destination address, and protocol. Note that the VPN filter applies to initial connections only. It does not apply to secondary connections, such as a SIP media connection, that are opened due to the action of application inspection. Extended Access Control List building block objects are used to define the traffic filter criteria. Choose or create a new Extended ACL for this group policy.
- **Restrict VPN to VLAN**—Also called “VLAN mapping,” this parameter specifies the egress VLAN interface for sessions to which this group policy applies. The ASA forwards all traffic from this group to the selected VLAN.

Use this attribute to assign a VLAN to the group policy to simplify access control. Assigning a value to this attribute is an alternative to using ACLs to filter traffic on a session. In addition to the default value (Unrestricted), the drop-down list shows only the VLANs that are configured in this ASA. Allowed values range from 1 to 4094.

### Session Settings Fields

- **Access Hours**—Choose or create a time range object. This object specifies the range of time this group policy is available to be applied to a remote access user. See [Time Range, on page 1537](#) for details.
- **Simultaneous Logins Per User**—Specifies the maximum number of simultaneous logins allowed for a user. The default value is 3. The minimum value is 0, which disables login and prevents user access. Allowing several simultaneous connections may compromise security and affect performance.
- **Maximum Connection Time / Alert Interval**—Specifies the maximum user connection time in minutes. At the end of this time, the system stops the connection. The minimum is 1 minute). The Alert interval specifies the interval of time before maximum connection time is reached to display a message to the user.
- **Idle Timeout / Alert Interval**—Specifies this user’s idle timeout period in minutes. If there is no communication activity on the user connection in this period, the system stops the connection. The minimum time is 1 minute. The default is 30 minutes. The Alert interval specifies the interval of time before idle time is reached to display a message to the user.

### Related Topics

[Configure Group Policy Objects](#), on page 1561

## Threat Defense IPsec Proposals

IPsec Proposals (or Transform Sets) are used when configuring VPN topologies. During the IPsec security association negotiation with ISAKMP, the peers agree to use a particular proposal to protect a particular data flow. The proposal must be the same for both peers.

There are separate IPsec proposal objects based on the IKE version, IKEv1, or IKEv2:

- When you create an IKEv1 IPsec Proposal (Transform Set) object, you select the mode in which IPsec operates, and define the required encryption and authentication types. You can select single options for the algorithms. If you want to support multiple combinations in a VPN, create multiple IKEv1 IPsec Proposal objects.
- When you create an IKEv2 IPsec Proposal object, you can select all of the encryption and Hash Algorithms allowed in a VPN. During IKEv2 negotiations, the peers select the most appropriate options that each support.

The Encapsulating Security Protocol (ESP) is used for both IKEv1 and IKEv2 IPsec Proposals. It provides authentication, encryption, and antireplay services. ESP is IP protocol type 50.

---

**Note** We recommend using both encryption and authentication on IPsec tunnels.

---

## Configure IKEv1 IPsec Proposal Objects

### Procedure

- 
- Step 1** Choose **Objects > Object Management** and then **VPN > IPsec IKEv1 Proposal** from the table of contents. Previously configured Proposals are listed including system defined defaults. Depending on your level of access, you may **Edit** (✎), **View** (👁), or **Delete** (🗑) a Proposal.
  - Step 2** Choose **Add** (+) **Add IPsec IKEv1 Proposal** to create a new Proposal.
  - Step 3** Enter a **Name** for this Proposal  
The name of the policy object. A maximum of 128 characters is allowed.
  - Step 4** Enter a **Description** for this Proposal.  
A description of the policy object. A maximum of 1024 characters is allowed.
  - Step 5** Choose the **ESP Encryption** method. The Encapsulating Security Protocol (ESP) encryption algorithm for this Proposal.  
For IKEv1, select one of the options. When deciding which encryption and Hash Algorithms to use for the IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN. For a full explanation of the options, see [Deciding Which Encryption Algorithm to Use, on page 1610](#).
  - Step 6** Select an option for **ESP Hash**.  
For a full explanation of the options, see [Deciding Which Hash Algorithms to Use, on page 1611](#).

- Step 7** Click **Save**  
The new Proposal is added to the list.
- 

## Configure IKEv2 IPsec Proposal Objects

### Procedure

---

- Step 1** Choose **Objects > Object Management** and then **VPN > IKEv2 IPsec Proposal** from the table of contents. Previously configured Proposals are listed including system defined defaults. Depending on your level of access, you may **Edit** (✎), **View** (👁), or **Delete** (🗑) a Proposal.
- Step 2** Choose **Add** (+) **Add IKEv2 IPsec Proposal** to create a new Proposal.
- Step 3** Enter a **Name** for this Proposal  
The name of the policy object. A maximum of 128 characters is allowed.
- Step 4** Enter a **Description** for this Proposal.  
A description of the policy object. A maximum of 1024 characters is allowed.
- Step 5** Choose the **ESP Hash** method, the hash or integrity algorithm to use in the Proposal for authentication.
- Note** Threat Defense does not support IPsec tunnels with NULL encryption. Make sure that you do not choose NULL encryption for IPsec IKEv2 proposal.
- For IKEv2, select all the options you want to support for **ESP Hash**. For a full explanation of the options, see [Deciding Which Hash Algorithms to Use, on page 1611](#).
- Step 6** Choose the **ESP Encryption** method. The Encapsulating Security Protocol (ESP) encryption algorithm for this Proposal.  
For IKEv2, click **Select** to open a dialog box where you can select all of the options you want to support. When deciding which encryption and Hash Algorithms to use for the IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN. For a full explanation of the options, see [Deciding Which Encryption Algorithm to Use, on page 1610](#).
- Step 7** Click **Save**  
The new Proposal is added to the list.
- 

## Threat Defense IKE Policies

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs). The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection. An IKE proposal is a set of algorithms that two peers use to secure the negotiation between them. IKE negotiation

begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters are used to protect subsequent IKE negotiations.

For IKEv1, IKE proposals contain a single set of algorithms and a modulus group. You can create multiple, prioritized policies to ensure that at least one policy matches a remote peer's policy. Unlike IKEv1, in an IKEv2 proposal, you can select multiple algorithms and modulus groups in one policy. Since peers choose during the Phase 1 negotiation, this makes it possible to create a single IKE proposal, but consider multiple, different proposals to give higher priority to your most desired options. For IKEv2, the policy object does not specify authentication, other policies must define the authentication requirements.

An IKE policy is required when you configure a site-to-site IPsec VPN. For more information, see [VPN, on page 1603](#).

## Configure IKEv1 Policy Objects

Use the IKEv1 Policy page to create, delete, or edit an IKEv1 policy object. These policy objects contain the parameters required for IKEv1 policies.

### Procedure

- 
- Step 1** Choose **Objects > Object Management** and then **VPN > IKEv1 Policy** from the table of contents. Previously configured policies are listed including system defined defaults. Depending on your level of access, you may **Edit** (✎), **View** (👁), or **Delete** (🗑) a proposal.
- Step 2** (Optional) Choose **Add (+)Add IKEv1 Policy** to create a new policy object.
- Step 3** Enter a **Name** for this policy. A maximum of 128 characters is allowed.
- Step 4** (Optional) Enter a **Description** for this proposal. A maximum of 1,024 characters is allowed.
- Step 5** Enter the **Priority** value of the IKE policy.
- The priority value determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec peer does not support the parameters selected in your first priority policy, it tries to use the parameters defined in the next lowest priority. Valid values range from 1 to 65,535. The lower the number, the higher the priority. If you leave this field blank, Management Center assigns the lowest unassigned value starting with 1, then 5, then continuing in increments of 5.
- Step 6** Choose the **Encryption** method.
- When deciding which encryption and Hash Algorithms to use for the IKEv1 policy, your choice is limited to algorithms supported by the peer devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. For IKEv1, select one of the options. For a full explanation of the options, see [Deciding Which Encryption Algorithm to Use, on page 1610](#).
- Step 7** Choose the **Hash** Algorithm that creates a Message Digest, which is used to ensure message integrity.
- When deciding which encryption and Hash Algorithms to use for the IKEv1 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. For a full explanation of the options, see [Deciding Which Hash Algorithms to Use, on page 1611](#).
- Step 8** Set the **Diffie-Hellman Group**.

The Diffie-Hellman group to use for encryption. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the group that you want to allow in the VPN. For a full explanation of the options, see [Deciding Which Diffie-Hellman Modulus Group to Use, on page 1611](#).

**Step 9** Set the **Lifetime** of the security association (SA), in seconds. You can specify a value from 120 to 2,147,483,647 seconds. The default is 86400.

When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

**Step 10** Set the **Authentication Method** to use between the two peers.

- **Preshared Key**—Preshared keys allow for a secret key to be shared between two peers and to be used by IKE during the authentication phase. If one of the participating peers is not configured with the same preshared key, the IKE SA cannot be established.
- **Certificate**—When you use Certificates as the authentication method for VPN connections, peers obtain digital certificates from a CA server in your PKI infrastructure, and trade them to authenticate each other.

**Note** In a VPN topology that supports IKEv1, the **Authentication Method** specified in the chosen IKEv1 Policy object becomes the default in the IKEv1 **Authentication Type** setting. These values must match, otherwise, your configuration will error.

**Step 11** Click **Save**  
The new IKEv1 policy is added to the list.

---

## Configure IKEv2 Policy Objects

Use the IKEv2 policy dialog box to create, delete, and edit an IKEv2 policy object. These policy objects contain the parameters required for IKEv2 policies.

### Procedure

- 
- Step 1** Choose **Objects > Object Management** and then **VPN > IKEv2 Policy** from the table of contents. Previously configured policies are listed including system defined defaults. Depending on your level of access, you may **Edit** () , **View** () , or **Delete** () a policy.
- Step 2** Choose **Add** () **Add IKEv2 Policy** to create a new policy.
- Step 3** Enter a **Name** for this policy.  
The name of the policy object. A maximum of 128 characters is allowed.
- Step 4** Enter a **Description** for this policy.  
A description of the policy object. A maximum of 1024 characters is allowed.
- Step 5** Enter the **Priority**.

The priority value of the IKE proposal. The priority value determines the order of the IKE proposals compared by the two negotiating peers when attempting to find a common security association (SA). If the remote IPsec peer does not support the parameters selected in your first priority policy, it tries to use the parameters defined in the next lowest priority policy. Valid values range from 1 to 65535. The lower the number, the higher the priority. If you leave this field blank, Management Center assigns the lowest unassigned value starting with 1, then 5, then continuing in increments of 5.

**Step 6** Set the **Lifetime** of the security association (SA), in seconds. You can specify a value from 120 to 2,147,483,647 seconds. The default is 86400.

When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

**Step 7** Choose the **Integrity Algorithms** portion of the Hash Algorithm used in the IKE policy. The Hash Algorithm creates a Message Digest, which is used to ensure message integrity.

When deciding which encryption and Hash Algorithms to use for the IKEv2 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. Select all the algorithms that you want to allow in the VPN. For a full explanation of the options, see [Deciding Which Hash Algorithms to Use, on page 1611](#).

**Step 8** Choose the **Encryption Algorithm** used to establish the Phase 1 SA for protecting Phase 2 negotiations.

When deciding which encryption and Hash Algorithms to use for the IKEv2 proposal, your choice is limited to algorithms supported by the managed devices. For an extranet device in the VPN topology, you must choose the algorithm that matches both peers. Select all the algorithms that you want to allow in the VPN. For a full explanation of the options, see [Deciding Which Encryption Algorithm to Use, on page 1610](#).

**Step 9** Choose the **PRF Algorithm**.

The pseudorandom function (PRF) portion of the Hash Algorithm used in the IKE policy. In IKEv1, the Integrity and PRF algorithms are not separated, but in IKEv2, you can specify different algorithms for these elements. Select all of the algorithms that you want to allow in the VPN. For a full explanation of the options, see [Deciding Which Hash Algorithms to Use, on page 1611](#).

**Step 10** Select and **Add a DH Group**.

The Diffie-Hellman group used for encryption. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the groups that you want to allow in the VPN. For a full explanation of the options, see [Deciding Which Diffie-Hellman Modulus Group to Use, on page 1611](#).

**Step 11** Click **Save**

If a valid combination of choices has been selected the new IKEv2 policy is added to the list. If not, errors are displayed and you must make changes accordingly to successfully save this policy.

## Secure Client Customization

You can now customize Secure Client and deploy these customizations to the VPN headend. The threat defense distributes these customizations to the endpoint when an end user connects from the Secure Client.

Secure Client Customization objects represent files used to customize Secure Client. The following are the supported Secure Client customizations:

- GUI text and messages
- Icons and images
- Scripts
- Binaries
- Custom Installer Transforms
- Localized Installer Transforms

For more information about configuring these Secure Client customizations, see [Customize Cisco Secure Client, on page 1730](#).

## File Objects

Use the Add and Edit File Object dialog boxes to create, and edit file objects. File objects represent files used in configurations, typically for remote access VPN policies. They can contain Secure Client Profile and Secure Client Image files.

Profiles are also created for each AnyConnect module and Secure Client Management VPN using independent profile editors and deployed to administrator-defined end user requirements and authentication policies on endpoints as part of Secure Client, and they make the preconfigured network profiles available to end users.

When you create a file object, the management center makes a copy of the file in its repository. These files are backed up whenever you create a backup of the database, and they are restored if you restore the database. When copying a file to the platform to be used in a file object, do not copy the file directly to the file repository.

When you deploy configurations that specify a file object, the associated file is downloaded to the device in the appropriate directory.

You can click one of the following options against each file:

- **Download** —Click to download the Secure Client file.
- **Edit** —Modify the file object details.
- **Delete** —Delete the Secure Client file object. When you delete a file object, the associated file is not deleted from the file repository, only the object is deleted.

### Navigation Path

**Objects > Object Management > VPN > Secure Client File.**

### Fields

- **Name**—Enter the name of the file to identify the file object; you can add up to 128 characters.
- **File Name**—Click **Browse** to select the file. The file name and full path of the file are added when you select the file.
- **File Type**—Choose the file type corresponding to the file you have selected. The following file types are available:
  - **Secure Client Image**—Select this type when you add the Secure Client image you have downloaded from the [Cisco Software Download Center](#).

You can associate any new or additional Secure Client images to the remote access VPN policy. You can also unassociate the unsupported or end of life client packages that are no longer required.

- **Secure Client VPN Profile**—Choose this type for the Secure Client VPN profile file.  
The profile file is created using the GUI-based Secure Client Profile Editor, an independent configuration tool. See the *Secure Client Profile Editor* chapter in the appropriate release of the [Cisco Secure Client \(including AnyConnect\) User Guide](#) for details.
- **Secure Client Management VPN Profile**—Select this type when you add a profile file for the Secure Client management VPN tunnel.  
Download the Secure Client **VPN Management Tunnel Standalone Profile Editor** from [Cisco Software Download Center](#) if you have not done already and create a profile with required settings for the Secure Client management VPN tunnel.
- **AMP Enabler Service Profile**—The profile is used for the Secure Client AMP Enabler. The AMP Enabler along with this profile is pushed to the endpoints from threat defense when a remote access VPN user connects to the VPN.
- **Feedback Profile**—You can add a Customer Experience Feedback profile and select this type to receive information about the features and modules customers have enabled and use.
- **ISE Posture Profile**—Choose this option if you are adding a profile file for the Secure Client ISE Posture module.
- **NAM Service Profile**—Configure and add the NAM profile file using the Network Access Manager profile editor.
- **Network Visibility Service Profile**—Profile file for Secure Client Network Visibility module. You can create the profile using the NVM profile editor.
- **Umbrella Roaming Security Profile**—You must select this file type if you are deploying the Umbrella Roaming Security module using the .json file created using the profile editor.
- **Web Security Service Profile**—Select this file type when you add a profile file for the Web security module.
- **Secure Firewall Posture Package**—Select this file type when you add a Secure Firewall Posture Package file. This file is used while configuring a Dynamic Access Policy (DAP) to collect information about the operating system, anti-virus, anti-spyware, and firewall software installed on the endpoints.
- **Secure Client External Browser Package**—This file type is for selecting an external browser package file for SAML single sign-on web authentication.  
You can add the package file when a new version of the external package file is available.  
For more information, see [Configure AAA Settings for Remote Access VPN, on page 1698](#).

- **Description**—Add an optional description.

- [Installing a Certificate Using a PKCS12 File, on page 1582](#)
- [Troubleshooting Threat Defense Certificates, on page 1583](#)
- [History for Certificates, on page 1584](#)

## Requirements and Prerequisites for Certificates

### Supported Domains

Any

### User Roles

Admin

Network Admin

## Secure Firewall Threat Defense VPN Certificate Guidelines and Limitations

- When a PKI enrollment object is associated with and then installed on a device, the certificate enrollment process starts immediately. The process is automatic for self-signed and SCEP enrollment types; it does not require any additional administrator's action. Manual certificate enrollment requires administrator's action.
- When the certificate enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your VPN Authentication Method.

- threat defense devices support certificate enrollment using Microsoft Certificate Authority(CA) Service, and CA Services provided on Cisco Adaptive Security Appliances(ASA) and Cisco IOS Router.
- threat defense devices cannot be configured as a certificate authority (CA).

### Guidelines for Certificate Management Across Domains and Devices

- Certificate enrollment can be done in a child or parent domain.
- When enrollment is done from a parent domain, the certificate enrollment object also needs to be in the same domain. If the trustpoint on a device is overridden in the child domain, the overridden value will be deployed on the device.
- When the certificate enrollment is done on a device in a leaf domain, the enrollment will be visible to the parent domain or another child domain. Also, adding additional certificates is possible.
- When a leaf domain is deleted, certificate enrollments on the contained devices will be automatically removed.
- Once a device has certificates enrolled in one domain, it will be allowed to be enrolled in any other domain. The certificates can be added in the other domain.
- When you move a device from one domain to another, the certificates also get moved accordingly. You will receive an alert to delete the enrollments on these devices.

## Managing Threat Defense Certificates

See [PKI Infrastructure and Digital Certificates](#) , on page 1612 for an introduction to Digital Certificates.

See [Certificate Enrollment Objects](#), on page 1509 for a description of the objects used to enroll and obtain certificates on managed devices.

### Procedure

---

#### Step 1 Select **Devices** > **Certificates**.

You can see the following columns for each device listed on this screen:

- **Name**—Lists the devices that already have trustpoints associated with them. Expand the device to see the list of associated trustpoints.
- **Domain**—Displays the certificates that are enrolled in a specific domain.
- **Enrollment Type**—Displays the type of enrollment used for a trustpoint.
- **Status**—Provides the status of the **CA Certificate** and **Identity Certificate**. You can view the certificate contents, when `Available`, by clicking the magnifying glass.

When you view the CA certificate information, you can view the hierarchy of all the certifying authorities, which issued your CA certificate.

If the enrollment fails, click status to view the failure message.

- Click **Enable weak-crypto** on the right to enable weak cipher usage in certificates. When you click the toggle button, you get a warning to confirm before enabling weak ciphers. Click **Yes** to enable weak ciphers.

**Note** When a certificate enrollment fails due to weak cipher usage, you get a prompt to enable the weak cipher. You can choose to enable weak cipher when you need to use weak encryption.

- The additional column lists icons to perform the following tasks:
  - **Export Certificate**—Click to export and download a copy of the certificate. You can choose to export the PKCS12 (Complete Certificate Chain) or the PEM(Identity Certificate Only) format. You must provide a pass phrase to export a PKCS12 certificate format to import the file later.
  - **Re-enroll certificate**—Re-enroll an existing certificate.
  - **Refresh certificate status**—Refresh a certificate to synchronize the Firepower Threat Defense device certificate status to the Firepower Management Center.
  - **Delete certificate**—Delete all the associated certificates for a trustpoint.

**Step 2** Choose (+) **Add** to associate and install an enrollment object on a device.

When a certificate enrollment object is associated with and then installed on a device, the process of certificate enrollment starts immediately. The process is automatic for self-signed and SCEP enrollment types, meaning it does not require any additional administrator action. Manual certificate enrollment requires extra administrator action.

**Note** The certificate enrollment on a device does not block the user interface and the enrollment process gets executed in the background, enabling the user to perform certificate enrollment on other devices in parallel. The progress of these parallel operations can be monitored on the same user interface. The respective icons display the certificate enrollment status.

---

## Automatically Update CA Bundles

You can set the management center to automatically update the CA certificates through CLI commands. By default, the CA certificates are automatically updated when you install or upgrade to version 7.0.5.

---

**Note** In an IPv6-only deployment, the automatic update of CA certificates may fail, because, some of the Cisco servers do not support IPv6. In such cases, force update the CA certificates using the **configure cert-update run-now force** command.

---

## Procedure

**Step 1** Log into the FMC CLI using SSH, or, if virtual, open the VM console.

**Step 2** You can verify whether the CA certificates in the local system are the latest or not:

**configure cert-update test**

This command compares the CA bundle on the local system with the latest CA bundle (from the Cisco server). If the CA bundle is up to date, no connection check is executed and the test result is displayed as the one below:

**Example:**

```
> configure cert-update test
Test succeeded, certs can safely be updated or are already up to date.
```

If the CA bundle is out of date, the connection check is executed on the downloaded CA bundle and the test result is displayed.

**Example:**

When the connection check fails:

```
> configure cert-update test
Test failed, not able to fully connect.
```

**Example:**

When the connection check succeeds, or the CA bundle is already up to date:

```
> configure cert-update test
Test succeeded, certs can safely be updated or are already up to date.
```

**Step 3** (Optional) To instantly update the CA bundles:

**configure cert-update run-now**

**Example:**

```
>configure cert-update run-now
Certs have been replaced or was already up to date.
```

When you execute this command, the CA certificates (from the Cisco server) are verified for SSL connectivity. If the SSL connectivity check fails for even one of the Cisco servers, the process is terminated.

**Example:**

```
> configure cert-update run-now
Certs failed some connection checks.
```

To proceed with the update despite connection failures, use the **force** keyword.

**Example:**

```
> configure cert-update run-now force
```

Certs failed some connection checks, but replace has been forced.

**Step 4** If you do not want the CA bundles to be automatically updated, disable the configuration:

**configure cert-update auto-update disable**

**Example:**

```
> configure cert-update auto-update disable
Autoupdate is disabled
```

**Step 5** To re-enable the automatic update of CA bundles:

**configure cert-update auto-update enable**

**Example:**

```
> configure cert-update auto-update enable
Autoupdate is enabled and set for every day at 12:18 UTC
```

When you enable the automatic update on the CA certificates, the update process is executed daily at a system-defined time.

**Step 6** (Optional) View the status of automatic update of CA certificates:

**show cert-update**

**Example:**

```
> show cert-update
Autoupdate is enabled and set for every day at 09:34 UTC
CA bundle was last modified 'Thu Sep 15 16:12:35 2022'
```

---

## Installing a Certificate Using Self-Signed Enrollment

### Procedure

---

**Step 1** On the **Devices > Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

**Step 2** Choose a device from the **Device** drop-down list.

**Step 3** Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the type Self-Signed from the drop-down list.
- Click (+), to add a new Certificate Enrollment Object, see [Adding Certificate Enrollment Objects, on page 1511](#).

**Step 4** Press **Add** to start the Self Signed, automatic, enrollment process.

For self signed enrollment type trustpoints, the **CA Certificate** status will always be displayed, since the managed device is acting as its own CA and does not need a CA certificate to generate its own Identity Certificate.

The **Identity Certificate** will go from `InProgress` to `Available` as the device creates its own self signed identity certificate.

**Step 5** Click the magnifying glass to view the self-signed Identity Certificate created for this device.

---

#### What to do next

When enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your Site to Site and Remote Access VPN Authentication Method

## Installing a Certificate using EST Enrollment

### Before you begin

**Note** Using EST enrollment establishes a direct connection between the managed device and the CA server. So be sure your device is connected to the CA server before beginning the enrollment process.

---

**Note** EST's ability to auto-enroll a device when its certificate expires is not supported.

---

### Procedure

**Step 1** On the **Devices > Certificates** screen, click **Add** to open the **Add New Certificate** dialog.

**Step 2** Choose a device from the **Device** drop-down list.

**Step 3** Associate a certificate enrollment object with this device in one of the following ways:

- Choose the EST certificate enrollment object from the **Cert Enrollment** drop-down list.
- Click (+), to add a new Certificate Enrollment Object, see [Adding Certificate Enrollment Objects, on page 1511](#).

**Step 4** Click **Add** to enroll the certificate on the device.

The **Identity Certificate** will go from `InProgress` to `Available` as the device obtains its identity certificate using EST from the specified CA. Sometimes, a manual refresh might be required to obtain the identity certificate.

**Step 5** Click the magnifying glass to view the Identity Certificate created and installed on this device.

---

# Installing a Certificate Using SCEP Enrollment

## Before you begin

**Note** Using SCEP enrollment establishes a direct connection between the managed device and the CA server. So be sure your device is connected to the CA server before beginning the enrollment process.

## Procedure

- 
- Step 1** On the **Devices > Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.
- Step 2** Choose a device from the **Device** drop-down list.
- Step 3** Associate a certificate enrollment object with this device in one of the following ways:
- Choose a Certificate Enrollment Object of the type SCEP from the drop-down list.
  - Click (+), to add a new Certificate Enrollment Object, see [Adding Certificate Enrollment Objects, on page 1511](#).
- Step 4** Press **Add**, to start the automatic enrollment process.
- For SCEP enrollment type trustpoints, the **CA Certificate** status will transition from `InProgress` to `Available` as the CA Certificate is obtained from the CA server and installed on the device.
- The **Identity Certificate** will go from `InProgress` to `Available` as the device obtains its identity certificate using SCEP from the specified CA. Sometimes, a manual refresh might be required to obtain the identity certificate.
- Step 5** Click the magnifying glass to view the Identity Certificate created and installed on this device.

---

## What to do next

When enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your Site to Site and Remote Access VPN Authentication Method

# Installing a Certificate Using Manual Enrollment

## Procedure

- 
- Step 1** On the **Devices > Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.
- Step 2** Choose a device from the **Device** drop-down list.
- Step 3** Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the type Manual from the drop-down list.
- Click (+), to add a new Certificate Enrollment Object, see [Adding Certificate Enrollment Objects, on page 1511](#).

**Step 4** Press **Add** to start the enrollment process.

**Step 5** Execute the appropriate activity with your PKI CA Server to obtain an identity certificate.

- Click **Identity Certificate** warning to view and copy the CSR.
- Execute the appropriate activity with your PKI CA Server to obtain an identity certificate using this CSR.

This activity is completely independent of the Secure Firewall Management Center or the managed device. When complete, you will have an Identity Certificate for the managed device. You can place it in a file.

- To finish the manual process, install the obtained identity certificate onto the managed device.

Return to the Secure Firewall Management Center dialog and select **Browse Identity Certificate** to choose the identity certificate file.

**Note** Ensure not to choose a binary certificate (PKCS12, DER, and alike) file because threat defense does not support them.

**Step 6** Select **Import** to import the Identity Certificate.

The Identity Certificate status will be `Available` when the import complete.

**Step 7** Click the magnifying glass to view the **Identity Certificate** for this device.

---

### What to do next

When enrollment is complete, a trustpoint exists on the device with the same name as the certificate enrollment object. Use this trustpoint in the configuration of your Site to Site and Remote Access VPN Authentication Method

## Installing a Certificate Using a PKCS12 File

### Procedure

**Step 1** Go to **Devices > Certificates** screen, choose **Add** to open the **Add New Certificate** dialog.

**Step 2** Choose a pre-configured managed device from the **Device** drop down list.

**Step 3** Associate a certificate enrollment object with this device in one of the following ways:

- Choose a Certificate Enrollment Object of the PKCS type from the drop-down list.
- Click (+), to add a new Certificate Enrollment Object, see [Adding Certificate Enrollment Objects, on page 1511](#).

**Step 4** Press **Add**.

The CA Certificate and Identity Certificate status will go from `In Progress` to `Available` as it installs the PKCS12 file on the device.

**Note** When you upload the PKCS12 file for the first time, the file is stored in management center as part of the CertEnrollment object. For any failed enrollments due to a wrong passphrase or failed deployment, retry enrolling the PKCS12 certificate without uploading the file again. A PKCS12 file size should not be larger than 24K.

**Step 5** Once Available, click the magnifying glass to view the Identity Certificate for this device.

---

### What to do next

The certificate (trustpoint) on the managed device is named the same as the PKCS#12 file. Use this certificate in your VPN authentication configuration.

## Troubleshooting Threat Defense Certificates

See [Secure Firewall Threat Defense VPN Certificate Guidelines and Limitations, on page 1575](#) to determine if variations in your certificate enrollment environment may be causing a problem. Then consider the following:

- Ensure there is a route to the CA Server from the device.

If the CA Server's host name is given in the Enrollment Object, use Flex Config to configure DNS appropriately to reach the server. Alternatively, use the IP Address of the CA Server.

- If you are using a Microsoft 2012 CA Server, the default IPsec Template is not accepted by the managed device and must be changed.

To configure a working template, follow these steps as you use MS CA documentation as a reference.

1. Duplicate the IPsec (Offline Request) template.
2. In **Extensions > Application policies**, select *IP security end system*, instead of the *IP security IKE intermediate*.
3. Set the permissions and the template name.
4. Add the new template and change the registry settings to reflect the new template name.

- On the management center, you might receive the following health alert related to the threat defense device:

```
Code - F0853; Description - default Keyring's certificate is invalid, reason: expired
```

In such cases, use the following command to regenerate the default certificate in CLISH CLI:

```
> system support regenerate-security-keyring default
```

- A red cross appears in the CA certificate status with the following error:

```
Fail to configure CA certificate
```

Solution: See [Troubleshoot Certificate Error on FMC](#).

- To check the list of the certificates in a .pfx file, use tools such as `certutil` or `openssl`. You can see the whole chain with ID certificate, SubCA certificate, and CA certificate (if any).

- `certutil -dump cert.pfx`
- `openssl pkcs12 -info -in cert.pfx`

- The following error appears:

Identity certificate import required

Solution: See [Troubleshoot Certificate Error "Identity certificate import required" on FMC](#).

## History for Certificates

| Feature                           | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                        |
|-----------------------------------|---------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Support for OCSP and CRL IPv6 URL | 7.4                       | Any                    | You can now add IPv6 OCSP and CRL URLs for certificate authentication (revocation checking). The IPv6 addresses must be enclosed in square brackets.                           |
| Enhancements to Manual Enrollment | 6.7                       | Any                    | You can now create only a CA certificate without an identity certificate. You can also generate a CSR without a CA certificate and obtain an identity certificate from the CA. |
| PKCS CA Chain                     | 6.7                       | Any                    | You can view and manage the chain of certifying authorities (CAs) issuing your certificates. You can also export a copy of the certificates.                                   |

## PART **XIII**

### **SD-WAN**

- [SD-WAN Capabilities, on page 1587](#)

## CHAPTER 56

# SD-WAN Capabilities

This chapter describes the SD-WAN capabilities supported in the management center.

- [Overview of SD-WAN Capabilities, on page 1587](#)
- [Using SD-WAN Wizard for Secure Branch Network Deployment, on page 1588](#)

## Overview of SD-WAN Capabilities

Software-Defined WAN (SD-WAN) solutions replace traditional WAN routers and are agnostic to WAN transport technologies. SD-WAN provides dynamic, policy-based, application path selection across multiple WAN connections and supports service chaining for additional services such as WAN optimization and firewalls.

As organizations expand their operations across multiple branch locations, ensuring secure and streamlined connectivity becomes paramount. Deploying a secure branch network infrastructure involves complex configurations, which can be time-consuming and prone to configuration errors if not handled properly. However, organizations can overcome these challenges by leveraging the Cisco Secure Firewall Management Center (management center) and the Cisco Secure Firewall Threat Defense (threat defense) devices for a simplified and secure branch deployment.

In this guide, we explore the concept of simplifying secure branch deployment using a robust firewall solution. By integrating a secure firewall as a foundational component of the branch network architecture, organizations can establish a strong security baseline while simplifying the deployment process. This approach enables organizations to enforce unified security policies, optimize traffic routing, and ensure resilient connectivity.

Some of the SD-WAN capabilities supported on the Cisco Secure Firewall are:

- **Simplified management:**
  - SASE: Umbrella auto tunnel deployment
  - Dynamic VTI (DVTI) hub spoke topology simplification
- **Application awareness:**
  - Direct Internet Access (DIA) for public cloud and guest user
  - Policy based routing (PBR) using applications as a match criteria
  - Local tunnel ID support for Umbrella

- **Increased usable bandwidth:**
  - ECMP support for load balancing across multiple ISPs and VTIs
  - Application-based load balancing using PBR
- **High availability with near zero network downtime:**
  - Dual ISP configuration
  - Optimal path selection based on application-based interface monitoring.
- **Secure Elastic Connectivity:**
  - Route-based (VTI) VPN tunnels between headquarters (hub) and branches (spokes)
  - IPv4 and IPv6 BGP, IPv4 and IPv6 OSPF, and IPv4 EIGRP over VTI
  - DVTI hubs that support spokes with static or dynamic IP

## Using SD-WAN Wizard for Secure Branch Network Deployment

Management Center allows you to easily configure VPN tunnels and routing configuration between your centralized headquarters (hubs) and remote branch sites (spokes) using the new SD-WAN wizard.

### What are Hubs and Spokes?

Hubs: Devices that enable secure VPN connectivity to and from one or more remote branch devices or spokes. Hubs also act as a gateway for spokes to communicate with each other.

Spokes: Devices in remote branches that connect over VPN to a hub to securely access the corporate resources behind the hub. Spokes communicate with each other through the hub.

### Benefits of Using SD-WAN Wizard

- Simplifies and automates the VPN and routing configuration of your SD-WAN network.
- Creates route-based VPN tunnels and simplifies the configuration process by automating tasks such as:
  - Generating tunnel interfaces of the branches.
  - Assigning IP addresses to the tunnel interfaces.
  - Configuring BGP for the SD-WAN overlay network. These configurations ensure seamless connection between hubs and spokes, and spoke to spoke through the hub.
- Provides seamless routing because hubs act as route reflectors and enable the following:
  - Provide connectivity between the spokes.
  - Determine the best routing path based on the spokes' active and backup tunnels.
- Requires minimal user input.
- Easily add multiple branches at a time.

- Provides easy dual ISP configurations.
- Enables network scaling.

## Guidelines and Limitations for Using SD-WAN Wizard

### Guidelines

- When you configure the DVTIs of two hubs, ensure that they have the same IPsec tunnel mode (IPv4 or IPv6).
- In a dual-hub SD-WAN topology, the hubs can be in different geographic locations and have different protected networks behind them. To ensure direct communication between these networks, ensure that you configure the following:
  - A point-to-point route-based VPN topology between the two hubs (**Devices > Site-to-site > Add > Route-Based VPN**).
  - A dynamic routing protocol between the hubs (**Device > Device Management > Routing**).
- When you configure IP address pools for spokes, ensure the following:
  - The **Allow Overrides** check box must be unchecked.
  - If you are using multiple pools, the IP addresses of the pools must not overlap.
  - IP addresses must not overlap with any of the interfaces on the spoke.
- When you create security zones or interface groups, choose **Routed** as the **Interface Type**.
- Use the spoke security zone to configure an access control policy that allows tunnel traffic to and from the spokes.
- Configure the spokes' VPN interfaces in an ECMP zone to load balance the application traffic. If you do not configure the ECMP zone, the remaining paths act as backup paths when the primary path goes down.
- In SD-WAN topologies with dual ISPs on spokes, the tunnel identity and the tunnel source of the spokes must be unique.
- If a device has only IPv6 address configurations, you must configure the BGP router ID with a loopback or physical interface that has an IPv4 address (**Device > Device Management > Routing > General Settings > BGP**).

### Limitations

- You can configure a maximum of two hubs in an SD-WAN topology using the SD-WAN wizard.
- For each spoke, you can use only one WAN interface per topology. However, for dual-ISP setups, you can configure a second SD-WAN topology with the second WAN interface. For more information, see [Sample Configurations for Dual ISP Deployment Using SD-WAN Wizard, on page 1594](#).
- SD-WAN wizard does not support the following:
  - IKEv1

- Cluster devices are not supported on the hub and spoke because VTI is not supported on cluster devices.
- Extranet hubs and spokes such as ASA, Cisco IOS, Cisco Viptela, Umbrella, Meraki, or vendor devices.

## Prerequisites for Using the SD-WAN Wizard

- Management Center Essentials (formerly Base) license must allow export-controlled functionality. Choose **System > Licenses > Smart Licenses** to verify this functionality in the management center.
- You must be an Admin user.
- Hub devices must be Version 7.6.0 and later.
- Spoke devices must be Version 7.3.0 and later.
- The threat defense devices must have an internet-routable public IP address. The IP address can be static or dynamic.
- Assign appropriate logical names and IP addresses to the interfaces of the threat defense devices. For example, use *inside* for the interface connected to the LAN, and *outside* for the interface connected to the internet or WAN.
- If you are using certificate-based authentication, you must enroll the certificates in the hub and spokes.
- Configure routing, NAT, and AC policies to ensure underlay connectivity between the devices.

## Configure an SD-WAN Topology Using the SD-WAN Wizard

The SD-WAN wizard allows you to easily configure VPN tunnels between your centralized headquarters and remote branch sites.

### Before you begin

Ensure that you review [Prerequisites for Using the SD-WAN Wizard, on page 1590](#) and [Guidelines and Limitations for Using SD-WAN Wizard, on page 1589](#).

### Procedure

- 
- Step 1** Choose **Devices > Site To Site**, and click **Add**.
  - Step 2** Enter a name for the SD-WAN VPN topology in the **Topology Name** field.
  - Step 3** Click the **SD-WAN Topology** radio button and click **Create**.
  - Step 4** Configure a hub:
    - a) Click **Add Hub**.
    - b) From the **Device** drop-down list, choose a hub.
    - c) Click + next to the **Dynamic Virtual Tunnel Interface (DVTI)** drop-down list to add a dynamic VTI for the hub.

The **Add Virtual Tunnel Interface** dialog box is prepopulated with default configurations. However, you must configure the **Tunnel Source**, and the **Borrow IP Address**. For more information, see [Add a Dynamic Virtual Tunnel Interface for a Hub, on page 1594](#).

- d) Click **OK**.
- e) In the **Hub Gateway IP Address** field, enter the public IP address of the hub's VPN interface or the tunnel source of the dynamic VTI to which the spokes connect.  
  
This IP address is auto populated if the interface has a static IP address. If hub is behind a NAT device, you must manually configure the post-NAT IP address.
- f) From the **Spoke Tunnel IP Address Pool** drop-down list, choose an IP address pool or click + to create an address pool.  
  
When you add spokes, the wizard auto generates spoke tunnel interfaces, and assigns IP addresses to these spoke interfaces from this IP address pool.
- g) Click **Add** to save the hub configuration.
- h) (Optional) To add a secondary hub, repeat Step 4a to Step 4f.
- i) Click **Next**.

## Step 5

Configure spokes:

Click **Add Spoke** to add a single spoke device, or click **Add Spokes (Bulk Addition)** to add multiple spokes to your topology.

- Click **Add Spoke**. In the **Add Spoke** dialog box, configure the following parameters:
  - a. From the **Device** drop-down list, choose a spoke.
  - b. From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface to establish a VPN connection with the hub.
  - c. Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from this device to the remote peer. By default, this option is enabled.
  - d. Choose one of the following options from the **Identity Type** drop-down list:
    - **Key ID**—(Default value) This value is auto populated as `<sd-wan topologyname>_<device_IP_address>`, for example, `sdwantopo1_192.168.0.200`. You can also specify a key ID of your choice.
    - **Email ID**—Specify an email ID up to 127 characters.
    - **IP Address**—IP address of the spoke's VPN interface.
    - **Auto**—IP address of the spoke's VPN interface for pre-shared key authentication or the certificate Distinguished Name (DN) for certificate-based authentication.
    - **Hostname**—Fully qualified hostname of the spoke.
  - e. Click **Save** to save the spoke configuration.
- Click **Add Spokes (Bulk Addition)**. In the **Add Bulk Spokes** dialog box, configure the following parameters:
  - a. Choose one or more devices from the **Available Devices** list and click **Add** to move the devices to **Selected Devices**.

- b. Use one of the following methods to select the VPN interfaces of the spokes:
  - Click the **Interface Name Pattern** radio button and specify a string to match the logical name of the internet or WAN interface of the spokes, for example, `outside*`, `wan*`.  
If the spoke has multiple interfaces with the same pattern, the first interface that matches the pattern is selected for the topology.
  - Click the **Security Zone** radio button and choose a security zone with the VPN interfaces of the spokes from the drop-down list, or click + to create a security zone.
- c. Click **Next**.  
The wizard validates if the spokes have interfaces with the specified pattern. Only the validated devices are added to the topology.
- d. Click **Add**.
- e. Click **Next**.

For each spoke, the wizard automatically selects the hub's DVTI as the tunnel source IP address.

**Note** If the hub's tunnel source IP address is an IPv6 address, the wizard automatically selects the first IPv6 address of the spokes' selected interface. To edit the IPv6 address of a spoke's tunnel source, click the edit icon next to a spoke, choose an IPv6 address from the **IP Address** drop-down list, and click **Save**.

**Step 6** Configure authentication settings for the devices in the SD-WAN topology:

- a) **Authentication Type**—For device authentication, you can use a manual pre-shared key, an auto-generated pre-shared key, or a certificate.
  - **Pre-shared Manual Key**—Specify the pre-shared key for the VPN connection.
  - **Pre-shared Automatic Key**—(Default value) The wizard automatically defines the pre-shared key for the VPN connection. Specify the key length in the **Pre-shared Key Length** field. The range is 1 to 127.
  - **Certificate**—When you use certificates as the authentication method, the peers obtain digital certificates from a CA server in your PKI infrastructure, and use them to authenticate each other.
- b) Choose one or more algorithms from the **Transform Sets** drop-down list.
- c) Choose one or more algorithms from the **IKEv2 Policies** drop-down list.
- d) Click **Next**.

**Step 7** Configure the SD-WAN settings:

This step involves the auto generation of spoke tunnel interfaces, and BGP configuration of the overlay network.

- a) From the **Spoke Tunnel Interface Security Zone** drop-down list, choose a security zone or click + to create a security zone to which the wizard automatically adds the spokes' auto-generated Static Virtual Tunnel Interfaces (SVTIs).
- b) Check the **Enable BGP on the VPN Overlay Topology** check box to automate BGP configurations such as neighbor configurations between the overlay tunnel interfaces and basic route redistribution from the directly connected LAN interfaces of the hubs and spokes.

- c) In the **Autonomous System Number** field, enter an Autonomous System (AS) number.
- AS number is a unique number for a network with a single routing policy. BGP uses AS numbers to identify networks. The spoke's BGP neighbor configuration is generated based on the corresponding hub's AS number. Range is from 0 to 65536.
- If all the hubs and spokes are in the same region, by default, **64512** is the AS number.
  - If the primary and secondary hubs are in different regions, the primary hub and the spokes are configured with **64512** as the AS number, and the secondary hub is configured with a different AS number.
- d) In the **Community Tag for Local Routes** field, enter the BGP community attribute to tag connected and redistributed local routes. This attribute enables easy route filtering.
- e) Check the **Redistribute Connected Interfaces** check box and choose an interface group from the drop-down list or click + to create an interface group with connected inside or LAN interfaces for BGP route redistribution in the overlay topology.
- f) Check the **Enable Multiple Paths for BGP** check box to allow multiple BGP routes to be used at the same time to reach the same destination. This option enables BGP to load-balance traffic across multiple links.
- g) (Optional) Check the **Secondary Hub is in Different Autonomous System** check box. This check box appears only if you have a secondary hub in this topology.
- h) In the **Autonomous System Number** field, enter the AS number for the secondary hub.
- i) In the **Community Tag for Learned Routes** field, enter the BGP community attribute to tag routes learned from other SD-WAN peers over the VPN tunnel. This attribute is required only for eBGP configuration when the secondary hub has a different AS number. This field appears only if you have configured two hubs in the SD-WAN topology.
- j) Click **Next**.

**Step 8** Click **Finish** to save and validate the SD-WAN topology.

You can view the topology in the **Site-to-Site VPN Summary** page (**Devices > Site-to-site VPN**). After you deploy the configurations to all the devices, you can see the status of all the tunnels in this page.

---

### What to do next

- View the auto-generated spoke SVTIs and their IP addresses—Click the edit icon next to the spoke configuration and click **View Generated Tunnel Interfaces**.
- Deploy the configurations on the hub and spokes. Choose **Deploy**. Select devices and click **Deploy**.
- Verify the SD-WAN topology tunnel statuses. For more information, see [Verify Tunnel Statuses of an SD-WAN Topology, on page 1599](#).
- Configure ACLs for the spokes' tunnel interface security zones. Choose **Policies > Access Control**.
- For more information about configuration examples using SD-WAN wizard, see [Sample Configurations for Dual ISP Deployment Using SD-WAN Wizard, on page 1594](#)
- Configure a PBR policy on each spoke for application-aware routing based on the application performance metrics of the WAN interfaces. For more information, see [Route Application Traffic from the Branch to the Internet Using Direct Internet Access \(DIA\)](#).

## Add a Dynamic Virtual Tunnel Interface for a Hub

In the SD-WAN wizard, you must configure a DVTI for each hub. DVTI uses a virtual template to dynamically generate a unique virtual access interface for each VPN session.

### Before you begin

In the SD-WAN wizard, click **Add Hub**, and choose a hub from the **Device** drop-down list.

### Procedure

- 
- Step 1** Click + next to the **Dynamic Virtual Tunnel Interface (DVTI)** drop-down list to add a DVTI for the hub. The **Add Virtual Tunnel Interface** dialog box appears with the following prepopulated default configurations.
- Tunnel Type:** Dynamic.
  - Name:** `<tunnel_source_interface_logical_name>_dynamic_vti_<tunnel_ID>`. For example, `outside_dynamic_vti_1`.
  - Enabled** check box: Checked by default.
  - Template ID:** Unique ID for the DVTI.
  - Tunnel Source:** Physical interface that is the source of the DVTI and is auto populated by default.
  - IPsec Tunnel Mode:** IPv4, by default.
- Step 2** Choose a security zone for the dynamic VTI from the **Security Zone** drop-down list.
- Step 3** Choose a physical or loopback interface from the **Borrow IP** drop-down list, the dynamic VTI interface inherits this IP address.
- Ensure that you use an IP address different from the tunnel source IP address. We recommend that you use a loopback IP address.
- Step 4** Click **OK** to save the dynamic VTI.
- 

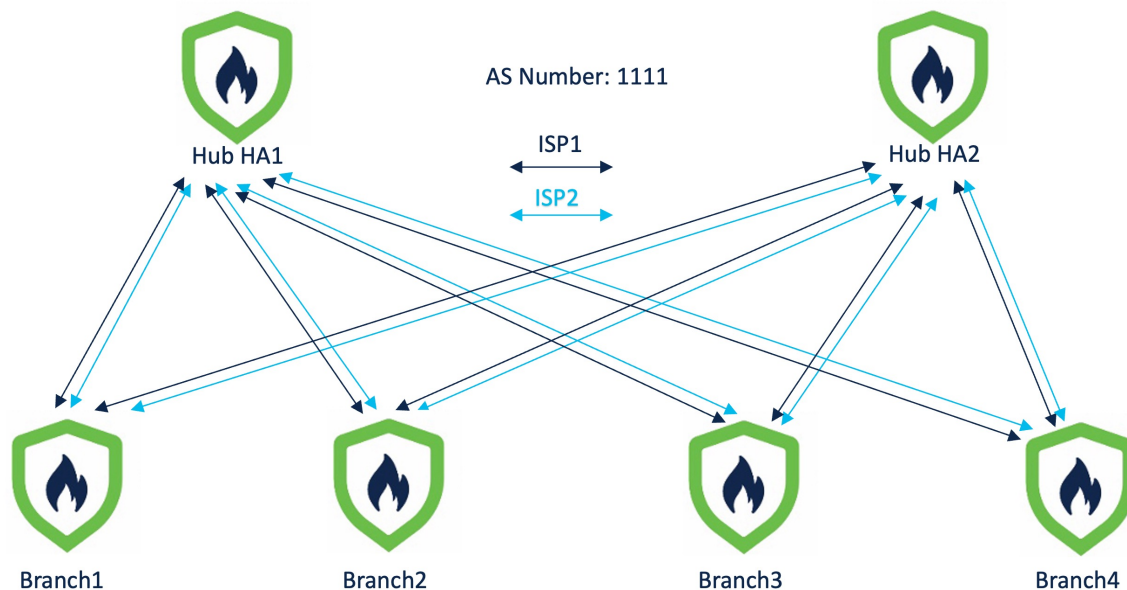

## Sample Configurations for Dual ISP Deployment Using SD-WAN Wizard

### Dual ISP Deployment: Two Hubs and Four Spokes in the Same Region

In the following dual ISP topology, the hubs and the spokes are in a single region, with AS number as 1111. The hubs and spokes use Internal Border Gateway Protocol (iBGP) as the routing protocol to exchange routing information.

- Hub HA1 and Hub HA2 are hub threat defense devices at the headquarters.
- Branch1, Branch2, Branch3, and Branch4 are spoke threat defense devices at the branches.
- ISP1 is the VPN interface of each spoke to ISP1.
- ISP2 is the VPN interface of each spoke to ISP2.

Figure 360: Dual ISP Topology with Two Hubs and Four Spokes in the Same Region

To configure this topology, you must create the following two SD-WAN topologies using the SD-WAN wizard:

#### SD-WAN Topology 1

| Parameter                           | Value                              |
|-------------------------------------|------------------------------------|
| Primary Hub                         | Hub HA1                            |
| Secondary Hub                       | Hub HA2                            |
| Spokes                              | Branch1, Branch2, Branch3, Branch4 |
| AS Number                           | 1111                               |
| VPN Interface (Spoke Tunnel Source) | ISP1                               |
| Number of Tunnels                   | 8                                  |

The total number of tunnels in SD-WAN Topology 1 is 8.

#### SD-WAN Topology 2

| Parameter     | Value                              |
|---------------|------------------------------------|
| Primary Hub   | Hub HA1                            |
| Secondary Hub | Hub HA2                            |
| Spokes        | Branch1, Branch2, Branch3, Branch4 |
| AS Number     | 1111                               |

| Parameter                           | Value |
|-------------------------------------|-------|
| VPN Interface (Spoke Tunnel Source) | ISP2  |
| Number of Tunnels                   | 8     |

The total number of tunnels in SD-WAN Topology 2 is 8.

The total number of VPN tunnels for this dual ISP deployment is 16.

---

**Note** If the hubs are in different geographic locations and have different protected networks behind them, to ensure direct communication between these networks, configure a point-to-point route-based VPN topology between the two hubs using the route-based VPN wizard.

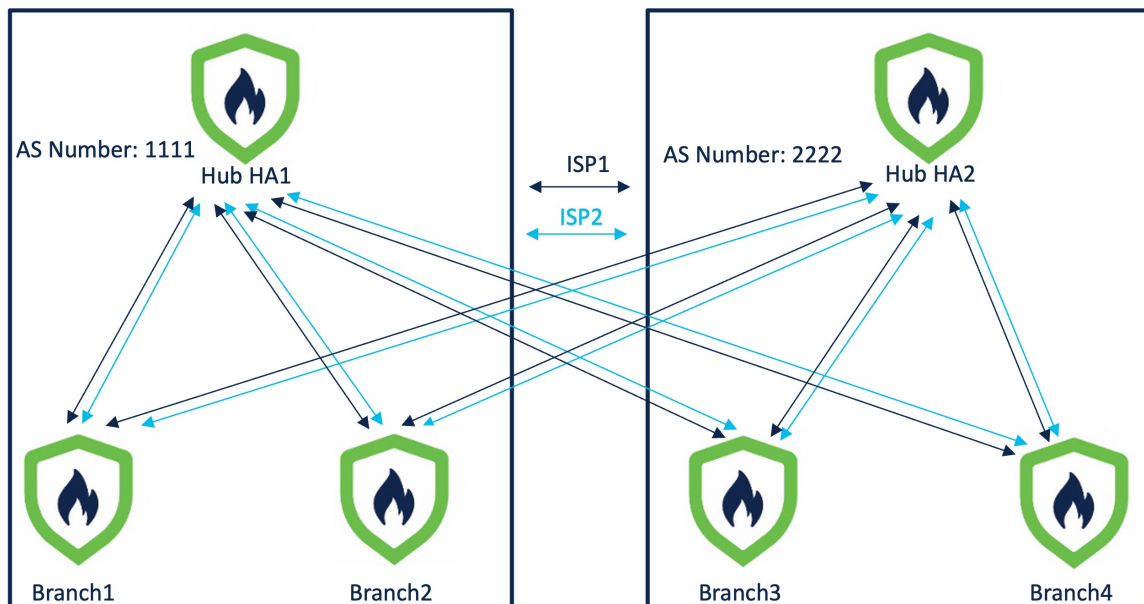

---

## Dual ISP Deployment: Two Hubs and Four Spokes in Different Regions

In the following dual ISP topology, the hubs are in different regions, and have two directly connected spokes each. The hubs and their directly connected spokes use Internal Border Gateway Protocol (iBGP) as the routing protocol, and the hubs use External Border Gateway Protocol (eBGP) to exchange routing information.

- Hub HA1 and Hub HA2 are hub threat defense devices at the headquarters.
- Branch1, Branch2, Branch3, and Branch4 are spoke threat defense devices at the branches.
- HQ1, Branch1, and Branch2 are in a single region with AS number as 1111.
- HQ2, Branch3, and Branch4 are in a single region with AS number as 2222.
- ISP1 is the VPN interface of each spoke to ISP1.
- ISP2 is the VPN interface of each spoke to ISP2.

Figure 361: Dual ISP Topology with Two Hubs and Four Spokes in Different Regions

To configure this topology, you must create the following four SD-WAN topologies using the SD-WAN wizard:

#### SD-WAN Topology 1

| Parameter                           | Value            |
|-------------------------------------|------------------|
| Primary Hub                         | Hub HA1          |
| Secondary Hub                       | Hub HA2          |
| Spokes                              | Branch1, Branch2 |
| AS Number                           | 1111             |
| Secondary AS Number                 | 2222             |
| VPN Interface (Spoke Tunnel Source) | ISP1             |

The number of tunnels in SD-WAN Topology 1 is 4.

#### SD-WAN Topology 2

| Parameter     | Value            |
|---------------|------------------|
| Primary Hub   | Hub HA1          |
| Secondary Hub | Hub HA2          |
| Spokes        | Branch1, Branch2 |
| AS Number     | 1111             |

| Parameter                           | Value |
|-------------------------------------|-------|
| Secondary AS Number                 | 2222  |
| VPN Interface (Spoke Tunnel Source) | ISP2  |

The number of tunnels in SD-WAN Topology 2 is 4.

### SD-WAN Topology 3

| Parameter                           | Value            |
|-------------------------------------|------------------|
| Primary Hub                         | Hub HA2          |
| Secondary Hub                       | Hub HA1          |
| Spokes                              | Branch3, Branch4 |
| AS Number                           | 2222             |
| Secondary AS Number                 | 1111             |
| VPN Interface (Spoke Tunnel Source) | ISP1             |

The number of tunnels in SD-WAN Topology 3 is 4.

### SD-WAN Topology 4

| Parameter                           | Value            |
|-------------------------------------|------------------|
| Primary Hub                         | Hub HA2          |
| Secondary Hub                       | Hub HA1          |
| Spokes                              | Branch3, Branch4 |
| AS Number                           | 2222             |
| Secondary AS Number                 | 1111             |
| VPN Interface (Spoke Tunnel Source) | ISP2             |

The number of tunnels in SD-WAN Topology 4 is 4.

The total number of VPN tunnels for this dual ISP deployment is 16.

---

**Note** If the hubs are in different geographic locations and have different protected networks behind them, to ensure direct communication between these networks, configure a point-to-point route-based VPN topology between the two hubs using the route-based VPN wizard.

---

## Verify Tunnel Statuses of an SD-WAN Topology

### Verify Tunnel Statuses on the Site-to-Site VPN Summary Page

To verify if the VPN tunnels of the SD-WAN topologies are up, choose **Device > VPN > Site-to-Site**.

Following are the five SD-WAN topologies with two hubs and four spokes in different regions that are connected to dual ISPs:

| Topology Name | VPN Type          | Network Topology | Tunnel Status Distribution | IKEV1 |
|---------------|-------------------|------------------|----------------------------|-------|
| > EBG-Topo1   | Route Based (VTI) | SD-WAN Topology  | 4- Tunnels                 |       |
| > EBG-Topo2   | Route Based (VTI) | SD-WAN Topology  | 4- Tunnels                 |       |
| > EBG-Topo3   | Route Based (VTI) | SD-WAN Topology  | 4- Tunnels                 |       |
| > EBG-Topo4   | Route Based (VTI) | SD-WAN Topology  | 4- Tunnels                 |       |
| ▼ SVTI-SVTI-1 | Route Based (VTI) | Point-to-Point   | 1- Tunnels                 |       |

| Node A      |                     |                          |             | Node B              |                       |
|-------------|---------------------|--------------------------|-------------|---------------------|-----------------------|
| Device      | VPN Interface       | VTI Interface            | Device      | VPN Interface       | VTI Interface         |
| FTD HUB-HA1 | hub_link (20.0.0.1) | hub_link... (22.22.21.2) | FTD HUB-HA2 | hub_link (20.0.0.2) | hub_link (22.22.21.2) |

### Verify Tunnel Statuses on the Site-to-Site VPN Dashboard

To view details of the SD-WAN VPN tunnels, choose **Overview > Dashboards > Site-to-site VPN**.

Following are the VPN tunnels for an SD-WAN topology with two hubs and four spokes in different regions that are connected to dual ISPs:

**Tunnel Summary**

100% Active  
17 connections

**Topology**

| Name        | 🔴 | 🟡 | 🟢 |
|-------------|---|---|---|
| EBGP-Topo1  | 0 | 0 | 4 |
| EBGP-Topo2  | 0 | 0 | 4 |
| EBGP-Topo3  | 0 | 0 | 4 |
| EBGP-Topo4  | 0 | 0 | 4 |
| SVTI-SVTI-1 | 0 | 0 | 1 |

| Node B                         |                             | Topology    | Status |
|--------------------------------|-----------------------------|-------------|--------|
| HUB-HA1[10.10.4.226] (VP...    | HUB-HA2[10.10.4.229] (VP... | SVTI-SVTI-1 | 🟢 Ac   |
| 10.10.4.231 (VPN IP: 11.1.1.1) | HUB-HA2[10.10.4.229] (VP... | EBGP-Topo1  | 🟢 Ac   |
| 10.10.4.231 (VPN IP: 11.2.1.1) | HUB-HA2[10.10.4.229] (VP... | EBGP-Topo3  | 🟢 Ac   |
| 10.10.4.232 (VPN IP: 12.1.1.1) | HUB-HA2[10.10.4.229] (VP... | EBGP-Topo1  | 🟢 Ac   |
| 10.10.4.232 (VPN IP: 12.2.1.1) | HUB-HA2[10.10.4.229] (VP... | EBGP-Topo3  | 🟢 Ac   |
| 10.10.4.233 (VPN IP: 21.1.1.1) | HUB-HA2[10.10.4.229] (VP... | EBGP-Topo2  | 🟢 Ac   |
| 10.10.4.233 (VPN IP: 21.1.1.1) | HUB-HA1[10.10.4.226] (VP... | EBGP-Topo2  | 🟢 Ac   |
| 10.10.4.231 (VPN IP: 11.1.1.1) | HUB-HA1[10.10.4.226] (VP... | EBGP-Topo1  | 🟢 Ac   |
| 10.10.4.232 (VPN IP: 12.1.1.1) | HUB-HA1[10.10.4.226] (VP... | EBGP-Topo1  | 🟢 Ac   |
| 10.10.4.231 (VPN IP: 11.2.1.1) | HUB-HA1[10.10.4.226] (VP... | EBGP-Topo3  | 🟢 Ac   |
| 10.10.4.232 (VPN IP: 12.2.1.1) | HUB-HA1[10.10.4.226] (VP... | EBGP-Topo3  | 🟢 Ac   |
| 10.10.4.233 (VPN IP: 21.2.1.1) | HUB-HA1[10.10.4.226] (VP... | EBGP-Topo4  | 🟢 Ac   |
| 10.10.4.234 (VPN IP: 22.1.1.1) | HUB-HA1[10.10.4.226] (VP... | EBGP-Topo2  | 🟢 Ac   |

To view more details of each VPN tunnel:

1. Hover over a tunnel.
2. Click the **View Full Information** (👁) icon. A pane with tunnel details and more actions appears.
3. Click the **CLI Details** tab in the side pane to view the show commands and details of the IPsec security associations.

The screenshot displays the 'Tunnel Details' pane. At the top, it shows 'Summary' for a tunnel between 'Node A' and 'Node B'. The statistics are as follows:

| Node A                             | Node B                             |
|------------------------------------|------------------------------------|
| Transmitted: 14.83 MB (15552256 B) | Transmitted: 14.83 MB (15552416 B) |
| Received: 33.37 MB (34992576 B)    | Received: 33.37 MB (34992720 B)    |

Below the summary, there are 'IPsec Security Associations (1)'. The pane is currently showing the 'Tunnel' tab. It lists two security associations with their respective statistics and remaining lifetimes:

| Remaining Lifetime for SPI ID: 0x944D58CF                                                                                               | Remaining Lifetime for SPI ID: 0xA6F557B8                                                                                              |
|-----------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|

At the bottom of the pane, there are two tabs for CLI commands: '(VPN Interface IP: ...)' and ') (VPN Interface IP: ...)'. Both tabs show the following commands:

- show crypto ipsec sa peer
- show vpn-sessiondb detail l2l filter ip...

Buttons for 'Close' and 'Refresh' are located at the bottom right of the pane.

### View Virtual Tunnel Interfaces of the Devices

To view the dynamic VTIs of hubs and static VTIs of spokes:

1. Choose **Devices > Device Management**.
2. Click the edit icon for a hub or a spoke device.
3. Click the **Interface** tab.
4. Click the **Virtual Tunnels** tab.

For each VTI, you can view details such as name, IP address, IPsec mode, tunnel source interface details, topology, and remote peer IP.

Following image shows an example of the virtual access interfaces created dynamically by a hub's DVTI:

## 10.10.4.226

| Tunnel4                           | ●      | outside2...  | IPv4       | 57.1.1.1/24 | GigabitEthern...        | outside2     | 11.2.1.1/24 | EBGP-Topo3 | 200.1.1.1      | Disabl     |

The SD-WAN wizard assigns IP addresses to these tunnel interfaces from the IP address pool of the hub.

**Verify Routing on the Hub and Branches**

To verify the BGP configuration of the hubs and spokes of the SD-WAN topologies:

1. Choose **Devices > Device Management**.
2. Click the edit icon for a hub or a spoke device.
3. Click the **Device** tab.
4. Click **CLI** in the **General** card. The **CLI Troubleshoot** window appears.
5. Enter the following commands in the **Command** field and click **Execute**:
  - **show route**

- `show bgp summary`

## CHAPTER 57

# VPN Overview

A virtual private network (VPN) connection establishes a secure tunnel between endpoints over a public network such as the Internet.

This chapter applies to Remote Access and Site-to-site VPNs on Secure Firewall Threat Defense devices. It describes the Internet Protocol Security (IPsec), the Internet Security Association and Key Management Protocol (ISAKMP, or IKE) and SSL standards that are used to build site-to-site and remote access VPNs.

## VPN Types

The management center supports the following types of VPN connections:

- Remote Access VPNs on threat defense devices.

Remote access VPNs are secure, encrypted connections, or tunnels, between remote users and your company's private network. The connection consists of a VPN endpoint device, which is a workstation or mobile device with VPN client capabilities, and a VPN headend device, or secure gateway, at the edge of the corporate private network.

Secure Firewall Threat Defense devices can be configured to support Remote Access VPNs over SSL or IPsec IKEv2 by the management center. Functioning as secure gateways in this capacity, they authenticate remote users, authorize access, and encrypt data to provide secure connections to your network. No other types of appliances, managed by the management center, support Remote Access VPN connections.

Secure Firewall Threat Defense secure gateways support the Secure Client full tunnel client. This client is required to provide secure SSL IPsec IKEv2 connections for remote users. This client gives remote users the benefits of a client without the need for network administrators to install and configure clients

on remote computers since it can be deployed to the client platform upon connectivity. It is the only client supported on endpoint devices.

- Site-to-site VPNs on threat defense devices.

A site-to-site VPN connects networks in different geographic locations. You can create site-to-site IPsec connections between managed devices, and between managed devices and other Cisco or third-party peers that comply with all relevant standards. These peers can have any mix of inside and outside IPv4 and IPv6 addresses. Site-to-site tunnels are built using the Internet Protocol Security (IPsec) protocol suite and IKEv1 or IKEv2. After the VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel.

## VPN Basics

Tunneling makes it possible to use a public TCP/IP network, such as the Internet, to create secure connections between remote users and private corporate networks. Each secure connection is called a tunnel.

IPsec-based VPN technologies use the Internet Security Association and Key Management Protocol (ISAKMP, or IKE) and IPsec tunneling standards to build and manage tunnels. ISAKMP and IPsec accomplish the following:

- Negotiate tunnel parameters.
- Establish tunnels.
- Authenticate users and data.
- Manage security keys.
- Encrypt and decrypt data.
- Manage data transfer across the tunnel.
- Manage data transfer inbound and outbound as a tunnel endpoint or router.

A device in a VPN functions as a bidirectional tunnel endpoint. It can receive plain packets from the private network, encapsulate them, create a tunnel, and send them to the other end of the tunnel where they are unencapsulated and sent to their final destination. It can also receive encapsulated packets from the public network, unencapsulate them, and send them to their final destination on the private network.

After the site-to-site VPN connection is established, the hosts behind the local gateway can connect to the hosts behind the remote gateway through the secure VPN tunnel. A connection consists of the IP addresses and hostnames of the two gateways, the subnets behind them, and the method the two gateways use to authenticate to each other.

## Internet Key Exchange (IKE)

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and to automatically establish IPsec security associations (SAs).

The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection.

An IKE policy is a set of algorithms that two peers use to secure the IKE negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters protect subsequent IKE negotiations. For IKE version 1 (IKEv1), IKE policies contain a single set of algorithms and a modulus group. Unlike IKEv1, in an IKEv2 policy, you can select multiple algorithms and modulus groups from which peers can choose during the Phase 1 negotiation. It is possible to create a single IKE policy, although you might want different policies to give higher priority to your most desired options. For site-to-site VPNs, you can create an IKE policy. IKEv1 and IKEv2 each support a maximum of 20 IKE policies, each with a different set of values. Assign a unique priority to each policy that you create. The lower the priority number, the higher the priority.

To define an IKE policy, specify:

- A unique priority (1 to 65,543, with 1 the highest priority).
- An encryption method for the IKE negotiation, to protect the data and ensure privacy.
- A Hashed Message Authentication Codes (HMAC) method (called integrity algorithm in IKEv2) to ensure the identity of the sender, and to ensure that the message has not been modified in transit.
- For IKEv2, a separate pseudorandom function (PRF) used as the algorithm to derive keying material and hashing operations required for the IKEv2 tunnel encryption. The options are the same as those used for the hash algorithm.
- A Diffie-Hellman group to determine the strength of the encryption-key-determination algorithm. The device uses this algorithm to derive the encryption and hash keys.
- An authentication method, to ensure the identity of the peers.
- A limit to the time the device uses an encryption key before replacing it.

When IKE negotiation begins, the peer that starts the negotiation sends all of its policies to the remote peer, and the remote peer searches for a match with its own policies, in priority order. A match between IKE policies exists if they have the same encryption, hash (integrity and PRF for IKEv2), authentication, and Diffie-Hellman values, and an SA lifetime less than or equal to the lifetime in the policy sent. If the lifetimes are not identical, the shorter lifetime—From the remote peer policy—Applies. By default, the Secure Firewall Management Center deploys an IKEv1 policy at the lowest priority for all VPN endpoints to ensure a successful negotiation.

## IPsec

IPsec is one of the most secure methods for setting up a VPN. IPsec provides data encryption at the IP packet level, offering a robust security solution that is standards-based. With IPsec, data is transmitted over a public network through tunnels. A tunnel is a secure, logical communication path between two peers. Traffic that enters an IPsec tunnel is secured by a combination of security protocols and algorithms.

An IPsec Proposal policy defines the settings required for IPsec tunnels. An IPsec proposal is a collection of one or more crypto-maps that are applied to the VPN interfaces on the devices. A crypto map combines all the components required to set up IPsec security associations, including:

- A proposal (or transform set) is a combination of security protocols and algorithms that secure traffic in an IPsec tunnel. During the IPsec security association (SA) negotiation, peers search for a proposal that is the same at both peers. When it is found, it is applied to create an SA that protects data flows in the access list for that crypto map, protecting the traffic in the VPN. There are separate IPsec proposals for IKEv1 and IKEv2. In IKEv1 proposals (or transform sets), for each parameter, you set one value. For IKEv2 proposals, you can configure multiple encryption and integration algorithms for a single proposal.

- A crypto map, combines all components required to set up IPsec security associations (SA), including IPsec rules, proposals, remote peers, and other parameters that are necessary to define an IPsec SA. When two peers try to establish an SA, they must each have at least one compatible crypto map entry.

Dynamic crypto map policies are used in site-to-site VPNs when an unknown remote peer tries to start an IPsec security association with the local hub. The hub cannot be the initiator of the security association negotiation. Dynamic crypto-policies allow remote peers to exchange IPsec traffic with a local hub even if the hub does not know the remote peer's identity. A dynamic crypto map policy essentially creates a crypto map entry without all the parameters configured. The missing parameters are later dynamically configured (as the result of an IPsec negotiation) to match a remote peer's requirements.

Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply dynamic crypto map policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. Note that in a full mesh VPN topology, you can apply only static crypto map policies.

---

**Note** Simultaneous IKEv2 dynamic crypto map is not supported for the same interface for both remote access and site-to-site VPNs on threat defense.

---

## VPN Packet Flow

On a threat defense device, by default no traffic is allowed to pass through access-control without explicit permission. VPN tunnel traffic as well, is not relayed to the endpoints until it has passed through Snort. Incoming tunnel packets are decrypted before being sent to the Snort process. Snort processes outgoing packets before encryption.

Access Control identifying the protected networks for each endpoint node of a VPN tunnel determines which traffic is allowed to pass through the threat defense device and reach the endpoints. For Remote Access VPN traffic, a Group Policy filter or an Access Control rule must be configured to permit VPN traffic flow.

In addition, the system does not send tunnel traffic to the public source when the tunnel is down.

## IPsec Flow Offload

You can configure supporting device models to use IPsec flow offload. After the initial setup of an IPsec site-to-site VPN or remote access VPN security association (SA), IPsec connections are offloaded to the field-programmable gate array (FPGA) in the device, which should improve device performance. On the Secure Firewall 1200 series, IPsec connections are offloaded to the Marvell Cryptographic Accelerator (CPT) to improve device performance.

Offloaded operations specifically relate to the pre-decryption and decryption processing on ingress, and the pre-encryption and encryption processing on egress. The system software handles the inner flow to apply your security policies.

IPsec flow offload is enabled by default, and applies to the following device types:

- Secure Firewall 1200
- Secure Firewall 3100

- Secure Firewall 4200

IPsec flow offload is also used when the device's VTI loopback interface is enabled.

#### Limitations for IPsec Flow Offload

The following IPsec flows are not offloaded:

- IKEv1 tunnels. Only IKEv2 tunnels will be offloaded. IKEv2 supports stronger ciphers.
- Flows that have volume-based rekeying configured.
- Flows that have compression configured.
- Transport mode flows. Only tunnel mode flows will be offloaded.
- AH format. Only ESP/NAT-T format will be supported.
- Flows that have post-fragmentation configured.
- Flows that have anti-replay window size other than 64bit and anti-replay is not disabled.
- Flows that have firewall filter enabled.

#### Configure IPsec Flow Offload

IPsec flow offload is enabled by default on hardware platforms that support the feature. To change the configuration, use FlexConfig to implement the **flow-offload-ipsec** command. See the ASA command reference for detailed information about the command.

## VPN Licensing

There is no specific licensing for enabling Secure Firewall Threat Defense VPN, it is available by default.

The management center determines whether to allow or block the usage of strong crypto on the threat defense device based on attributes provided by the smart licensing server.

This is controlled by whether you selected the option to allow export-controlled functionality on the device when you registered with the Cisco Smart License Manager. If you are using the evaluation license, or you did not enable export-controlled functionality, you cannot use strong encryption.

If you have created your VPN configurations with an evaluation license, and upgrade your license from evaluation to smart license with export-controlled functionality, check, and update your encryption algorithms for stronger encryption and for the VPNs to work properly. DES-based encryptions are no longer supported.

## How Secure Should a VPN Connection Be?

Because a VPN tunnel typically traverses a public network, most likely the Internet, you need to encrypt the connection to protect the traffic. You define the encryption and other security techniques to apply using IKE polices and IPsec proposals.

If your device license allows you to apply strong encryption, there is a wide range of encryption and hash algorithms, and Diffie-Hellman groups, from which to choose. However, as a general rule, the stronger the

encryption that you apply to the tunnel, the worse the system performance. Find a balance between security and performance that provides sufficient protection without compromising efficiency.

We cannot provide specific guidance on which options to choose. If you operate within a larger corporation or other organization, there might already be defined standards that you need to meet. If not, take the time to research the options.

The following topics explain the available options.

## Complying with Security Certification Requirements

Many VPN settings have options that allow you to comply with various security certification standards. Review your certification requirements and the available options to plan your VPN configuration.

## Deciding Which Encryption Algorithm to Use

When deciding which encryption algorithms to use for the IKE policy or IPsec proposal, your choice is limited to algorithms supported by the devices in the VPN.

For IKEv2, you can configure multiple encryption algorithms. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order. For IKEv1, you can select a single option only.

For IPsec proposals, the algorithm is used by the Encapsulating Security Protocol (ESP), which provides authentication, encryption, and anti-replay services. ESP is IP protocol type 50. In IKEv1 IPsec proposals, the algorithm name is prefixed with ESP-.

If your device license qualifies for strong encryption, you can choose from the following encryption algorithms. If you are not qualified for strong encryption, you can select DES only.

---

**Note** If you are qualified for strong encryption, before upgrading from the evaluation license to a smart license, check and update your encryption algorithms for stronger encryption so that the VPN configuration works properly. Choose AES-based algorithms. DES is not supported if you are registered using an account that supports strong encryption. After registration, you cannot deploy changes until you remove all uses of DES.

---

- **AES-GCM**—(IKEv2 only.) Advanced Encryption Standard in Galois/Counter Mode is a block cipher mode of operation providing confidentiality and data-origin authentication, and provides greater security than AES. AES-GCM offers three different key strengths: 128-, 192-, and 256-bit keys. A longer key provides higher security but a reduction in performance. GCM is a mode of AES that is required to support NSA Suite B. NSA Suite B is a set of cryptographic algorithms that devices must support to meet federal standards for cryptographic strength.
- **AES**—Advanced Encryption Standard is a symmetric cipher algorithm that provides greater security than DES and is computationally more efficient than 3DES. AES offers three different key strengths: 128-, 192-, and 256-bit keys. A longer key provides higher security but a reduction in performance.
- **DES**—Data Encryption Standard, which encrypts using 56-bit keys, is a symmetric secret-key block algorithm. If your license account does not meet the requirements for export controls, this is your only option.

- Null, ESP-Null—Do not use. A null encryption algorithm provides authentication without encryption. This is typically used for testing purposes only. However, it does not work at all on many platforms, including virtual.

## Deciding Which Hash Algorithms to Use

In IKE policies, the hash algorithm creates a message digest, which is used to ensure message integrity. In IKEv2, the hash algorithm is separated into two options, one for the integrity algorithm, and one for the pseudo-random function (PRF).

In IPsec proposals, the hash algorithm is used by the Encapsulating Security Protocol (ESP) for authentication. In IKEv2 IPsec Proposals, this is called the integrity hash. In IKEv1 IPsec proposals, the algorithm name is prefixed with ESP-, and there is also an -HMAC suffix (which stands for “hash method authentication code”).

For IKEv2, you can configure multiple hash algorithms. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order. For IKEv1, you can select a single option only.

You can choose from the following hash algorithms.

- SHA (Secure Hash Algorithm)—Standard SHA (SHA1) produces a 160-bit digest.  
The following SHA-2 options, which are even more secure, are available for IKEv2 configurations. Choose one of these if you want to implement the NSA Suite B cryptography specification.
  - SHA256—Specifies the Secure Hash Algorithm SHA 2 with the 256-bit digest.
  - SHA384—Specifies the Secure Hash Algorithm SHA 2 with the 384-bit digest.
  - SHA512—Specifies the Secure Hash Algorithm SHA 2 with the 512-bit digest.
- Null or None (NULL, ESP-NONE)—(IPsec Proposals only.) A null Hash Algorithm; this is typically used for testing purposes only. However, you should choose the null integrity algorithm if you select one of the AES-GCM options as the encryption algorithm. Even if you choose a non-null option, the integrity hash is ignored for these encryption standards.

## Deciding Which Diffie-Hellman Modulus Group to Use

You can use the following Diffie-Hellman key derivation algorithms to generate IPsec security association (SA) keys. Each group has a different size modulus. A larger modulus provides higher security, but requires more processing time. You must have a matching modulus group on both peers.

If you select AES encryption, to support the large key sizes required by AES, you should use Diffie-Hellman (DH) Group 5 or higher. IKEv1 policies do not support all of the groups listed below.

To implement the NSA Suite B cryptography specification, use IKEv2 and select one of the elliptic curve Diffie-Hellman (ECDH) options: 19, 20, or 21. Elliptic curve options and groups that use 2048-bit modulus are less exposed to attacks such as Logjam.

For IKEv2, you can configure multiple groups. The system orders the settings from the most secure to the least secure and negotiates with the peer using that order. For IKEv1, you can select a single option only.

- 14—Diffie-Hellman Group 14: 2048-bit modular exponential (MODP) group. Considered good protection for 192-bit keys.

- 15—Diffie-Hellman Group 15: 3072-bit MODP group.
- 16—Diffie-Hellman Group 16: 4096-bit MODP group.
- 19—Diffie-Hellman Group 19: National Institute of Standards and Technology (NIST) 256-bit elliptic curve modulo a prime (ECP) group.
- 20—Diffie-Hellman Group 20: NIST 384-bit ECP group.
- 21—Diffie-Hellman Group 21: NIST 521-bit ECP group.
- 31—Diffie-Hellman Group 31: Curve25519 256-bit EC Group.

## Deciding Which Authentication Method to Use

Preshared keys and digital certificates are the methods of authentication available for VPNs.

Site-to-site, IKEv1 and IKEv2 VPN connections can use both options.

Remote Access, which uses SSL and IPsec IKEv2 only, supports digital certificate authentication only.

Preshared keys allow for a secret key to be shared between two peers and used by IKE during the authentication phase. The same shared key must be configured at each peer or the IKE SA cannot be established.

Digital certificates use RSA key pairs to sign and encrypt IKE key management messages. Certificates provide non-repudiation of communication between two peers, meaning that it can be proved that the communication actually took place. When using this authentication method, you need a Public Key Infrastructure (PKI) defined where peers can obtain digital certificates from a Certification Authority (CA). CAs manage certificate requests and issue certificates to participating network devices providing centralized key management for all of the participating devices.

Preshared keys do not scale well, using a CA improves the manageability and scalability of your IPsec network. With a CA, you do not need to configure keys between all encrypting devices. Instead, each participating device is registered with the CA, and requests a certificate from the CA. Each device that has its own certificate and the public key of the CA can authenticate every other device within a given CA's domain.

### Pre-shared Keys

Pre-shared key enables you to share a secret key between two peers. IKE uses the key in the authentication phase. You must configure the same shared key on each peer, or the IKE SA cannot be established.

To configure the pre-shared keys, choose whether you want to use a manual or automatically generated key, and then specify the key in the IKEv1/IKEv2 options. Then, when you deploy your configuration, the key is configured on all devices in the topology.

### PKI Infrastructure and Digital Certificates

#### Public Key Infrastructure

A PKI provides centralized key management for participating network devices. It is a defined set of policies, procedures, and roles that support *public key cryptography* by generating, verifying, and revoking *public key certificates* commonly known as *digital certificates*.

In public key cryptography, each endpoint of a connection has a key pair consisting of both a public and a private key. The key pairs are used by the VPN endpoints to sign and encrypt messages. The keys act as

complements, and anything encrypted with one of the keys can be decrypted with the other, securing the data flowing over the connection.

Generate a general purpose RSA, ECDSA, or EDDSA key pair, used for both signing and encryption, or you generate separate key pairs for each purpose. Separate signing and encryption keys help to reduce exposure of the keys. SSL uses a key for encryption but not signing, however, IKE uses a key for signing but not encryption. By using separate keys for each, exposure of the keys is minimized.

### Digital Certificates or Identify Certificates

When you use Digital Certificates as the authentication method for VPN connections, peers are configured to obtain digital certificates from a Certificate Authority (CA). CAs are trusted authorities that “sign” certificates to verify their authenticity, thereby guaranteeing the identity of the device or user.

CA servers manage public CA certificate requests and issue certificates to participating network devices as part of a Public Key Infrastructure (PKI), this activity is called Certificate Enrollment. These digital certificates, also called identity certificates contain:

- The digital identification of the owner for authentication, such as name, serial number, company, department, or IP address.
- A public key needed to send and receive encrypted data to the certificate owner.
- The secure digital signature of a CA.

Certificates also provide non-repudiation of communication between two peers, meaning that it they prove that the communication actually took place.

### Certificate Enrollment

Using a PKI improves the manageability and scalability of your VPN since you do not have to configure pre-shared keys between all the encrypting devices. Instead, you individually *enroll* each participating device with a CA server, which is explicitly trusted to validate identities and create an identity certificate for the device. When this has been accomplished, each participating peer sends their identity certificate to the other peer to validate their identities and establish encrypted sessions with the public keys contained in the certificates. See [Certificate Enrollment Objects, on page 1509](#) for details on enrolling threat defense devices.

### Certificate Authority Certificates

In order to validate a peer’s certificate, each participating device must retrieve the CA's certificate from the server. A CA certificate is used to sign other certificates. It is self-signed and called a root certificate. This certificate contains the public key of the CA, used to decrypt and validate the CA's digital signature and the contents of the received peer's certificate. The CA certificate may be obtained by:

- Using the Simple Certificate Enrollment Protocol (SCEP) or Enrollment over Secure Transport (EST) to retrieve the CA’s certificate from the CA server
- Manually copying the CA's certificate from another participating device

### Trustpoints

Once enrollment is complete, a trustpoint is created on the managed device. It is the object representation of a CA and associated certificates. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

**PKCS#12 File**

A PKCS#12, or PFX, file holds the server certificate, any intermediate certificates, and the private key in one encrypted file. This type of file may be imported directly into a device to create a trustpoint.

**Revocation Checking**

A CA may also revoke certificates for peers that no longer participate in your network. Revoked certificates are either managed by an Online Certificate Status Protocol (OCSP) server or are listed in a certificate revocation list (CRL) stored on an LDAP server. A peer may check these before accepting a certificate from another peer.

## Removed or Deprecated Hash Algorithms, Encryption Algorithms, and Diffie-Hellman Modulus Groups

Support has been removed for less secure ciphers. We recommend that you update your VPN configuration before you upgrade to threat defense 6.70 to supported DH and encryption algorithms to ensure the VPN works correctly.

Update your IKE proposals and IPsec policies to match the ones supported in threat defense 6.70 and then deploy the configuration changes.

The following less secure ciphers have been removed or deprecated in threat defense 6.70 onwards:

- **Diffie-Hellman GROUP 5** is deprecated for IKEv1 and IKEv2.
- Diffie-Hellman groups 2 and 24 have been removed.
- **Encryption algorithms:** 3DES, AES-GMAC, AES-GMAC-192, AES-GMAC-256 have been removed.

---

**Note** **DES** continues to be supported in evaluation mode or for users who do not satisfy export controls for strong encryption.

**NULL** is removed in IKEv2 policy, but supported in both IKEv1 and IKEv2 IPsec transform-sets.

---

## VPN Topology Options

When you create a new VPN topology you must, at minimum, give it a unique name, specify a topology type, and select the IKE version. You can select from three types of topologies, each containing a group of VPN tunnels:

- Point-to-point (PTP) topologies establish a VPN tunnel between two endpoints.
- Hub and Spoke topologies establish a group of VPN tunnels connecting a hub endpoint to a group of spoke endpoints.
- Full Mesh topologies establish a group of VPN tunnels among a set of endpoints.

Define a pre-shared key for VPN authentication manually or automatically, there is no default key. When choosing automatic, the Secure Firewall Management Center generates a pre-shared key and assigns it to all the nodes in the topology.

## Point-to-Point VPN Topology

In a point-to-point VPN topology, two endpoints communicate directly with each other. You configure the two endpoints as peer devices, and either device can start the secured connection.

The following diagram displays a typical point-to-point VPN topology.

## Hub and Spoke VPN Topology

In a Hub and Spoke VPN topology, a central endpoint (hub node) connects with multiple remote endpoints (spoke nodes). Each connection between the hub node and an individual spoke endpoint is a separate VPN tunnel. The hosts behind any of the spoke nodes can communicate with each other through the hub node.

The Hub and Spoke topology commonly represent a VPN that connects an organization's main and branch office locations using secure connections over the Internet or other third-party network. These deployments provide all employees with controlled access to the organization's network. Typically, the hub node is located at the main office. Spoke nodes are located at branch offices and start most of the traffic.

The following diagram displays a typical Hub and Spoke VPN topology.

## Full Mesh VPN Topology

In a Full Mesh VPN topology, all endpoints can communicate with every other endpoint by an individual VPN tunnel. This topology offers redundancy so that when one endpoint fails, the remaining endpoints can still communicate with each other. It commonly represents a VPN that connects a group of decentralized branch office locations. The number of VPN-enabled managed devices you deploy in this configuration depends on the level of redundancy you require.

The following diagram displays a typical Full Mesh VPN topology.

872205

## Implicit Topologies

In addition to the three main VPN topologies, other more complex topologies can be created as combinations of these topologies. They include:

- **Partial mesh**—A network in which some devices are organized in a full mesh topology, and other devices form either a hub-and-spoke or a point-to-point connection to some of the fully meshed devices. A partial mesh does not provide the level of redundancy of a full mesh topology, but it is less expensive to implement. Partial mesh topologies are used in peripheral networks that connect to a fully meshed backbone.
- **Tiered hub-and-spoke**—A network of hub-and-spoke topologies in which a device can behave as a hub in one or more topologies and a spoke in other topologies. Traffic is permitted from spoke groups to their most immediate hub.
- **Joined hub-and-spoke**—A combination of two topologies (hub-and-spoke, point-to-point, or full mesh) that connect to form a point-to-point tunnel. For example, a joined hub-and-spoke topology could comprise two hub-and-spoke topologies, with the hubs acting as peer devices in a point-to-point topology.

## About Site-to-Site VPN

Secure Firewall Threat Defense site-to-site VPN supports the following features:

- Both IPsec IKEv1 & IKEv2 protocols.
- Certificates and automatic or manual preshared keys for authentication.
- IPv4 & IPv6. All combinations of inside and outside are supported.
- IPsec IKEv2 Site-to-Site VPN topologies provide configuration settings to comply with security certifications.
- Static and dynamic Interfaces.
- HA environments for both management center and threat defense.
- VPN alerts when the tunnel goes down.

- Tunnel statistics available using the threat defense Unified CLI.
- IKEv1 and IKEv2 back-up peer configuration for point-to-point extranet and hub-and-spoke VPNs.
- Extranet device as hub in 'Hub and Spokes' deployments.
- Dynamic IP address for a managed endpoint pairing with extranet device in 'Point to Point' deployments.
- Dynamic IP address for extranet device as an endpoint.
- Hub as extranet in 'Hub and Spokes' deployments.

### VPN Topology

To create a new site-to-site VPN topology you must, specify a unique name, a topology type, choose the IKE version that is used for IPsec IKEv1 or IKEv2, or both. Also, determine your authentication method. Once configured, you deploy the topology to threat defense devices. The Secure Firewall Management Center configures site-to-site VPNs on threat defense devices only.

You can select from three types of topologies, containing one or more VPN tunnels:

- Point-to-point (PTP) deployments establish a VPN tunnel between two endpoints.
- Hub and Spoke deployments establish a group of VPN tunnels connecting a hub endpoint to a group of spoke nodes.
- Full Mesh deployments establish a group of VPN tunnels among a set of endpoints.

### IPsec and IKE

In the Secure Firewall Management Center, site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. Policies and proposals are sets of parameters that define the characteristics of a site-to-site VPN, such as the security protocols and algorithms that are used to secure traffic in an IPsec tunnel. Several policy types may be required to define a full configuration image that can be assigned to a VPN topology.

### Authentication

For authentication of VPN connections, configure a preshared key in the topology, or a trustpoint on each device. Preshared keys allow for a secret key, used during the IKE authentication phase, to be shared between two peers. A trustpoint includes the identity of the CA, CA-specific parameters, and an association with a single enrolled identity certificate.

### Extranet Devices

Each topology type can include extranet devices, devices that you don't manage in management center. These include:

- Cisco devices that Secure Firewall Management Center supports, but for which your organization isn't responsible. Such as spokes in networks managed by other organizations within your company, or a connection to a service provider or partner's network.
- Non-Cisco devices. You can't use Secure Firewall Management Center to create and deploy configurations to non-Cisco devices.

Add non-Cisco devices, or Cisco devices not managed by the Secure Firewall Management Center, to a VPN topology as "Extranet" devices. Also specify the IP address of each remote device.

## Secure Firewall Threat Defense Site-to-site VPN Guidelines and Limitations

- Site-to-site VPN supports ECMP zone interfaces.
- You must configure all nodes in a topology with either crypto ACL or a protected network. You cannot configure a topology with crypto ACL on one node and protected network on another.
- You can configure a VPN connection across domains by using an extranet peer for the endpoint not in the current domain.
- You can backup Threat Defense VPNs using the management center backup.
- IKEv1 does not support CC/UCAPL-compliant devices. We recommend that you use IKEv2 for these devices.
- You cannot move a VPN topology between domains.
- VPN does not support network objects with a 'range' option.
- Threat Defense VPNs do not currently support PDF export and policy comparison.
- There is no per-tunnel or per-device edit option for threat defense VPNs, you can edit only the whole topology.
- The management center does not verify the device interface address verification for transport mode when you select a crypto ACL.
- There is no support for automatic mirror ACE generation. Mirror ACE generation for the peer is a manual process on either side.
- With crypto ACL, the management center supports only point to point VPN and does not support tunnel health events.
- Whenever IKE ports 500/4500 are in use or when there are some active PAT translations, you cannot configure a site-to-site VPN on the same ports as it fails to start the service on those ports.
- Tunnel status is not updated in realtime, but at an interval of five minutes in the management center.
- You cannot use the character " (double quote) as part of pre-shared keys. If you have used " in a pre-shared key, ensure that you change the character.
- In a site-to-site VPN configuration with two devices managed by the same management center, you cannot configure the devices as backup peers. You must configure one of peer devices in the topology as an extranet device.

## Types of Site-to-Site VPN Topologies

| Site-to-Site VPN Topology | Description                                                                                                                                                                                                  | More Information                                                        |
|---------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------|
| Route-Based VPN           | Configure secure traffic dynamically between peers in a network based on routing over Virtual Tunnel Interfaces (VTIs).                                                                                      | <a href="#">Create a Route-based Site-to-Site VPN, on page 1645</a>     |
| Policy-Based VPN          | Configure secure traffic between peers in a network based on a static policy using protected networks.                                                                                                       | <a href="#">Configure a Policy-based Site-to-Site VPN, on page 1624</a> |
| SASE Topology             | Configure an IPsec IKEv2 tunnel from a threat defense device to an Umbrella Secure Internet Gateway (SIG). This tunnel forwards all internet-bound traffic to the Umbrella SIG for inspection and filtering. | <a href="#">Configure a SASE Tunnel for Umbrella, on page 1665</a>      |

## Requirements and Prerequisites for Site-to-Site VPN

### Model Support

Threat Defense

### Supported Domains

Leaf

### User Roles

Admin

### Supported Interfaces

| Topology Type | Interface Type                                                                                                                                                                                                                                                                                                                                     |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Policy-Based  | <ul style="list-style-type: none"> <li>• Physical interfaces               <ul style="list-style-type: none"> <li>• Non-management</li> <li>• Interface Mode must be either Routed or None</li> </ul> </li> <li>• Subinterface interfaces</li> <li>• Redundant interfaces</li> <li>• Etherchannel interfaces</li> <li>• VLAN interfaces</li> </ul> |
| Route-Based   | Static Virtual Tunnel Interfaces                                                                                                                                                                                                                                                                                                                   |

## Manage Site-to-Site VPNs

The Site-to-Site VPN page provides a snapshot of site-to-site VPN tunnels. You can view the status of the tunnels and filter the tunnels based on the device, topology, or tunnel type. The page lists 20 topologies per page and you can navigate between pages to view more topology details. You can click individual VPN topologies to expand and view details of the endpoints.

### Before you begin

For certificate authentication of your site-to-site VPNs, you must prepare the devices by allocating trustpoints as described in [Certificates, on page 1575](#).

### Procedure

Select **Devices > VPN > Site To Site** to manage your threat defense site-to-site VPN configurations and deployments.

The page lists the site-to-site VPNs topologies and indicates the status of tunnels using color codes:

- Active (Green)—There is an active IPsec Tunnel.
- Unknown (Amber)—No tunnel establishment event has been received from the device yet.
- Down (Red)—There are no active IPsec tunnels.
- Deployment Pending—Topology has not been deployed on the device yet.

Choose from the following:

- **Refresh**—View the updated status of the VPNs.
- **Add**—Create new policy based or route-based Site to Site VPNs.

- **Edit**—Modify the settings of an existing VPN topology.

**Note** You cannot edit the topology type after you initially save it. To change the topology type, delete the topology and create a new one.

Two users shouldn't edit the same topology simultaneously; however, the web interface doesn't prevent simultaneous editing.

- **Delete**—To delete a VPN deployment, click **Delete** (  ).

- **Deploy**—Choose **Deploy** > **Deployment**; see [Deploy Configuration Changes, on page 240](#).

**Note** Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

## Configure a Policy-based Site-to-Site VPN

### Procedure

- 
- Step 1** Choose **Devices** > **Site To Site**. Then click + **Site To Site VPN**, or edit a listed VPN topology.
- Step 2** Enter a unique **Topology Name**. We recommend naming your topology to indicate that it is a threat defense VPN, and its topology type.
- Step 3** Click **Policy Based (Crypto Map)** to configure a site-to-site VPN.
- Step 4** Choose the **Network Topology** for this VPN.
- Step 5** Choose the IKE versions to use during IKE negotiations. **IKEv1** or **IKEv2**.  
Default is IKEv2. Select either or both options as appropriate; select IKEv1 if any device in the topology doesn't support IKEv2.  
You can also configure a backup peer for point-to-point extranet VPNs. For more information, see [Threat Defense VPN Endpoint Options, on page 1625](#).
- Step 6** Required: Add Endpoints for this VPN deployment by clicking **Add** (  ) for each node in the topology.  
Configure each endpoint field as described in [Threat Defense VPN Endpoint Options, on page 1625](#).
- For Point to point, configure **Node A** and **Node B**.
  - For Hub and Spoke, configure a **Hub Node** and **Spoke Nodes**
  - For Full Mesh, configure multiple **Nodes**
- Step 7** (Optional) Specify non-default IKE options for this deployment as described in [Threat Defense VPN IKE Options, on page 1629](#)
- Step 8** (Optional) Specify non-default IPsec options for this deployment as described in [Threat Defense VPN IPsec Options, on page 1631](#)

**Step 9** (Optional) Specify non-default Advanced options for this deployment as described in [Threat Defense Advanced Site-to-site VPN Deployment Options, on page 1633](#).

**Step 10** Click **Save**.  
The endpoints are added to your configuration.

---

### What to do next

Deploy configuration changes.

**Note** Some VPN settings are validated only during deployment. Be sure to verify that your deployment was successful.

If you get an alert that your VPN tunnel is inactive even when the VPN session is up, follow the VPN troubleshooting instructions to verify and ensure that your VPN is active. .

---

## Threat Defense VPN Endpoint Options

### Navigation Path

**Devices > Site To Site**. Then click + **Site To Site VPN**, or edit a listed VPN topology. Click the **Endpoint** tab.

### Fields

#### Device

Choose an endpoint node for your deployment:

- A threat defense device managed by this management center
- A threat defense high availability container managed by this management center
- An **Extranet** device, any device (Cisco or third party) not managed by this management center.

#### Device Name

For extranet devices only, provide a name for this device. We recommend naming it such that it is identifiable as an unmanaged device.

#### Interface

If you chose a managed device as your endpoint, choose an interface on that managed device.

For 'Point to Point' deployments, you can also configure an endpoint with dynamic interface. An endpoint with a dynamic interface can pair only with an extranet device and can't pair with an endpoint, which has a managed device.

You can configure device interfaces at **Devices > Device Management > Add/Edit device > Interfaces**.

#### IP Address

- If you choose an extranet device, a device **not** managed by the management center, specify an IP address for the endpoint.

For an extranet device, select **Static** and specify an IP address or select **Dynamic** to allow dynamic extranet devices.

- If you chose a managed device as an endpoint, choose a single IPv4 address or multiple IPv6 addresses from the drop-down list. These IP addresses are already assigned to this interface on the managed device.
- All endpoints in a topology must have the same IP addressing scheme. IPv4 tunnels can carry IPv6 traffic and vice versa. The Protected Networks define which addressing scheme the tunneled traffic uses.
- If the managed device is a high-availability container, choose from a list of interfaces.

### This IP is Private

Check the check box if the endpoint resides behind a firewall with network address translation (NAT).

**Note** Use this option only when the peer is managed by the same management center and don't use this option if the peer is an extranet device.

### Public IP address

If you checked the **This IP is Private** check box, specify a public IP address for the firewall. If the endpoint is a responder, specify this value.

### Connection Type

Specify the allowed negotiation as bidirectional, answer-only, or originate-only. Supported combinations for the connection type are:

**Table 96: Connection Type Supported Combinations**

| Remote Node    | Central Node   |
|----------------|----------------|
| Originate-Only | Answer-Only    |
| Bi-Directional | Answer-Only    |
| Bi-Directional | Bi-Directional |

### Certificate Map

Choose a preconfigured certificate map object, or click **Add** (+) to add a certificate map object. The certificate map defines what information is necessary in the received client certificate to be valid for VPN connectivity. See [Certificate Map Objects, on page 1557](#) for details.

### Protected Networks

**Caution** Hub and Spoke topology—To avoid traffic drop for a dynamic crypto map, ensure that you don't select the protected network *any* for both the endpoints.

If the protected network is configured as *any*, on both the endpoints, the crypto ACL that works upon the tunnel is not generated.

Defines the networks that are protected by this VPN endpoint. Select the networks by selecting the list of Subnet/IP Address that define the networks that are protected by this endpoint. Click **Add (+)** to select from available Network Objects or add new Network Objects. See [Creating Network Objects](#), on page 1499. Access control lists are generated from the choices made here.

- **Subnet/IP Address (Network)**—VPN endpoints can't have the same IP address and protected networks in a VPN endpoint pair cannot overlap. If protected networks for an endpoint contain IPv4 or IPv6 entries, the other endpoint's protected network must have at least one entry of the same type (IPv4 or IPv6). If it doesn't, the other endpoint's IP address must be of the same type and not overlap with the entries in the protected network. (Use /32 CIDR address blocks for IPv4 and /128 CIDR address blocks for IPv6.) If both of these checks fail, the endpoint pair is invalid.

**Note** By default, **Reverse Route Injection is enabled** is enabled in management center.

**Subnet/IP Address (Network)** remains the default selection.

When you've selected Protected Networks as *Any* and observe default route traffic being dropped, disable the Reverse Route Injection. Choose **VPN > Site to Site > edit a VPN > IPsec > Enable Reverse Route Injection**. Deploy the configuration changes to remove set reverse-route (Reverse Route Injection) from the crypto map configuration and remove the VPN-advertised reverse route that causes the reverse tunnel traffic to be dropped.

- **Access List (Extended)**—An extended access list provides the capability to control the type of traffic that will be accepted by this endpoint, like GRE or OSPF traffic. Traffic may be restricted either by address or port. Click **Add (+)** to add access control list objects.

**Note** Access Control List is supported only in the point to point topology.

### Exempt VPN traffic from network address translation

Check this check box to exempt the VPN traffic from the Network Address Translation (NAT) rules.

If you do not exempt the VPN traffic from the NAT rules, the traffic gets dropped or is not routed through the VPN tunnel to the remote device. After you enable this option, you can view the NAT exemptions for the device in the NAT policy page (**Device > NAT > NAT Exemptions**).

### Inside interfaces directly connected to the internal network

Specify the security zone or interface group for the inside interface(s) where the protected networks reside. By default, the inside interface is any.

Click + to configure one or more interfaces from a security zone or an interface group that can map to one or more inside interfaces. Ensure that the interface type of the security zone or an interface group is Routed.

### Advanced Settings

**Enable Dynamic Reverse Route Injection**—Reverse Route Injection (RRI) enables routes to be automatically inserted into the routing process, for the networks and hosts protected by a remote tunnel

endpoint. Dynamic RRI routes are created only upon the successful establishment of IPsec security associations (SA's).

**Note**

- Dynamic RRI is supported only on IKEv2, and not supported on IKEv1 or IKEv1 + IKEv2.
- Dynamic RRI isn't supported on originate-only peer, Full Mesh topology, and Extranet peer.
- In Point-to-Point, only one peer can have dynamic RRI enabled.
- Between Hub and Spoke, only one of the endpoints can have dynamic RRI enabled.
- Dynamic RRI cannot be combined with a dynamic crypto map.

**Send Local Identity to Peers**—Select this option to send local identity information to the peer device. Select one of the following **Local Identity Configuration** from the list and configure the local identity:

- **IP address**—Use the IP address of the interface for the identity.
- **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
- **Email ID**—Specify the email ID to use for the identity. The email ID can be up to 127 characters.
- **Hostname**—Use the fully qualified hostname.
- **Key ID**—Specify the key-id to use for the identity. The key ID must be fewer than 65 characters.

The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows threat defense to have multiple IPsec tunnels behind a NAT to connect to the Cisco Umbrella Secure Internet Gateway (SIG).

For information about configuring a unique tunnel ID on Umbrella, see **Cisco Umbrella SIG User Guide**.

**VPN Filter**—Select an extended access list from the list or click **Add** to create a new extended access list object to filter the site-to-site VPN traffic.

The VPN filter provides more security and filters site-to-site VPN data using an extended access list. The extended access list object selected for the VPN filter lets you filter pre-encrypted traffic before entering the VPN tunnel and decrypted traffic that exits a VPN tunnel. The **sysopt permit-vpn** option, when enabled, would bypass the access control policy rules for the traffic coming from the VPN tunnel. When the **sysopt permit-vpn** option is enabled, the VPN filter helps in identifying and filtering the site-to-site VPN traffic.

**Note**

The VPN filter is supported only on Point to Point, and Hub and Spoke topologies. It isn't supported on Mesh topology.

For Hub and Spoke topology, you can choose to override the hub VPN filter on the spoke endpoints in case a different VPN filter needs to be enabled on a specific tunnel.

Select the **Override VPN Filter on the Hub** option to override the hub VPN filter on the spokes. Select the **Remote VPN Filter** extended access list object or create an access list to override.

---

**Note** For an extranet device as a spoke, only the **Override VPN filter on the Hub** option is available.

For more information about sysopt permit-VPN, see [Threat Defense Advanced Site-to-site VPN Tunnel Options, on page 1635](#).

## Threat Defense VPN IKE Options

For the versions of IKE you have chosen for this topology, specify the **IKEv1/IKEv2 Settings**.

---

**Note** Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.

---

### Navigation Path

**Devices** > **Site To Site**. Then click + **Site To Site VPN**, or edit a listed VPN topology. Click the **IKE** tab.

### Fields

#### Policy

Choose the required IKEv1 or IKEv2 policy objects from the predefined list or create new objects to use. You can choose multiple IKEv1 and IKEv2 policies. IKEv1 and IKEv2 support a maximum of 20 IKE policies, each with a different set of values. Assign a unique priority to each policy that you create. The lower the priority number, the higher the priority.

For details, see [Threat Defense IKE Policies, on page 1569](#)

#### Authentication Type

Site-to-site VPN supports two authentication methods, pre-shared key and certificate. For an explanation of the two methods, see [Deciding Which Authentication Method to Use, on page 1612](#).

---

**Note** In a VPN topology that supports IKEv1, the **Authentication Method** specified in the chosen IKEv1 Policy object becomes the default in the IKEv1 **Authentication Type** setting. These values must match, otherwise, your configuration will error.

---

- **Pre-shared Automatic Key**—The management center automatically defines the pre-shared key for this VPN. Specify the **Pre-shared Key Length**, the number of characters in the key, 1-27.

The character " (double quote) isn't supported as part of pre-shared keys. If you've used " in a pre-shared key, ensure that you change the character after you upgrade to Secure Firewall Threat Defense 6.30 or higher.

- **Pre-shared Manual Key**—Manually assign the pre-shared key for this VPN. Specify the **Key** and then reenter the same to **Confirm Key**.

When you choose this option for IKEv2, the **Enforce hex-based pre-shared key only** check box appears, check if desired. If enforced, you must enter a valid hex value for the key, an even number of 2-256 characters, using numerals 0-9, or A-F.

- **Certificate**—When you use certificates as the authentication method for VPN connections, peers obtain digital certificates from a CA server in your PKI infrastructure, and trade them to authenticate each other.

In the **Certificate** field, select a preconfigured certificate enrollment object. This enrollment object generates a trustpoint with the same name on the managed device. The certificate enrollment object should be associated with and installed on the device, post which the enrollment process is complete, and then a trustpoint is created.

A trustpoint is a representation of a CA or identity pair. A trustpoint includes the identity of the CA, CA-specific configuration parameters, and an association with one enrolled identity certificate.

Before you select this option, note the following:

- Ensure you've enrolled a certificate enrollment object on all the endpoints in the topology—A certificate enrollment object contains the Certification Authority (CA) server information and enrollment parameters that are required for creating Certificate Signing Requests (CSRs) and obtaining Identity Certificates from the specified CA. Certificate Enrollment Objects are used to enroll your managed devices into your PKI infrastructure, and create trustpoints (CA objects) on devices that support VPN connections. For instructions on creating a certificate enrollment object, see [Adding Certificate Enrollment Objects, on page 1511](#), and for instructions on enrolling the object on the endpoints see one of the following as applicable:
  - [Installing a Certificate Using Self-Signed Enrollment , on page 1579](#)
  - [Installing a Certificate using EST Enrollment, on page 1580](#)
  - [Installing a Certificate Using SCEP Enrollment, on page 1581](#)
  - [Installing a Certificate Using Manual Enrollment, on page 1581](#)
  - [Installing a Certificate Using a PKCS12 File, on page 1582](#)

**Note** For a site-to-site VPN topology, ensure that the same certificate enrollment object is enrolled in all the endpoints in the topology. For further details, see the table below.

- Refer the following table to understand the enrollment requirement for different scenarios. Some of the scenarios require you to override the certificate enrollment object for specific devices. See [Managing Object Overrides, on page 1461](#) to understand how to override objects.

| Certificate Enrollment Types | Device identity certificate for all endpoints is from the same CA                 |                                                                               | Device identity certificate for all endpoints is from different CAs |
|------------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------|---------------------------------------------------------------------|
|                              | Device-specific parameters are NOT specified in the certificate enrollment object | Device-specific parameters are specified in the certificate enrollment object |                                                                     |
| <b>Manual</b>                | No override required                                                              | Override required                                                             | Override required                                                   |
| <b>EST</b>                   | No override required                                                              | Override required                                                             | Override required                                                   |

| Certificate Enrollment Types | Device identity certificate for all endpoints is from the same CA                 |                                                                               | Device identity certificate for all endpoints is from different CAs |
|------------------------------|-----------------------------------------------------------------------------------|-------------------------------------------------------------------------------|---------------------------------------------------------------------|
|                              | Device-specific parameters are NOT specified in the certificate enrollment object | Device-specific parameters are specified in the certificate enrollment object |                                                                     |
| SCEP                         | No override required                                                              | Override required                                                             | Override required                                                   |
| PKCS                         | Override required                                                                 | Override required                                                             | Override required                                                   |
| Self-signed                  | Not applicable                                                                    | Not applicable                                                                | Not applicable                                                      |

- Understand the VPN certificate limitations mentioned in [Secure Firewall Threat Defense VPN Certificate Guidelines and Limitations](#), on page 1575.

**Note**

If you use a Windows Certificate Authority (CA), the default application policies extension is **IP security IKE intermediate**. If you use this default setting, you must select the **Ignore IPsec Key Usage** option in the Advanced Settings section on the **Key** tab in the **PKI Certificate Enrollment** dialog box for the object you select. Otherwise, the endpoints can't complete the site-to-site VPN connection.

## Threat Defense VPN IPsec Options

**Note**

Settings in this dialog apply to the entire topology, all tunnels, and all managed devices.

### Crypto-Map Type

A crypto map combines all the components required to set up IPsec security associations (SA). When two peers try to establish an SA, they must each have at least one compatible crypto map entry. The IPsec security negotiation uses the proposals defined in the crypto map entry to protect the data flows specified by that crypto map's IPsec rules. Choose static or dynamic for this deployment's crypto-map:

- **Static**—Use a static crypto map in a point-to-point or full mesh VPN topology.
- **Dynamic**—Dynamic crypto-maps essentially create a crypto map entry without all the parameters configured. The missing parameters are later dynamically configured (as the result of an IPsec negotiation) to match a remote peer's requirements.

Dynamic crypto map policies are applicable to both hub-and-spoke and point-to-point VPN topologies. To apply these policies, specify a dynamic IP address for one of the peers in the topology and ensure that the dynamic crypto-map is enabled on this topology. In a full mesh VPN topology, you can apply only static crypto map policies.

## IKEv2 Mode

For IPsec IKEv2 only, specify the encapsulation mode for applying ESP encryption and authentication to the tunnel. This determines what part of the original IP packet has ESP applied.

- **Tunnel mode**—(default) Encapsulation mode is set to tunnel mode. Tunnel mode applies ESP encryption and authentication to the entire original IP packet (IP header and data), hiding the ultimate source and destination addresses and becoming the payload in a new IP packet.

The major advantage of tunnel mode is that you don't need to modify the end systems to receive the benefits of IPsec. This mode allows a network device, such as a router, to act as an IPsec proxy. That is, the router performs encryption on behalf of the hosts. The source router encrypts packets and forwards them along the IPsec tunnel. The destination router decrypts the original IP datagram and forwards it onto the destination system. Tunnel mode also protects against traffic analysis; with tunnel mode, an attacker can only determine the tunnel endpoints and not the true source and destination of the tunneled packets, even if they are the same as the tunnel endpoints.

- **Transport preferred**—Encapsulation mode is set to transport mode with an option to fall back to tunnel mode if the peer doesn't support it. In transport mode only the IP payload is encrypted, and the original IP headers are left intact. Therefore, the admin must select a protected network that matches the VPN interface IP address.

This mode has the advantages of adding only a few bytes to each packet and allowing devices on the public network to see the final source and destination of the packet. With transport mode, you can enable special processing (for example, QoS) on the intermediate network based on the information in the IP header. However, the layer 4 header is encrypted, which limits examination of the packet.

- **Transport required**—Encapsulation mode is set to transport mode only, falling back to tunnel mode is allowed. If the endpoints can't successfully negotiate transport mode, due to one endpoint not supporting it, the VPN connection is not made.

## Proposals

Click **Edit** (✎) to specify the proposals for your chosen IKEv1 or IKEv2 method. Select from the available **IKEv1 IPsec Proposals** or **IKEv2 IPsec Proposals** objects, or create and then select a new one. See [Configure IKEv1 IPsec Proposal Objects, on page 1568](#) and [Configure IKEv2 IPsec Proposal Objects, on page 1569](#) for details.

## Enable Security Association (SA) Strength Enforcement

Enabling this option ensures that the encryption algorithm used by the child IPsec SA isn't stronger (in terms of the number of bits in the key) than the parent IKE SA.

## Enable Reverse Route Injection

Reverse Route Injection (RRI) enables static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint.

## Enable Perfect Forward Secrecy

Whether to use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the Modulus Group list.

## Modulus Group

The Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing

time. The two peers must have a matching modulus group. For a full explanation of the options, see [Deciding Which Diffie-Hellman Modulus Group to Use, on page 1611](#).

#### Lifetime Duration

The number of seconds a security association exists before expiring. The default is 28,800 seconds.

#### Lifetime Size

The volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before it expires. The default is 4,608,000 kilobytes. Infinite data isn't allowed.

#### ESPv3 Settings

##### Validate incoming ICMP error messages

Choose whether to validate ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.

##### Enable 'Do Not Fragment' Policy

Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header.

##### Policy

- Copy DF bit—Maintains the DF bit.
- Clear DF bit—Ignores the DF bit.
- Set DF bit—Sets and uses the DF bit.

##### Enable Traffic Flow Confidentiality (TFC) Packets

Enable dummy TFC packets that mask the traffic profile which traverses the tunnel. Use the **Burst**, **Payload Size**, and **Timeout** parameters to generate random length packets at random intervals across the specified SA.

---

**Note** You can enable dummy Traffic Flow Confidentiality (TFC) packets at random lengths and intervals on an IPsec security association (SA). You must have an IKEv2 IPsec proposal set before enabling TFC.

Enabling TFC packets prevents the VPN tunnel from being idle. Thus the VPN idle timeout configured in the group policy doesn't work as expected when you enable the TFC packets.

---

## Threat Defense Advanced Site-to-site VPN Deployment Options

The following sections describe the advanced options you can specify in your site-to-site VPN deployment. These settings apply to the entire topology, all tunnels, and all managed devices.

### Threat Defense VPN Advanced IKE Options

#### Advanced > IKE > ISAKAMP Settings

##### IKE Keepalive

Enable or disables IKE Keepalives. You can set this option to EnableInfinite so that the device never starts the keepalive monitoring itself.

**Threshold**

Specifies the IKE keep alive confidence interval. This interval is the number of seconds allowing a peer to idle before beginning keepalive monitoring. The minimum and default interval is 10 seconds; the maximum interval is 3600 seconds.

**Retry Interval**

Specifies number of seconds to wait between IKE keep alive retries. The default is 2 seconds, the maximum is 10 seconds.

**Identity Sent to Peers:**

Choose the identity that the peers will use to identify themselves during IKE negotiations:

- **autoOrDN**(default)—Determines IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication (not supported).
- **ipAddress**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
- **hostname**—Uses the fully qualified domain name of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.

---

**Note** Enable or disable this option for all your VPN connections.

---

**Enable Aggressive Mode**

Select this negotiation method for exchanging key information if the IP address isn't known and DNS resolution might not be available on the devices. Negotiation is based on hostname and domain name.

**Enable Notification on Tunnel Disconnect**

Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA does not match the traffic selectors for that SA. This notification is disabled by default.

**Advanced > IKE > IVEv2 Security Association (SA) Settings**

More session controls are available for IKE v2 that limit the number of open SAs. By default, there's no limit to the number of open SAs.

**Cookie Challenge**

Whether to send cookie challenges to peer devices in response to SA initiate packets, which can help thwart denial of service (DoS) attacks. The default is to use cookie challenges when 50% of the available SAs are in negotiation. Select one of these options:

- Custom
- Never (default)
- Always

**Threshold to Challenge Incoming Cookies**

The percentage of the total allowed SAs that are in-negotiation. This triggers cookie challenges for any future SA negotiations. The range is zero to 100%.

**Number of SAs Allowed in Negotiation**

Limits the maximum number of SAs that can be in negotiation at any time. If used with Cookie Challenge, configure the cookie challenge threshold lower than this limit for an effective cross-check.

**Maximum number of SAs Allowed**

Limits the number of allowed IKEv2 connections. Default is unlimited.

**Enable Notification on Tunnel Disconnect**

Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA doesn't match the traffic selectors for that SA. Sending this notification is disabled by default.

## Threat Defense VPN Advanced IPsec Options

**Advanced > IPsec > IPsec Settings****Enable Fragmentation Before Encryption**

This option lets traffic travel across NAT devices that don't support IP fragmentation. It doesn't impede the operation of NAT devices that do support IP fragmentation.

**Path Maximum Transmission Unit Aging**

Check to enable Path Maximum Transmission Unit (PMTU) Aging, the interval to reset the PMTU of a Security Association (SA).

**Value Reset Interval**

Enter the number of minutes at which the PMTU value of an SA is reset to its original value. Valid range is 10 to 30 minutes, default is unlimited.

## Threat Defense Advanced Site-to-site VPN Tunnel Options

**Navigation Path**

**Devices > Site To Site**, then click + **Site To Site VPN**, or edit a listed VPN Topology. Click the **Advanced** tab, and select **Tunnel** in the navigation pane.

**Tunnel Options**

Only available for Hub and Spoke, and Full Mesh topologies. This section doesn't appear for Point to Point configurations.

- **Enable Spoke to Spoke Connectivity through Hub**—Disabled by default. Choosing this field enables the devices on each end of the spokes to extend their connection through the hub node to the other device.

**NAT Settings**

- **Keepalive Messages Traversal** —Enabled by default. This parameter is a global setting that enables NAT-T for all endpoints within a topology. Check this check box to enable keepalive messages for NAT traversal. NAT traversal keepalive is used for the transmission of keepalive messages when there's a device (middle device) located between a VPN-connected hub and spoke, and that device performs NAT on the IPsec flow.

NAT traversal allows seamless communication between the peer threat defense devices when there are NAT devices between these devices. For hub and spoke topologies, this option is available only for the spoke.

If you select this option, configure the **Interval**, in seconds, between the keepalive signals sent between the spoke and the middle device to indicate that the session is active. The value can be from 5 to 3600 seconds. The default is 20 seconds.

### Access Control for VPN Traffic

**Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)**—By default, the threat defense applies access control policy inspection on the decrypted traffic. Enable this option to bypass the ACL inspection. The threat defense still applies the VPN Filter ACL and authorization ACL downloaded from the AAA server to the VPN traffic.

Enable or disable the option for all your VPN connections. If you disable this option, ensure that the traffic is allowed by the access control policy or prefilter policy.

---

**Note** For route-based VPNs, **sysopt permit-vpn** does not work. You must always create access control rules to allow route-based VPN traffic.

---

### Certificate Map Settings

- **Use the certificate map configured in the Endpoints to determine the tunnel**—If this option is enabled (checked), the tunnel is determined by matching the contents of the received certificate to the certificate map objects configured in the endpoint nodes.
- **Use the certificate OU field to determine the tunnel**—Indicates that if a node isn't determined based on the configured mapping (the above option) if selected, then use the value of the organizational unit (OU) in the subject distinguished name (DN) of the received certificate to determine the tunnel.
- **Use the IKE identity to determine the tunnel**—Indicates that if a node isn't determined based on a rule matching or taken from the OU (the above options) if selected, then the certificate-based IKE sessions are mapped to a tunnel based on the content of the phase1 IKE ID.
- **Use the peer IP address to determine the tunnel**—Indicates that if a tunnel isn't determined based on a rule matching or taken from the OU or IKE ID methods (the above options) if selected, then use the established peer IP address.

## About Virtual Tunnel Interfaces

Management Center supports a routable logical interface called the Virtual Tunnel Interface (VTI). VTIs do not require a static mapping of IPsec sessions to a physical interface. The IPsec tunnel endpoint is associated with a virtual interface. You can use these interfaces like other interfaces and apply static and dynamic routing policies.

As an alternative to policy-based VPN, you can create a VPN tunnel between peers using VTIs. VTIs support route-based VPN with IPsec profiles attached to the end of each tunnel. VTIs use static or dynamic routes. The device encrypts or decrypts the traffic from or to the tunnel interface and forwards it according to the routing table. Deployments become easier, and having VTI which supports route-based VPN with dynamic routing protocol also satisfies many requirements of a virtual private cloud. Management Center enables you to easily migrate from crypto-map based VPN configuration to VTI-based VPN.

You can configure route-based VPN with static or dynamic VTI using the site-to-site VPN wizard. Traffic is encrypted using static route, BGP, OSPFv2/v3, or EIGRP.

You can create a routed security zone, add VTI interfaces to it, and define access control rules for the decrypted traffic control over the VTI tunnel.

You can create VTI-based VPNs between:

- Two threat defense devices.
- A threat defense and public cloud.
- One threat defense and another threat defense with service provider redundancy.
- A threat defense and any other device with VTI interfaces.
- A threat defense and another device with policy-based VPN configuration.

There are two types of VTI interfaces: static VTI and dynamic VTI.

For more information, see [Static VTI, on page 1637](#) and [Dynamic VTI, on page 1638](#).

## Static VTI

Static VTI uses tunnel interfaces to create a tunnel that is always-on between two sites. You must define a physical interface as a tunnel source for a static VTI. You can associate a maximum of 1024 VTIs per device. To create a static VTI interface in the management center, see [Add a VTI Interface, on page 1644](#).

The figure below shows a VPN topology using static VTIs.

On Threat Defense 1:

- Static VTI IP address is 192.168.10.1
- Tunnel source is 10.0.149.220
- Tunnel destination is 10.0.149.221

On Threat Defense 2:

- Static VTI IP address is 192.168.10.2
- Tunnel source is 10.0.149.221
- Tunnel destination is 10.0.149.220

### Benefits

- Minimizes and simplifies configuration.

You do not have to track all remote subnets for a crypto map access list, and configure complex access lists or crypto maps.

- Provides a routable interface.  
Supports IP routing protocols such as BGP, EIGRP, and OSPFv2/v3, and static routes.
- Supports backup VPN tunnels
- Supports load balancing using ECMP.
- Supports virtual routers.
- Provides differential access control for VPN traffic.

You can configure a VTI with a security zone and use it in an AC policy. This configuration:

- Allows you to classify and differentiate VPN traffic from clear-text traffic and permit VPN traffic selectively.
- Provides differential access-control for VPN traffic across different VPN tunnels.

## Dynamic VTI

Dynamic VTI uses a virtual template for dynamic instantiation and management of IPsec interfaces. The virtual template dynamically generates a unique virtual access interface for each VPN session. Dynamic VTI supports multiple IPsec security associations and accepts multiple IPsec selectors proposed by the spoke.

### Benefits

- Minimizes and simplifies configuration.  
You do not have to configure complex access lists or crypto maps.
- Simplifies management.
  - Easily manage peer configuration for large enterprise hub and spoke deployments.
  - Use only one dynamic VTI for multiple spokes, instead of configuring one static VTI per spoke.
- Provides a routable interface.  
Supports IP routing protocols such as BGP, EIGRP, and OSPFv2/v3, and static routes.
- Simplifies scaling  
Addition of new spokes does not require any additional VPN configuration on the hub. You may need to update NAT and routing configurations depending upon the setup.
- Support for backup VPN tunnels.
- Supports dynamic spokes.  
You do not have to update the hub configuration for spoke's DHCP IP address changes.
- Conserves IP addresses.
  - Uses the IP unnumbered interface functionality to borrow the IP address from another physical or loopback interface.
  - All virtual access interfaces associated to a dynamic VTI use the same IP address.

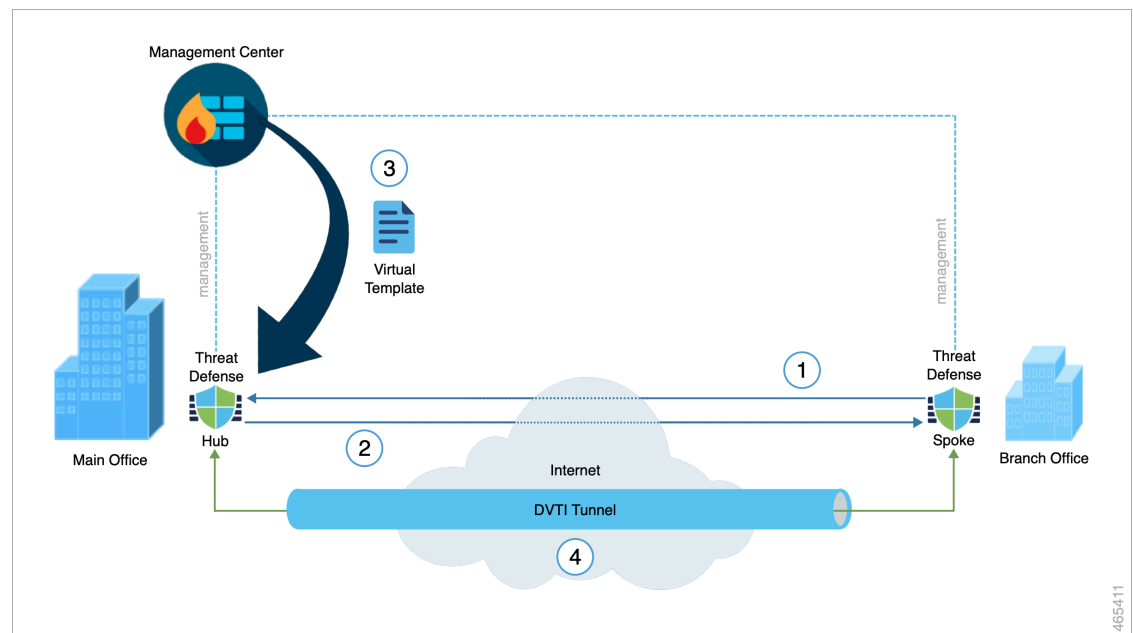

- Supports virtual routers.
- Provides differential access control for VPN traffic.

You can configure a VTI with a security zone and use it in an AC policy. This configuration:

- Allows you to classify and differentiate VPN traffic from clear-text traffic and permit VPN traffic selectively.
- Provides differential access-control for VPN traffic across different VPN tunnels.

### How Does the Management Center Create a Dynamic VTI Tunnel for a VPN Session

When a spoke initiates a tunnel request with the hub:

1. The spoke initiates an IKE exchange with the hub for a VPN connection.
2. The hub authenticates the spoke.
3. The management center assigns a dynamic virtual template on the hub for the spoke.  
The virtual template dynamically generates a virtual access interface on the hub. This interface is unique for the VPN session with the spoke.
4. The hub establishes a dynamic VTI tunnel with the spoke using the virtual access interface.
  - a. The hub and spoke exchange traffic over the tunnel using:
    - Specific traffic proposed by the spokes over IKE exchanges.
    - BGP/OSPF/EIRGP protocols over the IPsec tunnel.
  - b. After the VPN session ends, the tunnel disconnects and the hub deletes the corresponding virtual access interface.

To create a dynamic VTI interface in the management center, see [Add a VTI Interface, on page 1644](#).

To configure a route-based site-to-site VPN using dynamic VTI, see [Configure Dynamic VTI for a Route-based Site-to-Site VPN, on page 1657](#).

### Virtual Routers and Dynamic VTI

You can create virtual routers, associate dynamic VTIs with these virtual routers, and extend the capabilities of dynamic VTIs in your network. You can associate dynamic VTIs either with global or user-defined virtual routers. You can assign a dynamic VTI to only one virtual router.

A virtual router associated with:

- A dynamic VTI is called an Indoor VRF (IVRF).
- A tunnel source interface is known as Front Door VRF (FVRF).

A dynamic VTI and its corresponding protected network interface must be part of the same virtual router. You must map the borrow IP interface and the dynamic VTI to the same virtual router. A tunnel source interface can be part of multiple virtual routers.

To configure virtual routers using dynamic VTI for a route-based site-to-site VPN, see [How to Configure a Virtual Router with Dynamic VTI, on page 1282](#).

For more information about a configuration example, see [How to Secure Traffic from Networks with Multiple Virtual Routers over a Site-to-Site VPN with Dynamic VTI, on page 1314](#)

## Guidelines and Limitations for Virtual Tunnel Interfaces

### IPv6 Support

- VTI supports IPv6.
- You can use an IPv6 address for the tunnel source interface and use the same address as the tunnel endpoint.
- The management center supports the following combinations of VTI IP (or internal networks IP version) over public IP versions:
  - IPv6 over IPv6
  - IPv4 over IPv6
  - IPv4 over IPv4
  - IPv6 over IPv4
- VTI supports static and dynamic IPv6 addresses as the tunnel source and destination.
- The tunnel source interface can have IPv6 addresses and you can specify the tunnel endpoint address. If you don't specify the address, by default, the threat defense uses the first IPv6 global address in the list as the tunnel endpoint.

**BGP IPv6 Support**

VTI supports IPv6 BGP.

**EIGRP IPv4 Support**

VTI supports IPv4 EIGRP.

**OSPFv2 and OSPFv3 IPv6/IPv4 Support**

VTI supports IPv4 and IPv6 OSPF.

**Multi-instance and Clustering**

- VTI is supported in multi-instance.
- VTIs aren't supported with clustering.

**Firewall Mode**

VTI is supported in routed mode only.

**Limitations for Static VTI**

- Only 20 unique IPsec profiles are supported.
- In route-based routing, you can configure VTI only as an egress interface.

**Limitations for Dynamic VTI**

- Dynamic VTI does not support:
  - ECMP
  - VRF in multi-instance
  - Clustering
  - IKEv1
  - QoS
- If a spoke has a dynamic IP address and a hub has a dynamic VTI behind a NAT, the tunnel status will be unknown.
- For a dynamic extranet, when multiple spokes establish a connection, the site-to-site monitoring dashboard does not show the individual tunnels.
- If you configure a hub with dynamic VTI behind NAT with dynamic spokes, the VPN monitoring data will not be accurate.

### General Configuration Guidelines for Static and Dynamic VTI

- If you use dynamic crypto maps and dynamic VTIs in your site-to-site VPNs, only the dynamic VTI tunnels will come up. This behaviour occurs because both the crypto maps and dynamic VTIs try to use the default tunnel group.

We recommend that you do one of the following:

- Migrate your site-to-site VPNs to dynamic VTIs.
  - Use static crypto maps with their own tunnel-groups.
- VTIs are only configurable in IPsec mode.
  - Dynamic VTI supports only the hub and spoke topology in the management center.
  - Dynamic VTI supports only threat defense devices from version 7.3.
  - We recommend that you configure only a single hub for a route-based hub and spoke topology. To configure a topology with multiple hubs for a set of spokes, with one hub as the backup hub, configure multiple topologies with a single hub and the same set of spokes. For more information, see [Configure Multiple Hubs in a Route-based VPN, on page 1652](#).
  - You can use static, BGP, EIGRP IPv4, OSPFv2/v3 routes for traffic using the tunnel interface.
  - In an HA configuration with dynamic routing, the standby device cannot access the known subnets through the VTI tunnels as these tunnels are created with the active IP address.
  - You can configure a maximum of 1024 static and dynamic VTIs on a device. While calculating the VTI count, consider the following:
    - Include nameif subinterfaces to derive the total number of VTIs that can be configured on the device.
    - You can't configure nameif on the member interfaces of a portchannel. Therefore, the tunnel count is reduced by the count of actual main portchannel interfaces alone and not any of its member interfaces.
    - The VTI count on a platform is limited to the number of VLANs configurable on that platform. For example, Firepower 1120 supports 512 VLANs, the tunnel count is 512 *minus* the number of physical interfaces configured.
  - If you're configuring more than 400 VTIs on a device in a high-availability setup, you must configure 45 seconds as the unit holdtime for the threat defense HA.
  - The MTU for VTIs is automatically set, according to the underlying physical interface.
  - For dynamic VTI, the virtual access interface inherits the MTU from the configured tunnel source interface. If you don't specify the tunnel source interface, the virtual access interface inherits the MTU from the source interface from which the threat defense accepts the VPN session request.
  - Static VTI supports IKE versions v1, v2, and uses IPsec for sending and receiving data between the tunnel's source and destination.
  - Dynamic VTI supports only IKE version v2, and uses IPsec for sending and receiving data between the tunnel's source and destination.
  - For static and dynamic VTI, ensure that you don't use the borrow IP interface as the tunnel source IP address for any VTI interface.

- When you configure a route-based site-to-site VPN using static or dynamic VTI interfaces, ensure that the value of the TTL hop is more than one if you use BGP.
- If NAT has to be applied, the IKE and ESP packets are encapsulated in the UDP header.
- IKE and IPsec security associations are re-keyed continuously regardless of data traffic in the tunnel. This ensures that VTI tunnels are always up.
- Tunnel group name must match what the peer sends as its IKEv1 or IKEv2 identity.
- For IKEv1 in LAN-to-LAN tunnel groups, you can use names which aren't IP addresses, if the tunnel authentication method is digital certificates and/or the peer is configured to use aggressive mode.
- VTI and crypto map configurations can coexist on the same physical interface, if the peer address configured in the crypto map and the tunnel destination for the VTI are different.
- By default, all traffic sent through a VTI is encrypted.
- Access rules can be applied on a VTI interface to control traffic through VTI.
- You can associate VTI interfaces with ECMP zones and configure ECMP static routes to achieve the following:
  - Load balancing (Active/Active VTIs)—Connection can flow over any of the parallel VTI tunnels.
  - Seamless connection migration—When a VTI tunnel becomes unreachable, the flows are seamlessly migrated to another VTI interface that is configured in the same zone.
  - Asymmetric routing—Forward traffic flow through one VTI interface and configure the reverse traffic flow through another VTI interface.

For information on configuring ECMP, see [Configure an Equal Cost Static Route, on page 1338](#).

- For route-based VPNs, Bypass Access Control policy for decrypted traffic (**sysopt connection permit-vpn**) does not work. You must always create access control rules to allow route-based VPN traffic.

### Backup VTI Guidelines and Limitations

- Flow resiliency across tunnel failovers isn't supported. For example, the clear text TCP connection gets lost after a tunnel failover, and you need to reinitiate any FTP transfer that took place during the failover.
- Certificate authentication isn't supported in backup VTI.

### Guidelines for Dynamic VTI and Virtual Routers

- A dynamic VTI and its corresponding protected network interface must be part of the same virtual router.
- You must map the borrow IP interface and the dynamic VTI to the same virtual router.
- User-defined virtual routers support only BGPv4/v6 and OSPFv2 routing protocols.
- A tunnel source interface can be in a different user-defined virtual router than that associated with the dynamic VTI.

### Related Topics

- [Create a Route-based Site-to-Site VPN](#), on page 1645

# Add a VTI Interface

For configuring a route-based site-to-site VPN, you must create a VTI interface on the devices at both the nodes of the VTI tunnel.

When you specify the tunnel type as dynamic and configure the related parameters, the management center generates a dynamic virtual template. The virtual template dynamically generates the virtual access interface that is unique for each VPN session.

## Before you begin

Configure a loopback interface for redundancy of static and dynamic VTI VPN tunnels. For more information, see [Configure a Loopback Interface, on page 962](#).

For a Secure Firewall 1200, Secure Firewall 3100 or Secure Firewall 4200 device, IPsec flow offload is also used when the device's VTI loopback interface is enabled.

## Procedure

- 
- Step 1** Choose **Devices > Device Management**.
  - Step 2** Click the **Edit** icon next to the device on which you want to create a VTI interface.
  - Step 3** Choose **Add Interfaces > Virtual Tunnel Interface**.
  - Step 4** Select the **Tunnel Type** as **Static** or **Dynamic**.
  - Step 5** Enter the name and description for the interface. By default, the interface is enabled.  
Ensure that you specify a name that is not longer than 28 characters.
  - Step 6** (Optional) Choose a security zone from the **Security Zone** drop-down list to add the static VTI or dynamic VTI interface to that zone.  
If you want to perform traffic inspection based on a security zone, add the VTI interface to the security zone and configure an access control (AC) rule. To permit the VPN traffic over the tunnel, you need to add an AC rule with this security zone as the source zone.
  - Step 7** Enter the priority to load balance the traffic across multiple VTIs in the **Priority** field.  
The range is from 0 to 65535. The lowest number has the highest priority. This option is not applicable for dynamic VTI.
  - Step 8** Depending on the tunnel type, do one of the following:
    - For a dynamic VTI, enter a unique ID in the range of 1 to 10413 in the **Template ID** field.
    - For a static VTI, enter a unique tunnel ID in the range of 0 to 10413 in the **Tunnel ID** field.
  - Step 9** (Optional for dynamic VTI) Choose the tunnel source interface from the **Tunnel Source** drop-down list.  
The VPN tunnel terminates at this interface, a physical or loopback interface. Choose the IP address of the interface from the drop-down list. You can select the IP address irrespective of the IPsec tunnel mode. In case of multiple IPv6 addresses, select the address that you want to use as the tunnel endpoint.

- Step 10** Under **IPSec Tunnel Mode**, click the **IPv4** or **IPv6** radio button to specify the traffic type over the IPsec tunnel.
- Step 11** Under **IP Address**:
- **Configure IP**: Enter the IPv4 or IPv6 address for the static VTI interface. You cannot configure an IP address for a dynamic VTI interface. Use the **Borrow IP** field for the dynamic VTI interface.
  - **Borrow IP (IP unnumbered)**: Choose a physical or loopback interface from the drop-down list, the VTI interface inherits this IP address.
- Ensure that you use an IP address different from the tunnel source IP address. You can use this option for a static or dynamic VTI interface.
- Click + to configure a loopback interface. The loopback interface helps to overcome path failures. If an interface goes down, you can access all interfaces through the IP address assigned to the loopback interface.
- Step 12** Click **OK**.
- Step 13** Click **Save**.
- 

## Create a Route-based Site-to-Site VPN

You can configure a route-based site-to-site VPN for the following two topologies:

- **Point to Point** : Configure VTIs on both nodes of the tunnel and use the wizard to configure the VPN.
- **Hub and Spoke**: Configure VTIs on the hub and the spokes. Configure the hub with a dynamic VTI and spokes with static VTIs.

You can configure an extranet device as the hub and managed devices as spokes. You can configure multiple hubs and spokes, and also configure backup hubs and spokes.

- For extranet hubs and spokes, you can configure multiple IPs as backup.
- For managed spokes, you can configure a backup static VTI interface along with the primary VTI interface.

For more information on VTI, see [About Virtual Tunnel Interfaces, on page 1636](#).

---

**Note** All references to VTI stands for static VTI and dynamic VTI, unless mentioned.

---

### Procedure

---

- Step 1** Choose **Devices > Site To Site**.
- Step 2** Click + **Site To Site VPN**.
- Step 3** Enter a name for the VPN topology in the **Topology Name** field.
- Step 4** Choose **Route Based (VTI)** and do one of the following:

- Select **Point to Point** as the network topology. To configure endpoints for a route-based **Point to Point** topology, see [Configure Endpoints for a Point to Point Topology, on page 1646](#).
- Select **Hub and Spoke** as the network topology. To configure endpoints for a route-based **Hub and Spoke** topology, see [Configure Endpoints for a Hub and Spoke Topology, on page 1648](#).

- Step 5** (Optional) Specify the **IKE** options for the deployment as described in [Threat Defense VPN IKE Options, on page 1629](#).
- Step 6** (Optional) Specify the **IPsec** options for the deployment as described in [Threat Defense VPN IPsec Options, on page 1631](#).
- Step 7** (Optional) Specify the **Advanced** options for the deployment as described in [Threat Defense Advanced Site-to-site VPN Deployment Options, on page 1633](#).
- Step 8** Click **Save**.

---

### What to do next

After you configure VTI interfaces and VTI tunnel on both the devices, you must configure:

- A routing policy to route the VTI traffic between the devices over the VTI tunnel. For more information, see [Configure Routing and AC Policies for VTI, on page 1658](#).
- An access control rule to allow encrypted traffic. Choose **Policies > Access Control**.

## Configure Endpoints for a Point to Point Topology

Configure the following parameters to configure endpoints for a route-based site-to-site VPN for the **Point to Point** topology nodes:

### Before you begin

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in [Create a Route-based Site-to-Site VPN, on page 1645](#) and click the **Endpoints** tab.

### Procedure

- 
- Step 1** Under **Node A**, in the **Device** drop-down menu, select the name of the registered device (threat defense) or extranet as the first endpoint of your VTI tunnel.
- For an extranet peer, specify the following parameters:
- Specify the name of the device.
  - Enter the primary IP address in the **Endpoint IP address** field. If you configure a backup VTI, add a comma and, specify the backup IP address.
  - Click **OK**.

After configuring the above parameters for the extranet hub, specify the pre-shared key for the extranet in the **IKE** tab.

**Note** The AWS VPC has **AES-GCM-NUL-~~LSHA~~-LATEST** as the default policy. If the remote peer connects to AWS VPC, select **AES-GCM-NUL-~~LSHA~~-LATEST** from the **Policy** drop-down list to establish the VPN connection without changing the default value in AWS.

- Step 2** For a registered device, you can specify the VTI interface for Node A from the **Virtual Tunnel Interface** drop-down list.
- The selected tunnel interface is the source interface for Node A and the tunnel destination for Node B.
- If you want to create a new interface on Node A, click the + icon and configure the fields as described in [Add a VTI Interface, on page 1644](#).
- If you want to edit the configuration of an existing VTI, select the VTI in the **Virtual Tunnel Interface** drop-down field and click **Edit VTI**.
- Step 3** If your Node A device is behind a NAT device, check the **Tunnel Source IP is Private** check box. In the **Tunnel Source Public IP Address** field, enter the tunnel source public IP address.
- Step 4** **Send Local Identity to Peers**—Select this option to send local identity information to the peer device. Select one of the following **Local Identity Configuration** from the list and configure the local identity:
- **IP address**—Use the IP address of the interface for the identity.
  - **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
  - **Email ID**—Specify the email ID to use for the identity. The email ID can be up to 127 characters.
  - **Hostname**—Use the fully qualified hostname.
  - **Key ID**—Specify the key-id to use for the identity. The key ID must be fewer than 65 characters.
- The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows threat defense to have multiple IPsec tunnels behind a NAT to connect to a Cisco Umbrella Secure Internet Gateway (SIG).
- For information about configuring a unique tunnel ID on Umbrella, see **Cisco Umbrella SIG User Guide**.
- Step 5** (Optional) Click **Add Backup VTI** to specify an extra VTI as the backup interface and configure the parameters.
- Note** Ensure that both peers of the topology do not have the same tunnel source for the backup VTI. A device cannot have two VTIs with the same tunnel source and tunnel destination; hence, configure a unique tunnel source and tunnel destination combination.
- Though the virtual tunnel interface is specified under Backup VTI, the routing configuration determines which tunnel to be used as primary or backup.
- Step 6** Expand **Advance Settings** to configure additional configurations for the device. For more information, see [Advanced Configurations for a Point to Point Topology in a Route-based VPN, on page 1648](#).
- Step 7** Repeat the above procedure for Node B.
- Step 8** Click **OK**.

---

### What to do next

- (Optional) Specify the **IKE** options for the deployment as described in [Threat Defense VPN IKE Options, on page 1629](#).

- (Optional) Specify the **IPsec** options for the deployment as described in [Threat Defense VPN IPsec Options, on page 1631](#).
- (Optional) Specify the **Advanced** options for the deployment as described in [Threat Defense Advanced Site-to-site VPN Deployment Options, on page 1633](#).
- Click **Save**.
- To route traffic to the VTI, choose **Devices > Device Management**, edit the threat defense device and click the **Routing** tab.  
You can configure the static routes, or use BGP, OSPF v2/v3, or EIGRP for routing the VPN traffic.
- To permit VPN traffic, choose **Policies > Access Control**. Add a rule specifying the security zone of the VTI. For a backup VTI, ensure that you include the backup VTI in the same security zone as that of the primary VTI.

## Advanced Configurations for a Point to Point Topology in a Route-based VPN

Configure the following advanced configurations for a point-to-point topology in a route-based VPN:

### Before you begin

Configure the basic parameters for a point-to-point topology in a route-based VPN as described in [Configure Endpoints for a Point to Point Topology, on page 1646](#) and expand **Advance Settings**.

### Procedure

- 
- Step 1** Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.
- Step 2** Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the spokes and peers.
- Step 3** Choose one of the following from the **Connection Type** drop-down list:
- Answer Only:** The device can only respond when a peer device initiates a connection, it can't initiate any connection.
- Bidirectional:** The device can initiate or respond to a connection. This is the default option.
- 

## Configure Endpoints for a Hub and Spoke Topology

You can create a route-based site-to-site VPN using dynamic VTI only for hub and spoke topologies. The hub can use only a dynamic VTI and the spokes can use only static VTI interfaces. You can also configure an extranet device as a hub.

Configure the following parameters to configure endpoints for a route-based site-to-site VPN for the **Hub and Spoke** topology nodes:

### Before you begin

Configure the basic parameters for a hub and spoke topology in a route-based VPN as described in [Create a Route-based Site-to-Site VPN, on page 1645](#) and click the **Endpoints** tab.

## Procedure

### Step 1

Under **Hub Nodes**:

- a) Click + to configure the hub node in the **Add Endpoint** dialog box.
- b) Choose a hub from the **Device** drop-down list.

**Note** A threat defense device running on software version 7.2 can't be configured as a hub. It must be an extranet or a device running on software version 7.3 or later.

For an extranet hub, specify the following parameters:

1. Enter the name of the device.
2. Enter the primary IP address. If you configure a backup VTI, add a comma, and then specify the backup IP address.
3. Click **OK**.

After configuring the above parameters for the extranet hub, specify the pre-shared key for the extranet in the **IKE** tab.

**Note** The AWS VPC has **AES-GCM-NUL-LSHA-LATEST** as the default policy. If the remote peer connects to AWS VPC, select **AES-GCM-NUL-LSHA-LATEST** from the **Policy** drop-down list to establish the VPN connection without changing the default value in AWS.

- c) Choose a dynamic VTI from the **Dynamic Virtual Tunnel Interface** drop-down list.

Tunnel source configuration is mandatory for a dynamic VTI as the management center needs this information to determine the tunnel destination of the spoke.

Click + to add a new dynamic VTI. We recommend that you configure the Borrow IP for the dynamic interface from a loopback interface.

If you want to edit an existing dynamic VTI, select the interface, and click **Edit VTI**.

- d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box and configure the tunnel source IP address in the **Tunnel Source Public IP Address** field.
- e) Click **Routing Policy** to configure the routing policy for the hub.
- f) Click **AC Policy** to configure the access control policy.
- g) Expand **Advance Settings** to configure additional configurations on the hub. For more information, see [Advanced Configurations for Hub and Spokes in a Route-based VPN, on page 1651](#).
- h) Click **OK**.

### Step 2

Under **Spoke Nodes**:

- a) Click + to configure the spoke in the **Add Endpoint** dialog box.
- b) Choose a spoke from the **Device** drop-down list.

For an extranet spoke, specify the following parameters:

1. Enter the name of the device.
  2. Under **Endpoint IP Address**, choose one of the following:
    - **Static**: Enter the IP address of the device, and the backup IP address, if required.
    - **Dynamic**: Choose this option to dynamically assign the IP addresses for the extranet spokes.
  3. Click **OK**.
- c) Choose a static VTI from the **Static Virtual Tunnel Interface** drop-down list.
- Click + to add a new static VTI. Tunnel IP of the static VTI is auto populated, ensure that this IP address is unique for the spoke.
- If you want to edit an existing static VTI, select the interface, and click **Edit VTI**.
- d) (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box. The management center needs the tunnel source interface address to configure the tunnel destination IP address on the spokes. In the **Tunnel Source Public IP Address** field, enter the tunnel source public IP address.
- e) (Optional) **Send Local Identity to Peers**—Check this check box to send the local identity information to the peer device. Choose one of the following parameters from the **Local Identity Configuration** drop-down list and configure the local identity:
- **IP address**—Use the IP address of the interface for the identity.
  - **Auto**—Use the IP address for pre-shared key and Cert DN for certificate-based connections.
  - **Email ID**—Specify the email ID to use for the identity. The email ID can be up to 127 characters.
  - **Hostname**—Use the fully qualified hostname.
  - **Key ID**—Specify the key-id to use for the identity. The key ID must be less than 65 characters.
- The local identity is used to configure a unique identity per IKEv2 tunnel, instead of a global identity for all the tunnels. The unique identity allows threat defense to have multiple IPsec tunnels behind a NAT to connect to the Cisco Umbrella Secure internet Gateway (SIG).
- For more information about configuring a unique tunnel ID on Umbrella, see *Cisco Umbrella SIG User Guide*.
- f) (Optional) Click **Add Backup VTI** to specify an extra VTI interface as the backup interface.
- Note** Ensure that both peers of the topology do not have backup VTI configured on the same tunnel source. For instance, if Peer A is having two VTIs (primary and a backup) configured with a single tunnel source interface, say, 10.10.10.1/30, then Peer B also can't have its 2 VTIs with a single tunnel source IP, say 20.20.20.1/30.
- Though the virtual tunnel interface is specified under backup VTI, the routing configuration determines which tunnel to be used as primary or backup.
- g) Click **Routing Policy** to configure the routing policy for the spoke.
- h) Click **AC Policy** to configure the access control policy.
- i) Expand **Advance Settings** to configure additional configurations on the spoke. For more information, see [Advanced Configurations for Hub and Spokes in a Route-based VPN, on page 1651](#).

j) Click **OK**.

---

### What to do next

- (Optional) Specify the **IKE** options for the deployment as described in [Threat Defense VPN IKE Options, on page 1629](#).
- (Optional) Specify the **IPsec** options for the deployment as described in [Threat Defense VPN IPsec Options, on page 1631](#).
- (Optional) Specify the **Advanced** options for the deployment as described in [Threat Defense Advanced Site-to-site VPN Deployment Options, on page 1633](#).
- Click **Save**.

## Advanced Configurations for Hub and Spokes in a Route-based VPN

Configure the following advanced configurations for a hub and spoke in a route-based VPN:

### Before you begin

Configure the basic parameters for a hub and spoke in a route-based VPN as described in [Configure Endpoints for a Hub and Spoke Topology, on page 1648](#) and expand **Advance Settings**.

---

**Note** Only the **Connection Type** field is applicable to the device running on software version 7.2. The remaining fields don't apply to this version of the device.

---

### Procedure

- 
- Step 1** Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.
- For a hub, you must check this check box if you use BGP as the routing protocol. This configuration ensures that the loopback IP address is shared in the BGP routing table.
- For a spoke, this option is enabled by default.
- Step 2** Add the **Protected Networks** to define the networks protected by the VPN endpoint. Click + to select a protected network.
- For a hub, configure the protected networks behind the hub. This information and the spoke's protected network generate the spoke access list.
- You cannot create a static route for a virtual access interface on a hub with dynamic VTI. The hub creates and deletes these interfaces dynamically during tunnel establishment and termination.
- For a spoke, configure the spoke's protected network.
- To enable static routing for the spokes, after you configure the endpoints for your topology, click the **IPsec** tab and check the **Enable Reverse Route Injection** check box.

You do not need this option if you use BGP, OSPF, or EIGRP.

**Step 3** Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the spokes and peers.

For a hub: During an IKE exchange, the hub advertises the dynamically created virtual access interfaces to the spokes, and the spokes advertise their VTI IP addresses to the hub.

For a spoke: By default, this option is enabled.

**Step 4** In the **Connection Type** drop-down list, choose one of the following:

**Answer Only:** The device can only respond when a peer device initiates a connection, it can't initiate any connection.

**Bidirectional:** The device can initiate or respond to a connection. This is the default option.

## Configure Multiple Hubs in a Route-based VPN

You can configure a topology with multiple hubs for a set of spokes. With one hub as the backup hub, you can configure multiple topologies with a single hub and the same set of spokes.

In the following example, there are two hubs connected to the same set of spokes. Hub 1 is the primary hub and Hub 2 is the secondary hub. To configure this network in the management center, you must configure two route-based hub and spoke topologies:

- Topology 1: Hub 1 connected to spoke 1 and spoke 2.
- Topology 2: Hub 2 connected to spoke 1 and spoke 2.

To configure topology 1:

## Procedure

- 
- Step 1** Choose **Devices > Site To Site** and click + **Site To Site VPN**.
- Step 2** Enter a name for the VPN topology in the **Topology Name** field.
- Step 3** Choose **Route Based (VTI) > Hub and Spoke > Endpoints**.
- Step 4** Under **Hub Nodes**:
- Click + to add the hub.
  - Choose Hub 1 from the **Device** drop-down list.
  - Choose a dynamic VTI from the **Dynamic Virtual Tunnel Interface** drop-down list or click + to add a new dynamic VTI.  
  
We recommend that you configure the Borrow IP for the dynamic interface from a loopback interface.
  - (Optional) If your endpoint device is behind a NAT device, check the **Tunnel Source IP is Private** check box and configure the tunnel source IP address in the **Tunnel Source Public IP Address** field.
  - Click **Routing Policy** to configure the routing policy for the hub. You can configure dynamic routing using BGP.
  - Expand **Advance Settings**. You can configure the following advanced settings for the hub to enable IKEv2 routing, which can be used if you do not use dynamic routing.
    - (Optional) Check the **Send Virtual Tunnel Interface IP to the peers** check box.
    - Check the **Allow incoming IKEv2 routes from the peers** check box for the hub to accept routes from the spokes and update the routing table.
    - Choose **Connection Type** as Bidirectional from the drop-down list.
  - Click **OK**.
- Step 5** Under **Spoke Nodes**:
- Click + to add a spoke.
  - Choose Spoke 1 from the **Device** drop-down list.
  - Choose SVTI-1 as the static VTI for the spoke from the **Static Virtual Tunnel Interface** drop-down list or click + to add a new static VTI.  
  
Choose the outside interface as the tunnel source of SVTI-1. Tunnel IP of SVTI-1 is autopopulated, ensure that this IP address is unique for spoke 1 across peers in both the topologies.
  - Expand **Advance Settings**. If you do not use dynamic routing, you can configure these settings to enable IKEv2 routing for the spoke.
    - Check the **Send Virtual Tunnel Interface IP to the peers** check box to send the VTI IP address to the peer device.
    - Check the **Allow incoming IKEv2 routes from the peers** check box to allow incoming IKEv2 routes from the peers.
    - Choose **Connection Type** as Bidirectional from the drop-down list.
  - Click **OK**.
  - Repeat steps 5a to 5e to add spoke 2. Configure SVTI-1 as the static VTI of spoke 2.

**Step 6** Configure the IKE and IPSec parameters as required or use the default values.

---

#### What to do next

1. Repeat steps 3 to 6 to configure topology 2 with hub 2, spoke 1, and spoke 2.  
Configure SVTI-2 as the static VTI of spoke 1 and SVTI-2 as the static VTI of spoke 2 (refer the above illustration). Tunnel source for SVTI-2 should be the same outside interface.
2. For each spoke, configure the routing policy. For more information, see [Configure Routing for Multiple Hubs in a Route-based VPN, on page 1654](#).
3. Verify the configuration and tunnel statuses. For more information, see [Verify the Multiple Hubs Configuration in a Route-based VPN, on page 1655](#).

## Configure Routing for Multiple Hubs in a Route-based VPN

The following procedure explains how to configure dynamic routing on the hub and spokes, and configure Policy Based Routing on the spokes.

#### Before you begin

Configure topology 1 and 2 as explained in [Configure Multiple Hubs in a Route-based VPN, on page 1652](#).

#### Procedure

---

- Step 1** Configure dynamic routing for the hub using BGP.
- a) Choose **Device > Device Management > Routing**.
  - b) On the left pane, choose **General Settings > BGP**.
  - c) Check the **Enable BGP** check box and enter the **AS number**.  
You can configure the other fields as per your requirement.
  - d) Click **Save**.
  - e) On the left pane, choose **BGP > IPv4**.
  - f) Check the **Enable IPv4** check box.
  - g) Click the **Neighbor** tab, click **Add** and configure the parameters.
    1. **IP Address**: Enter the tunnel interface IP address of Spoke 1.
    2. **Remote AS**: AS number of Spoke 1.
    3. Check the **Enabled Address** check box.
    4. Click **OK**.

Repeat the above steps to add Spoke 2 as a neighbor.

- h) Click **Save**.
- i) Click the **Networks** tab and click **Add** to advertise the network behind the hub to the peers.

**Step 2** Configure dynamic routing for the spokes using BGP.

The BGP configuration for the spokes is similar to that of the hub except for the following differences:

- Configure Hub 1 and Hub 2 as the neighbors for both the spokes and use the tunnel interface IP address of the hubs.
- When you configure networks, use the network behind each spoke.

**Step 3** Configure Policy Based Routing on the spokes.

- a) On the left pane, choose **Policy Based Routing** and click **Add**.
- b) Choose the **Ingress Interface** from the drop-down list.
- c) Click **Add** to configure a Match ACL.

For example, for spoke 1, source network is 192.168.20.0/24 and destination network is 192.168.10.0/24.

- d) Choose Egress Interfaces from the **Send to** drop-down list.
- e) Choose Order from the **Interface Ordering** drop-down list.
- f) Select the SVTI-1 and SVTI-2 interfaces as the egress interfaces.
- g) Click **Save**.

If you want to use the hubs as a load-balancing pair, you must configure ECMP.

**Step 4** Deploy the configurations on the hub and spokes.

---

#### What to do next

Verify the configurations and tunnel statuses. For more information, see [Verify the Multiple Hubs Configuration in a Route-based VPN, on page 1655](#).

## Verify the Multiple Hubs Configuration in a Route-based VPN

To verify the multiple hub configurations and the tunnel statuses:

- After the deployment, check the tunnel status.
- Use the following show commands for each endpoint to verify the configurations:
  - **show run route-map**
  - **show run access-list**
  - **show route-map**
  - **show route**

## Route Traffic Through a Backup VTI Tunnel

Secure Firewall Threat Defense supports the configuration of a backup tunnel for the route-based (VTI) VPN. When the primary VTI is unable to route the traffic, the traffic in the VPN is tunneled through the backup VTI.

You can deploy the backup VTI tunnel in the following scenarios:

- Both peers having service provider redundancy backup.

In this case, there are two physical interfaces, acting as the tunnel sources for the two VTIs of the peers.

- Only one of the peers having service provider redundancy backup.

In this case, there's an interface backup on only one side of the peer and on the other end, there is only one tunnel source interface.

| Step | Do This                                                                                                                                                                     | More Info                                                                                                                                                                                                                     |

| 5    | Configure the access control policy.                                                                                                                                        | <ul style="list-style-type: none"> <li>• Choose <b>Policies &gt; Access Control</b>.</li> </ul>                                                                                                                               |

### Guidelines for Configuring a Backup VTI Tunnel

- For an extranet peer, you can specify the tunnel source IP address of the backup interface and configure the tunnel destination IP on the managed peer.

You can specify the backup peer IP address in the **Endpoint IP Address** field of the **Create New VPN Topology** wizard.

### Create New VPN Topology

Topology Name:\*

Policy Based (Crypto Map)  Route Based (VTI)

Network Topology:

IKE Version:\*  IKEv1  IKEv2

Endpoints   IKE   IPsec   Advanced

---

Node A

Device:\*

Device Name\*:

Endpoint IP Address\*:

- After you configure the backup interfaces, configure the routing policy and access control policy for routing traffic.

Though primary and backup VTIs are always available, traffic flows only through the tunnel that is configured in the routing policy. For detailed information, see [Configure Routing and AC Policies for VTI, on page 1658](#).

- When you configure a backup VTI, ensure that you include the backup tunnel to the same security zone as that of the primary VTI. No specific settings are required for the backup VTI in the AC policy page.
- If you configure a static route for the backup tunnel, configure a static route with a different metric to handle the failover of the traffic flow over the backup tunnel.

## Configure Dynamic VTI for a Route-based Site-to-Site VPN

To configure dynamic VTI for a route-based site-to-site VPN in the management center:

| Step | Do This                                                     | More Information                                                               |
|------|-------------------------------------------------------------|--------------------------------------------------------------------------------|
| 1    | Create a dynamic VTI interface on the hub.                  | <a href="#">Add a VTI Interface, on page 1644</a>                              |
| 2    | Create static VTI interfaces on the spokes.                 | <a href="#">Add a VTI Interface, on page 1644</a>                              |
| 3    | Create a route-based site-to-site VPN.                      | <a href="#">Create a Route-based Site-to-Site VPN, on page 1645</a>            |
| 4    | Configure the routing policy and the access control policy. | <a href="#">Configure Endpoints for a Hub and Spoke Topology, on page 1648</a> |

# How to Configure a Virtual Router with Dynamic VTI

To configure a virtual router with dynamic VTI for a route-based site-to-site VPN in the management center:

| Step | Do This                                                                                                          | More Information                                                               |
|------|------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------|
| 1    | Create a route-based site-to-site VPN with a dynamic VTI interface on the hub and static VTI(s) on the spoke(s). | <a href="#">Create a Route-based Site-to-Site VPN, on page 1645</a>            |
| 2    | Create a virtual router.                                                                                         | <a href="#">Create a Virtual Router, on page 1292</a>                          |
| 3    | Assign the interfaces to the virtual router.                                                                     | <a href="#">Configure a Virtual Router, on page 1293</a>                       |
| 4    | Configure routing policies for the hub and spoke.                                                                | <a href="#">Configure Endpoints for a Hub and Spoke Topology, on page 1648</a> |
| 5    | Configure access control policies for the hub and spoke.                                                         | <a href="#">Configure Endpoints for a Hub and Spoke Topology, on page 1648</a> |

## Configure Routing and AC Policies for VTI

After you configure VTI interfaces and the VTI tunnel on both the devices, you must configure:

- A routing policy to route VTI traffic between the devices over the VTI tunnel.
- An access control rule to allow encrypted traffic.

### Routing Configuration for VTI

For the VTI interfaces, you can configure static route or routing protocols such as BGP, EIGRP, OSPF/OSPFv3.

1. Choose **Devices > Device Management**, and edit the threat defense device.
2. Click **Routing**.
3. Configure static route, or BGP, EIGRP, OSPF/OSPFv3.

| Routing      | Parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        | More Information                                 |

| EIGRP   | <ul style="list-style-type: none"> <li>• Enable EIGRP, provide the AS number of the local device, and select the networks or hosts that participate in the EIGRP routing process.</li> <li>• Click the <b>Neighbors</b> tab and define the static neighbors for the EIGRP process.</li> <li>• To advertise summary addresses from a VTI interface, click the <b>Summary Address</b> tab, choose the VTI interface from the <b>Interface</b> drop-down. From the <b>Network</b> drop-down, choose the network to be summarized.</li> <li>• Click the <b>Interfaces</b> tab to configure the interface-specific EIGRP routing properties for the VTI interface.</li> </ul> <p>To enable EIGRP split-horizon on the interface, check the <b>Split Horizon</b> check box. You can also configure the <b>Hold Time</b> that is advertised by the device in the EIGRP hello packets.</p> |                                                |
| OSPF    | <ul style="list-style-type: none"> <li>• Check the <b>Process 1</b> check box, and choose the OSPF role.</li> <li>• Click the <b>Interface</b> tab and choose a VTI interface.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <a href="#">Configure OSPFv2, on page 1355</a> |
| OSPFv3  | <ul style="list-style-type: none"> <li>• Check the <b>Process 1</b> and <b>Enable Process 1</b> check boxes, and choose the OSPFv3 role.</li> <li>• Click the <b>Interface</b> tab and choose a VTI interface.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <a href="#">Configure OSPFv3, on page 1367</a> |

### AC Policy Rule

Add an access control rule to the access control policy on the device to allow encrypted traffic between the VTI tunnels with the following settings:

1. Create the rule with the Allow action.

2. Select the VTI security zone of the local device as the source zone and the VTI security zone of the remote peer as the destination zone.
3. Select the VTI security zone of the remote peer as the source zone and the VTI security zone of the local device as the destination zone.

For more information about configuring an access control rule, see [Create and Edit Access Control Rules](#), on page 1863.

## Deploy a SASE Tunnel on Umbrella

Cisco Umbrella is Cisco's cloud-based Secure Internet Gateway (SIG) platform that provides multiple levels of defense against internet-based threats. Umbrella integrates secure web gateway, DNS-layer security, and cloud access security broker (CASB) functionality to protect your systems against threats.

You can establish an IPsec IKEv2 tunnel from a threat defense device to Umbrella using the management center. This tunnel forwards all internet-bound traffic to the Umbrella SIG for inspection and filtering. This solution provides centralized security management so that network administrators don't have to separately manage the security settings of each branch.

To directly configure and deploy Umbrella tunnels from a threat defense device, you can create a SASE topology using a simple wizard. SASE topology is a new type of site-to-site VPN topology that supports:

- Static VTI-based site-to-site VPN.
- Hub and spoke topology, where Umbrella is the hub and the managed threat defense devices are the spokes.
- Pre-shared key based authentication.
- Threat Defense deployed in HA mode.
- Multi-instance: In a multi-instance deployment, you can integrate only one Umbrella account.

For high availability, you can configure two tunnels from a threat defense device and use the second tunnel as the backup tunnel. Ensure that you configure different local tunnel IDs for each tunnel.

For ease of configuration, the management center configures the default IPsec and IKEv2 policies.

Default IKEv2 policy configuration:

- Integrity Algorithm: NULL
- Encryption Algorithm: AES-GCM-256
- PRF Algorithm: SHA-256
- DH Group: 19, 20

Default IKEv2 IPsec policy configuration:

- ESP Hash: SHA-256
- ESP Encryption: AES-GCM-256

### Related Topics

[How to Deploy a SASE Tunnel on Umbrella](#), on page 1663

# Guidelines and Limitations for Configuring SASE Tunnels on Umbrella

SASE topology supports:

- Only PSK-based authentication
- IKEv2
- High availability

## General Configuration Guidelines

- The management center does not discover tunnels created directly on Umbrella or by other applications.
- You can add only devices managed by the management center as endpoints for the SASE topology. You cannot add extranet devices.

For high availability pairs, the HA pair names appear in the endpoint list.

- When you delete a tunnel from the management center and if it is unable to delete the tunnel from Umbrella, you must manually delete it by logging into Umbrella.
- You cannot edit or delete a SASE topology if the deployment to Umbrella is in progress. You can view the tunnel deployment status in the:
  - Cisco Umbrella Configuration dialog box of the wizard
  - Notifications page under the Deployments and Tasks tabs
  - Site to Site VPN Monitoring dashboard

- If you check the **Deploy configuration on threat defense nodes** check box in the wizard, the Umbrella SASE topology configuration is deployed on the threat defense only after the tunnels are deployed on Umbrella.

The management center requires the local tunnel ID to deploy the Umbrella configuration on the threat defense. Umbrella generates the complete tunnel ID (<prefix>@<umbrella generated ID>-umbrella.com) only after the management center deploys the tunnel on Umbrella.

- The management center does not recognize topologies with the Umbrella data center as an extranet hub, created before version 7.3, as SASE topologies. You must create new SASE topologies in version 7.3 and delete the existing topology.

## Limitations

SASE topology does not support:

- Clustering
- Certificate-based authentication
- IKEv1

# How to Deploy a SASE Tunnel on Umbrella

This section provides instructions to deploy a SASE tunnel on Umbrella from a threat defense device using the management center.

| Step | Do This                                       | More Info                                                                                                                                                                                                                       |

## Prerequisites for Configuring Umbrella SASE Tunnels

- You must have a Cisco Umbrella Secure Internet Gateway (SIG) Essentials subscription.
- You must enable your Smart License account with the export-controlled features to deploy tunnels on Umbrella from the management center. If this license is not enabled, you can only create a SASE topology. You cannot deploy tunnels on Umbrella.
- You must establish an account with Cisco Umbrella at <https://umbrella.cisco.com>, log into Umbrella at <http://login.umbrella.com>, and obtain the required information to establish connection to Cisco Umbrella.
- You must register Cisco Umbrella with the management center and configure the management key and the management secret in the Cisco Umbrella Connection Settings. The management center requires the management key and management secret to fetch the datacenter details from the Cisco Umbrella cloud. You must also configure the Organization ID, Network Device Key, Network Device Secret, and the Legacy Network Device Token in the Cisco Umbrella Connection Settings.

For more information, see:

- [Configure Cisco Umbrella Connection Settings](#)
- [Map Management Center Umbrella Parameters and Cisco Umbrella API Keys, on page 1664](#)
- Ensure that Umbrella data center is reachable from the threat defense.
- You can deploy a tunnel only between Cisco Umbrella and a threat defense version 7.1.0 and later.

## Map Management Center Umbrella Parameters and Cisco Umbrella API Keys

To register the Cisco Umbrella with the management center and configure the Umbrella parameters in the management center, you must:

1. Log in to Cisco Umbrella.
2. Choose **Admin > API Keys > Legacy Keys**.
3. Generate and copy the required API keys.
4. Use the API keys to configure the Cisco Umbrella connection parameters in the management center.

The figure below shows the parameters that you must configure in the Cisco Umbrella Connection in the management center. DNSCrypt Public Key is an optional parameter.

### Cisco Umbrella Connection

General **Advanced**

Organization ID\*

Network Device Key\*

Network Device Secret\*

Legacy Network Device Token\*

### Cisco Umbrella Connection

General **Advanced**

DNSCrypt Public Key

Management Key

Management Secret

[Test Connection](#)

[Save](#)

The figure below shows the Cisco Umbrella API keys that you must use to register the Cisco Umbrella with the management center.

Cisco Umbrella

API Keys

Umbrella's Legacy API keys are used to authenticate your Umbrella API requests to the Legacy APIs. These older APIs are still in use though we recommend migrating to the current Umbrella API Keys. To get started, expand a listed API and generate a key. For more information, see Umbrella's [Help](#).

| API Keys | Static Keys | Legacy Keys |
|----------|-------------|-------------|
| 0        | 3           | 4           |

|                          |        |

## Configure a SASE Tunnel for Umbrella

### Before you begin

Ensure that you review the prerequisites and guidelines in [Prerequisites for Configuring Umbrella SASE Tunnels, on page 1663](#) and [Guidelines and Limitations for Configuring SASE Tunnels on Umbrella, on page 1662](#).

### Procedure

- 
- Step 1** Log in to your management center, choose **Devices > VPN > Site To Site**.
- Step 2** Click **+ SASE Topology** to open the SASE topology wizard.
- Step 3** Enter a unique **Topology Name**.
- Step 4** **Pre-shared Key**: This key is auto-generated according to the Umbrella PSK requirements. For a single topology, the pre-shared key is common for all threat defense spokes and Umbrella.
- The device and Umbrella share this secret key, and IKEv2 uses it for authentication. If you want to configure this key, it must be between 16 and 64 characters in length, include at least one uppercase letter, one lowercase letter, one numeral, and have no special characters. Each topology must have a unique pre-shared key. If a topology has multiple tunnels, all the tunnels have the same pre-shared key.
- Step 5** Choose a data center from the **Umbrella Data center** drop-down list. (Configure routing on the threat defense to ensure reachability of the umbrella DC from the threat defense.)
- Step 6** Click **Add** to add a threat defense node.
- Choose a threat defense from the **Device** drop-down list.
 

Only devices managed by the management center appear in the list. For high availability pairs, the HA pair names appear in the endpoint list.
  - Choose a static VTI interface from the **VPN Interface** drop-down list.
 

To create a new static VTI interface, click **+**. The **Add Virtual Tunnel Interface** dialog box appears with the following pre-populated default configurations.

    - Tunnel Type is static.
    - Name is `<tunnel_source interface logical name>+ static_vti +<tunnel ID>`. For example, `outside_static_vti_2`.

- Tunnel ID is auto-populated with a unique ID.
- Tunnel Source Interface is auto-populated with an interface with an 'outside' prefix.
- IPsec tunnel mode is IPv4.
- IP address is from the 169.254.x.x/30 private IP address range.

c) Enter a prefix for the local tunnel ID in the **Local Tunnel ID** field.

The prefix can have a minimum of eight characters and a maximum of 100 characters. Umbrella generates the complete tunnel ID (<prefix>@<umbrella generated ID>-umbrella.com) after the management center deploys the tunnel on Umbrella. The management center then retrieves and updates the complete tunnel ID and deploys it on the threat defense device. Each tunnel has a unique local tunnel ID.

d) Click **Save** to add the endpoint device to the topology.

You can add multiple endpoints in a SASE topology.

**Step 7** Click **Next** to view the summary of the Umbrella SASE tunnel configuration.

- **Endpoints** pane: Displays the summary of the configured endpoints.
- **Encryption Settings** pane: Displays the default IKEv2 policies and IKEv2 IPsec transform sets for the topology.

**Step 8** Check the **Deploy configuration on threat defense nodes** check box to trigger deployment of the network tunnels to the threat defense. This deployment occurs after the tunnels are deployed on Umbrella. Local tunnel ID is required for the threat defense deployment.

**Step 9** Click **Save**.

This action:

- a. Saves the topology in the management center.
- b. Triggers deployment of the network tunnels to the Umbrella.
- c. Triggers deployment of the network tunnels to the threat defense devices, if the option is enabled. This action commits and deploys all the updated configurations and policies, including non-VPN policies, since the last deployment on the device.
- d. Opens the **Cisco Umbrella Configuration** window and displays the status of the tunnel deployment on Umbrella. For more details, see [View SASE Tunnel Status, on page 1667](#).

---

### What to do next

For the interesting traffic intended to flow through the SASE tunnel, configure a PBR policy with a specific match criteria to send the traffic through the VTI interface.

Ensure that you configure a PBR policy for each endpoint of the SASE topology.

## View SASE Tunnel Status

### Procedure

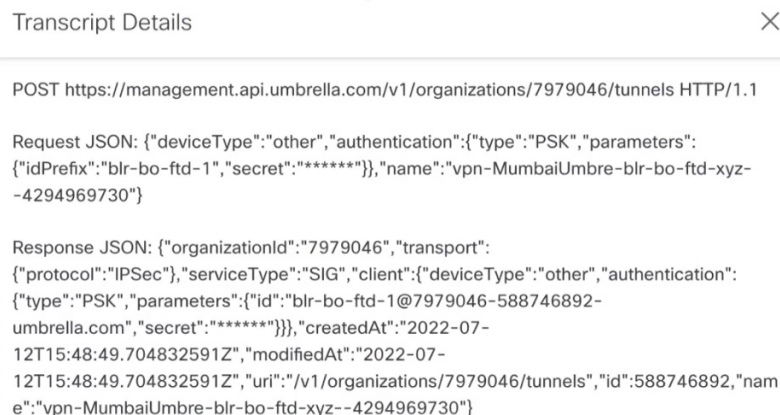

- Step 1** Choose **Devices > VPN > Site To Site**.
- Step 2** Click **+ SASE Topology**.
- Step 3** Enter a unique **Topology Name**, **Pre-shared Key**, choose a data center, add a device, and click **Next**.
- Step 4** View the summary of the Umbrella SASE Tunnel configuration and click **Save**. The **Cisco Umbrella Configuration** window appears.

You can view the topology details such as name, data center, data center IP address, start, and end time of the tunnel deployment.

You can view the deployment status of the tunnels on Umbrella. The different tunnel deployment statuses are:

- Pending: The management center hasn't pushed the configuration to Umbrella.
- Success: The management center successfully configured a tunnel on Umbrella.
- In Progress: The management center is deploying the tunnel on Umbrella.
- Failure: The management center couldn't configure a tunnel on Umbrella.

If the status appears as pending, or failure, use the transcript to troubleshoot the tunnel creation. Click the transcript button to view the transcript details such as the APIs, request payload, and the response received from Umbrella.

Transcript Details

POST https://management.api.umbrella.com/v1/organizations/7979046/tunnels HTTP/1.1

Request JSON: {"deviceType":"other","authentication":{"type":"PSK","parameters":{"idPrefix":"blr-bo-ftd-1","secret":"\*\*\*\*\*"},"name":"vpn-MumbaiUmbre-blr-bo-ftd-xyz--4294969730"}

Response JSON: {"organizationId":"7979046","transport":{"protocol":"IPSec"},"serviceType":"SIG","client":{"deviceType":"other","authentication":{"type":"PSK","parameters":{"id":"blr-bo-ftd-1@7979046-588746892-umbrella.com","secret":"\*\*\*\*\*"},"createdat":"2022-07-12T15:48:49.704832591Z","modifiedat":"2022-07-12T15:48:49.704832591Z","uri":"/v1/organizations/7979046/tunnels","id":"588746892","name":"vpn-MumbaiUmbre-blr-bo-ftd-xyz--4294969730"}}

- Step 5** Click **Umbrella Dashboard** to view the network tunnels in Cisco Umbrella.
- Step 6** View the Umbrella tunnel deployment status in:
- The **Notifications** page under the **Deployments** and **Tasks** tabs.

The screenshot displays two sections of the VPN monitoring dashboard. The top section is titled 'Tasks' and shows a summary of 20+ total tasks, with 0 waiting, 0 running, 0 retrying, 20+ success, and 0 failures. It lists two successful 'Umbrella Tunnel Deployment' tasks for Site to Site VPN vpn-MumbaiUmbrella, each completed in 2s and 3s respectively. The bottom section is titled 'Deployments' and shows 1 total deployment, with 0 running, 1 success, 0 warnings, and 0 failures. It lists a successful deployment to device for blr-bo-ftd.xyz...., completed in 4m 25s.

## Monitoring the Site-to-Site VPNs

The Secure Firewall Management Center provides a snapshot of the site-to-site VPN tunnels, including SASE topology tunnels, to determine the status of the site-to-site VPN tunnels. You can view the list of tunnels between peer devices and the status of each tunnel: Active, Inactive, or No Active Data. You can filter the data in the table according to the topology, device, and status. The table in the monitoring dashboard presents live data and you can configure to refresh the data at a specified interval. The table shows the peer-to-peer, hub and spoke, and full mesh topologies for crypto map-based VPNs. The tunnel information also contains the data for the route-based VPNs or Virtual Tunnel Interfaces (VTIs).

You can use this data to:

- Identify problematic VPN tunnels and troubleshoot.
- Verify connectivity between the site to site VPN peers devices.
- Monitor the health of the VPN tunnels to provide uninterrupted VPN connectivity between sites.

For information about configuring crypto-map based site to site VPNs, see [Configure a Policy-based Site-to-Site VPN, on page 1624](#).

For information about VTIs, see [About Virtual Tunnel Interfaces, on page 1636](#).

### Guidelines and Limitations

- The table shows the list of site-to-site, including SASE topology, VPNs that are deployed. It does not show the tunnels that are created and not deployed.
- The table does not show the information about the backup tunnels of policy-based VPNs and backup VTIs.

- For cluster deployments, the table does not show director change in real-time data. It shows only the director information that existed when the VPN was deployed. The director change reflects in the table only after the tunnel AM redeployed after the change.

### Site-to-site VPN Monitoring Dashboard

Choose **Overview > Dashboards > Site to Site VPN** to open the site to site monitoring dashboard.

The site-to-site VPN monitoring dashboard displays the following widgets for the site-to-site VPN tunnels:

- **Tunnel Status**—A table listing the tunnel status of the site-to-site VPNs, including the SASE tunnels for Umbrella, configured using the management center
- **Tunnel Summary**—Aggregated status of the tunnels in a donut graph.
- **Topology**—Status of tunnels summarized by topology.

### Status of VPN Tunnels

The site-to-site monitoring dashboard lists the VPN tunnels in the following states:

- **Inactive**—A policy-based (crypto map-based) VPN tunnel is inactive if all the IPSec tunnels are down. A VTI or and SASE topology VPN tunnel is down if the tunnel encounters any configuration or connectivity issues.
- **Active**—In the management center, policy-based site-to-site VPNs are configured based on IKE policies and IPsec proposals that are assigned to VPN topologies. A policy-based VPN tunnel is in the Active state if the management center identifies interesting traffic through the tunnel after the deployment. An IKE tunnel is up only if a minimum of one IPsec tunnel is up.  
  
Route-based VPN (VTI) and SASE topology VPN tunnels do not require interesting traffic to be in the Active state. They are in the Active state if they are configured and deployed without errors.
- **No Active Data**—Policy-based and SASE topology VPN tunnels remain in the No Active Data state until there is a traffic flow event through the tunnel for the first time. The No Active Data state also lists the policy-based and route-based VPNs that have been deployed with errors.

### Important Notes About Tunnel Statuses in the Management Center

- The VPN statuses in the management center are event-based. The management center does not initiate status updates. Hence, there might be mismatches between the tunnel statuses in the dashboard and the threat defense. You can view the correct status in the **CLI Details** tab of the **Tunnel Status** widget.
- When a threat defense switches over to a secondary threat defense, there is a mismatch between the status of the VPN tunnels in the management center and the threat defense. When the device switches back to the primary device, the correct tunnel status appears.
- The management center does not update the tunnel status of threat defense devices earlier than 7.3 after the devices reboot. We recommend that you bring the tunnel down using the command **vpn-sessiondb logoff index** and bring it up using the packet tracer.

### Tunnel Status

This table lists the site-to-site VPNs, including SASE topology VPN, configured using the management center. Hover over a topology and click View  to view the following details about the topology:

- **General**—Displays more information about the nodes such as IP address and interface name.
- **CLI Details**—Displays the CLI outputs for the following commands:
  - **show crypto ipsec sa peer** <node A/B\_ip\_address>: Displays the IPsec SAs built between Node A and B.
  - **show vpn-sessiondb l2l filter ipaddress** <node A/B\_ip\_address>: Displays information about VPN sessions.

For an extranet device, no command output appears.

Important details about the IKE and IPsec sessions, derived from the above command outputs, appear in a summarized, and user-friendly format. You can view the details of both nodes at a time. The icon next to the node name specifies the authentication type: preshared key or client certificate. The details include IKE statistics per tunnel and IPsec SA statistics as shown below:

**Figure 362: Tunnel Status > View > CLI Details**

The screenshot displays the 'Tunnel Details' window. At the top, it shows 'Summary' for 'Node A' and 'Node B'. The statistics are as follows:

| Node   | Transmitted           | Received              |
|--------|-----------------------|-----------------------|
| Node A | 14.83 MB (15552256 B) | 33.37 MB (34992576 B) |
| Node B | 14.83 MB (15552416 B) | 33.37 MB (34992720 B) |

Below the summary, there are sections for 'IPsec Security Associations (1)'. It includes tabs for 'L2L', 'Tunnel', 'PFS Group 21', 'IKEv2', and 'VTI'. The statistics for each node are:

| Node   | Encaps/Encrypt       | Dcaps/Decrypt        | Remaining Lifetime for SPI ID: 0x944D58CF                |
|--------|----------------------|----------------------|----------------------------------------------------------|
| Node A | 486008 / 486008 pkts | 486008 / 486008 pkts | Outbound: 5.25 GB (5637438000 B)<br>10:14:04 (17044 sec) |
| Node B | 486013 / 486013 pkts | 486010 / 486010 pkts | Inbound: 4.91 GB (5277438000 B)<br>10:14:03 (17043 sec)  |

Another section shows statistics for SPI ID: 0xA6F557B8:

| Node   | Inbound                                        | Outbound                                       |
|--------|------------------------------------------------|------------------------------------------------|
| Node A | 5.08 GB (5457438000 B)<br>10:14:04 (17044 sec) |                                                |
| Node B |                                                | 4.86 GB (5217438000 B)<br>10:14:03 (17043 sec) |

At the bottom, there are two panels for '(VPN Interface IP: ...)' showing CLI commands: 'show crypto ipsec sa peer' and 'show vpn-sessiondb detail l2l filter ip...'. The interface includes 'Close' and 'Refresh' buttons.

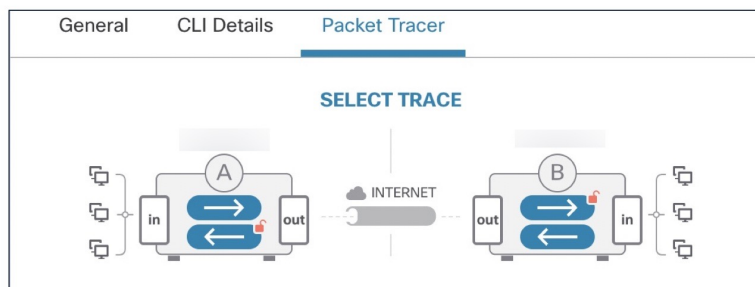

- **Packet Tracer**—Use packet tracer to troubleshoot the threat defense VPN tunnels.

### Packet Tracer

Packet tracer allows you to troubleshoot VPN tunnels between two threat defense devices. You can check if the VPN connection between device A and device B is up. This tool injects a packet into the device and tracks the packet flow from the ingress to the egress ports. The tool simulates traffic after you configure the ingress interfaces of the devices along with the protected networks. Packet tracer evaluates the packet against modules such as flow and route lookups, ACLs, protocol inspection, NAT, and QoS.

Figure 363: Packet Tracer

For each device, the tool runs an encrypted trace and a decrypted trace (packet is treated as decrypted VPN traffic). You can run four different traces between the ingress and egress ports of the devices. Click the individual encrypt and decrypt options to enable or disable the trace.

When you run the trace, the tool executes the trace sequentially in the following order:

1. Encrypted trace of A.
2. Decrypted trace of B.
3. Encrypted trace of B.
4. Decrypted trace of A.

After the trace completes, you can view the output of the trace with the results of each module.

---

**Note** You cannot run a decrypt trace for route-based (VTI-based) VPNs.

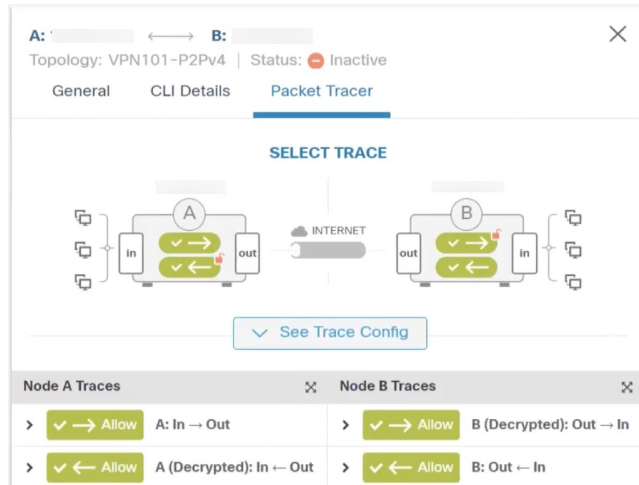

---

To run the Packet Tracer:

1. Click **See Detailed Config** to view the VPN interface name, VPN interface IP address, VTI interface name, and the VTI Interface IP address.
2. (Optional) Choose a protocol from the **Protocol** drop-down list. You can choose ICMP/8/0, TCP, or UDP. ICMP/8/0 is the default option. If you choose ICMP/8/0, 8 indicates the ICMP type as Echo Request and 0 indicates the ICMP code. If you choose TCP or UDP, choose the destination port from the **Destination Port** drop-down list. The range is from 0 to 65535.
3. Choose the ingress interface for both the devices on which to trace the packet from the **Ingress Interface** drop-down lists.
4. Enter an IP address from the same subnet as the ingress interface in the **Protected Network IP Address** fields.
5. Click **Trace Now**.

After you initiate the trace, you can view if the trace is successful or not for each module. If the tunnel is down, the path appears in red. If the tunnel is up, the path appears in green. If a tunnel is down, click **Re-trace** to run the tool again. For a crypto-map based VPN, when the tunnel is inactive with no interesting traffic, the initial trace can be red. Click **Re-trace** to run the trace again.

Figure 364: Packet Tracer after a Successful Trace

**Extranet Nodes:** You can initiate a packet trace for VPN tunnels with one node as an extranet. For an extranet node, you cannot choose the ingress interface. The remaining steps for the packet trace are the same. You can't run trace on the extranet side.

For example, if Node A is a managed threat defense and Node B is an extranet:

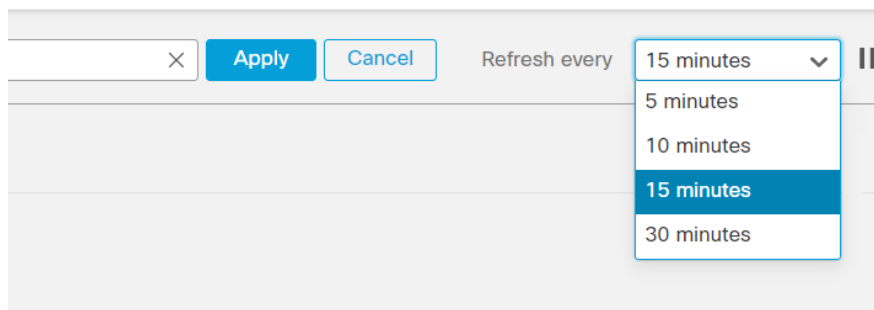

- Configure the ingress interface for node A.
- Configure the protected network for Node A and B.
- Click **Trace Now**. The traces appear for Node A and not for Node B.

### Automatic Data Refresh

The site to site VPN data in the table refreshes periodically. You can configure the refresh interval of the VPN monitoring data at a specific interval or turn the automatic data refresh off.

Click the **Refresh** interval drop-down to select from the available intervals to refresh the data in the table.

Figure 365: Refresh the Tunnel Data

Click **Pause** to stop the automatic data refresh for as long as you want. You can click the same button to resume refreshing the tunnel data.

**Figure 366: Pause the Periodic Data Refresh**

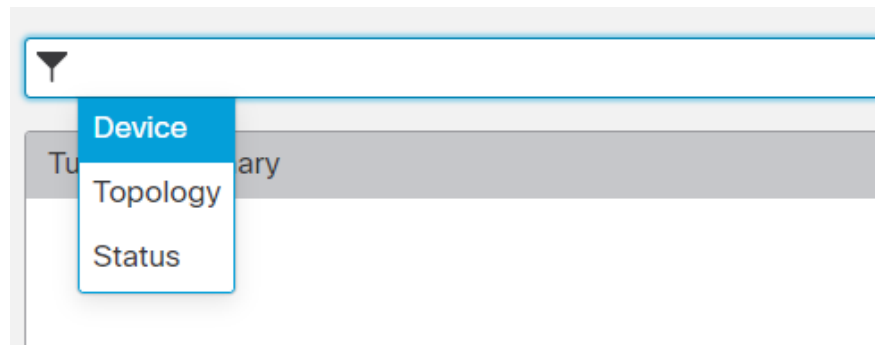

### Filter and Sort the Site to Site VPN Monitoring Data

You can filter and view the data in the VPN monitoring table by topology, device, and status.

For example, you can view the tunnels that are in the Down state in a specific topology.

Click within the filter box to choose the filter criteria and then specify the values to filter.

**Figure 367: Filter the Tunnel Data**

You can use multiple filtering criteria to view the data based on your requirement.

For example, you can choose to view only the tunnels that are in the Up and Down states, and ignore the ones in the Unknown state.

**Figure 368: Example: Filter Tunnel Data**

**Sort the data**—To sort the data by a column, click the column heading.

| OSPFv2/v3 IPv4/v6 support for VTI                      | 7.3                       | Any                    | Static and dynamic VTI interfaces support OSPFv2/v3 IPv4/v6 routing protocol.                                                                                                                                                                                                                                                                                                                                   |
| Packet Tracer in Site to Site VPN Monitoring Dashboard | 7.3                       | Any                    | Use the packet tracer tool in the site-to-site VPN monitoring dashboard to troubleshoot the threat defense VPN tunnels.<br><br>New/Modified screens:<br><b>Overview &gt; Dashboards &gt; Site to Site VPN</b>                                                                                                                                                                                                   |
| Remote Access VPN Dashboard                            | 7.3                       | Any                    | Use the Remote Access VPN dashboard to monitor real-time data from active remote access VPN sessions on the devices.<br><br>New/Modified screens:<br><b>Overview &gt; Dashboards &gt; Remote Access VPN</b>                                                                                                                                                                                                     |
| IPsec flow offload                                     | 7.2                       | Any                    | On the Secure Firewall 3100, IPsec flows are offloaded by default. After the initial setup of an IPsec site-to-site VPN or remote access VPN security association (SA), IPsec connections are offloaded to the field-programmable gate array (FPGA) in the device, which should improve device performance.<br><br>You can change the configuration using FlexConfig and the <b>flow-offload-ipsec</b> command. |

## CHAPTER 59

# Remote Access VPN

Remote Access virtual private network (VPN) allows individual users to connect to your network from a remote location using a computer or other supported devices connected to the Internet. This allows mobile workers to connect from their home networks or a public Wi-Fi network, for example.

The following topics explain how to configure remote access VPN for your network.

- [Remote Access VPN Overview, on page 1675](#)
- [License Requirements for Remote Access VPN, on page 1681](#)
- [Requirements and Prerequisites for Remote Access VPN, on page 1681](#)
- [Guidelines and Limitations for Remote Access VPNs, on page 1682](#)

## Remote Access VPN Overview

Secure Firewall Threat Defense provides secure gateway capabilities that support remote access SSL and IPsec-IKEv2 VPNs. The full tunnel client, Secure Client, provides secure SSL and IPsec-IKEv2 connections to the security gateway for remote users. When the client negotiates an SSL VPN connection with threat defense, it connects using Transport Layer Security (TLS) or Datagram Transport Layer Security (DTLS)

Secure Client is the only client supported on endpoint devices for remote VPN connectivity to threat defense devices. The client gives remote users the benefits of an SSL or IPsec-IKEv2 VPN client without the need for network administrators to install and configure clients on remote computers. The Secure Client for Windows, Mac, and Linux is deployed from the secure gateway upon connectivity. The Secure Client apps for Apple iOS and Android devices are installed from the platform app store.

Use the Remote Access VPN policy wizard to set up SSL and IPsec-IKEv2 remote access VPNs with basic capabilities. Then, enhance the policy configuration as you want and deploy it to your threat defense secure gateway devices.

## Remote Access VPN Features

The following table describes the features of Secure Firewall Threat Defense remote access VPN:

*Table 98: Remote access VPN features*

|                                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

# Secure Client Components

## Secure Client Deployment

Your remote access VPN policy can include the Secure Client Image and the Secure Client Profile for distribution to connecting endpoints. Or, the client software can be distributed using other methods. See the *Deploy Cisco Secure Client* chapter in the [Cisco Secure Client \(including AnyConnect\) Administrator Guide, Release 5](#).

Without a previously installed client, remote users enter the IP address in their browser of an interface configured to accept SSL or IPsec-IKEv2 VPN connections. Unless the security appliance is configured to redirect http:// requests to https://, remote users must enter the URL in the form https://*address*. After the user enters the URL, the browser connects to that interface and displays the login screen.

After a user logs in, if the secure gateway identifies the user as requiring the VPN client, it downloads the client that matches the operating system of the remote computer. After downloading, the client installs and configures itself, establishes a secure connection, and either remains or uninstalls itself (depending on the security appliance configuration) when the connection stops. In the case of a previously installed client, after login, the threat defense security gateway examines the client version and upgrades it as necessary.

## Secure Client Operation

When the client negotiates a connection with the security appliance, the client connects using Transport Layer Security (TLS), and optionally, Datagram Transport Layer Security (DTLS). DTLS avoids latency and bandwidth problems associated with some SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

When an IPsec-IKEv2 VPN client initiates a connection to the secure gateway, negotiation consists of authenticating the device through Internet Key Exchange (IKE), followed by user authentication using IKE Extended Authentication (Xauth). The group profile is pushed to the VPN client and an IPsec security association (SA) is created to complete the VPN.

## Secure Client Profile and Editor

The Secure Client Profile is a group of configuration parameters, stored in an XML file that the VPN client uses to configure its operation and appearance. These parameters (XML tags) include the names and addresses of host computers and settings to enable more client features.

You can configure a profile using the Secure Client Profile Editor. This editor is a convenient GUI-based configuration tool that is available as part of the Secure Client software package. It is an independent program that you run outside of the management center.

# Remote Access VPN Authentication

## Remote Access VPN Server Authentication

Secure Firewall Threat Defense secure gateways always use certificates to identify and authenticate themselves to the VPN client endpoint.

While you use the Remote Access VPN Policy Wizard, you can enroll the selected certificate on the targeted threat defense device. In the wizard, under **Access & Certificate** phase, select “Enroll the selected certificate object on the target devices” option. The certificate enrollment gets automatically initiated on the specified devices. As you complete the remote access VPN policy configuration, you can view the status of the enrolled

certificate under the device certificate homepage. The status provides a clear standing as to whether the certificate enrollment was successful or not. Your remote access VPN policy configuration is now fully completed and ready for deployment.

Obtaining a certificate for the secure gateway, also known as PKI enrollment, is explained in [Certificates, on page 1575](#). This chapter contains a full description of configuring, enrolling, and maintaining gateway certificates.

### Remote Access VPN Client AAA

For both SSL and IPsec-IKEv2, remote user authentication is done using usernames and passwords only, certificates only, or both.

---

**Note** If you are using client certificates in your deployment, they must be added to your client's platform independent of the Secure Firewall Threat Defense or Secure Firewall Management Center. Facilities such as SCEP or CA Services are not provided to populate your clients with certificates.

---

AAA servers enable managed devices acting as secure gateways to determine who a user is (authentication), what the user is permitted to do (authorization), and what the user did (accounting). Some examples of the AAA servers are RADIUS, LDAP/AD, TACACS+, and Kerberos. For Remote Access VPN on threat defense devices, AD, LDAP, and RADIUS AAA servers are supported for authentication.

Refer to the section [Understanding Policy Enforcement of Permissions and Attributes](#) to understand more about remote access VPN authorization.

Before you add or edit the remote access VPN policy, you must configure the Realm and RADIUS server groups you want to specify. For more information, see [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#) and [Add a RADIUS Server Group, on page 1463](#).

Without DNS configured, the device cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames, it can only resolve IP addresses.

The login information provided by a remote user is validated by an LDAP or AD realm or a RADIUS server group. These entities are integrated with the Secure Firewall Threat Defense secure gateway.

---

**Note** If users authenticate with remote access VPN using Active Directory as the authentication source, users must log in using their username; the format `domain\username` or `username@domain` fails. (Active Directory refers to this username as the *logon name* or sometimes as `sAMAccountName`.) For more information, see [User Naming Attributes](#) on MSDN.

---

If you use RADIUS to authenticate, users can log in with any of the preceding formats.

---

Once authenticated via a VPN connection, the remote user takes on a *VPN Identity*. This VPN Identity is used by *identity policies* on the Secure Firewall Threat Defense secure gateway to recognize and filter network traffic belonging to that remote user.

Identity policies are associated with access control policies, which determine who has access to network resources. It is in this way that the remote user blocked or allowed to access your network resources.

For more information, see the [About Identity Policies, on page 2609](#) and [Access Control Policies, on page 1829](#) sections.

**Related Topics**

[Configure AAA Settings for Remote Access VPN](#), on page 1698

**Understanding Policy Enforcement of Permissions and Attributes**

The Secure Firewall Threat Defense device supports applying user authorization attributes (also called user entitlements or permissions) to VPN connections from an external authentication server and/or authorization AAA server (RADIUS) or from a group policy on the threat defense device. If the threat defense device receives attributes from the external AAA server that conflicts with those configured on the group policy, then attributes from the AAA server always take the precedence.

The threat defense device applies attributes in the following order:

1. **User attributes on the external AAA server**—The server returns these attributes after successful user authentication and/or authorization.
2. **Group policy configured on the Firepower Threat Defense device**—If a RADIUS server returns the value of the RADIUS Class attribute IETF-Class-25 (OU= group-policy) for the user, the threat defense device places the user in the group policy of the same name and enforces any attributes in the group policy that are not returned by the server.
3. **Group policy assigned by the Connection Profile (also known as Tunnel Group)**—The Connection Profile has the preliminary settings for the connection, and includes a default group policy applied to the user before authentication.

---

**Note** The threat defense device does not support inheriting system default attributes from the default group policy, *DfltGrpPolicy*. The attributes on the group policy assigned to the connection profile are used for the user session, if they are not overridden by user attributes or the group policy from the AAA server as indicated above.

---

**Related Topics**

[Configure AAA Settings for Remote Access VPN](#), on page 1698

**Understanding AAA Server Connectivity**

LDAP, AD, and RADIUS AAA servers must be reachable from the threat defense device for your intended purposes: user-identity handling only, VPN authentication only, or both activities. AAA servers are used in remote access VPN for the following activities:

- **User-identity handling**— the servers must be reachable over the Management interface.  
On the threat defense, the Management interface has a separate routing process and configuration from data interfaces.
- **VPN authentication**—the servers must be reachable over a data interface or the Management interface.  
To use the Management interface, you must explicitly select Management as the source interface. Other management-only interfaces cannot be used.

To use the same AAA servers for both activities, we recommend specifying the Management interface as the source interface.

For more information about various interfaces, see [Regular Firewall Interfaces](#), on page 949.

After deployment, use the following CLI commands to monitor and troubleshoot AAA server connectivity from the threat defense device:

- **show aaa-server** to display AAA server statistics.
- **show network** and **show network-static-routes** to view the Management interface default route and static routes.
- **show route** to view data traffic routing table entries.
- **ping system** and **traceroute system** to verify the path to the AAA server through the Management interface.
- **ping interface** *ifname* and **traceroute** *destination* to verify the path to the AAA server through the data interfaces.
- **test aaa-server authentication** and **test aaa-server authorization** to test authentication and authorization on the AAA server.
- **clear aaa-server statistics** *groupname* or **clear aaa-server statistics protocol** *protocol* to clear AAA server statistics by group or protocol.
- **aaa-server** *groupname* **active host** *hostname* to activate a failed AAA server, or **aaa-server** *groupname* **fail host** *hostname* to fail a AAA server.
- **debug ldap level**, **debug aaa authentication**, **debug aaa authorization**, and **debug aaa accounting**.

## License Requirements for Remote Access VPN

### Threat Defense License

Threat Defense remote access VPN requires Strong Encryption and one of the following licenses for Secure Client:

- Secure Client Advantage
- Secure Client Premier
- Secure Client VPN Only

## Requirements and Prerequisites for Remote Access VPN

### Model Support

Threat Defense

### Supported Domains

Any

## User Roles

Admin

# Guidelines and Limitations for Remote Access VPNs

## Remote Access VPN Policy Configuration

- You can add a new remote access VPN policy only by using the wizard. You must proceed through the entire wizard to create a new policy; the policy will not be saved if you cancel before completing the wizard.
- Two users must **not** edit a remote access VPN policy at the same time; however, the web interface does not prevent simultaneous editing. If this occurs, the last saved configuration persists.
- Moving a Secure Firewall Threat Defense device from one domain to another domain is not possible if remote access VPN policy is assigned to that device.
- Remote access VPN does not support SSL while using SaaS or ECMP. We recommend that you use IPsec-IKEv2.
- Firepower 9300 and 4100 series in cluster mode do not support remote access VPN configuration.
- Remote access VPN connectivity could fail if there is a misconfigured threat defense NAT rule.
- If you are using DHCP to provide IP addresses to the client, and the client cannot obtain an address, check the NAT rules. Any NAT rule that applies to the RA VPN network should include the route lookup option. Route lookup can help ensure the DHCP requests are sent to the DHCP server through an appropriate interface.
- Whenever IKE ports 500/4500 or SSL port 443 is in use or when there are some PAT translations that are active, the Secure Client IPsec-IKEv2 or SSL remote access VPN cannot be configured on the same port as it fails to start the service on those ports. These ports must not be used on the threat defense device before configuring remote access VPN policy.
- While configuring remote access VPNs using the wizard, you can create in-line certificate enrollment objects, but you cannot use them to install the identity certificate. Certificate enrollment objects are used for generating the identity certificate on the threat defense device being configured as the remote access VPN gateway. Install the identity certificate on the device before deploying the remote access VPN policy to the device.

For more information about how to install the identity certificate based on the certificate enrollment object, see [The Object Manager, on page 1454](#).

- The ECMP zone interfaces can be used in remote access VPN with IPsec enabled.
- The ECMP zone interfaces cannot be used in remote access VPN with SSL enabled. Deployment of remote access VPN (SSL enabled) configuration fails if all the remote access VPN interfaces that belong to security zones or interface groups also belong to one or more ECMP zones. However, if only some of the remote access VPN interfaces belonging to the security zones or interface groups also belongs to one or more ECMP zones, deployment of the remote access VPN configuration succeeds excluding those interfaces.
- After you change the remote access VPN policy configurations, re-deploy the changes to the threat defense devices. The time it takes to deploy configuration changes depends on multiple factors such as

complexity of the policies and rules, type and volume of configurations you send to the device, and memory and device model. Before deploying remote access VPN policy changes, review the [Best Practices for Deploying Configuration Changes, on page 238](#).

- Issuing commands such as **curl** against the RA VPN headend is not directly supported, and might not have desirable results. For example, the headend does not respond to HTTP HEAD requests.
- You can configure browser proxy using FlexConfig.

### Concurrent VPN Sessions Capacity Planning (threat defense virtual Models)

The maximum concurrent VPN sessions are governed by the installed threat defense virtual smart-licensed entitlement tier, and enforced via a rate limiter. There is a maximum limit to the number of concurrent remote access VPN sessions allowed on a device based on the licensed device model. This limit is designed so that system performance does not degrade to unacceptable levels. Use these limits for capacity planning.

| Device Model              | Maximum Concurrent Remote Access VPN Sessions |
|---------------------------|-----------------------------------------------|
| Threat Defense Virtual5   | 50                                            |
| Threat Defense Virtual10  | 250                                           |
| Threat Defense Virtual20  | 250                                           |
| Threat Defense Virtual30  | 250                                           |
| Threat Defense Virtual50  | 750                                           |
| Threat Defense Virtual100 | 10,000                                        |

### Concurrent VPN Sessions Capacity Planning (Hardware Models)

The maximum concurrent VPN sessions are governed by platform-specific limits and have no dependency on the license. There is a maximum limit to the number of concurrent remote access VPN sessions allowed on a device based on the device model. This limit is designed so that system performance does not degrade to unacceptable levels. Use these limits for capacity planning.

| Device Model         | Maximum Concurrent Remote Access VPN Sessions |
|----------------------|-----------------------------------------------|
| Firepower 1010       | 75                                            |
| Firepower 1120       | 150                                           |
| Firepower 1140       | 400                                           |
| Firepower 2110       | 1500                                          |
| Firepower 2120       | 3500                                          |
| Firepower 2130       | 7500                                          |
| Firepower 2140       | 10,000                                        |
| Secure Firewall 3110 | 3000                                          |

| Device Model                         | Maximum Concurrent Remote Access VPN Sessions |
|--------------------------------------|-----------------------------------------------|
| Secure Firewall 3120                 | 6000                                          |
| Secure Firewall 3130                 | 15,000                                        |
| Secure Firewall 3140                 | 20,000                                        |
| Firepower 4100, all models           | 10,000                                        |
| Firepower 9300 appliance, all models | 20,000                                        |
| ISA 3000                             | 25                                            |

For capacity of other hardware models, contact your sales representative.

**Note** The threat defense device denies the VPN connections once the maximum session limit per platform is reached. The connection is denied with a syslog message. Refer the syslog messages %ASA-4-113029 and %ASA-4-113038 in the syslog messaging guide. For more information, see [Cisco Secure Firewall ASA Series Syslog Messages](#).

### Controlling Cipher Usage for VPN

To prevent use of ciphers greater than DES, pre-deployment checks are available at the following locations in the management center:

**Devices > Platform Settings > Edit > SSL.**

**Devices > VPN > Remote Access > Edit > Advanced > IPsec.**

For more information about SSL settings and IPsec, see [SSL](#), on page 1105 and [Configure Remote Access VPN IPsec/IKEv2 Parameters](#), on page 1729.

### Authentication, Authorization, and Accounting

Configure DNS on each device in the topology in to use remote access VPN. Without DNS, the device cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames; it can only resolve IP addresses.

You can configure DNS using the **Platform Settings**. For more information, see [DNS](#), on page 1075 and [DNS Server Group](#), on page 1482.

### Client Certificates

If you are using client certificates in your deployment, they must be added to your client's platform independent of the Secure Firewall Threat Defense or Secure Firewall Management Center. Facilities such as SCEP or CA Services are not provided to populate your clients with certificates.

### Unsupported Features of Secure Client

The only supported VPN client is the Cisco Secure Client. No other clients or native VPNs are supported. Clientless VPN is not supported for VPN connectivity; it is only used to deploy the Secure Client using a web browser.

**Note** Using multiple Secure Client packages on threat defense devices can increase memory usage and affect the device's performance. We recommend that you do not use multiple Secure Client packages on low-end threat defense devices to avoid continuous reboots because of memory exhaustion.

The following Secure Client features are not supported when connecting to a threat defense secure gateway:

- TACACS, Kerberos (KCD Authentication and RSA SDI).

## Configuring a New Remote Access VPN Connection

This section provides instructions to configure a new remote access VPN policy with Secure Firewall Threat Defense devices as VPN gateways and Cisco Secure Client as the VPN client.

| Step | Do This                                                                       | More Info                                                                                                                                                        |
|------|-------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1    | Review the guidelines and prerequisites.                                      | <a href="#">Guidelines and Limitations for Remote Access VPNs, on page 1682</a><br><a href="#">Prerequisites for Configuring Remote Access VPN, on page 1685</a> |
| 2    | Create a new remote access VPN policy using the wizard.                       | <a href="#">Create a New Remote Access VPN Policy, on page 1686</a>                                                                                              |
| 3    | Update the access control policy deployed on the device.                      | <a href="#">Update the Access Control Policy on the Secure Firewall Threat Defense Device, on page 1689</a>                                                      |
| 4    | (Optional) Configure a NAT exemption rule if NAT is configured on the device. | <a href="#">(Optional) Configure NAT Exemption, on page 1689</a>                                                                                                 |
| 5    | Configure DNS.                                                                | <a href="#">Configure DNS, on page 1691</a>                                                                                                                      |
| 6    | Add Secure Client Profile.                                                    | <a href="#">Add Secure Client Profile XML File, on page 1691</a>                                                                                                 |
| 7    | Deploy the remote access VPN policy.                                          | <a href="#">Deploy Configuration Changes, on page 240</a>                                                                                                        |
| 8    | (Optional) Verify the remote access VPN policy configuration.                 | <a href="#">Verify the Configuration, on page 1694</a>                                                                                                           |

### Prerequisites for Configuring Remote Access VPN

- Deploy Secure Firewall Threat Defense devices and configure Secure Firewall Management Center to manage the device with required licenses with export-controlled features enabled. For more information, see [VPN Licensing, on page 1609](#).

- Configure the certificate enrollment object that is used to obtain the identity certificate for each threat defense device that act as a remote access VPN gateway.
- Configure the RADIUS server group object and any AD or LDAP realms being used by remote access VPN policies.
- Ensure that the AAA Server is reachable from the threat defense device for the remote access VPN configuration to work. Configure routing (at **Devices > Device Management > Edit Device > Routing**) to ensure connectivity to the AAA servers.

For remote access VPN double authentication, ensure that both the primary and secondary authentication servers are reachable from the threat defense device for the double authentication configuration to work.

- Purchase and enable one of the following Cisco Secure Client licenses: Secure Client Advantage, Secure Client Premier, or Secure Client VPN Only to enable the threat defense remote access VPN.
- Download the latest Secure Client image files from [Cisco Software Download Center](#).  
On your Secure Firewall Management Center web interface, go to **Objects > Object Management > VPN > Secure Client File** and add the new Secure Client image files.
- Create a security zone or interface group that contains the network interfaces that users will access for VPN connections. See [Interface, on page 1494](#).
- Download the Secure Client Profile Editor from [Cisco Software Download Center](#) to create the Secure Client profile. You can use the standalone profile editor to create a new or modify an existing Secure Client profile.

## Create a New Remote Access VPN Policy

The Remote Access VPN Policy Wizard guides you to quickly and easily set up remote access VPNs with basic capabilities. You can further enhance the policy configuration by specifying additional attributes as you want and deploy it to your Secure Firewall Threat Defense secure gateway devices.

### Before you begin

- Ensure that you complete all the prerequisites listed in [Prerequisites for Configuring Remote Access VPN, on page 1685](#).

### Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** Click **Add** to create a new remote access VPN policy with basic policy configuration, using the Remote Access VPN Policy wizard.  
You must proceed through the entire wizard to create a new policy; the policy is not saved if you cancel before you complete the wizard.
- Step 3** Select the target devices and protocols.  
The threat defense devices that you select here functions as your remote access VPN gateways for the VPN client users.

You can select threat defense devices when you create a remote access VPN policy or change them later. See [Set Target Devices for a Remote Access VPN Policy, on page 1695](#).

You can select **SSL** or **IPSec-IKEv2**, or both the VPN protocols. Threat Defense supports both the protocols to establish secure connections over a public network through VPN tunnels.

**Note** Threat Defense does not support IPSec tunnels with NULL encryption. If you have selected IPSec-IKEv2, make sure that you do not choose NULL encryption for IPSec IKEv2 proposal. See [Configure IKEv2 IPsec Proposal Objects, on page 1569](#).

For SSL settings, see [SSL , on page 1105](#).

**Step 4** Click **Next**.

**Step 5** Configure the **Connection Profile** and **Group Policy** settings.

A connection profile specifies a set of parameters that define how the remote users connect to the VPN device. The parameters include settings and attributes for authentication, address assignments to VPN clients, and group policies. Threat Defense device provides a default connection profile named *DefaultWEBVPNGroup* when you configure a remote access VPN policy.

For more information, see [Configure Connection Profile Settings, on page 1696](#).

**Step 6** Configure the **Authentication, Authorization & Accounting** settings.

For information about configuring,

- AAA settings, see [Configure AAA Settings for Remote Access VPN, on page 1698](#)
- LDAP attribute maps, see [Configuring LDAP Attribute Mapping, on page 1720](#)
- SAML 2.0 single sign-on authentication, see [Configuring a SAML Single Sign-On Authentication, on page 1763](#)

**Step 7** Configure the **Client Address Assignment** settings.

Client IP address can be assigned from AAA server, DHCP server and IP address pools. When multiple options are selected, IP address assignment is done in the order of AAA server, DHCP server, and IP address pool. Assignment of client IP addresses from the AAA server is supported only for realm and RADIUS authorization. Ensure that realm or RADIUS server is configured to provide client IP address.

**Step 8** Configure the **Group Policy** settings.

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience for VPN users. You configure attributes such as user authorization profile, IP addresses, Secure Client settings, VLAN mapping, and user session settings and so on using the group policy. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile. For more information, see [Configuring Group Policies, on page 1720](#).

**Step 9** Click **Next**.

**Step 10** Select the **Secure Client Image** that the VPN users will use to connect to the remote access VPN.

The Secure Client provides secure SSL or IPSec (IKEv2) connections to the Secure Firewall Threat Defense device for remote users with full VPN profiling to corporate resources. After the remote access VPN policy is deployed on the threat defense device, VPN users can enter the IP address of the configured device interface in their browser to download and install the Secure Client.

For information about configuring the client profile and client modules, see [Group Policy Secure Client Options, on page 1563](#).

**Step 11** Click **Next**.

**Step 12** Configure **Network Interface for Incoming VPN Access**.

Interface objects segment your network to help you manage and classify traffic flow. A security zone object simply groups interfaces. These groups may span multiple devices; you can also configure multiple zones interface objects on a single device. There are two types of interface objects:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

(Optional) Check the **Enable DTLS on member interfaces** check box, if required. DTLS is applicable only for SSL protocol.

**Step 13** Configure **Device Certificates**.

Device certificate (also called Identity certificate) identifies the VPN gateway to the remote access clients. Select a certificate which is used to authenticate the VPN gateway. From the **Certificate Enrollment** drop-down list, choose a certificate or click + to add a certificate.

**Step 14** Configure **Access Control for VPN Traffic**.

By default, all decrypted traffic in the VPN tunnel is subjected to the Access Control Policy. Check the **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** check box to bypass decrypted traffic from the Access Control Policy. This option bypasses the Access Control Policy inspection, but VPN filter ACL and authorization ACL downloaded from AAA server are still applied to VPN traffic.

**Note** If you select this option, you need not update the access control policy for remote access VPN as specified in [Update the Access Control Policy on the Secure Firewall Threat Defense Device, on page 1689](#).

**Step 15** Click **Next**.

**Step 16** View the **Summary** of the remote access VPN policy configuration.

The Summary page displays all the remote access VPN settings you have configured so far and provides links to the additional configurations that need to be performed before deploying the remote access VPN policy on the selected devices.

Click **Back** to make changes to the configuration, if required.

**Step 17** Click **Finish** to complete the basic configuration for the remote access VPN policy.

When you complete the Remote Access VPN Policy Wizard, the policy listing page appears. Later, set up DNS configuration, configure access control for VPN users, and enable NAT exemption (if necessary) to complete a basic remote access VPN Policy configuration.

---

### What to do next

Use the Remote Access VPN dashboard (**Overview > Dashboards > Remote Access VPN**) to monitor real-time data from active remote access VPN sessions on the devices. You can quickly determine problems related to user sessions and mitigate the problems for your network and users.

## Update the Access Control Policy on the Secure Firewall Threat Defense Device

Before deploying the remote access VPN policy, you must update the access control policy on the targeted Secure Firewall Threat Defense device with a rule that allows VPN traffic. The rule must allow all traffic coming in from the outside interface, with source as the defined VPN pool networks and destination as the corporate network.

- 
- Note** If you have selected the **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** option on the Access Interface tab, you need not update the access control policy for remote access VPN.
- Enable or disable the option for all your VPN connections. If you disable this option, make sure that the traffic is allowed by the access control policy or pre-filter policy.
- For more information, see [Configure Access Interfaces for Remote Access VPN, on page 1714](#).
- 

### Before you begin

Complete the remote access VPN policy configuration using the Remote Access VPN Policy wizard.

### Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Policies > Access Control**.
- Step 2** Click **Edit** on the access control policy that you want to update.
- Step 3** Click **Add Rule** to add a new rule.
- Step 4** Specify the **Name** for the rule and select **Enabled**.
- Step 5** Select the **Action**, **Allow** or **Trust**.
- Step 6** Select the following on the **Zones** tab:
- Select the outside zone from Available Zones and click **Add to Source**.
  - Select the inside zone from Available Zones and click **Add to Destination**.
- Step 7** Select the following on the **Networks** tab:
- Select the inside network (inside interface and/or a corporate network) from Available networks and click **Add to Destination**.
  - Select the VPN address pool network from **Available Networks** and click **Add to Source Networks**.
- Step 8** Configure other required access control rule settings and click **Add**.
- Step 9** Save the rule and access control policy.
- 

## (Optional) Configure NAT Exemption

NAT exemption exempts addresses from translation and allows both translated and remote hosts to initiate connections with your protected hosts. Like identity NAT, you do not limit translation for a host on specific interfaces; you must use NAT exemption for connections through all interfaces. However, NAT exemption

enables you to specify the real and destination addresses when determining the real addresses to translate (similar to policy NAT). Use static identity NAT to consider ports in the access list.

When you configure static identity NAT for remote access or site-to-site VPN, you must configure NAT with the route lookup option. Without route lookup, the threat defense sends traffic out of the interface specified in the NAT command, regardless of what the routing table says. For example, you do not want the threat defense to send the DHCP scope traffic through an incorrect interface; it will never return to the interface IP address. The route lookup option lets the threat defense send, or intercept, the traffic directly on the interface IP address instead of through the interface. For traffic from the VPN client to a host on the inside network, the route lookup option will still result in the correct egress interface (inside), so normal traffic flow is not affected.

### Before you begin

Check if NAT is configured on the targeted devices where remote access VPN policy is deployed. If NAT is enabled on the targeted devices, you must define a NAT policy to exempt VPN traffic.

## Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, click **Devices > NAT**.
- Step 2** Select a NAT policy to update or click **New Policy > Threat Defense NAT** to create a NAT policy with a NAT rule to allow connections through all interfaces.
- Step 3** Click **Add Rule** to add a NAT rule.
- Step 4** On the Add NAT Rule window, select the following:
- Select the NAT Rule as **Manual NAT Rule**.
  - Select the Type as **Static**.
  - Click **Interface Objects** and select the Source and destination interface objects.
- Note** This interface object must be the same as the interface selected in the remote access VPN policy. For more information, see [Configure Access Interfaces for Remote Access VPN, on page 1714](#).
- Click **Translation** and select the source and destination networks:
    - **Original Source** and **Translated Source**
    - **Original Destination** and **Translated Destination**
- Step 5** On the Advanced tab, select **Do not proxy ARP on Destination Interface**.
- Do not proxy ARP on Destination Interface**—Disables proxy ARP for incoming packets to the mapped IP addresses. If you use addresses on the same network as the mapped interface, the system uses proxy ARP to answer any ARP requests for the mapped addresses, thus intercepting traffic destined for a mapped address. This solution simplifies routing because the device does not have to be the gateway for any additional networks. You can disable proxy ARP if desired, in which case you need to be sure to have proper routes on the upstream router.
- Step 6** Click **OK**.
-

## Configure DNS

Configure DNS on each threat defense device in order to use remote access VPN. Without DNS, the devices cannot resolve AAA server names, named URLs, and CA Servers with FQDN or Hostnames. It can only resolve IP addresses.

### Procedure

- 
- Step 1** Configure DNS server details and domain-lookup interfaces using the Platform Settings. For more information, see [DNS, on page 1075](#) and [DNS Server Group, on page 1482](#).
  - Step 2** Configure split-tunnel in group policy to allow DNS traffic through remote access VPN tunnel if the DNS server is reachable through VNP network. For more information, see [Configure Group Policy Objects, on page 1561](#).
- 

## Add Secure Client Profile XML File

The Secure Client Profile is a group of configuration parameters stored in an XML file that the client uses to configure its operation and appearance. These parameters (XML tags) include the names and addresses of host computers and settings to enable more client features.

You can create the Secure Client Profile using the Secure Client Profile Editor, a GUI-based configuration tool that is available as part of the Secure Client software package. It is an independent program that you run outside of the management center. For more information about Secure Client Profile Editor, see [Cisco Secure Client \(including AnyConnect\) Administrator Guide](#).

### Before you begin

A Secure Firewall Threat Defense remote access VPN policy requires assignment of the Secure Client Profile to the VPN clients. You can attach the client profile to a group policy.

Download the Secure Client Profile Editor from [Cisco Software Download Center](#).

### Procedure

- 
- Step 1** Choose **Devices > Remote Access**.
  - Step 2** Click **Edit** on the remote access VPN policy which you want to update.
  - Step 3** Click **Edit** on the connection profile to which you want to add the Secure Client profile.
  - Step 4** Click **Edit Group Policy**. If you choose to add a new group policy, click **Add**.
  - Step 5** Choose **Secure Client > Profile**.
  - Step 6** Choose a profile from the **Client Profile** drop-down list. If you choose to add a new client profile, click **Add** and do the following:
    - a) Specify the profile **Name**.
    - b) Click **Browse** and select the Secure Client Profile XML file.

**Note** For two-factor authentication, make sure that the timeout is set to 60 seconds or more in the Secure Client profile.

c) Click **Save**.

**Step 7** Save your changes.

---

## (Optional) Configure Split Tunneling

Split tunnel allows VPN connectivity to a remote network across a secure tunnel and also to a network outside VPN tunnel. Configure split tunneling if you want to allow your VPN users to access an outside network while they remain connected to the remote access VPN. To configure a split-tunnel list, you must create a Standard Access List or Extended Access List.

For more information, see [Configuring Group Policies](#), on page 1720.

### Procedure

---

- Step 1** Choose **Devices > Remote Access**.
  - Step 2** Click **Edit** on the remote access VPN policy for which you want to configure split tunneling.
  - Step 3** Click **Edit** on the required connection profile.
  - Step 4** Click **Add** to add a group policy or click **Edit Group Policy**.
  - Step 5** Choose **General > Split Tunneling**.
  - Step 6** From the **IPv4 Split Tunneling** or **IPv6 Split Tunneling** list, select **Exclude networks specified below** and then select the networks that you want to exclude from VPN traffic.  
  
The default setting allows all traffic over the VPN tunnel.
  - Step 7** Click **Standard Access List** or **Extended Access List**, and select an access list from the drop-down or add a new one.
  - Step 8** If you choose to add a new standard or extended access list, do the following:
    - a) Specify the **Name** for the new access list and click **Add**.
    - b) Choose **Allow** from the **Action** drop-down.
    - c) Select the network traffic that you want to allow over the VPN tunnel and click **Add**.
  - Step 9** Save your changes.
- 

### Related Topics

[Access List](#), on page 1468

## (Optional) Configure Dynamic Split Tunneling

Dynamic split tunneling allows you to fine-tune split tunneling based on DNS domain names. You can configure domains that must be included or excluded in the remote access VPN tunnel. Excluded domains are not blocked. Instead, traffic to those domains is kept outside the VPN tunnel. For example, you could send traffic to Cisco WebEx on the public Internet, thus freeing bandwidth in your VPN tunnel for traffic that is

targeted to servers within your protected network. For more information about configuring this feature, see [Configure AnyConnect Dynamic Split Tunnel on FTD Managed by FMC](#).

### Before you begin

You can configure this feature using the management center and threat defense from versions 7.0 or later. If you have an older version of the management center, you can configure it using FlexConfig as instructed in the [Advanced AnyConnect VPN Deployments for Firepower Threat Defense with FMC](#).

## Procedure

- 
- Step 1** Configure the group policy to use Dynamic Split Tunnel.
- Choose **Devices > Remote Access**.
  - Click **Edit** on the remote access VPN policy for which you want to configure dynamic split tunneling.
  - Click **Edit** on the required connection profile.
  - Click **Edit Group Policy**.
- Step 2** Configure the Secure Client custom attribute in the **Add/Edit Group Policy** dialog box.
- Click the Secure Client tab.
  - Click **Custom Attributes** and click +.
  - Choose **Dynamic Split Tunneling** from the **Secure Client Attribute** drop-down list.
  - Click + to create a new custom attribute object.
  - Enter the name for the custom attribute object.
  - Include domains**—Specify domain names that will be included in the remote access VPN tunnel.  
You can include domains in the tunnel that will be excluded based on IP addresses.
  - Exclude domains**—Specify domain names that will be excluded from the remote access VPN.  
Excluded domains are not blocked, traffic to these domains is kept outside the VPN tunnel.
  - Click **Save**.
  - Click **Add**.
- Step 3** Verify the configured custom attribute and click **Save** to save the group policy.
- Step 4** Click **Save** to save the connection profile.
- Step 5** Click **Save** to save the remote access VPN policy.
- 

### What to do next

- Deploy the configuration to threat defense.
- Verify the configured dynamic split tunnel configuration on the threat defense and the Secure Client. For more information, see [Verify Dynamic Split Tunneling Configuration, on page 1694](#).

## Verify Dynamic Split Tunneling Configuration

### On the Threat Defense

Use the following commands to verify the dynamic split tunneling configuration:

- `show running-config webvpn`
- `show running-config anyconnect-custom-data`
- `show running-config group-policy <group-policy-name>`

### On the Secure Client

Click the Statistics (  ) icon and choose **VPN > Statistics**. You can confirm the domains under the Dynamic Split Exclusion/Inclusion category.

## Verify the Configuration

### Procedure

- 
- Step 1** Open a web browser on a machine on the outside network.
- Step 2** Enter the URL of the threat defense remote access VPN gateway device.
- Step 3** Enter the username and password when prompted, and click **Logon**.
- Note** Connection to the VPN establishes automatically if you install Secure Client on the system.
- The VPN prompts you to download Secure Client if Secure Client is not installed.
- Step 4** Download Secure Client if it is not installed and connect to the VPN.  
The Secure Client installs itself. On successful authentication, you establish connection to the Secure Firewall Threat Defense remote access VPN gateway. The remote access VPN enforces the applicable identity or QoS policy according to your VPN policy configuration.
- 

## Create a Copy of an Existing Remote Access VPN Policy

You can copy an existing remote access VPN policy to create a new one with all the settings, including the connection profiles and access interfaces. You can then assign devices to the new policy and deploy the VPN on the assigned devices as required.

- 
- Note** Users with read-only permission for remote access VPN cannot create copy of the VPN. Users with read-only privileges in the domain can copy the remote access VPNs.
-

## Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
  - Step 2** Click **Copy** on the policy that you want to copy.
  - Step 3** Specify a **Name** for the new remote access VPN.
  - Step 4** Click **OK**.
- 

### What to do next

To assign devices to the new policy, see [Set Target Devices for a Remote Access VPN Policy, on page 1695](#).

# Set Target Devices for a Remote Access VPN Policy

After you create remote access VPN policy, you can assign the policy to threat defense devices.

## Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
  - Step 2** Click **Edit** (✎) next to the remote access VPN policy that you want to edit.
  - Step 3** Click **Policy Assignments**.
  - Step 4** Do any of the following:
    - To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** list and click **Add**. You can also drag and drop the available devices to select.
    - To remove a device assignment, click **Delete** (🗑) next to a device, high-availability pair, or device group in the **Selected Devices** list.
  - Step 5** Click **OK**.
  - Step 6** Click **Save**.
- 

### What to do next

- [Deploy configuration changes](#).

# Associate Local Realm with Remote Access VPN Policy

You can associate local realm to remote access VPN policy to enable local user authentication.

For information about creating and managing realms, see [Manage a Realm, on page 2497](#).

For information about configuring local user authentication for remote access VPNs, see [Configure AAA Settings for Remote Access VPN, on page 1698](#).

## Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
  - Step 2** Click **Edit** (✎) next to the remote access VPN policy that you want to edit.
  - Step 3** Click the link next to **Local Realm**.
  - Step 4** Select the **Local Realm Server** from the list, or click **Add** to add a new local realm.
  - Step 5** Click **OK**.
  - Step 6** Click **Save**.
- 

### What to do next

- [Deploy configuration changes](#).

# Additional Remote Access VPN Configurations

## Configure Connection Profile Settings

Remote Access VPN policy contains the connection profiles targeted for specific devices. These policies pertain to creating the tunnel itself, such as, how AAA is accomplished, and how addresses are assigned (DHCP or Address Pools) to VPN clients. They also include user attributes, which are identified in group policies configured on the threat defense device or obtained from a AAA server. A device also provides a default connection profile named *DefaultWEBVPGGroup*. The connection profile that is configured using the wizard appears in the list.

If you decide to grant different rights to different groups of VPN users, then you can add specific connection profiles for each of the user groups and maintain multiple connection profiles in your remote access VPN policy.

## Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
  - Step 2** Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.
  - Step 3** Select a **Connection Profile** and click **Edit**.
  - Step 4** (Optional) If you choose to add new connection profile, click **Add**.
  - Step 5** Configure IP Addresses for VPN Clients.  
[Configure IP Addresses for VPN Clients, on page 1697](#)
  - Step 6** (Optional) Update AAA Settings for remote access VPNs.  
[Configure AAA Settings for Remote Access VPN, on page 1698](#)

- Step 7** (Optional) Create or update Aliases.  
[Create or Update Aliases for a Connection Profile, on page 1713](#)
- Step 8** Save your changes.

---

## Configure IP Addresses for VPN Clients

Client address assignment allows you to assign IP addresses for the remote access VPN users.

You can assign IP Address for remote VPN clients from the local IP address pools, DHCP Servers, and AAA servers. The AAA servers are assigned first, followed by others. Configure the **Client Address Assignment** policy in the **Advanced** tab to define the assignment criteria. The IP pools defined in this connection profile will only be used if no IP pools are defined in group policy associated with the connection profile, or the system default group policy **DfltGrpPolicy**.

**IPv4 Address Pools**—SSL VPN clients receive new IP addresses when they connect to the Threat Defense device. Address pools define a range of addresses that remote clients can receive. You can add a maximum of six pools for IPv4 and IPv6 addresses each.

---

**Note** You can use the IP address from the existing IP pools in the Management Center or create a new pool using the **Add** option. Also, you can create an IP pool in Management Center using the **Objects > Object Management > Address Pools** path. For more information, see [Address Pools, on page 1472](#).

---

### Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**. Existing remote access policies are listed.
- Step 2** Select a remote access VPN policy and click the edit icon.
- Step 3** Select the connection profile that you want to update and click the edit icon.
- Step 4** Under the **Client Address Assignment** tab, do the following:
- Step 5** Click + next to **Address Pools**:
- Click + next to **Address Pools** to add IP addresses, and select **IPv4** or **IPv6** to add the corresponding address pool. Select the IP address pool from **Available Pools** and click **Add**.  
**Note** If you share your remote access VPN policy among multiple Secure Firewall Threat Defense devices, bear in mind that all devices share the same address pool unless you use device-level object overrides to replace the global definition with a unique address pool for each device. Unique address pools are required to avoid overlapping addresses in cases where the devices are not using NAT.
  - Click + next to **Available Pools** in the **Address Pools** window to add a new IPv4 or IPv6 address pool. When you choose the IPv4 pool, provide a starting and ending IP address. When you choose to include a new IPv6 address pool, enter **Number of Addresses** in the range 1-16384. Select the **Allow Overrides** option to avoid conflicts with IP address when objects are shared across many devices. For more information, see [Address Pools, on page 1472](#).
  - Click **OK**.

If you plan to edit the IP address pools, we recommend that you perform the following steps during a maintenance window:

1. Unassign the device from the remote access VPN.
2. Select the device and click **Deploy**.  
This deployment removes all the remote access VPN configurations from the device, terminates the remote access VPN sessions, the sessions are not reestablished.
3. Click the edit icon next to the IP address pools to edit it, edit any other remote access VPN configurations, if required, on the Management Center.
4. Assign the device to the updated remote access VPN policy.
5. Deploy the configurations on the device.  
The remote access VPN clients can connect to the device after the maintenance window.

**Step 6** Click + next to **DHCP Servers** to add DHCP servers:

**Note** The DHCP server address can be configured only with IPv4 address.

- a) Specify the name and DHCP (Dynamic Host Configuration Protocol) server address as network objects. Click **Add** to choose the server from the object list. Click **Delete** to delete a DHCP server.
- b) Click **Add** in the **New Objects** page to add a new network object. Enter the new object name, description, network, and select the **Allow Overrides** option as applicable. For more information, see [Creating Network Objects, on page 1499](#) and [Allowing Object Overrides, on page 1462](#).
- c) Click **OK**.

**Step 7** Click **Save**.

---

#### Related Topics

[Configure Connection Profile Settings, on page 1696](#)

## Configure AAA Settings for Remote Access VPN

### Before you begin

- Ensure that the required machine and user certificates are deployed on the endpoints. For information about threat defense certificates, see [Managing Threat Defense Certificates, on page 1576](#).
- Configure Secure Client profiles with required certificates. For more information, see *Cisco Secure Client (including AnyConnect) Administrator Guide*.

### Procedure

---

- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.
- Step 3** Select a connection profile to update AAA settings, click **Edit > AAA**.
- Step 4** Select the following for **Authentication**:

- **Authentication Method**—Determines how a user is identified before being allowed access to the network and network services. It controls access by requiring valid user credentials, which are typically a username and password. It may also include the certificate from the client. Supported authentication methods are **AAA only**, **Client Certificate only**, and **AAA + Client Certificate**.

When you select the **Authentication Method** as:

- **AAA Only**—If you select the **Authentication Server** as **RADIUS**, by default, the Authorization Server has the same value. Select the **Accounting Server** from the drop-down list. Whenever you select **AD** and **LDAP** from the Authentication Server drop-down list, you must select the **Authorization Server** and **Accounting Server** manually.
- **SAML**—Each user is authenticated using the SAML single sign-on server. For more information, see [Single Sign-On Authentication with SAML 2.0, on page 1761](#).

**Override Identity Provider Certificate**—Select to override the primary identity provider certificate of the SAML provider with an IdP certificate specific to a connection profile or SAML application. Select the IdP certificate from the drop-down.

Microsoft Azure can support multiple applications for the same entity ID. Each application (mapped to a different connection profile) requires a unique certificate. If you want to retain an existing entity ID for the single-sign-on object in current connection profile and use a different IdP certificate, you can select this option.

This enables support for multiple SAML applications per Microsoft Azure SAML identity provider.

The primary identity certificate is configured in the single sign-on server object.

For information about configuring a single sign-on server object, see [Add a Single Sign-on Server, on page 1466](#).

Choose your **SAML Login Experience** to configure a browser for SAML web authentication:

- **VPN client embedded browser**—Choose this option to use the browser embedded with the VPN client for web authentication. The authentication applies to the VPN connection only.
- **Default OS Browser**—Choose this option to configure the operating system that default or native browser that supports WebAuthN (FIDO2 standard for web authentication). This option enables single sign-on(SSO) support for web authentication methods such as biometric authentication.

The default browser requires an external browser package for web authentication. The package `Default-External-Browser-Package` is configured by default. You can change the default external browser package by editing a remote access VPN policy and selecting the file under **Advanced > Secure Client Images > Package File**.

You can also add a new package file by selecting. **Objects > Object Management > VPN > Secure Client File > Add Secure Client File**.

- **Client Certificate Only**—Each user is authenticated with a client certificate. The client certificate must be configured on VPN client endpoints. By default, the user name is derived from the client certificate fields CN and OU. If the user name is specified in other fields in the client certificate, use 'Primary' and 'Secondary' field to map appropriate fields.

Select **Enable multiple certificate authentication** to authenticate the VPN client using the machine and user certificates.

If you have enabled multiple certificate authentication, you can select one of the following certificates to map the username and authenticate the VPN user:

- **First Certificate**—Select this option to map the username from the machine certificate sent from the VPN client.
- **Second Certificate**—Select this option to map the username from the user certificate sent from the client.

**Note** If you do not enable multiple certificate authentication, the user certificate (second certificate) is used for authentication by default.

If you select the **Map specific field** option, which includes the username from the client certificate, the **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN as username** option, the system automatically retrieves the user identity. A distinguished name (DN) is a unique identification, made up of individual fields used as the identifier when matching users to a connection profile. DN rules are used for enhanced certificate authentication.

The primary and Secondary fields pertaining to the **Map specific field** option contain these common values:

- C (Country)
  - CN (Common Name)
  - DNQ (DN Qualifier)
  - EA (Email Address)
  - GENQ (Generational Qualifier)
  - GN (Given Name)
  - I (Initial)
  - L (Locality)
  - N (Name)
  - O (Organisation)
  - OU (Organisational Unit)
  - SER (Serial Number)
  - SN (Surname)
  - SP (State Province)
  - T (Title)
  - UID (User ID)
  - UPN (User Principal Name)
- **Client Certificate & AAA**— Each user is authenticated with both a client certificate and AAA server. Select the required certificate and AAA configurations for authentication.

Whichever authentication method you choose, select or deselect **Allow connection only if user exists in authorization database**.

- **Client Certificate & SAML**— Each user is authenticated with both a client certificate and SAML server. Select the required certificate and SAML configurations for authentication.
  - **Allow connection only if username from certificate and SAML are the same**—Select to allow VPN connection only if the username from the certificate matches the SAML single sign-on username.
  - **Use username from client certificate for Authorization**—When you choose the option to pick username from client certificate for authorization, you must configure the fields to pick from the client certificate.

You can choose to map a specific field as the username or use the entire distinguished name (DN) for authorization:

- **Map specific field**— Select to include the username from the client certificate; the **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively.
- **Use entire DN as username**— The system automatically retrieves the user identity for authorization.

You can also create a Dynamic Access Policy (DAP) to match user-specific SAML assertion attributes or username to DAP certificate attributes. See [Configure AAA Criteria Settings for DAP, on page 1784](#).

- **Authentication Server**—Authentication is the way a user is identified before being allowed access to the network and network services. Authentication requires valid user credentials, a certificate, or both. You can use authentication alone, or with authorization and accounting.

Select an authentication server from the list if you have added a server already or else create an authentication server:

- **LOCAL**—Use a local database from the threat defense for user authentication. To configure local authentication, threat defense must be Version 7.0 and later.
  - **Local Realm**—Select a local realm or click **Add** to configure a realm. See [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).
- **Realm**—Configure an LDAP or AD realm. See [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).
- **RADIUS Server Group**—Add a RADIUS server group object with RADIUS servers. See [Add a RADIUS Server Group, on page 1463](#).
- **Single Sign-On Server**—Create a single sign-on server object for SAML authentication. See [Add a Single Sign-on Server, on page 1466](#).

**Fallback to LOCAL Authentication**— The user is authenticated using the local database and the VPN tunnel can be established even if the AAA server group is unavailable, provided that the local database is configured.

- **Use secondary authentication** — Secondary authentication is configured in addition to primary authentication to provide additional security for VPN sessions. Secondary authentication is applicable only to **AAA only** and **Client Certificate & AAA** authentication methods.

Secondary authentication is an optional feature that requires a VPN user to enter two sets of username and password on the Secure Client login screen. You can also configure to pre-fill the secondary username from the authentication server or client certificate. Remote access VPN authentication is granted only if both primary and secondary authentications are successful. VPN authentication is denied if any one of the authentication servers is not reachable or one authentication fails.

You must configure a secondary authentication server group (AAA server) for the second username and password before configuring secondary authentication. For example, you can set the primary authentication server to an LDAP or Active Directory realm and the secondary authentication to a RADIUS server.

**Note** By default, secondary authentication is not required.

**Authentication Server**— Secondary authentication server to provide secondary username and password for VPN users.

- **Fallback to LOCAL Authentication**— This user is authenticated using the local database and the VPN tunnel can be established even if the AAA server group is unavailable, provided that the local database is configured.

Select the following under **Username for secondary authentication**:

- **Prompt**: Prompts the users to enter the username and password while logging on to VPN gateway.
- **Use primary authentication username**: The username is taken from the primary authentication server for both primary and secondary authentication; you must enter two passwords.
- **Map username from client certificate**: Prefills the secondary username from the client certificate.

If you have enabled multiple certificate authentication, you can select one of the following certificates:

- **First Certificate**— Select this option to map the username from the machine certificate sent from the VPN client.
- **Second Certificate**— Select this option to map the username from the user certificate sent from the client.
- If you select **Map specific field** option, which includes the username from the client certificate. The **Primary** and **Secondary** fields display default values: **CN (Common Name)** and **OU (Organisational Unit)** respectively. If you select the **Use entire DN (Distinguished Name) as username** option, the system automatically retrieves the user identity.

See **Authentication Method** descriptions for more information about primary and secondary field mapping.

- **Prefill username from certificate on user login window**: Prefills the secondary username from the client certificate when the user connects via Secure Client.
  - **Hide username in login window**: The secondary username is pre-filled from the client certificate, but hidden to the user so that the user does not modify the pre-filled username.
- **Use secondary username for VPN session**: The secondary username is used for reporting user activity during a VPN session.

**Step 5** Select the following for **Authorization**:

- **Authorization Server**—After authentication is complete, authorization controls the services and commands available to each authenticated user. Authorization works by assembling a set of attributes that describe what the user is authorized to perform, their actual capabilities, and restrictions. When you do not use authorization, authentication alone provides the same access to all authenticated users. Authorization requires authentication.

To know more about how remote access VPN authorization works, see [Understanding Policy Enforcement of Permissions and Attributes, on page 1680](#).

When a RADIUS Server is configured for user authorization in the connection profile, the remote access VPN system administrator can configure multiple authorization attributes for users or user-groups. The authorization attributes that are configured on the RADIUS server can be specific for a user or a user-group. Once users are authenticated, these specific authorization attributes are pushed to the threat defense device.

**Note** The AAA server attributes obtained from the authorization server override the attribute values that may have been previously configured on the group policy or the connection profile.

- Check **Allow connection only if user exists in authorization database** if desired.

When enabled, the system checks the username of the client must exist in the authorization database to allow a successful connection. If the username does not exist in the authorization database, then the connection is denied.

- When you select a realm as the Authorization Server, you must configure an LDAP attribute map. You can choose a single server for authentication and authorization or a different servers. Click **Configure LDAP Attribute Map** to add LDAP attribute maps for authorization.

**Note** Threat Defense does not support SAML Identity Provider as the Authorization server. If the Active Directory behind the SAML Identity Provider is reachable via management center and threat defense, you can configure authorization following these steps:

- Add realm for the AD Server. See [Create an LDAP Realm or an Active Directory Realm and Realm Directory, on page 2475](#).
- Select the realm object as the Authorization Server in remote access VPN connection profile.
- Configure LDAP attribute map for the selected realm.

For information about configuring LDAP attribute maps, see [Configuring LDAP Attribute Mapping, on page 1720](#).

**Step 6** Select the following for **Accounting**:

- **Accounting Server**—Accounting is used to track the services that users are accessing and the amount of network resources they are consuming. When AAA accounting is activated, the network access server reports user activity to the RADIUS server. Accounting information includes when sessions start and stop, usernames, the number of bytes that pass through the device for each session, the services used, and the duration of each session. This data can then be analyzed for network management, client billing, or auditing. You can use accounting alone or together with authentication and authorization.

Specify the RADIUS Server Group object that will be used to account for the remote access VPN session.

**Step 7** Select the following **Advanced Settings**:

- **Strip Realm from username**—Select to remove the realm from the username before passing the username on to the AAA server. For example, if you select this option and provide *domain\username*, the domain is stripped off from the username and sent to AAA server for authentication. By default this option is unchecked.
- **Strip Group from username**—Select to remove the group name from the username before passing the username on to the AAA server. By default this option is unchecked.

**Note** A realm is an administrative domain. Enabling these options allows the authentication to be based on the username alone. You can enable any combination of these options. However, you must select both check boxes if your server cannot parse delimiters.

- **Password Management**—Enable managing the password for the remote access VPN users. Select to notify ahead of the password expiry or on the day the password expires.

**Step 8** Click **Save**.**Related Topics**

**RADIUS Server Attributes for Secure Firewall Threat Defense**

The threat defense device supports applying user authorization attributes (also called user entitlements or permissions) to VPN connections from the external RADIUS server that are configured for authentication and/or authorization in the remote access VPN policy.

**Note** Secure Firewall Threat Defense devices support attributes with vendor ID 3076.

The following user authorization attributes are sent to the threat defense device from the RADIUS server.

- RADIUS attributes 146 and 150 are sent from threat defense devices to the RADIUS server for authentication and authorization requests.
- All three (146, 150, and 151) attributes are sent from threat defense devices to the RADIUS server for accounting start, interim-update, and stop requests.

**Table 99: RADIUS Attributes Sent from Secure Firewall Threat Defense to RADIUS Server**

| Attribute                                    | Attribute Number | Syntax, Type | Single or Multi-valued | Description or Value                                           |
|----------------------------------------------|------------------|--------------|------------------------|----------------------------------------------------------------|
| Connection Profile Name or Tunnel Group Name | 146              | String       | Single                 | 1-253 characters                                               |
| Client Type                                  | 150              | Integer      | Single                 | 2 = Secure Client SSL VPN, 6 = Secure Client IPsec VPN (IKEv2) |
| Session Type                                 | 151              | Integer      | Single                 | 1 = Secure Client SSL VPN, 2 = Secure Client IPsec VPN (IKEv2) |

Table 100: Supported RADIUS Authorization Attributes

| Attribute Name                  | Threat Defense | Attr. No. | Syntax/Type | Single or Multi- Valued | Description or Value                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------------|----------------|-----------|-------------|-------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Access-Hours                    | Y              | 1         | String      | Single                  | Name of the time range, for example, Business                                                                                                                                                                                                                                                                                                                                                                 |
| Access-List-Inbound             | Y              | 86        | String      | Single                  | Both of the Access-List attributes take the name of the ACL that is configured on the threat defense device. Create these ACLs using the Smart CLI Extension List object type (select <b>Device &gt; Advanced Configuration &gt; Smart CLI &gt; Objects</b> ). These ACLs control traffic flow in the inbound (entering the threat defense device) or outbound (leaving the threat defense device) direction. |
| Access-List-Outbound            | Y              | 87        | String      | Single                  |                                                                                                                                                                                                                                                                                                                                                                                                               |
| Address-Pools                   | Y              | 217       | String      | Single                  | The name of a network object defined on the threat defense device that identifies a subnet, which is used as the address pool for clients connecting to the device to access VPN. Define the network object on the configuration page and then associate the network object with a policy or a connection profile.                                                                                            |
| Allow-Network-Extension-Mode    | Y              | 64        | Boolean     | Single                  | 0 = Disabled 1 = Enabled                                                                                                                                                                                                                                                                                                                                                                                      |
| Authenticated-User-Idle-Timeout | Y              | 50        | Integer     | Single                  | 1-35791394 minutes                                                                                                                                                                                                                                                                                                                                                                                            |
| Authorization-DN-Field          | Y              | 67        | String      | Single                  | Possible values: UID, OU, O, CN, L, SP, C, DN, GN, SN, I, GENQ, DNQ, SER, use-entire-name                                                                                                                                                                                                                                                                                                                     |
| Authorization-Required          |                | 66        | Integer     | Single                  | 0 = No 1 = Yes                                                                                                                                                                                                                                                                                                                                                                                                |
| Authorization-Type              | Y              | 65        | Integer     | Single                  | 0 = None 1 = RADIUS 2 = LDAP                                                                                                                                                                                                                                                                                                                                                                                  |
| Banner1                         | Y              | 15        | String      | Single                  | Banner string to display for Cisco VPN remote access sessions: IPsec IKEv1, Secure Client SSL-TLS/DTLS/IKEv2, and Clientless SSL.                                                                                                                                                                                                                                                                             |
| Banner2                         | Y              | 36        | String      | Single                  | Banner string to display for Cisco VPN remote access sessions: IPsec IKEv1, Secure Client SSL-TLS/DTLS/IKEv2, and Clientless SSL. The Banner2 string is concatenated to the Banner1 string, if Banner1 is defined.                                                                                                                                                                                            |

| Extended-Authentication-On-Rekey  | Y              | 122       | Integer     | Single                  | 0 = Disabled 1 = Enabled                                                                                                                                                                                                                                                                                                                                                                                                       |
| Framed-Interface-Id               | Y              | 96        | String      | Single                  | Assigned IPv6 interface ID. Combines with Framed-IPv6-Prefix to create a complete assigned address. For example: Framed-Interface-ID=1:1:1:1 combined with Framed-IPv6-Prefix=2001:0db8::/64 gives the assigned IP address 2001:0db8::1:1:1:1.                                                                                                                                                                                 |
| Framed-IPv6-Prefix                | Y              | 97        | String      | Single                  | Assigned IPv6 prefix and length. Combines with Framed-Interface-Id to create a complete assigned address. For example: prefix 2001:0db8::/64 combined with Framed-Interface-Id=1:1:1:1 gives the IP address 2001:0db8::1:1:1:1. You can use this attribute to assign an IP address without using Framed-Interface-Id by assigning the full IPv6 address with prefix length for example, Framed-IPv6-Prefix=2001:0db8::1:1:1:1. |
| Group-Policy                      | Y              | 25        | String      | Single                  | Sets the group policy for the remote access VPN. You can use one of the following formats: <ul style="list-style-type: none"> <li>• <i>group policy name</i></li> <li>• OU=<i>group policy name</i></li> <li>• OU=<i>group policy name</i>;</li> </ul>                                                                                                                                                                         |

Table 101: RADIUS Attributes Sent to Secure Firewall Threat Defense

| Attribute         | Attribute Number | Syntax, Type                                       | Single or Multi-valued | Description or Value                                                                                                                                                                                                                      |
|-------------------|------------------|----------------------------------------------------|------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Address-Pools     | 217              | String                                             | Single                 | The name of a network object defined on the threat defense device that identifies a subnet, which will be used as the address pool for clients connecting to the remote access VPN. Define the network object on the <b>Objects</b> page. |
| Banner1           | 15               | String                                             | Single                 | The banner to display when the user logs in.                                                                                                                                                                                              |
| Banner2           | 36               | String                                             | Single                 | The second part of the banner to display when the user logs in. Banner2 is appended to Banner1.                                                                                                                                           |
| Downloadable ACLs | Cisco-AV-Pair    | merge-dacl<br>{before-avpair<br> <br>after-avpair} |                        | Supported via Cisco-AV-Pair configuration.                                                                                                                                                                                                |

| Attribute           | Attribute Number | Syntax, Type | Single or Multi-valued | Description or Value                                                                                                                                                                                                                                                                                                                 |
|---------------------|------------------|--------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Filter ACLs         | 86, 87           | String       | Single                 | Filter ACLs are referred to by ACL name in the RADIUS server. It requires the ACL configuration to be already present on the threat defense device, so that it can be used during RADIUS authorization.<br><br>86=Access-List-Inbound<br>87=Access-List-Outbound                                                                     |
| Group-Policy        | 25               | String       | Single                 | The group policy to use in the connection. You must create the group policy on the remote access VPN <b>Group Policy</b> page. You can use one of the following formats: <ul style="list-style-type: none"> <li>• <i>group policy name</i></li> <li>• OU=<i>group policy name</i></li> <li>• OU=<i>group policy name</i>;</li> </ul> |
| Simultaneous-Logins | 2                | Integer      | Single                 | The number of separate simultaneous connections the user is allowed to establish, 0 - 2147483647.                                                                                                                                                                                                                                    |
| VLAN                | 140              | Integer      | Single                 | The VLAN on which to confine the user's connection, 0 - 4094. You must also configure this VLAN on a subinterface on the threat defense device.                                                                                                                                                                                      |

You must set the values of the IE-Proxy-Server-Method attribute returned from ISE to one of the following:

- IE\_PROXY\_METHOD\_PACFILE: 8
- IE\_PROXY\_METHOD\_PACFILE\_AND\_AUTODETECT: 11
- IE\_PROXY\_METHOD\_PACFILE\_AND\_USE\_SERVER: 12
- IE\_PROXY\_METHOD\_PACFILE\_AND\_AUTODETECT\_AND\_USE\_SERVER: 15

Threat Defense will deliver a proxy setting only if one of the above values is used for the IE-Proxy-Server-Method attribute.

## Create or Update Aliases for a Connection Profile

Aliases contain alternate names or URLs for a specific connection profile. Remote access VPN administrators can enable or disable the Alias names and Alias URLs. VPN users can choose an Alias name when they connect to the Secure Firewall Threat Defense device. Aliases names for all connections configured on this device can be turned on or off for display. You can also configure the list of Alias URLs, which your endpoints can select while initiating the remote access VPN connection. If users connect using the Alias URL, system will automatically log them using the connection profile that matches the Alias URL.

## Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** Click **Edit** on the policy that you want to modify.
- Step 3** Click **Edit** on the connection profile for which you want to create or update aliases.
- Step 4** Click **Aliases**.
- Step 5** To add an Alias name, do the following:
- Click **Add** under **Alias Names**.
  - Specify the **Alias Name**.
  - Select the **Enabled** check box in each window to enable the aliases.
  - Click **OK**.
- Step 6** To add an Alias URL, do the following:
- Click **Add** under **URL Alias**.
  - Select the **Alias URL** from the list or create a new URL object. For more information see [Creating URL Objects, on page 1541](#).
  - Select the **Enabled** check box in each window to enable the aliases.
  - Click **OK**.
- Step 7** Save your changes.

---

## Configure Access Interfaces for Remote Access VPN

The **Access Interface** table lists the interface groups and security zones that contain the device interfaces. These are configured for remote access SSL or IPsec IKEv2 VPN connections. The table displays the name of each interface group or security-zone, the interface trustpoints used by the interface, and whether Datagram Transport Layer Security (DTLS) is enabled.

## Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.
- Step 3** Click the **Access Interface** tab.
- Step 4** To add an access interface, click + and specify values for the following in the **Add Access Interface** dialog box:
- Access Interface**—Select the interface group or security zone to which the interface belongs.  
The interface group or security zone must be a Routed type. Other interface types are not supported for remote access VPN connectivity.
  - Associate the **Protocol** object with the access interface by selecting the following options:

- **Enable IPsec-IKEv2**—Select this option to enable **IKEv2** settings.
- **Enable SSL**—Select this option to enable **SSL** settings.

- Select **Enable Datagram Transport Layer Security**.

When selected, it enables Datagram Transport Layer Security (DTLS) on the interface and allows the AnyConnect VPN module of Cisco Secure Client to establish an SSL VPN connection using two simultaneous tunnels—an SSL tunnel and a DTLS tunnel.

Enabling DTLS avoids the latency and bandwidth problems associated with certain SSL connections and improves the performance of real-time applications that are sensitive to packet delays.

To configure SSL settings, and TLS and DTLS versions, see [About SSL Settings, on page 1105](#).

To configure SSL settings for the AnyConnect VPN module of Cisco Secure Client, see [Group Policy Secure Client Options, on page 1563](#).

- Select the **Configure Interface Specific Identity Certificate** check box and select **Interface Identity Certificate** from the drop-down list.

If you do not select the Interface Identity Certificate, the **Trustpoint** will be used by default.

If you do not select the Interface Identity Certificate or Trustpoint, the **SSL Global Identity Certificate** will be used by default.

c) Click **OK** to save the changes.

**Step 5** Select the following under **Access Settings**:

- **Allow Users to select connection profile while logging in**—If you have multiple connection profiles, check this check box to allow user to select the correct connection profile during login. You must select this option for **IPsec-IKEv2** VPNs.
- **Enable HTTP-only VPN Cookies**—Check this check box to enable HTTP-only VPN cookies.

**Step 6** Use the following options to configure **SSL Settings**:

- **Web Access Port Number**—The port to use for VPN sessions. The default port is 443.
- **DTLS Port Number**—The UDP port to use for DTLS connections. The default port is 443.
- **SSL Global Identity Certificate**— The selected **SSL Global Identity Certificate** will be used for all the associated interfaces if the **Interface Specific Identity Certificate** is not provided.

**Step 7** For **IPsec-IKEv2 Settings**, select the **IKEv2 Identity Certificate** from the list or add an identity certificate.

**Step 8** Under the **Access Control for VPN Traffic** section, select the following option if you want to bypass access control policy:

- **Bypass Access Control policy for decrypted traffic (sysopt permit-vpn)** — Decrypted traffic is subjected to Access Control Policy inspection by default. Enabling the Bypass Access Control policy for decrypted traffic option bypasses the ACL inspection, but VPN Filter ACL and authorization ACL downloaded from AAA server are still applied to VPN traffic.

**Note** If you select this option, you need not update the access control policy for remote access VPN as specified in [Update the Access Control Policy on the Secure Firewall Threat Defense Device, on page 1689](#).

**Step 9** Click **Save** to save the access interface changes.

---

## Configure Advanced Options for Remote Access VPN

### Cisco Secure Client Image

#### Secure Client Image

The Secure Client provides secure SSL or IPsec (IKEv2) connections to the threat defense device for remote users with full VPN profiling to corporate resources. Without a previously-installed client, remote users can enter the IP address of an interface configured to accept clientless VPN connections in their browser to download and install the Secure Client. The threat defense device downloads the client that matches the operating system of the remote computer. After downloading, the client installs and establishes a secure connection. In case of a previously installed client, when the user authenticates, the threat defense device, examines the version of the client, and upgrades the client if necessary.

The Remote Access VPN administrator associates any new or additional Secure Client images to the VPN policy. The administrator can unassociate the unsupported or end of life client packages that are no longer required.

The Secure Firewall Management Center determines the type of operating system by using the file package name. If the user renamed the file without indicating the operating system information, the valid operating system type must be selected from the list box.

Download the Secure Client image file by visiting [Cisco Software Download Center](#).

#### Related Topics

[Adding a Secure Client Image to the Secure Firewall Management Center](#), on page 1716

### Adding a Secure Client Image to the Secure Firewall Management Center

You can upload the Secure Client image to the Secure Firewall Management Center by using the **Secure Client File** object. For more information, see [File Objects](#), on page 1573. For more information about the client image, see [Cisco Secure Client Image](#), on page 1716.

#### Procedure

- 
- Step 1** Choose **Devices > Remote Access**, choose and edit a listed remote access policy, then choose the **Advanced** tab.
  - Step 2** Click **Add** to add a Secure Client image.
  - Step 3** Click **Add** in the **Available Secure Client Images** portion of the **Secure Client Images** dialog.
  - Step 4** Enter the **Name** and **Description**(optional) for the available Secure Client Image.
  - Step 5** Click **Browse**, locate and select the client image that you want to upload.
  - Step 6** Click **Save** to upload the image to the management center.

When you upload the client image to the Secure Firewall Management Center, the operating system information for the image appears automatically.

**Step 7** To change the order of client images, Click **Show Re-order buttons** and move the client image up or down.

---

## Update Secure Client Image for Remote Access VPN Clients

When new Secure Client updates are available in [Cisco Software Download Center](#), you can download the packages manually and add them to the remote access VPN policy so that the new client packages are upgraded on the VPN client systems according to their operating systems.

### Before you begin

Instructions in this section help you update new Secure Client images to remote access VPN clients connecting to Secure Firewall Threat Defense VPN gateway. Ensure that the following configurations are complete before updating your Secure Client images:

- Download the latest Secure Client image files from [Cisco Software Download Center](#).
- On your Secure Firewall Management Center web interface, go to **Objects > Object Management > VPN > Secure Client File** and add the new Secure Client image files.

## Procedure

- 
- Step 1** On your Secure Firewall Management Center web interface, choose **Devices > VPN > Remote Access**.
- Step 2** Click **Edit** on the remote access VPN policy that you want to update.
- Step 3** Click **Advanced > Secure Client Image > Add**.
- Step 4** Select a client image file from **Available Secure Client Images** and click **Add**.  
If the required client image is not listed, click **Add** to browse and upload an image.
- Step 5** Click **OK**.
- Step 6** Save the remote access VPN policy.  
After the remote access VPN policy changes are deployed, the new Secure Client images are updated on the Secure Firewall Threat Defense device that is configured as the remote access VPN gateway. When a new VPN user connects to the VPN gateway, the user gets the new Secure Client image to download depending on the operating system of the client system. For existing VPN users, the Secure Client image gets updated in their next VPN session.
- 

## Add a Cisco Secure Client External Browser Package to the Secure Firewall Management Center

If you have the Secure Client external browser package image on your local disk, use this procedure to upload the same to the Secure Firewall Management Center. After you upload the external browser package, you can update the external browser package for your remote access VPN connections.

You can upload the external browser package file to the Secure Firewall Management Center by using the **Secure Client File** object. For more information, see [File Objects, on page 1573](#).

### Points to Remember

- Only one external browser package can be added to the threat defense device.
- After the external browser package is added to the management center, the browser is pushed to the threat defense only after the external browser is enabled in the remote access VPN configuration.

### Procedure

- 
- Step 1** On the Secure Firewall Management Center web interface, choose **Devices > Remote Access**, choose and edit a listed remote access policy, then choose the **Advanced** tab.
- Step 2** Click **Add** in the **Secure Client External Browser Package** portion of the **Secure Client Images** page.
- Step 3** Enter the **Name** and **Description** for the Secure Client package.
- Step 4** Click **Browse** and locate the external browser package file to upload.
- Step 5** Click **Save** to upload the image to the Secure Firewall Management Center.
- Note** If you want to update the remote access VPN connection with an existing external browser package, select the file from the **Package File** drop-down.
- Step 6** Save the remote access VPN policy.
-

## Remote Access VPN Address Assignment Policy

The threat defense device can use an IPv4 or IPv6 policy for assigning IP addresses to Remote Access VPN clients. If you configure more than one address assignment method, the threat defense device tries each of the options until it finds an IP address.

### IPv4 or IPv6 Policy

You can use the IPv4 or IPv6 policy to address an IP address to remote access VPN clients. You must try with the IPv4 policy to begin and later followed by IPv6 policy.

- **Use Authorization Server**—Retrieves the address from an external authorization server on a per-user basis. If you are using an authorization server that has IP address configured, we recommend using this method. Address assignment is supported by RADIUS-based authorization server only. It is not supported for AD/LDAP. This method is available for both IPv4 and IPv6 assignment policies.
- **Use DHCP**—Obtains IP addresses from a DHCP server configured in a connection profile. You can also define the range of IP addresses that the DHCP server can use by configuring DHCP network scope in the group policy. If you use DHCP, configure the server in the **Objects > Object Management > Network** pane. This method is available for IPv4 assignment policies.

For more information about DHCP network scope configuration, see [Group Policy General Options, on page 1561](#).

- **Use an internal address pool**—Internally configured address pools are the easiest method of address pool assignment to configure. If you use this method, create the IP address pools in the **Objects > Object**

**Management >Address Pools** pane and select the same in the connection profile. This method is available for both IPv4 and IPv6 assignment policies.

- **Allow reuse an IP address so many minutes after it is released**—Delays the reuse of an IP address after its return to the address pool. Adding a delay helps to prevent problems firewalls can experience when an IP address is reassigned quickly. By default, the delay is set to zero. If you want to extend the delay, enter the number of minutes in the range of 0–480 to delay the IP address reassignment. This configurable element is available for IPv4 assignment policies.

[Remote Access VPN Authentication](#), on page 1678

## Configure Certificate Maps

Certificate maps let you define rules matching a user certificate to a connection profile based on the contents of the certificate fields. Certificate maps provide certificate authentication on secure gateways.

The rules or the certificate maps are defined in [Certificate Map Objects, on page 1557](#).

### Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.
- Step 3** Choose **Advanced > Certificate Maps**.
- Step 4** Select the following options from the **General Settings for Connection Profile Mapping** pane:
- Selections are priority-based, matching continues down the list of options when the first selection does not match. Matching is complete when the rules are satisfied. If the rules are not satisfied, the default connection profile listed at the bottom of this page is used for the connection. Select any, or all of the following options to establish authentication and to determine which connection profile (tunnel group) must be mapped to the client.
- **Use Group URL if Group URL and Certificate Map match different Connection profiles**
  - **Use the configured rules to match a certificate to a Connection Profile**—Enable this to use the rules defined in the Connection Profile Maps.
- Note** Configuring a certificate mapping implies certificate-based authentication. The remote user will be prompted for a client certificate regardless of the configured authentication method.
- Step 5** Under the **Certificate to Connection Profile Mapping** section, click **Add Mapping** to create certificate to connection profile mapping for this policy.
- a) Choose or create a **Certificate Map Name** object.
  - b) Select the **Connection Profile** that want to use if the rules in the certificate map object are satisfied.
  - c) Click **OK** to create the mapping.
- Step 6** Click **Save**.
-

## Configuring Group Policies

A group policy is a set of attribute and value pairs, stored in a group policy object, that define the remote access VPN experience. For example, in the group policy object, you configure general attributes such as addresses, protocols, and connection settings.

The group policy applied to a user is determined when the VPN tunnel is being established. The RADIUS authorization server assigns the group policy, or it is obtained from the current connection profile.

---

**Note** There is no group policy attribute inheritance on the threat defense. A group policy object is used, in its entirety, for a user. The group policy object identified by the AAA server upon login is used, or, if that is not specified, the default group policy configured for the VPN connection is used. The provided default group policy can be set to your default values, but will only be used if it is assigned to a connection profile and no other group policy has been identified for the user.

---

### Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
  - Step 2** Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.
  - Step 3** Choose **Advanced > Group Policies > Add**.
  - Step 4** Select group policies from the **Available Group Policy** list and click **Add**. You can select one or more group policies to associate with this remote access VPN policy.
  - Step 5** Click **OK** to complete the group policy selection.
  - Step 6** Save your changes.

---

## Configuring LDAP Attribute Mapping

An LDAP attribute name maps LDAP user or group attribute name to a Cisco-understandable name. The attribute map equates attributes that exist in the Active Directory (AD) or LDAP server with Cisco attribute names. You can map any standard LDAP attribute to a well-known vendor specific attribute (VSA). You can map one or more LDAP attributes to one or more Cisco LDAP attributes. When the AD or LDAP server returns authentication to the threat defense device during remote access VPN connection establishment, the threat defense device can use the information to adjust how the Secure Client completes the connection.

When you want to provide VPN users with different access permissions or VPN content, you can configure different VPN policies on the VPN server and assign these policy-sets to each user based on their credentials. You can achieve this in threat defense by configuring LDAP authorization, with LDAP attribute maps. In order to use LDAP to assign a group policy to a user, you must configure a map that maps an LDAP attribute.

An LDAP attribute map consists of three components:

- **Realm**—Specifies the name for the LDAP attribute map; the name is generated based on the selected realm.
- **Attribute Name Map**—Maps the LDAP user or group attribute name to Cisco-understandable name.

- **Attribute Value Map**—Maps value in the LDAP user or group attribute to the value of a Cisco attribute for the selected name mapping.

The group policies that are used in an LDAP attribute map get added to the list of group policies in the remote access VPN configuration. Removing a group policy from the remote access VPN configuration also removes the associated LDAP attribute mapping.

In versions 6.4 to 6.6, you can configure LDAP attribute maps only using FlexConfig. For more information, see [Configure AnyConnect Modules and Profiles Using FlexConfig](#).

In versions 7.0 and later, you can use the following procedure:

## Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
  - Step 2** Select an existing remote access VPN policy in the list and click the corresponding **Edit** icon.
  - Step 3** Click **Advanced > LDAP Attribute Mapping**.
  - Step 4** Click **Add**.
  - Step 5** On the Configure LDAP Attribute Map page, select a **Realm** to configure the attribute map.
  - Step 6** Click **Add**.

You can configure multiple attribute maps. Each attribute map requires that you configure a name map and value maps.

**Note** Ensure that you follow these guidelines while creating an LDAP attribute map:

- Configure at least one mapping for an LDAP attribute; multiple mappings with the same LDAP attribute name is not allowed.
  - Configure a minimum of one name map to create an LDAP attribute map.
  - You can remove any LDAP attribute map if the attribute map is not associated with any connection profile in the remote access VPN configuration.
  - Use the correct spelling and capitalization in the LDAP attribute map for *both* the Cisco and LDAP attribute names and values.
- a) Specify the **LDAP Attribute Name** and then select the required **Cisco Attribute Name** from the list.
  - b) Click **Add Value Map** and Specify the **LDAP Attribute Value** and **Cisco Attribute Value**.
- Repeat this step to add more value maps.

- Step 7** Click **OK** to complete LDAP attribute map configuration.
  - Step 8** Click **Save** to save the changes to the LDAP attribute mapping.
- 

## Example

For a detailed example, see [Configure RA VPN with LDAP Authentication and Authorization for FTD](#).

## Configuring VPN Load Balancing

### About VPN Load Balancing

VPN load balancing in threat defense allows you group two or more devices logically and distribute remote access VPN sessions among the devices equally. VPN load balancing shares Secure Client VPN sessions among the devices in a load balancing group.

VPN load balancing is based on simple distribution of traffic without taking into account throughput or other factors. A VPN load-balancing group consists of two or more threat defense devices. One device acts as the director, and the other devices are member devices. Devices in a group do not need to be of the exact same type, or have identical software versions or configurations. Any threat defense device that supports remote access VPN can participate in a load balancing group. Threat Defense supports VPN load balancing with Secure Client SAML authentication.

All active devices in a VPN load-balancing group carry session loads. VPN load balancing directs traffic to the least-loaded device in the group, distributing the load among all devices. It makes efficient use of system resources and provides increased performance and high availability.

### Components of VPN Load Balancing

Following are the components of VPN load balancing:

- **Load-balancing group**—A virtual group of two or more threat defense devices to share the VPN sessions.

A VPN load-balancing group can consist of threat defense devices of the same release or of mixed releases; but the device must support remote access VPN configuration.

See [Configure Group Settings for VPN Load Balancing, on page 1723](#) and [Configure Additional Settings for Load Balancing, on page 1724](#).

- **Director**—One device from the group acts a director. It distributes the load among other members in the group and participate is serving the VPN sessions.

The director monitors all devices in the group, keeps track of how loaded each device is, and distributes the session load accordingly. The role of director is not tied to a physical device; it can shift among devices. For example, if the current director fails, one of the member devices in the group takes over that role and immediately becomes the new director.

- **Members**—Devices other than the director in a group are called members. They participate in load balancing and share the remote access VPN connections.

[Configure Settings for Participating Devices, on page 1724](#).

### Prerequisites for VPN Load Balancing

- **Certificates**—threat defense's certificate must contain the IP addresses or FQDN of the director and members to which the connection is redirected. Or else, the certificate will be deemed untrusted. The certificate must use Subject Alternate Name (SAN) or wildcard certificate
- **Group URL**—Add the group URL for VPN load-balancing group IP address to the connection profiles. Specify a group URL to eliminate the need for the user to select a group at login.

- **IP Address Pool**—Choose unique IP address pool for member devices, and override the IP pool in management center for each of the member devices.
- Devices that are behind Network Address Translation (NAT) can also be part of a load balancing group.

### Guidelines and Limitations for VPN Load Balancing

- VPN load balancing is disabled by default. You must explicitly enable VPN load balancing.
- Only the threat defense devices that are co-located can be added to a load-balancing group.
- A load-balancing group must have a minimum of two threat defense devices.
- Devices in threat defense high availability can participate in a load-balancing group.
- Devices that are behind Network Address Translation (NAT) can also be part of a load balancing group.
- When a member or a director device goes down, remote access VPN connections that are served by that device will be dropped. You must initiate the VPN connection again.
- Identity certificate on each device must have Subject Alternate Name (SAN) or wildcard.

### Configure Group Settings for VPN Load Balancing

You can enable VPN load balancing and configure group settings that are applicable to all the members of the load-balancing group. When you create the group, you can configure participation settings for load balancing.

#### Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
  - Step 2** Click **Edit** on the remote access VPN policy that you want to update.
  - Step 3** Click **Advanced > Load Balancing**.
  - Step 4** Click the **Enable Load balancing between member devices** toggle button to enable load balancing. The **Edit Group Configuration** page opens. Group parameters apply to all devices under the load-balancing group.
  - Step 5** Specify the **Group IPv4 Address** and **Group IPv6 Address** as applicable.  
The IP address that you specify here is for the entire load-balancing group and the director opens this IP address for incoming VPN connections.
  - Step 6** Select the **Communication Interface** for the load-balancing group. Click **Add** to add an interface group or security zone.  
Communication interface is a private interface through which the director and members share information about their load.
  - Step 7** Enter the **UDP Port** for communication between the director and members in a group. The default port is 9023.
  - Step 8** Enable the **IPsec Encryption** toggle button to activate IPsec encryption for the communication between the director and members.

Enabling the encryption establishes an IKEv1/IPsec tunnel between the director and members using a pre-shared key.

- Step 9** Enter **Encryption Key** for IPsec encryption and confirm the encryption key.  
**Step 10** Click **OK**.
- 

### Configure Additional Settings for Load Balancing

The additional settings for VPN load balancing include FQDN and IKEv2 redirection.

#### Procedure

---

- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** Click **Edit** on the remote access VPN policy that you want to update.
- Step 3** Click **Advanced > Load Balancing**.
- Step 4** Turn on the **Enable Load balancing between member devices** toggle button to enable load balancing if not done already.
- Step 5** Click **Settings**.
- Step 6** Turn on the **Send FQDN to peer devices instead of IP** toggle button to enable redirection using a fully qualified domain name.
- By default, threat defense sends only IP addresses in VPN load balancing redirection to a client.
- Step 7** Select one of the **IKEv2 Redirect** phases:
- **Redirect during SA authentication**
  - **Redirect during SA initialization**
- Step 8** Click **OK**.
- Step 9** Save your changes.
- 

### Configure Settings for Participating Devices

The device participation settings determine how the devices share load in VPN load balancing. Configure a participating device by enabling VPN load balancing on the device and defining device-specific properties. These values vary from device to device. You can provide a priority number for the devices participating in load balancing. A higher priority number gives the device a better chance to become the director over other devices. But you cannot select a device to be the director of the group.

#### Procedure

---

- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** Click **Edit** next to the remote access VPN policy that you want to modify.
- Step 3** Click **Advanced > Load Balancing**.

- Step 4** Turn on the **Enable Load balancing between member devices** toggle button to enable load balancing if you have not enabled already.
- Step 5** Configure **Device Participation** settings:
- The **Device Participation** section lists all the target devices of the selected remote access VPN configuration. You can configure these devices to share the load of the incoming VPN sessions.
- Turn on the **Load Balancing** toggle button to enable load balancing for a device and then click **Edit**.
  - Enter the device **Priority**.  
By default, the device priority is set to 5. You can choose a number from 1 through 10.
  - Specify the **IPv4 NAT** or **IPv6 NAT** address for VPN interface IP address if the device is behind NAT.
  - Click **OK**.
- Step 6** Click **Save** to save the remote access VPN policy settings.
- 

## Configuring IPsec Settings for Remote Access VPNs

The IPsec settings are applicable only if you selected IPsec as the VPN protocol while configuring your remote access VPN policy. If not, you can enable IKEv2 using the Edit Access Interface dialog box. See [Configure Access Interfaces for Remote Access VPN, on page 1714](#) for more information.

### Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** From the list of available VPN policies, select the policy for which you want to modify the settings.
- Step 3** Click **Advanced**.
- The list of IPsec settings appears in a navigation pane on the left of the screen.
- Step 4** Use the navigation pane to edit the following IPsec options:
- Crypto Maps**—The Crypto Maps page lists the interface groups on which IKEv2 protocol is enabled. Crypto Maps are auto generated for the interfaces on which IKEv2 protocol is enabled. To edit a Crypto Map, see [Configure Remote Access VPN Crypto Maps, on page 1726](#). You can add or remove interface groups to the selected VPN policy in **Access Interface**. See [Configure Access Interfaces for Remote Access VPN, on page 1714](#) for more information.
  - IKE Policy**—The IKE Policy page lists all the IKE policy objects applicable for the selected VPN policy when Secure Client endpoints connect using the IPsec protocol. See [IKE Policies in Remote Access VPNs, on page 1728](#) for more information. To add a new IKE policy, see [Configure IKEv2 Policy Objects, on page 1571](#). Threat Defense supports only Secure Client IKEv2 clients. Third-party standard IKEv2 clients are not supported.
  - IPsec/IKEv2 Parameters**—The IPsec/IKEv2 Parameters page enables you to modify the IKEv2 session settings, IKEv2 Security Association settings, IPsec settings, and NAT Transparency settings. See [Configure Remote Access VPN IPsec/IKEv2 Parameters, on page 1729](#) for more information.
- Step 5** Click **Save**.
-

## Configure Remote Access VPN Crypto Maps

Crypto maps are automatically generated for the interfaces on which IPsec-IKEv2 protocol has been enabled. You can add or remove interface groups to the selected VPN policy in **Access Interface**. See [Configure Access Interfaces for Remote Access VPN, on page 1714](#) for more information.

### Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** From the list of available VPN policies, select the policy for which you want to modify the settings.
- Step 3** Click the **Advanced > Crypto Maps**, and select a row in the table and click **Edit** to edit the Crypto map options.
- Step 4** Select **IKEv2 IPsec Proposals** and select the transform sets to specify which authentication and encryption algorithms will be used to secure the traffic in the tunnel.
- Step 5** Select **Enable Reverse Route Injection** to enable static routes to be automatically inserted into the routing process for those networks and hosts protected by a remote tunnel endpoint.
- Step 6** Select **Enable Client Services** and specify the port number.

The Client Services Server provides HTTPS (SSL) access to allow the Secure Client Downloader to receive software upgrades, profiles, localization and customization files, CSD, SCEP, and other file downloads required by the client. If you select this option, specify the client services port number. If you do not enable the Client Services Server, users will not be able to download any of these files that the Secure Client might need.

**Note** You can use the same port that you use for SSL VPN running on the same device. Even if you have an SSL VPN configured, you must select this option to enable file downloads over SSL for IPsec-IKEv2 clients.

- Step 7** Select **Enable Perfect Forward Secrecy** and select the **Modulus group**.

Use Perfect Forward Secrecy (PFS) to generate and use a unique session key for each encrypted exchange. The unique session key protects the exchange from subsequent decryption, even if the entire exchange was recorded and the attacker has obtained the preshared or private keys used by the endpoint devices. If you select this option, also select the Diffie-Hellman key derivation algorithm to use when generating the PFS session key in the **Modulus Group** list.

Modulus group is the Diffie-Hellman group to use for deriving a shared secret between the two IPsec peers without transmitting it to each other. A larger modulus provides higher security but requires more processing time. The two peers must have a matching modulus group. Select the modulus group that you want to allow in the remote access VPN configuration:

- 1—Diffie-Hellman Group 1 (768-bit modulus).
- 2—Diffie-Hellman Group 2 (1024-bit modulus).
- 5—Diffie-Hellman Group 5 (1536-bit modulus, considered good protection for 128-bit keys, but group 14 is better). If you are using AES encryption, use this group (or higher).
- 14—Diffie-Hellman Group 14 (2048-bit modulus, considered good protection for 128-bit keys).
- 19—Diffie-Hellman Group 19 (256-bit elliptical curve field size).
- 20—Diffie-Hellman Group 20 (384-bit elliptical curve field size).

- 21—Diffie-Hellman Group 21 (521-bit elliptical curve field size).
- 24—Diffie-Hellman Group 24 (2048-bit modulus and 256-bit prime order subgroup).

**Step 8** Specify the **Lifetime Duration (seconds)**.

The lifetime of the security association (SA), in seconds. When the lifetime is exceeded, the SA expires and must be renegotiated between the two peers. Generally, the shorter the lifetime (up to a point), the more secure your IKE negotiations will be. However, with longer lifetimes, future IPsec security associations can be set up more quickly than with shorter lifetimes.

You can specify a value from 120 to 2147483647 seconds. The default is 28800 seconds.

**Step 9** Specify the **Lifetime Size (kbytes)**.

The volume of traffic (in kilobytes) that can pass between IPsec peers using a given security association before it expires.

You can specify a value from 10 to 2147483647 kbytes. The default is 4,608,000 kilobytes. No specification allows infinite data.

**Step 10** Select the following **ESPv3 Settings**:

- **Validate incoming ICMP error messages**—Choose whether to validate ICMP error messages received through an IPsec tunnel and destined for an interior host on the private network.
- **Enable 'Do Not Fragment' Policy**—Define how the IPsec subsystem handles large packets that have the do-not-fragment (DF) bit set in the IP header, and select one of the following from the **Policy** list:
  - Copy—Maintains the DF bit.
  - Clear—Ignores the DF bit.
  - Set—Sets and uses the DF bit.
- Select **Enable Traffic Flow Confidentiality (TFC) Packets**— Enable dummy TFC packets that mask the traffic profile which traverses the tunnel. Use the **Burst**, **Payload Size**, and **Timeout** parameters to generate random length packets at random intervals across the specified SA.

**Note** Enabling traffic flow confidentiality (TFC) packets prevents the VPN tunnel from being idle. Thus the VPN idle timeout configured in the group policy does not work as expected when you enable the TFC packets. See [Group Policy Advanced Options, on page 1567](#).

  - Burst—Specify a value from 1 to 16 bytes.
  - Payload Size—Specify a value from 64 to 1024 bytes.
  - Timeout—Specify a value from 10 to 60 seconds.

**Step 11** Click **OK**.

---

## IKE Policies in Remote Access VPNs

Internet Key Exchange (IKE) is a key management protocol that is used to authenticate IPsec peers, negotiate and distribute IPsec encryption keys, and automatically establish IPsec security associations (SAs). The IKE negotiation comprises two phases. Phase 1 negotiates a security association between two IKE peers, which enables the peers to communicate securely in Phase 2. During Phase 2 negotiation, IKE establishes SAs for other applications, such as IPsec. Both phases use proposals when they negotiate a connection. An IKE proposal is a set of algorithms that two peers use to secure the negotiation between them. IKE negotiation begins by each peer agreeing on a common (shared) IKE policy. This policy states which security parameters are used to protect subsequent IKE negotiations.

---

**Note** threat defense supports only IKEv2 for remote access VPNs.

---

Unlike IKEv1, in an IKEv2 proposal, you can select multiple algorithms and modulus groups in one policy. Since peers choose during the Phase 1 negotiation, this makes it possible to create a single IKE proposal, but consider creating multiple, different proposals to give higher priority to your most desired options. For IKEv2, the policy object does not specify authentication, other policies must define the authentication requirements.

An IKE policy is required when you configure a remote access IPsec VPN.

### Configuring Remote Access VPN IKE Policies

The IKE Policy table specifies all the IKE policy objects applicable for the selected VPN configuration when Secure Client endpoints connect using the IPsec protocol. For more information, see [IKE Policies in Remote Access VPNs, on page 1728](#).

---

**Note** threat defense supports only IKEv2 for remote access VPNs.

---

## Procedure

- 
- Step 1** Choose **Devices > VPN > Remote Access**.
  - Step 2** From the list of available VPN policies, select the policy for which you want to modify the settings.
  - Step 3** Click **Advanced > IKE Policy**.
  - Step 4** Click **Add** to select from the available IKEv2 policies, or add a new IKEv2 policy and specify the following:
    - **Name**—Name of the IKEv2 policy.
    - **Description**—Optional description of the IKEv2 policy
    - **Priority**—The priority value determines the order of the IKE policy compared by the two negotiating peers when attempting to find a common security association (SA).
    - **Lifetime**—Lifetime of the security association (SA), in seconds
    - **Integrity**—The Integrity Algorithms portion of the Hash Algorithm used in the IKEv2 policy.
    - **Encryption**—The Encryption Algorithm used to establish the Phase 1 SA for protecting Phase 2 negotiations.

- **PRF Hash**—The pseudorandom function (PRF) portion of the Hash Algorithm used in the IKE policy. In IKEv2, you can specify different algorithms for these elements.
- **DH Group**—The Diffie-Hellman group used for encryption.

**Step 5** Click **Save**.

---

## Configure Remote Access VPN IPsec/IKEv2 Parameters

### Procedure

---

- Step 1** Choose **Devices > VPN > Remote Access**.
- Step 2** From the list of available VPN policies, select the policy for which you want to modify the settings.
- Step 3** Click **Advanced > IPsec > IPsec/IKEv2 Parameters**.
- Step 4** Select the following for **IKEv2 Session Settings**:
- **Identity Sent to Peers**—Choose the identity that the peers will use to identify themselves during IKE negotiations:
    - **Auto**—Determines the IKE negotiation by connection type: IP address for preshared key, or Cert DN for certificate authentication (not supported).
    - **IP address**—Uses the IP addresses of the hosts exchanging ISAKMP identity information.
    - **Hostname**—Uses the fully qualified domain name (FQDN) of the hosts exchanging ISAKMP identity information. This name comprises the hostname and the domain name.
  - **Enable Notification on Tunnel Disconnect**—Allows an administrator to enable or disable the sending of an IKE notification to the peer when an inbound packet that is received on an SA does not match the traffic selectors for that SA. Sending this notification is disabled by default.
  - **Do not allow device reboot until all sessions are terminated**—Check to enable waiting for all active sessions to voluntarily terminate before the system reboots. This is disabled by default.
- Step 5** Select the following for **IKEv2 Security Association (SA) Settings**:
- **Cookie Challenge**—Whether to send cookie challenges to peer devices in response to SA initiated packets, which can help thwart denial of service (DoS) attacks. The default is to use cookie challenges when 50% of the available SAs are in negotiation. Select one of these options:
    - **Custom**—Specify **Threshold to Challenge Incoming Cookies**, the percentage of the total allowed SAs that are in-negotiation. This triggers cookie challenges for any future SA negotiations. The range is zero to 100%. The default is 50%.
    - **Always**— Select to send cookie challenges to peer devices always.
