CONTENTS

PART I

Getting Started with Device Configuration 87

CHAPTER 1

Device Management 1

- About Device Management 1
- About the Management Center and Device Management 2
- What Can Be Managed by a Secure Firewall Management Center? 2
- About the Management Connection 3
- Beyond Policies and Events 3
- About Device Management Interfaces 4
 - Management and Event Interfaces on the Threat Defense 4
 - Using the Threat Defense Data Interface for Management 4
 - Management Interface Support Per Device Model 5
 - Network Routes on Device Management Interfaces 6
 - NAT Environments 7
 - Management and Event Traffic Channel Examples 9
- Requirements and Prerequisites for Device Management 10
- Log Into the Command Line Interface on the Device 11
- Complete the Threat Defense Initial Configuration for Manual Registration 12
 - Complete the Threat Defense Initial Configuration Using the Device Manager 13
 - Complete the Threat Defense Initial Configuration Using the CLI 19
- Configure an Event Interface 25
- Add a Device to the Management Center Using a Registration Key 27
- Add a Device to the Management Center Using the Serial Number (Zero-Touch Provisioning) 31
- 35
- Add a Chassis to the Management Center 35
- Unregister a Device from the Management Center 37

Add a Device Group	38
Shut Down or Restart the Device	39
Download the Managed Device List	40
Configure Device Settings	40
Edit General Settings	41
Generate Troubleshooting Files	42
View CLI Output	45
Copy a Configuration to Another Device	47
Export and Import the Device Configuration	48
Edit License Settings	52
View System Information	52
View the Inspection Engine	53
View Health Information	53
Edit Management Settings	53
Update the Hostname or IP Address in the Management Center	53
Change Both Management Center and Threat Defense IP Addresses	55
Change the Manager Access Interface from Management to Data	59
Change the Manager Access Interface from Data to Management	63
Configure a Redundant Manager Access Data Interface	65
View Manager Access Details for Data Interface Management	71
Modify Threat Defense Management Interfaces at the CLI	75
Modify the Threat Defense Data Interface Used for Management at the CLI	81
Manually Roll Back the Configuration if the Management Center Loses Connectivity	84
Troubleshoot Management Connectivity on a Data Interface	85
View Inventory Details	90
Edit Applied Policies	91
Edit Advanced Settings	92
Configure Automatic Application Bypass	93
Configure Object Group Search	94
Configure Interface Object Optimization	95
Edit Deployment Settings	96
Edit Cluster Health Monitor Settings	99
Change the Management Settings for the Device	103
Edit the Management Center IP Address or Hostname on the Device	103

Identify a New Management Center	104
Switch from the Device Manager to the Management Center	105
Switch from Management Center to Device Manager	110
Resolve Serial Number (Zero-Touch Provisioning) Registration Issues	111
Hot Swap an SSD on the Secure Firewall 3100/4200	113
Disable the USB Port	115
Disable the USB Port on a Device	116
Disable the USB Port in Multi-Instance Mode	117
Migrate the Configuration to a New Model	118
Supported Devices for Migration	118
License for Migration	119
Prerequisites for Migration	119
What Configurations Does the Wizard Migrate?	120
Limitations for Migration	121
Migrate the Secure Firewall Threat Defense	122
Best Practices for Migration	123
History for Device Management Basics	124

CHAPTER 2

Device Management Using Device Templates	131
About Device Management using Device Templates	131
Methods to Register Devices using Templates	132
Variables and Network Object Overrides	132
Model Mapping	132
Requirements and Prerequisites for Device Management using Device Templates	133
Licenses for Device Management using Device Templates	134
Guidelines and Limitations for Device Management using Device Templates	134
Template Management	137
Workflow for Device Management using Device Templates	138
Add a Device Template	138
Create a New Device Template	138
Generate a New Device Template from an Existing Device	139
Import a Device Template	139
Configure a Device Template	140
Add a Physical Interface	140

Add a Logical Interface	141
Edit an Interface	141
Configure Other Device Settings	142
Configure Template Settings	142
Edit General Settings	143
Edit Licenses	143
Edit Applied Policies	144
Edit Advanced Settings	144
Edit Deployment Settings	145
Configure Template Parameters	146
Add Model Mapping	149
Configure Site-to-Site VPN Connections in a Device Template	150
Device Template with Site-to-Site VPN Connections Workflow	150
Configure an SD-WAN VPN Connection	150
Configure a Route-Based Site-to-Site VPN Connection	151
Configure a Policy-Based Site-to-Site VPN Connection	153
Register a Device Using Device Template and Add it to a Route-Based VPN Topology	154
Add a Device to an SD-WAN Topology in a Dual ISP Deployment	155
Add a Device to the Management Center	156
Add a Device Using a Registration Key and a Device Template	157
Zero-Touch Provisioning	158
Add Devices Using Serial Numbers and a Device Template (Zero-Touch Provisioning)	158
CSV Template File	160
Apply Templates to Existing Devices	161
Apply a Template	161
Reapply a Template	162
Validation of Template Configuration Before and After Application of Template on Device	163
Monitoring Device Templates	163
Viewing Associated Devices	163
Generating a Template Apply Report	164
Delete Device Template	165
Configure a Template for Threat Defense Devices Managed Using the Data Interface	165
Device Template Operations on Threat Defense HA Devices	167
Audit Logs	167

Device Templates in Domains	167
Troubleshooting Device Templates	169
History for Device Management using Device Templates	172

CHAPTER 3
Users 173

About Users	173
Internal and External Users	173
CLI Access	173
CLI User Roles	174
Requirements and Prerequisites for User Accounts for Devices	174
Guidelines and Limitations for User Accounts for Devices	175
Add an Internal User at the CLI	175
Configure External Authentication for the Threat Defense	177
About External Authentication for the Threat Defense	177
About LDAP	178
About RADIUS	178
Add an LDAP External Authentication Object for Threat Defense	178
Add a RADIUS External Authentication Object for Threat Defense	184
Enable External Authentication for Users on Threat Defense Devices	189
Troubleshooting LDAP Authentication Connections	189
History for Users	191

CHAPTER 4
Change Management 193

About Change Management	193
How to Configure Devices in the Change Management Workflow	194
Creating Separate Approver and Configuration Roles	194
Policies and Objects that Support Change Management	195
Requirements and Prerequisites for Change Management	197
Guidelines and Limitations for Change Management	197
Enabling or Disabling Change Management	198
Managing Tickets	199
Creating Change Management Tickets	200
Opening a Ticket for Configuration Changes	201
Previewing a Ticket	201

Submitting a Ticket	202
Discarding a Ticket	202
Approving or Rejecting a Ticket	203
Taking Over or Reassigning Tickets	203
History for Change Management	204

CHAPTER 5
Configuration Deployment 205

About Configuration Deployment	205
Configuration Changes that Require Deployment	205
Deployment Preview	206
Selective Policy Deployment	207
System Username	209
Auto-Enabling of Application Detectors	210
Asset Rediscovery with Network Discovery Policy Changes	210
Snort Restart Scenarios	210
Restart Warnings for Devices	210
Inspect Traffic During Policy Apply	211
Snort Restart Traffic Behavior	212
Configurations that Restart the Snort Process When Deployed or Activated	214
Changes that Immediately Restart the Snort Process	215
Requirements and Prerequisites for Policy Management	216
Best Practices for Deploying Configuration Changes	216
Deploy the Configuration	217
Deploy Configuration Changes	218
Redeploy Existing Configurations to a Device	223
Manage Deployments	225
View Deployment Status	225
View Deployment History	225
Set the Number of Configuration Versions	229
Roll Back a Deployment	230
Perform a Rollback	232
View the Deployment Rollback Transcript	233
Download Policy Changes Report for Multiple Devices	234
Compare Policies	235

Generate Current Policy Reports	236
History for Configuration Deployment	237

PART II**Device Operations 241****CHAPTER 6****Transparent or Routed Firewall Mode 243**

About the Firewall Mode	243
About Routed Firewall Mode	243
About Transparent Firewall Mode	244
Using the Transparent Firewall in Your Network	244
Passing Traffic For Routed-Mode Features	244
About Bridge Groups	245
Bridge Virtual Interface (BVI)	245
Bridge Groups in Transparent Firewall Mode	245
Bridge Groups in Routed Firewall Mode	246
Allowing Layer 3 Traffic	247
Allowed MAC Addresses	247
BPDU Handling	247
MAC Address vs. Route Lookups	248
Unsupported Features for Bridge Groups in Transparent Mode	249
Unsupported Features for Bridge Groups in Routed Mode	250
Default Settings	251
Guidelines for Firewall Mode	251
Set the Firewall Mode	252

CHAPTER 7**Logical Devices on the Firepower 4100/9300 255**

About Interfaces	255
Chassis Management Interface	255
Interface Types	256
FXOS Interfaces vs. Application Interfaces	258
Shared Interface Scalability	260
Shared Interface Best Practices	260
Shared Interface Usage Examples	262
Viewing Shared Interface Resources	268

Inline Set Link State Propagation for the Threat Defense	269
About Logical Devices	269
Standalone and Clustered Logical Devices	270
Logical Device Application Instances: Container and Native	270
Container Instance Interfaces	270
How the Chassis Classifies Packets	271
Classification Examples	271
Cascading Container Instances	275
Typical Multi-Instance Deployment	276
Automatic MAC Addresses for Container Instance Interfaces	277
Container Instance Resource Management	278
Performance Scaling Factor for Multi-Instance Capability	278
Container Instances and High Availability	278
Container Instances and Clustering	278
Licenses for Container Instances	278
Requirements and Prerequisites for Logical Devices	279
Requirements and Prerequisites for Hardware and Software Combinations	279
Requirements and Prerequisites for Container Instances	281
Requirements and Prerequisites for High Availability	282
Requirements and Prerequisites for Clustering	282
Guidelines and Limitations for Logical Devices	286
Guidelines and Limitations for Interfaces	286
General Guidelines and Limitations	289
Configure Interfaces	289
Enable or Disable an Interface	289
Configure a Physical Interface	290
Add an EtherChannel (Port Channel)	291
Add a VLAN Subinterface for Container Instances	293
Configure Logical Devices	294
Add a Resource Profile for Container Instances	294
Add a Standalone Threat Defense	295
Add a High Availability Pair	301
Change an Interface on a Threat Defense Logical Device	302
Connect to the Console of the Application	304

History for Logical Devices 306

CHAPTER 8

Multi-Instance Mode for the Secure Firewall 3100/4200 311

About Multi-Instance Mode 311

Multi-Instance Mode vs. Appliance Mode 311

Chassis Management Interface 312

Instance Interfaces 312

Interface Types 313

Chassis Interfaces vs. Instance Interfaces 313

Shared Interface Scalability 315

Shared Interface Best Practices 315

How the Chassis Classifies Packets 317

Classification Examples 318

Cascading Instances 321

Typical Multi-Instance Deployment 322

Automatic MAC Addresses for Instance Interfaces 323

Performance Scaling Factor for Multi-Instance Mode 324

Instances and High Availability 324

Licenses for Instances 324

Requirements and Prerequisites for Instances 324

Guidelines and Limitations for Instances 326

Configure Instances 328

Convert a Device to Multi-Instance Mode 328

Configure Chassis Interfaces 332

Configure a Physical Interface 332

Configure an EtherChannel 335

Configure a Subinterface 339

Add an Instance 341

Customize the System Configuration 347

Configure SNMP 347

Import or Export the Chassis Configuration 348

Configure Chassis Platform Settings 351

Create a Chassis Platform Settings Policy 351

Configure DNS 352

Configure SSH and SSH Access List	353
Configure Syslog	358
Configure Time Synchronization	363
Configure Time Zones	365
Manage Multi-Instance Mode	366
Enable Multi-Instance Mode at the CLI	366
Change Interfaces Assigned to an Instance	369
Change Chassis Management Settings at the FXOS CLI	371
Monitoring Multi-Instance Mode	373
Monitoring Multi-Instance Setup	373
Monitoring Instance Interfaces	374
History for Multi-Instance Mode	376

CHAPTER 9
High Availability 377

About Secure Firewall Threat Defense High Availability	377
High Availability System Requirements	377
Hardware Requirements	378
Software Requirements	378
License Requirements for Threat Defense Devices in a High Availability Pair	378
Failover and Stateful Failover Links	379
Failover Link	379
Stateful Failover Link	380
Avoiding Interrupted Failover and Data Links	380
MAC Addresses and IP Addresses in High Availability	382
Stateful Failover	384
Supported Features	384
Unsupported Features	386
Bridge Group Requirements for High Availability	386
Failover Health Monitoring	386
Unit Health Monitoring	387
Heartbeat Module Redundancy	387
Interface Monitoring	387
Failover Triggers and Detection Timing	389
About Active/Standby Failover	390

Primary/Secondary Roles and Active/Standby Status	390
Active Unit Determination at Startup	390
Failover Events	390
Config-Sync Optimization	391
Requirements and Prerequisites for High Availability	392
Guidelines for High Availability	392
Add a High Availability Pair	395
Configure Optional High Availability Parameters	397
Configure Standby IP Addresses and Interface Monitoring	397
Edit High Availability Failover Criteria	398
Configure Virtual MAC Addresses	398
Manage High Availability	399
Switch the Active Peer in the Threat Defense High Availability Pair	399
Refresh Node Status for a Single Threat Defense High Availability Pair	400
Suspend and Resume High Availability	400
Replace a Unit in Threat Defense High Availability Pair	401
Replace a Primary Threat Defense HA Unit with no Backup	401
Replace a Secondary Threat Defense HA Unit with no Backup	402
Break a High Availability Pair	403
Unregister a High Availability Pair and Register to a New Management Center	405
Monitoring High Availability	406
View Failover History	406
View Stateful Failover Statistics	406
Troubleshoot Configuration Sync Failure	406
History for High Availability	407

CHAPTER 10

Clustering for the Secure Firewall 3100/4200	409
About Clustering for the Secure Firewall 3100/4200	409
How the Cluster Fits into Your Network	409
Control and Data Node Roles	410
Cluster Interfaces	410
Cluster Control Link	410
Configuration Replication	410
Management Network	410

Licenses for Clustering	411
Requirements and Prerequisites for Clustering	411
Guidelines for Clustering	412
Configure Clustering	416
About Cluster Interfaces	416
Cluster Control Link	416
Spanned EtherChannels (Recommended)	418
Individual Interfaces (Routed Firewall Mode Only)	421
Cable and Add Devices to the Management Center	423
Create a Cluster	424
Configure Interfaces	432
Configure Spanned EtherChannels	432
Configure Individual Interfaces	433
Configure Cluster Health Monitor Settings	435
Manage Cluster Nodes	440
Add a New Cluster Node	440
Break a Node	442
Break the Cluster	443
Disable Clustering	444
Rejoin the Cluster	445
Change the Control Node	445
Edit the Cluster Configuration	446
Reconcile Cluster Nodes	447
Unregister the Cluster or Nodes and Register to a New Management Center	449
Monitoring the Cluster	450
Cluster Health Monitor Dashboard	452
Viewing Cluster Health	453
Cluster Metrics	454
Troubleshooting the Cluster	455
Perform a Ping on the Cluster Control Link	456
Examples for Clustering	457
Firewall on a Stick	458
Traffic Segregation	459
Reference for Clustering	459

Threat Defense Features and Clustering	459
Unsupported Features with Clustering	459
Centralized Features for Clustering	460
Connection Settings and Clustering	461
FTP and Clustering	461
Multicast Routing in Individual Interface Mode	461
Multicast Routing in Individual Interface Mode	461
NAT and Clustering	461
Dynamic Routing	463
Dynamic Routing in Individual Interface Mode	464
SIP Inspection and Clustering	465
SNMP and Clustering	465
Syslog and Clustering	465
Cisco TrustSec and Clustering	465
VPN and Clustering	465
Performance Scaling Factor	465
Control Node Election	466
High Availability Within the Cluster	466
Node Health Monitoring	466
Interface Monitoring	467
Status After Failure	467
Rejoining the Cluster	467
Data Path Connection State Replication	468
How the Cluster Manages Connections	468
Connection Roles	469
New Connection Ownership	470
Sample Data Flow for TCP	470
Sample Data Flow for ICMP and UDP	471
History for Clustering	472
CHAPTER 11	Clustering for Threat Defense Virtual in a Private Cloud 475
	About Threat Defense Virtual Clustering in the Private Cloud 475
	How the Cluster Fits into Your Network 475
	Control and Data Node Roles 476

Individual Interfaces	476
Policy-Based Routing	477
Equal-Cost Multi-Path Routing	477
Cluster Control Link	478
Cluster Control Link Traffic Overview	478
Configuration Replication	479
Management Network	479
Licenses for Threat Defense Virtual Clustering	479
Requirements and Prerequisites for Threat Defense Virtual Clustering	479
Guidelines for Threat Defense Virtual Clustering	481
Configure Threat Defense Virtual Clustering	481
Add Devices to the Management Center	482
Create a Cluster	482
Configure Interfaces	490
Configure Cluster Health Monitor Settings	491
Manage Cluster Nodes	496
Add a New Cluster Node	496
Break a Node	498
Break the Cluster	499
Disable Clustering	500
Rejoin the Cluster	501
Change the Control Node	501
Edit the Cluster Configuration	502
Reconcile Cluster Nodes	503
Delete (Unregister) the Cluster or Nodes and Register to a New Management Center	505
Monitoring the Cluster	506
Cluster Health Monitor Dashboard	509
Viewing Cluster Health	510
Cluster Metrics	511
Troubleshooting the Cluster	512
Perform a Ping on the Cluster Control Link	513
Reference for Clustering	514
Threat Defense Features and Clustering	514
Unsupported Features and Clustering	514

Centralized Features for Clustering	515
Connection Settings and Clustering	515
Dynamic Routing and Clustering	516
FTP and Clustering	516
NAT and Clustering	517
SIP Inspection and Clustering	518
SNMP and Clustering	518
Syslog and Clustering	518
Cisco Trustsec and Clustering	519
VPN and Clustering	519
Performance Scaling Factor	519
Control Node Election	519
High Availability within the Cluster	520
Node Health Monitoring	520
Interface Monitoring	520
Status After Failure	520
Rejoining the Cluster	521
Data Path Connection State Replication	521
How the Cluster Manages Connections	522
Connection Roles	522
New Connection Ownership	523
Sample Data Flow for TCP	523
Sample Data Flow for ICMP and UDP	524
History for Threat Defense Virtual Clustering in a Private Cloud	526

CHAPTER 12

Clustering for Threat Defense Virtual in a Public Cloud	529
About Threat Defense Virtual Clustering in the Public Cloud	530
How the Cluster Fits into Your Network	530
Individual Interfaces	530
Control and Data Node Roles	531
Cluster Control Link	531
Cluster Control Link Traffic Overview	532
Configuration Replication	532
Management Network	532

Licenses for Threat Defense Virtual Clustering	532
Requirements and Prerequisites for Threat Defense Virtual Clustering	533
Guidelines for Threat Defense Virtual Clustering	534
Deploy the Cluster in AWS	536
AWS Gateway Load Balancer and Geneve Single-Arm Proxy	536
Sample Topologies	537
End-to-End Process for Deploying Threat Defense Virtual Cluster on AWS	538
Templates	540
Deploy the Stack in AWS Using a CloudFormation Template	541
Autoscale Parameter Configuration	549
Configure IMDSv2 Required Mode in Threat Defense Virtual Clustering by Updating Stack	550
Deploy the Cluster in AWS Manually	551
Create the Day0 Configuration for AWS	551
Deploy Cluster Nodes	555
Configure Target Failover for Secure Firewall Threat Defense Virtual Clustering with GWLB in AWS	556
Enable Target Failover for Secure Firewall Threat Defense Virtual Clustering in AWS	557
Deploy the Cluster in Azure	558
Sample Topology for GWLB-based Cluster Deployment	558
Azure Gateway Load Balancer and Paired Proxy	559
End-to-End Process for Deploying Threat Defense Virtual Cluster in Azure with GWLB	560
Templates	562
Prerequisites	562
Deploy Cluster on Azure with GWLB Using an Azure Resource Manager Template	563
Sample Topology for NLB-based Cluster Deployment	566
End-to-End Process for Deploying Threat Defense Virtual Cluster in Azure with NLB	566
Templates	568
Prerequisites	569
Deploy Cluster on Azure with NLB Using an Azure Resource Manager Template	569
Deploy the Cluster in Azure Manually	571
Create the Day0 Configuration for Azure	571
Deploy Cluster Nodes Manually - GWLB-based Deployment	576
Deploy Cluster Nodes Manually - NLB-based Deployment	576
Troubleshooting Cluster Deployment in Azure	577

Deploy the Cluster in GCP	578
Sample Topology	578
End-to-End Process for Deploying Threat Defense Virtual Cluster in GCP	579
Templates	580
Deploy the Instance Group in GCP Using an Instance Template	580
Deploy the Cluster in GCP Manually	582
Create the Day0 Configuration for GCP	582
Deploy Cluster Nodes Manually	584
Allow Health Checks for GCP Network Load Balancers	585
Add the Cluster to the Management Center (Manual Deployment)	586
Configure Cluster Health Monitor Settings	593
Manage Cluster Nodes	597
Disable Clustering	597
Rejoin the Cluster	598
Reconcile Cluster Nodes	598
Unregister the Cluster or Nodes and Register to a New Management Center	599
Monitoring the Cluster	600
Cluster Health Monitor Dashboard	603
Viewing Cluster Health	604
Cluster Metrics	605
Troubleshooting the Cluster	606
Perform a Ping on the Cluster Control Link	607
Upgrading the Cluster	608
Reference for Clustering	609
Threat Defense Features and Clustering	609
Unsupported Features and Clustering	609
Centralized Features for Clustering	610
Cisco Trustsec and Clustering	610
Connection Settings and Clustering	610
Dynamic Routing and Clustering	611
FTP and Clustering	611
NAT and Clustering	612
SIP Inspection and Clustering	613
SNMP and Clustering	613

Syslog and Clustering	613
VPN and Clustering	613
Performance Scaling Factor	614
Control Node Election	614
High Availability within the Cluster	615
Node Health Monitoring	615
Interface Monitoring	615
Status After Failure	615
Rejoining the Cluster	615
Data Path Connection State Replication	616
How the Cluster Manages Connections	616
Connection Roles	616
New Connection Ownership	618
Sample Data Flow for TCP	618
Sample Data Flow for ICMP and UDP	619
History for Threat Defense Virtual Clustering in the Public Cloud	620

CHAPTER 13
Clustering for the Firepower 4100/9300 623

About Clustering on the Firepower 4100/9300 Chassis	623
Bootstrap Configuration	624
Cluster Members	624
Cluster Control Link	624
Size the Cluster Control Link	625
Cluster Control Link Redundancy	625
Cluster Control Link Reliability for Inter-Chassis Clustering	626
Cluster Control Link Network	626
Management Network	626
Management Interface	626
Cluster Interfaces	626
Spanned EtherChannels	626
Connecting to a Redundant Switch System	627
Configuration Replication	627
Licenses for Clustering	627
Requirements and Prerequisites for Clustering	628

Clustering Guidelines and Limitations	631
Configure Clustering	635
FXOS: Add a Threat Defense Cluster	635
Create a Threat Defense Cluster	635
Add More Cluster Nodes	646
Management Center: Add a Cluster	649
Management Center: Configure Cluster, Data Interfaces	655
Management Center: Configure Cluster Health Monitor Settings	657
FXOS: Remove a Cluster Node	661
Management Center: Manage Cluster Members	663
Add a New Cluster Member	663
Replace a Cluster Member	664
Deactivate a Member	665
Rejoin the Cluster	666
Unregister a Data Node	666
Change the Control Unit	667
Reconcile Cluster Members	668
Management Center: Monitoring the Cluster	668
Cluster Health Monitor Dashboard	670
Viewing Cluster Health	671
Cluster Metrics	673
Management Center: Troubleshooting the Cluster	673
Perform a Ping on the Cluster Control Link	674
Examples for Clustering	676
Firewall on a Stick	676
Traffic Segregation	677
Reference for Clustering	677
Threat Defense Features and Clustering	677
Unsupported Features with Clustering	677
Centralized Features for Clustering	678
Connection Settings	679
Dynamic Routing and Clustering	679
FTP and Clustering	680
Multicast Routing and Clustering	680

- NAT and Clustering 680
- SIP Inspection and Clustering 681
- SNMP and Clustering 681
- Syslog and Clustering 682
- TLS/SSL Connections and Clustering 682
- Cisco TrustSec and Clustering 682
- VPN and Clustering 682
- Performance Scaling Factor 682
- Control Unit Election 682
- High Availability Within the Cluster 683
 - Chassis-Application Monitoring 683
 - Unit Health Monitoring 683
 - Interface Monitoring 684
 - Decorator Application Monitoring 684
 - Status After Failure 684
 - Rejoining the Cluster 684
 - Data Path Connection State Replication 685
- How the Cluster Manages Connections 686
 - Connection Roles 686
 - New Connection Ownership 687
 - Sample Data Flow for TCP 687
 - Sample Data Flow for ICMP and UDP 688
- History for Clustering 689

PART III

Interfaces and Device Settings 695

CHAPTER 14

Interface Overview 697

- Management Interface 697
 - Management Interface 697
 - Diagnostic Interface 698
- Interface Mode and Types 698
- Security Zones and Interface Groups 700
- Auto-MDI/MDIX Feature 701
- Default Settings for Interfaces 702

Create Security Zone and Interface Group Objects	702
Enable the Physical Interface and Configure Ethernet Settings	703
Configure EtherChannel Interfaces	705
About EtherChannels	706
About EtherChannels	706
Guidelines for EtherChannels	709
Configure an EtherChannel	710
Sync Interface Changes with the Management Center	713
Manage the Network Module for the Secure Firewall 3100/4200	716
Configure Breakout Ports	717
Add a Network Module	720
Hot Swap the Network Module	722
Replace the Network Module with a Different Type	724
Remove the Network Module	728
Merge the Management and Diagnostic Interfaces	730
Unmerge the Management Interface	736
History for Interfaces	737

CHAPTER 15
Regular Firewall Interfaces 741

Requirements and Prerequisites for Regular Firewall Interfaces	741
Configure Firepower 1010 Switch Ports	741
About Firepower 1010 Switch Ports	742
Understanding Switch Ports and Interfaces	742
Auto-MDI/MDIX Feature	742
Guidelines and Limitations for Switch Ports	743
Configure Switch Ports and Power Over Ethernet	744
Enable or Disable Switch Port Mode	744
Configure a VLAN Interface	745
Configure Switch Ports as Access Ports	747
Configure Switch Ports as Trunk Ports	749
Configure Power Over Ethernet	751
Configure Loopback Interfaces	752
About Loopback Interfaces	752
Guidelines and Limitations for Loopback Interfaces	753

Configure a Loopback Interface	753
Rate-Limit Traffic to the Loopback Interface	754
Configure VLAN Subinterfaces and 802.1Q Trunking	758
Guidelines and Limitations for VLAN Subinterfaces	758
Maximum Number of VLAN Subinterfaces by Device Model	759
Add a Subinterface	759
Configure VXLAN Interfaces	761
About VXLAN Interfaces	761
Encapsulation	761
VXLAN Tunnel Endpoint	761
VTEP Source Interface	762
VNI Interfaces	762
VXLAN Packet Processing	763
Peer VTEPs	763
VXLAN Use Cases	764
Requirements and Prerequisites for VXLAN Interfaces	769
Guidelines for VXLAN Interfaces	769
Configure VXLAN or Geneve Interfaces	770
Configure VXLAN Interfaces	770
Configure Geneve Interfaces	773
Allow Gateway Load Balancer Health Checks	775
Configure Routed and Transparent Mode Interfaces	775
About Routed and Transparent Mode Interfaces	775
Dual IP Stack (IPv4 and IPv6)	776
31-Bit Subnet Mask	776
Guidelines and Limitations for Routed and Transparent Mode Interfaces	777
Configure Routed Mode Interfaces	778
Configure Bridge Group Interfaces	783
Configure General Bridge Group Member Interface Parameters	783
Configure the Bridge Virtual Interface (BVI)	785
Configure IPv6 Addressing	787
About IPv6	787
Configure the IPv6 Prefix Delegation Client	788
Configure a Global IPv6 Address	791

Configure IPv6 Neighbor Discovery	796
Configure Advanced Interface Settings	798
About Advanced Interface Configuration	798
About MAC Addresses	798
About the MTU	799
About the TCP MSS	800
ARP Inspection for Bridge Group Traffic	802
MAC Address Table	802
Default Settings	802
Guidelines for ARP Inspection and the MAC Address Table	803
Configure the MTU	803
Configure the MAC Address	804
Add a Static ARP Entry	805
Add a Static MAC Address and Disable MAC Learning for a Bridge Group	806
Set Security Configuration Parameters	806
History for Regular Firewall Interfaces for Secure Firewall Threat Defense	808

CHAPTER 16**Inline Sets and Passive Interfaces 815**

About IPS Interfaces	815
IPS Interface Types	815
About Hardware Bypass for Inline Sets	816
Hardware Bypass Triggers	816
Hardware Bypass Switchover	817
Snort Fail Open vs. Hardware Bypass	817
Hardware Bypass Status	817
Requirements and Prerequisites for Inline Sets	817
Guidelines for Inline Sets and Passive Interfaces	819
Configure a Passive Interface	821
Configure an Inline Set	822
History for Inline Sets and Passive Interfaces	825

CHAPTER 17**DHCP and DDNS 827**

About DHCP and DDNS Services	827
About the DHCPv4 Server	827

DHCP Options	827
About the DHCPv6 Stateless Server	828
About the DHCP Relay Agent	828
Requirements and Prerequisites for DHCP and DDNS	829
Guidelines for DHCP and DDNS Services	829
Configure the DHCPv4 Server	830
Configure the DHCPv6 Stateless Server	832
Create the DHCP IPv6 Pool	832
Enable the DHCPv6 Stateless Server	835
Configure the DHCP Relay Agent	836
Configure Dynamic DNS	837
History for DHCP and DDNS	843

CHAPTER 18
SNMP for the Firepower 1000 845

About SNMP for the Firepower 1000	845
Enabling SNMP and Configuring SNMP Properties for Firepower 1000	845
Creating an SNMP Trap for Firepower 1000	847
Creating an SNMP User for Firepower 1000	848

CHAPTER 19
Quality of Service 851

Introduction to QoS	851
About QoS Policies	851
Requirements and Prerequisites for QoS	852
Rate Limiting with QoS Policies	852
Creating a QoS Policy	853
Setting Target Devices for a QoS Policy	854
Configuring QoS Rules	854
QoS Rule Components	855
QoS Rule Conditions	856
Interface Rule Conditions	856
Network Rule Conditions	857
User Rule Conditions	857
Application Rule Conditions	857
Port Rule Conditions	858

URL Rule Conditions	860
Custom SGT Rule Conditions	860
ISE SGT vs Custom SGT Rule Conditions	860
Autotransition from Custom SGTs to ISE SGTs	861
History for QoS	861

CHAPTER 20**Platform Settings 863**

Introduction to Platform Settings	864
Requirements and Prerequisites for Platform Settings Policies	864
Manage Platform Settings Policies	864
Chassis Platform Settings	865
ARP Inspection	865
Banner	866
DNS	867
External Authentication	870
Enable Virtual-Router-Aware Interface for External Authentication of Platform	875
Fragment Settings	876
HTTP Access	877
ICMP Access	878
NetFlow	879
Add Collector in NetFlow	880
Add Traffic Class to NetFlow	881
SSH Access	881
SMTP Server	883
SNMP	884
About SNMP	885
SNMP Terminology	885
MIBs and Traps	886
Supported Tables and Objects in MIBs	886
Add SNMPv3 Users	890
Add SNMP Hosts	893
Configure SNMP Traps	894
Configure SSL Settings	896
About SSL Settings	897

Syslog	900
About Syslog	900
Severity Levels	901
Syslog Message Filtering	902
Syslog Message Classes	902
Guidelines for Logging	905
Configure Syslog Logging for Threat Defense Devices	906
Threat Defense Platform Settings That Apply to Security Event Syslog Messages	907
Enable Logging and Configure Basic Settings	908
Enable Logging Destinations	909
Send Syslog Messages to an E-mail Address	910
Create a Custom Event List	911
Limit the Rate of Syslog Message Generation	912
Configure Syslog Settings	913
Configure a Syslog Server	914
Timeouts	917
Time Synchronization	918
Time Zone	920
UCAPL/CC Compliance	920
Performance Profile	921
History for Platform Settings	922

CHAPTER 21

Network Address Translation	929
Why Use NAT?	929
NAT Basics	930
NAT Terminology	930
NAT Types	930
NAT in Routed and Transparent Mode	931
NAT in Routed Mode	931
NAT in Transparent Mode or Within a Bridge Group	932
Auto NAT and Manual NAT	933
Auto NAT	933
Manual NAT	933
Comparing Auto NAT and Manual NAT	934

NAT Rule Order	934
NAT Interfaces	936
NAT Exemption	937
Configuring Routing for NAT	937
Addresses on the Same Network as the Mapped Interface	937
Addresses on a Unique Network	938
The Same Address as the Real Address (Identity NAT)	938
Requirements and Prerequisites for NAT Policies	938
Guidelines for NAT	939
Firewall Mode Guidelines for NAT	939
IPv6 NAT Guidelines	939
IPv6 NAT Best Practices	940
NAT Support for Inspected Protocols	940
FQDN Destination Guidelines	942
Additional Guidelines for NAT	943
Manage NAT Policies	945
Creating NAT Policies	945
Configuring NAT Policy Targets	946
Configure NAT for Threat Defense	946
Customizing NAT Rules for Multiple Devices	948
Searching and Filtering the NAT Rule Table	950
Enabling, Disabling, or Deleting Multiple Rules	951
Dynamic NAT	952
About Dynamic NAT	952
Dynamic NAT Disadvantages and Advantages	953
Configure Dynamic Auto NAT	953
Configure Dynamic Manual NAT	955
Dynamic PAT	957
About Dynamic PAT	957
Dynamic PAT Disadvantages and Advantages	958
PAT Pool Object Guidelines	958
Configure Dynamic Auto PAT	959
Configure Dynamic Manual PAT	961
Configure PAT with Port Block Allocation	964

Static NAT	966
About Static NAT	967
Configure Static Auto NAT	970
Configure Static Manual NAT	972
Identity NAT	975
Configure Identity Auto NAT	975
Configure Identity Manual NAT	977
NAT Rule Properties for Threat Defense	979
Interface Objects NAT Properties	980
Translation Properties for Auto NAT	980
Translation Properties for Manual NAT	981
PAT Pool NAT Properties	983
Advanced NAT Properties	984
Translating IPv6 Networks	985
NAT64/46: Translating IPv6 Addresses to IPv4	985
NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet	986
NAT64/46 Example: Inside IPv6 Network with Outside IPv4 Internet and DNS Translation	988
NAT66: Translating IPv6 Addresses to Different IPv6 Addresses	992
NAT66 Example, Static Translation between Networks	992
NAT66 Example, Simple IPv6 Interface PAT	995
Monitoring NAT	998
Examples for NAT	999
Providing Access to an Inside Web Server (Static Auto NAT)	999
Dynamic Auto NAT for Inside Hosts and Static NAT for an Outside Web Server	1002
Inside Load Balancer with Multiple Mapped Addresses (Static Auto NAT, One-to-Many)	1006
Single Address for FTP, HTTP, and SMTP (Static Auto NAT-with-Port-Translation)	1009
Different Translation Depending on the Destination (Dynamic Manual PAT)	1014
Different Translation Depending on the Destination Address and Port (Dynamic Manual PAT)	1019
NAT and Site-to-Site VPN	1024
Rewriting DNS Queries and Responses Using NAT	1028
DNS64 Reply Modification	1029
DNS Reply Modification, DNS Server on Outside	1036
DNS Reply Modification, DNS Server on Host Network	1039
History for Threat Defense NAT	1042

CHAPTER 22	Alarms for the Cisco ISA 3000	1045
	About Alarms	1045
	Alarm Input Interfaces	1046
	Alarm Output Interface	1046
	Syslog Alarms	1047
	SNMP Alarms	1047
	Defaults for Alarms	1047
	Requirements and Prerequisites for Alarms	1048
	Configure the Alarms for the ISA 3000	1048
	Configure Alarm Input Contacts	1048
	Configure Power Supply Alarms	1051
	Configure Temperature Alarms	1053
	Monitoring Alarms	1056
	Monitoring Alarm Status	1056
	Monitoring Syslog Messages for Alarms	1056
	Turning Off the External Alarm	1057
	History for Alarms	1057

PART IV	Routing	1059
----------------	----------------	-------------

CHAPTER 23	Static and Default Routes	1061
	About Static and Default Routes	1061
	Default Route	1061
	Static Routes	1062
	Route to null0 Interface to Drop Unwanted Traffic	1062
	Route Priorities	1062
	Transparent Firewall Mode and Bridge Group Routes	1062
	Static Route Tracking	1063
	Requirements and Prerequisites for Static Routes	1063
	Guidelines for Static and Default Routes	1064
	Add a Static Route	1064
	Reference for Routing	1066
	Path Determination	1066

Supported Route Types	1066
Static Versus Dynamic	1066
Single-Path Versus Multipath	1067
Flat Versus Hierarchical	1067
Link-State Versus Distance Vector	1067
Supported Internet Protocols for Routing	1067
Routing Table	1068
How the Routing Table Is Populated	1068
How Forwarding Decisions Are Made	1070
Dynamic Routing and High Availability	1071
Dynamic Routing in Clustering	1071
Dynamic Routing in Individual Interface Mode	1072
Routing Table for Management Traffic	1073
Equal-Cost Multi-Path (ECMP) Routing	1074
About Route Maps	1075
Permit and Deny Clauses	1075
Match and Set Clause Values	1075
<hr/>	
CHAPTER 24	Virtual Routers 1077
About Virtual Routers and Virtual Routing and Forwarding (VRF)	1077
About Virtual Routers and Dynamic VTI	1078
How to Configure a Virtual Router with Dynamic VTI	1078
Applications of Virtual Routers	1078
Global and User-Defined Virtual Routers	1079
Configuring Policies to be Virtual-Router-Aware	1080
Interconnecting Virtual Routers	1080
Overlapping IP Addresses	1082
Configuring SNMP on User-Defined Virtual Routers	1083
Maximum Number of Virtual Routers By Device Model	1083
Requirements and Prerequisites for Virtual Routers	1084
Guidelines and Limitations for Virtual Routers	1085
Modifications to the Management Center Web Interface - Routing Page	1087
Manage Virtual Routers	1087
Create a Virtual Router	1088

Configure a Virtual Router	1088
Modify a Virtual Router	1090
Remove Virtual Routers	1090
Monitoring Virtual Routers	1091
Configuration Examples for Virtual Routers	1091
How to Route to a Distant Server through Virtual Routers	1091
How to Provide Internet Access with Overlapping Address Spaces	1096
How to Allow RA VPN Access to Internal Networks in Virtual Routing	1103
How to Secure Traffic from Networks in Multiple Virtual Routers over a Site-to-Site VPN	1106
How to Secure Traffic from Networks with Multiple Virtual Routers over a Site-to-Site VPN with Dynamic VTI	1109
How to Route Traffic between Two Overlapping Network Host in Virtual Routing	1111
How to Manage Overlapping Segments in Routed Firewall Mode with BVI Interfaces	1114
How to Configure User Authentication with Overlapping Networks	1118
How to Interconnect Virtual Routers using BGP	1124
History for Virtual Routers	1130

CHAPTER 25**ECMP 1133**

About ECMP	1133
Guidelines and Limitations for ECMP	1133
Manage ECMP Page	1134
Create an ECMP Zone	1135
Configure an Equal Cost Static Route	1136
Modify an ECMP Zone	1137
Remove an ECMP Zone	1137
Configuration Example for ECMP	1138
History for ECMP in Secure Firewall Threat Defense	1141

CHAPTER 26**Bidirectional Forwarding Detection Routing 1143**

About BFD Routing	1143
Guidelines for BFD Routing	1143
Configure BFD	1145
Configure BFD Policies	1145
Configure Single-Hop BFD Policies	1146

	Configure Multi-Hop BFD Policies	1146
	History for BFD Routing	1147
CHAPTER 27	OSPF	1149
	OSPF	1149
	About OSPF	1149
	OSPF Support for Fast Hello Packets	1151
	Prerequisites for OSPF Support for Fast Hello Packets	1151
	OSPF Hello Interval and Dead Interval	1151
	OSPF Fast Hello Packets	1151
	Benefits of OSPF Fast Hello Packets	1151
	Implementation Differences Between OSPFv2 and OSPFv3	1152
	Requirements and Prerequisites for OSPF	1152
	Guidelines for OSPF	1152
	Configure OSPFv2	1155
	Configure OSPF Areas, Ranges, and Virtual Links	1155
	Configure OSPF Redistribution	1158
	Configure OSPF Inter-Area Filtering	1159
	Configure OSPF Filter Rules	1160
	Configure OSPF Summary Addresses	1161
	Configure OSPF Interfaces and Neighbors	1162
	Configure OSPF Advanced Properties	1164
	Configure OSPFv3	1167
	Configure OSPFv3 Areas, Route Summaries, and Virtual Links	1167
	Configure OSPFv3 Redistribution	1169
	Configure OSPFv3 Summary Prefixes	1170
	Configure OSPFv3 Interfaces, Authentication, and Neighbors	1171
	Configure OSPFv3 Advanced Properties	1173
	History for OSPF	1176
CHAPTER 28	EIGRP	1177
	About EIGRP Routing	1177
	Requirements and Prerequisites for EIGRP	1178
	Guidelines and Limitations of EIGRP Routing	1178

Configure EIGRP	1180
Configure EIGRP Settings	1180
Configure EIGRP Neighbors Settings	1181
Configure EIGRP Filter Rules Settings	1181
Configure EIGRP Redistribution Settings	1182
Configure EIGRP Summary Address Settings	1183
Configure EIGRP Interfaces Settings	1183
Configure EIGRP Advanced Settings	1184
History for EIGRP	1186
<hr/>	
CHAPTER 29	BGP 1187
About BGP	1187
Routing Table Changes	1187
When to Use BGP	1188
BGP Path Selection	1189
BGP Multipath	1189
Requirements and Prerequisites for BGP	1190
Guidelines for BGP	1190
Configure BGP	1191
Configure BGP Basic Settings	1192
Configure BGP General Settings	1194
Configure BGP Neighbor Settings	1195
Configure BGP Aggregate Address Settings	1199
Configure BGPv4 Filtering Settings	1200
Configure BGP Network Settings	1200
Configure BGP Redistribution Settings	1201
Configure BGP Route Injection Settings	1202
Configure BGP Route Import/Export Settings	1202
History for BGP in Secure Firewall Threat Defense	1204

CHAPTER 30 **RIP 1207**

About RIP	1207
Routing Update Process	1207
RIP Routing Metric	1208

RIP Stability Features	1208
RIP Timers	1208
Requirements and Prerequisites for RIP	1209
Guidelines for RIP	1209
Configure RIP	1210

CHAPTER 31
Multicast 1213

About Multicast Routing	1213
IGMP Protocol	1213
Stub Multicast Routing	1214
PIM Multicast Routing	1214
PIM Source Specific Multicast Support	1215
Multicast Bidirectional PIM	1215
PIM Bootstrap Router (BSR)	1216
PIM Bootstrap Router (BSR) Terminology	1216
Multicast Group Concept	1217
Multicast Addresses	1217
Clustering	1217
Requirements and Prerequisites for Multicast Routing	1217
Guidelines for Multicast Routing	1217
Configure IGMP Features	1218
Enable Multicast Routing	1219
Configure IGMP Protocol	1219
Configure IGMP Access Groups	1221
Configure IGMP Static Groups	1221
Configure IGMP Join Groups	1222
Configure PIM Features	1223
Configure PIM Protocol	1223
Configure PIM Neighbor Filters	1224
Configure PIM Bidirectional Neighbor Filters	1225
Configure PIM Rendezvous Points	1226
Configure PIM Route Trees	1226
Configure PIM Request Filters	1227
Configure the Secure Firewall Threat Defense Device as a Candidate Bootstrap Router	1228

- Configure Multicast Routes 1229
- Configure Multicast Boundary Filters 1229

CHAPTER 32**Policy Based Routing 1231**

- About Policy Based Routing 1231
- Guidelines and Limitations for Policy Based Routing 1233
- Path Monitoring 1234
 - Configure Path Monitoring Settings 1236
- Configure Policy-Based Routing Policy 1237
 - Add Path Monitoring Dashboard 1240
- Configuration Example for Policy Based Routing 1240
- Configuration Example for PBR with Path Monitoring 1245
- History for Policy Based Routing 1247

PART V**Objects and Certificates 1249**

CHAPTER 33**Object Management 1251**

- Introduction to Objects 1252
- The Object Manager 1254
 - Importing Objects 1254
 - Editing Objects 1257
 - Viewing Objects and Their Usage 1258
 - Filtering Objects or Object Groups 1259
- Object Groups 1259
 - Grouping Reusable Objects 1259
- Object Overrides 1260
 - Managing Object Overrides 1262
 - Allowing Object Overrides 1262
 - Adding Object Overrides 1262
 - Editing Object Overrides 1263
- AAA Server 1263
 - Add a RADIUS Server Group 1263
 - RADIUS Server Group Options 1264
 - RADIUS Server Options 1265

Add a Single Sign-on Server	1267
Access List	1268
Configure Extended ACL Objects	1269
Configure Standard ACL Objects	1271
Address Pools	1272
Application Filters	1273
AS Path	1273
BFD Template	1274
Cipher Suite List	1275
Creating Cipher Suite Lists	1275
Community List	1276
Extended Community	1277
DHCP IPv6 Pool	1279
Distinguished Name	1279
Creating Distinguished Name Objects	1281
DNS Server Group	1281
Creating DNS Server Group Objects	1282
External Attributes	1282
Dynamic Objects	1282
Create Dynamic Objects for the First Time	1283
Create Dynamic Objects with the Embedded Cisco Secure Dynamic Attributes Connector	1284
Create Dynamic Objects with Cisco Defense Orchestrator	1285
Create Dynamic Objects with the On-Premises Cisco Secure Dynamic Attributes Connector	1287
Work With Dynamic Objects	1288
Dynamic Object Mappings	1288
About API-Created Dynamic Objects	1288
Security Group Tag	1289
Creating Security Group Tag Objects	1290
File List	1290
Source Files for File Lists	1291
Adding Individual SHA-256 Values to File Lists	1291
Uploading Individual Files to File Lists	1292
Uploading Source Files to File Lists	1293
Editing SHA-256 Values in File Lists	1294

Downloading Source Files from File Lists	1294
FlexConfig	1295
Geolocation	1295
Creating Geolocation Objects	1296
Interface	1296
Key Chain	1296
Creating Key Chain Objects	1297
Network	1298
Network Wildcard Mask	1300
Creating Network Objects	1301
Importing Network Objects	1301
PKI	1301
Internal Certificate Authority Objects	1302
CA Certificate and Private Key Import	1303
Importing a CA Certificate and Private Key	1303
Generating a New CA Certificate and Private Key	1304
New Signed Certificates	1304
Creating an Unsigned CA Certificate and CSR	1304
Uploading a Signed Certificate Issued in Response to a CSR	1305
CA Certificate and Private Key Downloads	1305
Downloading a CA Certificate and Private Key	1306
Trusted Certificate Authority Objects	1306
Trusted CA Object	1306
Adding a Trusted CA Object	1307
Certificate Revocation Lists in Trusted CA Objects	1307
Adding a Certificate Revocation List to a Trusted CA Object	1308
External Certificate Objects	1308
Adding External Certificate Objects	1308
Internal Certificate Objects	1309
Adding Internal Certificate Objects	1310
Certificate Enrollment Objects	1310
Adding Certificate Enrollment Objects	1311
Add Certificate Enrollment	1313
Certificate Enrollment Object EST Options	1313

Certificate Enrollment Object SCEP Options	1314
Certificate Enrollment Object Certificate Parameters	1315
Certificate Enrollment Object Key Options	1316
Certificate Enrollment Object Revocation Options	1318
Policy List	1318
Port	1320
Creating Port Objects	1321
Importing Port Objects	1321
Prefix List	1321
Configure IPv6 Prefix List	1321
Configure IPv4 Prefix List	1322
Route Map	1323
Security Intelligence	1327
How to Modify Security Intelligence Objects	1328
Global and Domain Security Intelligence Lists	1328
Security Intelligence Lists and Multitenancy	1329
Add Entries to Global Security Intelligence Lists	1330
Delete Entries from Global Security Intelligence Lists	1331
List and Feed Updates for Security Intelligence	1332
Changing the Update Frequency for Security Intelligence Feeds	1332
Custom Security Intelligence Lists and Feeds	1332
Custom Lists and Feeds: Requirements	1332
URL Lists and Feeds: URL Syntax and Matching Criteria	1333
Custom Security Intelligence Feeds	1334
Custom Security Intelligence Lists	1336
Sinkhole	1338
Creating Sinkhole Objects	1338
SLA Monitor	1338
Time Range	1340
Creating Time Range Objects	1340
Time Zone	1341
Tunnel Zone	1342
URL	1342
Creating URL Objects	1343

Variable Set	1343
Variable Sets in Intrusion Policies	1345
Variables	1345
Predefined Default Variables	1346
Network Variables	1348
Port Variables	1349
Advanced Variables	1350
Variable Reset	1350
Adding Variables to Sets	1351
Nesting Variables	1353
Managing Variable Sets	1354
Creating Variable Sets	1355
Managing Variables	1355
Adding Variables	1356
Editing Variables	1357
VLAN Tag	1358
Creating VLAN Tag Objects	1358
VPN	1359
Certificate Map Objects	1359
Secure Client Custom Attributes Objects	1360
Add Secure Client Custom Attributes Objects	1361
Add Custom Attributes to a Group Policy	1362
Threat Defense Group Policy Objects	1362
Configure Group Policy Objects	1363
Group Policy General Options	1364
Group Policy Secure Client Options	1366
Group Policy Advanced Options	1369
Threat Defense IPsec Proposals	1370
Configure IKEv1 IPsec Proposal Objects	1370
Configure IKEv2 IPsec Proposal Objects	1371
Threat Defense IKE Policies	1372
Configure IKEv1 Policy Objects	1372
Configure IKEv2 Policy Objects	1373
Secure Client Customization	1375

File Objects	1375
History for Object Management	1377

CHAPTER 34**Certificates 1381**

Requirements and Prerequisites for Certificates	1381
Secure Firewall Threat Defense VPN Certificate Guidelines and Limitations	1381
Managing Threat Defense Certificates	1382
Automatically Update CA Bundles	1383
Installing a Certificate Using Self-Signed Enrollment	1385
Installing a Certificate using EST Enrollment	1386
Installing a Certificate Using SCEP Enrollment	1387
Installing a Certificate Using Manual Enrollment	1387
Installing a Certificate Using a PKCS12 File	1388
Troubleshooting Threat Defense Certificates	1389
History for Certificates	1390

PART VI**VPN 1391****CHAPTER 35****VPN Overview 1393**

VPN Types	1393
VPN Basics	1394
Internet Key Exchange (IKE)	1394
IPsec	1395
VPN Packet Flow	1396
IPsec Flow Offload	1396
VPN Licensing	1397
How Secure Should a VPN Connection Be?	1397
Complying with Security Certification Requirements	1398
Deciding Which Encryption Algorithm to Use	1398
Deciding Which Hash Algorithms to Use	1399
Deciding Which Diffie-Hellman Modulus Group to Use	1399
Deciding Which Authentication Method to Use	1400
Pre-shared Keys	1400
PKI Infrastructure and Digital Certificates	1400

Removed or Deprecated Hash Algorithms, Encryption Algorithms, and Diffie-Hellman Modulus Groups	1402
VPN Topology Options	1402
Point-to-Point VPN Topology	1403
Hub and Spoke VPN Topology	1403
Full Mesh VPN Topology	1404
Implicit Topologies	1405

CHAPTER 36
Site-to-Site VPNs 1407

About Site-to-Site VPN	1407
Secure Firewall Threat Defense Site-to-site VPN Guidelines and Limitations	1409
Types of Site-to-Site VPN Topologies	1410
Requirements and Prerequisites for Site-to-Site VPN	1410
Manage Site-to-Site VPNs	1411
Configure a Policy-based Site-to-Site VPN	1412
Threat Defense VPN Endpoint Options	1413
Threat Defense VPN IKE Options	1417
Threat Defense VPN IPsec Options	1419
Threat Defense Advanced Site-to-site VPN Deployment Options	1421
Threat Defense VPN Advanced IKE Options	1421
Threat Defense VPN Advanced IPsec Options	1423
Threat Defense Advanced Site-to-site VPN Tunnel Options	1423
About Virtual Tunnel Interfaces	1424
Static VTI	1425
Dynamic VTI	1426
Guidelines and Limitations for Virtual Tunnel Interfaces	1428
Add a VTI Interface	1432
Create a Route-based Site-to-Site VPN	1433
Configure Endpoints for a Point to Point Topology	1434
Advanced Configurations for a Point to Point Topology in a Route-based VPN	1436
Configure Endpoints for a Hub and Spoke Topology	1437
Advanced Configurations for Hub and Spokes in a Route-based VPN	1439
Configure Multiple Hubs in a Route-based VPN	1440
Configure Routing for Multiple Hubs in a Route-based VPN	1442

Verify the Multiple Hubs Configuration in a Route-based VPN	1443
Route Traffic Through a Backup VTI Tunnel	1443
Configure Dynamic VTI for a Route-based Site-to-Site VPN	1445
How to Configure a Virtual Router with Dynamic VTI	1446
Configure Routing and AC Policies for VTI	1446
View Virtual Tunnel Information	1449
Deploy a SASE Tunnel on Umbrella	1449
Guidelines and Limitations for Configuring SASE Tunnels on Umbrella	1450
How to Deploy a SASE Tunnel on Umbrella	1451
Prerequisites for Configuring Umbrella SASE Tunnels	1452
Map Management Center Umbrella Parameters and Cisco Umbrella API Keys	1452
Configure a SASE Tunnel for Umbrella	1454
View SASE Tunnel Status	1455
Monitoring the Site-to-Site VPNs	1457
History for Site-to-Site VPN	1463
<hr/>	
CHAPTER 37	Remote Access VPN 1467
Remote Access VPN Overview	1467
Remote Access VPN Features	1468
Secure Client Components	1470
Remote Access VPN Authentication	1470
Understanding Policy Enforcement of Permissions and Attributes	1472
Understanding AAA Server Connectivity	1472
License Requirements for Remote Access VPN	1473
Requirements and Prerequisites for Remote Access VPN	1473
Remote Access VPN Guidelines and Limitations	1474
Configuring a New Remote Access VPN Connection	1477
Prerequisites for Configuring Remote Access VPN	1477
Create a New Remote Access VPN Policy	1478
Update the Access Control Policy on the Secure Firewall Threat Defense Device	1480
(Optional) Configure NAT Exemption	1481
Configure DNS	1482
Add Secure Client Profile XML File	1482
(Optional) Configure Split Tunneling	1483

(Optional) Configure Dynamic Split Tunneling	1484
Verify Dynamic Split Tunneling Configuration	1485
Verify the Configuration	1485
Create a Copy of an Existing Remote Access VPN Policy	1485
Set Target Devices for a Remote Access VPN Policy	1486
Associate Local Realm with Remote Access VPN Policy	1487
Additional Remote Access VPN Configurations	1487
Configure Connection Profile Settings	1487
Configure IP Addresses for VPN Clients	1488
Configure AAA Settings for Remote Access VPN	1489
Create or Update Aliases for a Connection Profile	1505
Configure Access Interfaces for Remote Access VPN	1505
Configure Advanced Options for Remote Access VPN	1507
Cisco Secure Client Image	1507
Remote Access VPN Address Assignment Policy	1509
Configure Certificate to Connection Profile Mapping	1510
Configure Group Policies	1511
Configuring LDAP Attribute Mapping	1511
Configuring VPN Load Balancing	1513
Configure IPsec Settings	1516
Customize Cisco Secure Client	1521
Configure Secure Client Management VPN Tunnel	1531
Requirements and Prerequisites for Secure Client Management VPN Tunnel	1532
Limitations of Secure Client Management VPN Tunnel	1532
Configuring Secure Client Management VPN Tunnel on Threat Defense	1533
Multiple Certificate Authentication	1535
Guidelines and Limitations of Multiple Certificate Authentication	1535
Configuring Multiple Certificate Authentication	1535
Customizing Remote Access VPN AAA Settings	1536
Authenticate VPN Users via Client Certificates	1536
Configure VPN User Authentication via Client Certificate and AAA Server	1538
Manage Password Changes over VPN Sessions	1540
Send Accounting Records to the RADIUS Server	1540
Delegating Group Policy Selection to Authorization Server	1541

Override the Selection of Group Policy or Other Attributes by the Authorization Server	1542
Deny VPN Access to a User Group	1543
Restrict Connection Profile Selection for a User Group	1544
Update the Secure Client Profile for Remote Access VPN Clients	1544
RADIUS Dynamic Authorization	1545
Configuring RADIUS Dynamic Authorization	1546
Two-Factor Authentication	1547
Configuring RSA Two-Factor Authentication	1547
Configuring Duo Two-Factor Authentication	1548
Secondary Authentication	1550
Configure Remote Access VPN Secondary Authentication	1550
Single Sign-On Authentication with SAML 2.0	1552
Guidelines and Limitations for SAML 2.0	1553
Configuring a SAML Single Sign-On Authentication	1554
Configuring SAML Authorization	1555
Advanced Secure Client Configurations	1557
Configure Secure Client Modules on a Threat Defense	1557
Types of Secure Client Modules	1557
Prerequisites for Configuring Secure Client Modules	1558
Guidelines for Configuring Secure Client Modules	1559
Install Secure Client Modules using a Threat Defense	1560
Configure a Remote Access VPN Group Policy with Secure Client Modules	1560
Verify Secure Client Modules Configuration	1561
Configure Application-Based (Per App VPN) Remote Access VPN on Mobile Devices	1562
Prerequisites and Licensing for Configuring Per App VPN Tunnels	1562
Determine the Application IDs for Mobile Applications	1563
Configure Application-Based VPN Tunnels	1563
Verify Per App Configuration	1565
Remote Access VPN Examples	1565
How to Limit Secure Client Bandwidth Per User	1565
How to Use VPN Identity for User-Id Based Access Control Rules	1566
Configure Threat Defense Multiple Certificate Authentication	1566
History for Remote Access VPNs	1570

CHAPTER 38	Dynamic Access Policies	1573
	About Secure Firewall Threat Defense Dynamic Access Policy	1573
	Hierarchy of Policy Enforcement of Permissions and Attributes in Threat Defense	1573
	Licensing for Dynamic Access Policies	1575
	Prerequisites for Dynamic Access Policy	1575
	Guidelines and Limitations for Dynamic Access Policies	1576
	Configure a Dynamic Access Policy (DAP)	1576
	Create a Dynamic Access Policy	1576
	Create a Dynamic Access Policy Record	1576
	Configure AAA Criteria Settings for DAP	1577
	Configure Endpoint Attribute Selection Criteria in DAP	1578
	Add an Anti-Malware Endpoint Attribute to a DAP	1579
	Add a Device Endpoint Attribute to a DAP	1579
	Add Secure Client Endpoint Attributes to a DAP	1580
	Add NAC Endpoint Attributes to a DAP	1580
	Add an Application Attribute to a DAP	1580
	Add a Personal Firewall Endpoint Attribute to a DAP	1581
	Add an Operating System Endpoint Attribute to a DAP	1581
	Add a Process Endpoint Attribute to a DAP	1581
	Add a Registry Endpoint Attribute to a DAP	1582
	Add a File Endpoint Attribute to a DAP	1582
	Add Certificate Authentication Attributes to a DAP	1582
	Configure Advanced Settings for DAP	1583
	Associate Dynamic Access Policy with Remote Access VPN	1583
	History for Dynamic Access Policy	1584
CHAPTER 39	VPN Monitoring and Troubleshooting	1585
	VPN Summary Dashboard	1585
	Viewing the VPN Summary Dashboard	1585
	Remote Access VPN Dashboard	1586
	SD-WAN Summary Dashboard	1587
	Prerequisites for Using SD-WAN Summary Dashboard	1588
	Monitor WAN Devices and Interfaces Using the SD-WAN Summary Dashboard	1590

Monitor Application Performance Metrics of WAN Interfaces Using the SD-WAN Summary Dashboard **1592**

VPN Session and User Information **1592**

 Viewing Remote Access VPN Active Sessions **1592**

 Viewing Remote Access VPN User Activity **1593**

Site to Site VPN Connection Event Monitoring **1593**

 View Site to Site VPN Connection Events **1593**

VPN Troubleshooting **1594**

 System Messages **1594**

 VPN System Logs **1594**

 Debug Commands **1594**

 debug aaa **1596**

 debug crypto **1597**

 debug ldap **1600**

 debug ssl **1600**

 debug webvpn **1600**

PART VII

Access Control 1603

CHAPTER 40

Access Control Overview 1605

Introduction to Access Control **1605**

Introduction to Rules **1606**

 Filtering Rules by Device **1606**

 Rule and Other Policy Warnings **1607**

Access Control Policy Default Action **1608**

Deep Inspection Using File and Intrusion Policies **1610**

 Access Control Traffic Handling with Intrusion and File Policies **1611**

 File and Intrusion Inspection Order **1612**

Access Control Policy Inheritance **1613**

Best Practices for Application Control **1614**

 Recommendations for Application Control **1614**

 Best Practices for Configuring Application Control **1617**

 Application Characteristics **1618**

 Application-Specific Notes and Limitations **1619**

Best Practices for Access Control Rules	1620
General Best Practices for Access Control	1620
Best Practices for Ordering Rules	1621
Rule Preemption	1622
Rule Actions and Rule Order	1622
Application Rule Order	1623
URL Rule Order	1624
Best Practices for Simplifying and Focusing Rules	1624
Maximum Number of Access Control Rules and Intrusion Policies	1625

CHAPTER 41**Access Control Policies 1627**

Access Control Policy Components	1627
System-Created Access Control Policies	1628
Requirements and Prerequisites for Access Control Policies	1628
Managing Access Control Policies	1629
Creating a Basic Access Control Policy	1630
Editing an Access Control Policy	1631
Locking an Access Control Policy	1633
Managing Access Control Policy Inheritance	1634
Choosing a Base Access Control Policy	1635
Inheriting Access Control Policy Settings from the Base Policy	1635
Locking Settings in Descendant Access Control Policies	1635
Requiring an Access Control Policy in a Domain	1636
Setting Target Devices for an Access Control Policy	1637
Logging Settings for Access Control Policies	1637
Access Control Policy Advanced Settings	1638
Associating Other Policies with Access Control	1643
Identifying and Fixing Anomalies with Policy Analyzer & Optimizer	1644
Viewing Rule Hit Counts	1645
Analyzing Rule Conflicts and Warnings	1647
Searching for Rules	1649
History for Access Control Policies	1650

CHAPTER 42**Access Control Rules 1653**

Introduction to Access Control Rules	1653
Access Control Rule Management	1655
Access Control Rule Components	1656
Access Control Rule Order	1657
Access Control Rule Actions	1658
Access Control Rule Monitor Action	1658
Access Control Rule Trust Action	1658
Access Control Rule Blocking Actions	1659
Access Control Rule Interactive Blocking Actions	1659
Access Control Rule Allow Action	1660
Requirements and Prerequisites for Access Control Rules	1661
Guidelines and Limitations for Access Control Rules	1662
Managing Access Control Rules	1663
Adding an Access Control Rule Category	1663
Create and Edit Access Control Rules	1663
Access Control Rule Conditions	1665
Enabling and Disabling Access Control Rules	1673
Copying Access Control Rules from One Access Control Policy to Another	1674
Moving Access Control Rules to a Prefilter Policy	1674
Positioning an Access Control Rule	1677
Adding Comments to an Access Control Rule	1677
Examples for Access Control Rules	1678
How to Control Access Using Security Zones	1678
How to Control Application Usage	1678
How to Block Threats	1680
How to Block QUIC Traffic	1682
History for Access Control Rules	1684

CHAPTER 43

Cisco Secure Dynamic Attributes Connector	1687
About the Cisco Secure Dynamic Attributes Connector	1687
How It Works	1689
History for the Cisco Secure Dynamic Attributes Connector	1690
System Requirements for the Cisco Secure Dynamic Attributes Connector	1691
Enable the Cisco Secure Dynamic Attributes Connector	1691

Configure Networks and Subnets for Docker Containers	1692
About the Dashboard	1694
Dashboard of an Unconfigured System	1695
Dashboard of a Configured System	1696
Add, Edit, or Delete Connectors	1697
Add, Edit, or Delete Dynamic Attributes Filters	1699
Create a Connector	1700
Amazon Web Services Connector—About User Permissions and Imported Data	1702
Create an AWS User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector	1702
Create an AWS Connector	1704
Amazon Web Services Security Groups Connector—About User Permissions and Imported Data	1705
Create an AWS User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector	1705
Create an AWS Security Groups Connector	1706
Create an AWS Service Tags Connector	1707
Azure Connector—About User Permissions and Imported Data	1708
Create an Azure User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector	1708
Create an Azure Connector	1711
Create an Azure Service Tags Connector	1711
Create a Cisco Cyber Vision Connector	1712
Create a Generic Text Connector	1713
Create a GitHub Connector	1714
Google Cloud Connector—About User Permissions and Imported Data	1715
Create a Google Cloud User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector	1715
Create a Google Cloud Connector	1717
Create an Office 365 Connector	1717
vCenter Connector—About User Permissions and Imported Data	1718
Create a vCenter User with Minimal Permissions for the Cisco Secure Dynamic Attributes Connector	1719
Create a vCenter Connector	1720
Create a Webex Connector	1722
Create a Zoom Connector	1722

Create Dynamic Attributes Filters	1723
Dynamic Attribute Filter Examples	1725
Manually Get a Certificate Authority (CA) Chain	1726
Use Dynamic Objects in Access Control Policies	1729
About Dynamic Objects in Access Control Rules	1729
Create Access Control Rules Using Dynamic Attributes Filters	1730
Disable the Cisco Secure Dynamic Attributes Connector	1731
Troubleshoot Using the Command Line	1732
Troubleshoot Using the Management Center	1734
Manually Get a Certificate Authority (CA) Chain	1734
Security Requirements	1737
Internet Access Requirements	1738
History for the Cisco Secure Dynamic Attributes Connector	1739

CHAPTER 44**URL Filtering 1741**

URL Filtering Overview	1741
About URL Filtering with Category and Reputation	1741
URL Category and Reputation Descriptions	1743
URL Filtering Data from the Cisco Cloud	1743
Best Practices for URL Filtering	1743
Filtering HTTPS Traffic	1746
Use Categories in URL Filtering	1747
License Requirements for URL Filtering	1748
Requirements and Prerequisites for URL Filtering	1748
How to Configure URL Filtering with Category and Reputation	1749
Enable URL Filtering Using Category and Reputation	1750
URL Filtering Options	1750
Configuring URL Conditions	1751
Rules with URL Conditions	1753
URL Rule Order	1753
DNS Filtering: Identify URL Reputation and Category During DNS Lookup	1754
Enable DNS Filtering to Identify URLs During Domain Lookup	1754
DNS Filtering Limitations	1755
DNS Filtering and Events	1755

Manual URL Filtering	1755
Manual URL Filtering Options	1755
Supplement or Selectively Override Category and Reputation-Based URL Filtering	1756
Configure HTTP Response Pages	1757
Limitations to HTTP Response Pages	1757
Requirements and Prerequisites for HTTP Response Pages	1758
Choosing HTTP Response Pages	1758
Configure Interactive Blocking with HTTP Response Pages	1759
Configuring Interactive Blocking	1759
Setting the User Bypass Timeout for a Blocked Website	1760
Configure URL Filtering Health Monitors	1761
Dispute URL Category and Reputation	1761
If the URL Category Set Changes, Take Action	1762
URL Category and Reputation Changes: Effect on Events	1763
Troubleshoot URL Filtering	1763
History for URL Filtering	1766

CHAPTER 45

Security Intelligence	1769
About Security Intelligence	1769
Best Practices for Security Intelligence	1770
License Requirements for Security Intelligence	1770
Requirements and Prerequisites for Security Intelligence	1771
Security Intelligence Sources	1771
Configure Security Intelligence	1772
Security Intelligence Options	1774
Security Intelligence Categories	1775
Block List Icons	1777
Configuration Example: Security Intelligence Blocking	1777
Security Intelligence Monitoring	1778
Override Security Intelligence Blocking	1778
Troubleshooting Security Intelligence	1779
Security Intelligence Categories Are Missing from the Available Options List	1779
History for Security Intelligence Block Listing	1780

CHAPTER 46**DNS Policies 1781**

- DNS Policy Overview **1781**
- Cisco Umbrella DNS Policies **1782**
- DNS Policy Components **1782**
- License Requirements for DNS Policies **1783**
- Requirements and Prerequisites for DNS Policies **1783**
- Managing DNS and Umbrella DNS Policies **1784**
 - Creating Basic DNS Policies **1784**
 - Editing DNS Policies **1785**
- DNS Rules **1785**
 - Creating and Editing DNS Rules **1786**
 - DNS Rule Management **1787**
 - Enabling and Disabling DNS Rules **1787**
 - DNS Rule Order Evaluation **1787**
 - DNS Rule Actions **1788**
 - DNS Rule Conditions **1789**
 - Security Zone Rule Conditions **1789**
 - Network Rule Conditions **1790**
 - VLAN Tags Rule Conditions **1790**
 - DNS Rule Conditions **1791**
- How to Create DNS Rules **1791**
 - Controlling Traffic Based on DNS and Security Zone **1791**
 - Controlling Traffic Based on DNS and Network **1791**
 - Controlling Traffic Based on DNS and VLAN **1792**
 - Controlling Traffic Based on DNS List or Feed **1793**
- DNS Policy Deploy **1793**
- Cisco Umbrella DNS Policies **1794**
 - How to Redirect DNS Requests to Cisco Umbrella **1794**
 - Prerequisites for Configuring the Umbrella DNS Connector **1795**
 - Configure Cisco Umbrella Connection Settings **1796**
 - Create an Umbrella DNS Policy **1797**
 - Edit Umbrella DNS Policies and Rules **1797**
 - Associate the Umbrella DNS Policy with an Access Control Policy **1798**

CHAPTER 47**Prefiltering and Prefilter Policies 1799**

- About Prefiltering 1799
 - About Prefilter Policies 1799
 - Tunnel vs Prefilter Rules 1800
 - Prefiltering vs Access Control 1801
 - Passthrough Tunnels and Access Control 1803
- Best Practices for Fastpath Prefiltering 1804
- Best Practices for Encapsulated Traffic Handling 1804
- Requirements and Prerequisites for Prefilter Policies 1805
- Configure Prefiltering 1806
 - Tunnel and Prefilter Rule Components 1807
 - Prefilter Rule Conditions 1809
 - Interface Rule Conditions 1809
 - Network Rule Conditions 1809
 - VLAN Tags Rule Conditions 1810
 - Port Rule Conditions for Prefilter Rules 1810
 - Time and Day Rule Conditions 1811
 - Tunnel Rule Conditions 1811
 - Encapsulation Rule Conditions 1811
- Tunnel Zones and Prefiltering 1812
 - Using Tunnel Zones 1812
 - Creating Tunnel Zones 1814
- Moving Prefilter Rules to an Access Control Policy 1815
- Prefilter Policy Hit Counts 1816
- Large Flow Offloads 1817
 - Flow Offload Limitations 1818
- History for Prefiltering 1820

CHAPTER 48**Service Policies 1821**

- About Threat Defense Service Policies 1821
 - How Service Policies Relate to FlexConfig and Other Features 1822
 - What Are Connection Settings? 1822
- Requirements and Prerequisites for Service Policies 1823

Guidelines and Limitations for Service Policies	1823
Configure Threat Defense Service Policies	1824
Configure a Service Policy Rule	1825
Bypass TCP State Checks for Asymmetrical Routing (TCP State Bypass)	1827
The Asymmetrical Routing Problem	1828
Guidelines and Limitations for TCP State Bypass	1829
Configure TCP State Bypass	1829
Disable TCP Sequence Randomization	1831
Examples for Service Policy Rules	1832
Protect Servers from a SYN Flood DoS Attack (TCP Intercept)	1832
Make the Threat Defense Device Appear on Traceroutes	1835
Monitoring Service Policies	1837
History for Threat Defense Service Policy	1837

CHAPTER 49**Threat Detection 1839**

Portscan Detection and Prevention	1839
Pre-Defined Sensitivity Levels for Portscan Detection	1839
Detection in the Low Sensitivity Level	1841
Best Practices for Portscan Prevention	1841
Requirements and Prerequisites for Threat Detection	1842
Guidelines and Limitations for Threat Detection	1842
Configure Portscan Detection and Prevention	1843
Monitoring Threat Detection	1845
Viewing Portscan Alerts	1845
Monitoring Portscan on the Firewall	1846
Unblocking A Host	1846
History for Threat Detection	1847

CHAPTER 50**Intelligent Application Bypass 1849**

Introduction to IAB	1849
IAB Options	1850
Requirements and Prerequisites for Intelligent Application Bypass	1852
Configuring Intelligent Application Bypass	1852
IAB Logging and Analysis	1853

CHAPTER 51	Content Restriction	1857
	About Content Restriction	1857
	Requirements and Prerequisites for Content Restriction	1858
	Guidelines and Limitations for Content Restriction	1859
	Using Access Control Rules to Enforce Content Restriction	1859
	Safe Search Options for Access Control Rules	1860
	Using a DNS Sinkhole to Enforce Content Restriction	1860

CHAPTER 52	Zero Trust Access	1863
	About Zero Trust Access	1863
	How Threat Defense Works with Zero Trust Access	1864
	Why Use Zero Trust Access?	1865
	Components of a Zero Trust Access Configuration	1865
	Zero Trust Access Workflow	1866
	Limitations for Zero Trust Access	1867
	Prerequisites for Zero Trust Application Policy	1868
	Manage Zero Trust Application Policies	1868
	Create a Zero Trust Application Policy	1869
	Create an Application Group	1870
	Create an Application	1871
	Set Targeted Devices for Zero Trust Access Policy	1873
	Edit a Zero Trust Application Policy	1874
	Monitor Zero Trust Sessions	1875
	History for Zero Trust Access	1877

PART VIII	SD-WAN	1879
------------------	---------------	-------------

CHAPTER 53	SD-WAN Capabilities	1881
	Overview of SD-WAN Capabilities	1881
	Features	1882
	Using SD-WAN Wizard for Secure Branch Network Deployment	1883
	Guidelines and Limitations for Using SD-WAN Wizard	1884
	Prerequisites for Using the SD-WAN Wizard	1885

- Configure an SD-WAN Topology Using the SD-WAN Wizard 1885
 - Add a Dynamic Virtual Tunnel Interface for a Hub 1889
- Sample Configurations for Dual ISP Deployment Using SD-WAN Wizard 1890
 - Dual ISP Deployment: Two Hubs and Four Spokes in the Same Region 1890
 - Dual ISP Deployment: Two Hubs and Four Spokes in Different Regions 1891
- Verify Tunnel Statuses of an SD-WAN Topology 1894
- Use Cases for SD-WAN Capabilities 1897

PART IX

Intrusion Detection and Prevention 1899

CHAPTER 54

Network Analysis and Intrusion Policies Overview 1901

- Network Analysis and Intrusion Policy Basics 1901
- How Policies Examine Traffic For Intrusions 1902
 - Decoding, Normalizing, and Preprocessing: Network Analysis Policies 1903
 - Access Control Rules: Intrusion Policy Selection 1904
 - Intrusion Inspection: Intrusion Policies, Rules, and Variable Sets 1905
 - Intrusion Event Generation 1906
- System-Provided and Custom Network Analysis and Intrusion Policies 1907
 - System-Provided Network Analysis and Intrusion Policies 1907
 - Benefits of Custom Network Analysis and Intrusion Policies 1909
 - Benefits of Custom Network Analysis Policies 1909
 - Benefits of Custom Intrusion Policies 1910
 - Limitations of Custom Policies 1911
- License Requirements for Network Analysis and Intrusion Policies 1913
- Requirements and Prerequisites for Network Analysis and Intrusion Policies 1913
- The Navigation Panel: Network Analysis and Intrusion Policies 1913
- Conflicts and Changes: Network Analysis and Intrusion Policies 1915
 - Exiting a Network Analysis or Intrusion Policy 1916

CHAPTER 55

Getting Started with Intrusion Policies 1917

- Intrusion Policy Basics 1917
- License Requirements for Intrusion Policies 1918
- Requirements and Prerequisites for Intrusion Policies 1919
- Managing Intrusion Policies 1919

Custom Intrusion Policy Creation	1920
Creating a Custom Snort 2 Intrusion Policy	1920
Editing Snort 2 Intrusion Policies	1921
Intrusion Policy Changes	1922
Access Control Rule Configuration to Perform Intrusion Prevention	1922
Access Control Rule Configuration and Intrusion Policies	1923
Configuring an Access Control Rule to Perform Intrusion Prevention	1923
Drop Behavior in an Inline Deployment	1923
Setting Drop Behavior in an Inline Deployment	1924
Drop Behavior in a Dual System Deployment	1924
Intrusion Policy Advanced Settings	1925
Optimizing Performance for Intrusion Detection and Prevention	1926

CHAPTER 56**Tuning Intrusion Policies Using Rules 1927**

Intrusion Rule Tuning Basics	1927
Intrusion Rule Types	1927
License Requirements for Intrusion Rules	1928
Requirements and Prerequisites for Intrusion Rules	1929
Viewing Intrusion Rules in an Intrusion Policy	1929
Intrusion Rules Page Columns	1929
Intrusion Rule Details	1930
Viewing Intrusion Rule Details	1931
Setting a Threshold for an Intrusion Rule	1932
Setting Suppression for an Intrusion Rule	1932
Setting a Dynamic Rule State from the Rule Details Page	1933
Setting an SNMP Alert for an Intrusion Rule	1933
Adding a Comment to an Intrusion Rule	1934
Intrusion Rule Filters in an Intrusion Policy	1934
Intrusion Rule Filters Notes	1934
Intrusion Policy Rule Filters Construction Guidelines	1935
Intrusion Rule Configuration Filters	1937
Intrusion Rule Content Filters	1937
Intrusion Rule Categories	1938
Intrusion Rule Filter Components	1939

Intrusion Rule Filter Usage	1940
Setting a Rule Filter in an Intrusion Policy	1940
Intrusion Rule States	1941
Intrusion Rule State Options	1941
Setting Intrusion Rule States	1942
Intrusion Event Notification Filters in an Intrusion Policy	1942
Intrusion Event Thresholds	1943
Intrusion Event Thresholds Configuration	1943
Adding and Modifying Intrusion Event Thresholds	1944
Viewing and Deleting Intrusion Event Thresholds	1945
Intrusion Policy Suppression Configuration	1946
Intrusion Policy Suppression Types	1946
Suppressing Intrusion Events for a Specific Rule	1946
Viewing and Deleting Suppression Conditions	1947
Dynamic Intrusion Rule States	1948
Dynamic Intrusion Rule State Configuration	1949
Setting a Dynamic Rule State from the Rules Page	1949
Adding Intrusion Rule Comments	1951
<hr/>	
CHAPTER 57	Custom Intrusion Rules 1953
Custom Intrusion Rules Overview	1953
License Requirements for the Intrusion Rule Editor	1954
Requirements and Prerequisites for the Intrusion Rule Editor	1954
Rule Anatomy	1954
The Intrusion Rule Header	1955
Intrusion Rule Header Action	1956
Intrusion Rule Header Protocol	1956
Intrusion Rule Header Direction	1957
Intrusion Rule Header Source and Destination IP Addresses	1957
Intrusion Rule Header Source and Destination Ports	1960
Intrusion Event Details	1961
Adding a Custom Classification	1964
Defining an Event Priority	1965
Defining an Event Reference	1965

Custom Rule Creation	1965
Writing New Rules	1966
Modifying Existing Rules	1967
Viewing Rule Documentation	1968
Adding Comments to Intrusion Rules	1969
Deleting Custom Rules	1970
Searching for Rules	1970
Search Criteria for Intrusion Rules	1971
Rule Filtering on the Intrusion Rules Editor Page	1972
Filtering Guidelines	1972
Keyword Filtering	1973
Character String Filtering	1974
Combination Keyword and Character String Filtering	1974
Filtering Rules	1974
Keywords and Arguments in Intrusion Rules	1975
The content and protected_content Keywords	1975
Basic content and protected_content Keyword Arguments	1977
content and protected_content Keyword Search Locations	1978
Overview: HTTP content and protected_content Keyword Arguments	1980
Overview: content Keyword Fast Pattern Matcher	1984
The replace Keyword	1986
The byte_jump Keyword	1987
The byte_test Keyword	1990
The byte_extract Keyword	1992
The byte_math Keyword	1995
Overview: The pcre Keyword	1997
pcre Syntax	1998
pcre Modifier Options	2000
pcre Example Keyword Values	2003
The metadata Keyword	2005
Service Metadata	2006
Metadata Search Guidelines	2011
IP Header Values	2012
ICMP Header Values	2014

TCP Header Values and Stream Size	2015
The stream_reassembly Keyword	2019
SSL Keywords	2019
The appid Keyword	2021
Application Layer Protocol Values	2022
The RPC Keyword	2022
The ASN.1 Keyword	2022
The urilen Keyword	2023
DCE/RPC Keywords	2024
SIP Keywords	2027
GTP Keywords	2029
SCADA Keywords	2041
Modbus Keywords	2041
DNP3 Keywords	2042
CIP and ENIP Keywords	2045
S7Commplus Keywords	2046
Packet Characteristics	2047
Active Response Keywords	2049
The resp Keyword	2049
The react Keyword	2050
The detection_filter Keyword	2051
The tag Keyword	2052
The flowbits Keyword	2053
flowbits Keyword Options	2053
Guidelines for Using the flowbits Keyword	2055
flowbits Keyword Examples	2055
The http_encode Keyword	2060
http_encode Keyword Syntax	2061
http_encode Keyword example: Using Two http_encode Keywords to Search for Two Encodings	2061
Overview: The file_type and file_group Keywords	2061
The file_type and file_group Keywords	2062
The file_data Keyword	2063
The pkt_data Keyword	2064

The base64_decode and base64_data Keywords 2064

CHAPTER 58

Layers in Intrusion and Network Analysis Policies 2067

Layer Basics 2067

License Requirements for Network Analysis and Intrusion Policy Layers 2067

Requirements and Prerequisites for Network Analysis and Intrusion Policy Layers 2068

The Layer Stack 2068

The Base Layer 2069

System-Provided Base Policies 2069

Custom Base Policies 2069

The Effect of Rule Updates on Base Policies 2070

Changing the Base Policy 2071

The Cisco Recommendations Layer 2071

Layer Management 2072

Shared Layers 2073

Managing Layers 2074

Navigating Layers 2075

Intrusion Rules in Layers 2075

Configuring Intrusion Rules in Layers 2076

Removing Rule Settings from Multiple Layers 2077

Accepting Rule Changes from a Custom Base Policy 2078

Preprocessors and Advanced Settings in Layers 2079

Configuring Preprocessors and Advanced Settings in Layers 2080

CHAPTER 59

Tailoring Intrusion Protection to Your Network Assets 2081

About Cisco Recommended Rules 2081

Default Settings for Cisco Recommendations 2082

Advanced Settings for Cisco Recommendations 2083

Generating and Applying Cisco Recommendations 2084

Script Detection 2085

CHAPTER 60

Sensitive Data Detection 2087

Sensitive Data Detection Basics 2087

Global Sensitive Data Detection Options 2088

Individual Sensitive Data Type Options	2089
System-Provided Sensitive Data Types	2090
License Requirements for Sensitive Data Detection	2090
Requirements and Prerequisites for Sensitive Data Detection	2090
Configuring Sensitive Data Detection	2091
Monitored Application Protocols and Sensitive Data	2092
Selecting Application Protocols to Monitor	2093
Special Case: Sensitive Data Detection in FTP Traffic	2094
Custom Sensitive Data Types	2094
Data Patterns in Custom Sensitive Data Types	2095
Configuring Custom Sensitive Data Types	2096
Editing Custom Sensitive Data Types	2097

CHAPTER 61**Global Limit for Intrusion Event Logging 2099**

Global Rule Thresholding Basics	2099
Global Rule Thresholding Options	2100
License Requirements for Global Thresholds	2101
Requirements and Prerequisites for Global Thresholds	2102
Configuring Global Thresholds	2102
Disabling the Global Threshold	2103

CHAPTER 62**Intrusion Prevention Performance Tuning 2105**

About Intrusion Prevention Performance Tuning	2105
License Requirements for Intrusion Prevention Performance Tuning	2106
Requirements and Prerequisites for Intrusion Prevention Performance Tuning	2106
Limiting Pattern Matching for Intrusions	2106
Regular Expression Limits Overrides for Intrusion Rules	2107
Overriding Regular Expression Limits for Intrusion Rules	2108
Per Packet Intrusion Event Generation Limits	2109
Limiting Intrusion Events Generated Per Packet	2109
Packet and Intrusion Rule Latency Threshold Configuration	2110
Latency-Based Performance Settings	2110
Packet Latency Thresholding	2110
Packet Latency Thresholding Notes	2111

Enabling Packet Latency Thresholding	2112
Configuring Packet Latency Thresholding	2112
Rule Latency Thresholding	2113
Rule Latency Thresholding Notes	2114
Configuring Rule Latency Thresholding	2115
Intrusion Performance Statistic Logging Configuration	2116
Configuring Intrusion Performance Statistic Logging	2116

PART X
Network Malware Protection and File Policies 2119

CHAPTER 63
Network Malware Protection and File Policies 2121

About Network Malware Protection and File Policies	2121
File Policies	2122
Requirements and Prerequisites for File Policies	2122
License Requirements for File and Malware Policies	2123
Best Practices for File Policies and Malware Detection	2123
File Rule Best Practices	2123
File Detection Best Practices	2124
File Blocking Best Practices	2124
File Policy Best Practices	2125
How to Configure Malware Protection	2126
Plan and Prepare for Malware Protection	2127
Configure File Policies	2128
Add File Policies to Your Access Control Configuration	2128
Configuring an Access Control Rule to Perform Malware Protection	2129
Set Up Maintenance and Monitoring of Malware Protection	2130
Cloud Connections for Malware Protection	2131
AMP Cloud Connection Configurations	2132
Requirements and Best Practices for AMP Cloud Connections	2132
Choose an AMP Cloud	2132
Cisco AMP Private Cloud	2133
Managing Connections to the AMP Cloud (Public or Private)	2135
Change AMP Options	2136
Dynamic Analysis Connections	2136

Requirements for Dynamic Analysis	2136
Viewing the Default Dynamic Analysis Connection	2136
Dynamic Analysis On-Premises Appliance (Cisco Secure Malware Analytics)	2137
Enabling Access to Dynamic Analysis Results in the Public Cloud	2138
Maintain Your System: Update File Types Eligible for Dynamic Analysis	2139
File Policies and File Rules	2140
Create or Edit a File Policy	2140
Advanced and Archive File Inspection Options	2140
Managing File Policies	2143
File Rules	2144
File Rule Components	2145
File Rule Actions	2146
Creating File Rules	2153
Access Control Rule Logging for Malware Protection	2154
Retrospective Disposition Changes	2154
File and Malware Inspection Performance and Storage Options	2154
Tuning File and Malware Inspection Performance and Storage	2156
(Optional) Malware Protection with AMP for Endpoints	2157
Comparison of Malware Protection: Firepower vs. AMP for Endpoints	2157
About Integrating Firepower with AMP for Endpoints	2158
Benefits of Integrating Firepower and AMP for Endpoints	2158
AMP for Endpoints and AMP Private Cloud	2159
Integrate Firepower and Secure Endpoint	2159
History for Network Malware Protection and File Policies	2161

PART XI
Encrypted Traffic Handling 2163

CHAPTER 64
Traffic Decryption Overview 2165

Traffic Decryption Explained	2165
TLS/SSL Handshake Processing	2167
ClientHello Message Handling	2167
ServerHello and Server Certificate Message Handling	2170
Decryption Rule and Policy Basics	2172
The Case for Decryption	2173

When to Decrypt Traffic, When Not to Decrypt	2173
Decrypt and Resign (Outgoing Traffic)	2175
Known Key Decryption (Incoming Traffic)	2175
Other Decryption Rule Actions	2176
Decryption Rule Components	2176
Decryption Rule Order Evaluation	2177
Multi-Rule Example	2178
TLS Crypto Acceleration	2179
TLS Crypto Acceleration Guidelines and Limitations	2180
View the Status of TLS Crypto Acceleration	2181
DTLS Crypto Acceleration	2182
Prerequisites for DTLS Crypto Acceleration	2182
Monitoring DTLS Crypto Acceleration	2183
How to Configure Decryption Policies and Rules	2184
History for Decryption Policy	2185

CHAPTER 65
Decryption Policies 2189

About Decryption Policies	2189
Requirements and Prerequisites for Decryption Policies	2191
Create a Decryption Policy	2191
Create a Decryption Policy with Outbound Connection Protection	2191
Create a Decryption Policy with Inbound Connection Protection	2194
Decryption Policy Exclusions	2195
Generate an Internal CA for Outbound Protection	2198
Upload an Internal CA for Outbound Protection	2199
Upload an Internal Certificate for Inbound Protection	2199
Create a Decryption Policy with Other Rule Actions	2200
Decryption Policy Default Actions	2201
Default Handling Options for Undecryptable Traffic	2202
Set Default Handling for Undecryptable Traffic	2203
Decryption Policy Advanced Options	2204
TLS 1.3 Decryption Best Practices	2206

CHAPTER 66
Decryption Rules 2209

Decryption Rules Overview	2209
Requirements and Prerequisites for Decryption Rules	2209
Decryption Rule Guidelines and Limitations	2210
Guidelines for Using TLS/SSL Decryption	2210
Decryption Rule Unsupported Features	2211
TLS/SSL Do Not Decrypt Guidelines	2211
TLS/SSL Decrypt - Resign Guidelines	2213
TLS/SSL Decrypt - Known Key Guidelines	2215
TLS/SSL Block Guidelines	2216
TLS/SSL Certificate Pinning Guidelines	2216
TLS/SSL Heartbeat Guidelines	2216
TLS/SSL Anonymous Cipher Suite Limitation	2217
TLS/SSL Normalizer Guidelines	2217
Other Decryption Rule Guidelines	2217
Decryption Rule Traffic Handling	2218
Encrypted Traffic Inspection Configuration	2220
Decryption Rule Order Evaluation	2221
Decryption Rule Conditions	2222
Security Zone Rule Conditions	2223
Security Zone Conditions and Multitenancy	2223
Network Rule Conditions	2224
VLAN Tags Rule Conditions	2224
User Rule Conditions	2224
Application Rule Conditions	2225
Port Rule Conditions	2226
Category Rule Conditions	2227
Server Certificate-Based Decryption Rule Conditions	2227
Certificate Decryption Rule Conditions	2228
Distinguished Name (DN) Rule Conditions	2228
Trusting External Certificate Authorities	2233
Certificate Status Decryption Rule Conditions	2234
Cipher Suite Decryption Rule Conditions	2237
Encryption Protocol Version Decryption Rule Conditions	2240
Decryption Rule Actions	2240

Decryption Rule Monitor Action	2240
Decryption Rule Do Not Decrypt Action	2241
Decryption Rule Blocking Actions	2242
Decryption Rule Decrypt Actions	2242
Monitor TLS/SSL Hardware Acceleration	2242
Informational Counters	2243
Alert Counters	2243
Error Counters	2243
Fatal Counters	2244
Troubleshoot Decryption Rules	2244
About TLS/SSL Oversubscription	2245
Troubleshoot TLS/SSL Oversubscription	2245
About TLS Heartbeat	2247
Troubleshoot TLS Heartbeat	2247
About TLS/SSL Pinning	2248
Troubleshoot TLS/SSL Pinning	2249
Troubleshoot Unknown or Bad Certificates or Certificate Authorities	2251
Verify TLS/SSL Cipher Suites	2253
Troubleshooting Using Crypto Archives	2254
<hr/>	
CHAPTER 67	Decryption Rules and Policy Example
	2257
Decryption Rule Examples	2257
Run the Decryption Policy Wizard	2257
Decryption Policy Exclusions	2259
First Manual Do Not Decrypt Rule: Specific Traffic	2262
Next Manual Rule: Decrypt Specific Test Traffic	2263
Last Manual Decryption Rules: Block or Monitor Certificates and Protocol Versions	2264
Example: Decryption Rule to Monitor or Block Certificate Status	2266
Example: Decryption Rule to Monitor or Block Protocol Versions	2268
Optional Example: Manual Decryption Rule to Monitor or Block Certificate Distinguished Name	2269
Associate the Decryption Policy with an Access Control Policy and Advanced Settings	2271
Traffic to Prefilter	2273
Decryption Rule Settings	2273

PART XII**User Identity 2275**

CHAPTER 68**User Identity Overview 2277**

- About User Identity 2277
 - Identity Terminology 2278
 - About User Identity Sources 2278
 - Best Practices for User Identity 2280
 - Identity Deployments 2282
 - How to Set Up an Identity Policy 2284
 - The User Activity Database 2287
 - The Users Database 2288
- Host and User Limits 2289
 - Host Limit 2289
 - User Limits for Microsoft Active Directory 2290
 - User Limits for Microsoft Azure Active Directory Realms 2292
 - User Limits for Microsoft Azure Active Directory Realms 2293

CHAPTER 69**Realms 2295**

- About Realms and Realm Sequences 2295
 - Realms and Trusted Domains 2297
 - Supported Servers for Realms 2300
 - Supported Server Object Class and Attribute Names 2301
- License Requirements for Realms 2302
- Requirements and Prerequisites for Realms 2302
- Create a Microsoft Azure AD (SAML) Realm 2302
 - How to Create a Microsoft Azure AD (SAML) for Passive Authentication 2303
 - About Azure AD and Cisco ISE with Resource Owned Password Credentials 2304
 - About Azure AD and Cisco ISE with TEAP/EAP-TLS 2305
 - How to Configure ISE for Microsoft Azure AD (SAML) 2306
 - Configure Microsoft Azure Active Directory for Passive Authentication 2306
 - Configure Azure AD Basic Settings 2307
 - Get Required Information For Your Microsoft Azure AD (SAML) Realm 2308
 - Create a Microsoft Azure AD (SAML) Realm for Passive Authentication 2310

How to Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal)	2314
Configure Azure AD Basic Settings	2316
Configure a Single Sign-On (SSO) App in Azure AD	2317
Create a Decryption Rule with Decrypt - Resign Action	2319
Get Required Information For Your Microsoft Azure AD (SAML) Realm (Active Authentication Only)	2320
Create a Microsoft Azure AD (SAML) Realm for Active Authentication (Captive Portal)	2323
Create an LDAP Realm or an Active Directory Realm and Realm Directory	2328
Prerequisites for Kerberos Authentication	2330
Realm Fields	2331
Realm Directory and Synchronize fields	2334
Connect Securely to Active Directory	2337
Find the Active Directory Server's Name	2337
Export the Active Directory Server's Root Certificate	2338
Synchronize Users and Groups	2339
Create a Realm Sequence	2340
Configure the Management Center for Cross-Domain-Trust: The Setup	2342
Configure the Secure Firewall Management Center for Cross-Domain-Trust Step 1: Configure Realms and Directories	2343
Configure the management center for Cross-Domain-Trust Step 2: Synchronize Users and Groups	2347
Configure the management center for Cross-Domain-Trust Step 3: Resolve Issues	2348
Manage a Realm	2349
Compare Realms	2350
Troubleshoot Realms and User Downloads	2350
Detect Realm or User Mismatches	2354
Troubleshoot Cross-Domain Trust	2355
History for Realms	2358
<hr/>	
CHAPTER 70	User Control with the Passive Identity Agent 2359
	The Passive Identity Agent Identity Source 2359
	Deploy the Passive Identity Agent 2360
	Simple Passive Identity Agent Deployment 2361
	Single Passive Identity Agent Monitoring Multiple Domain Controllers 2361
	Multiple Passive Identity Agents Monitoring Multiple Domain Controllers 2362

Passive Identity Agent Primary/Secondary Agent Deployments	2364
How to Create a Passive Identity Agent Identity Source	2365
Configure the Passive Identity Agent	2367
Create a Microsoft Active Directory Realm	2367
Create a Passive Identity Agent Identity Source	2367
Create a Standalone Passive Identity Agent Identity Source	2368
Create a Primary or Secondary Passive Identity Agent Identity Source	2370
About Passive Identity Agent Roles	2372
Create a Secure Firewall Management Center User for the Passive Identity Agent	2373
Troubleshoot the Passive Identity Agent	2375
Install the Passive Identity Agent Software	2375
Uninstall the Passive Identity Agent Software	2379
Monitor the Passive Identity Agent	2379
Manage the Passive Identity Agent	2380
Edit Passive Identity Agents	2381
Delete a Standalone Passive Identity Agent	2381
Delete Primary and Secondary Passive Identity Agents	2381
Troubleshoot the Passive Identity Agent	2382
Security Requirements for the Passive Identity Agent	2382
Internet Access Requirements for the Passive Identity Agent	2383
History for the Passive Identity Agent	2383
<hr/>	
CHAPTER 71	User Control with ISE/ISE-PIC 2385
The ISE/ISE-PIC Identity Source	2385
Source and Destination Security Group Tag (SGT) Matching	2386
License Requirements for ISE/ISE-PIC	2387
Requirements and Prerequisites for ISE/ISE-PIC	2387
ISE/ISE-PIC Guidelines and Limitations	2387
How to Configure ISE/ISE-PIC for User Control	2390
How to Configure ISE/ISE-PIC Without a Realm	2390
How to Configure ISE/ISE-PIC for User Control Using a Realm	2391
Configure ISE/ISE-PIC	2392
Configure Security Groups and SXP Publishing in ISE	2392
Export Certificates from the ISE/ISE-PIC Server for Use in the Management Center	2394

Export a System Certificate	2395
Generate a Self-Signed Certificate	2396
Import ISE/ISE-PIC Certificates	2396
Ways to Configure the Cisco Identity Services Engine (Cisco ISE) Identity Source	2397
About Cisco ISE Quick Configuration	2398
Prerequisites for ISE Quick Configuration	2398
Quick Configuration	2399
ISE Quick Configuration Results	2401
Cisco ISE Advanced Configuration	2403
ISE/ISE-PIC Configuration Fields	2405
Troubleshoot the ISE/ISE-PIC or Cisco TrustSec Issues	2406
History for ISE/ISE-PIC	2408

CHAPTER 72**User Control with Captive Portal 2411**

The Captive Portal Identity Source	2411
About Hostname Redirect	2412
License Requirements for Captive Portal	2412
Requirements and Prerequisites for Captive Portal	2412
Captive Portal Guidelines and Limitations	2412
How to Configure the Captive Portal for User Control	2415
Configure the Captive Portal Part 1: Create a Network Object	2416
Configure the Captive Portal Part 2: Create an Identity Policy and Active Authentication Rule	2418
Update a Custom Authentication Form	2420
Configure the Captive Portal Part 3: Create a TCP Port Access Control Rule	2420
Configure the Captive Portal Part 4: Create a User Access Control Rule	2421
Captive Portal Example: Create a Decryption Policy with an Outbound Rule	2422
Configure Captive Portal Part 6: Associate Identity and Decryption Policies with the Access Control Policy	2424
Captive Portal Fields	2425
Exclude Applications from Captive Portal	2426
Troubleshoot the Captive Portal Identity Source	2427
History for Captive Portal	2429

CHAPTER 73**User Control with Remote Access VPN 2431**

The Remote Access VPN Identity Source	2431
Configure RA VPN for User Control	2432
Troubleshoot the Remote Access VPN Identity Source	2432
Not Observing Correct Settings for VPN Statistics	2433
History for RA VPN	2434

CHAPTER 74
User Control with TS Agent 2435

The Terminal Services (TS) Agent Identity Source	2435
TS Agent Guidelines	2436
User Control with TS Agent	2436
Troubleshoot the TS Agent Identity Source	2436
History for TS Agent	2437

CHAPTER 75
User Identity Policies 2439

About Identity Policies	2439
License Requirements for Identity Policies	2440
Requirements and Prerequisites for Identity Policies	2440
Create an Identity Policy	2441
Create an Identity Mapping Filter	2442
Identity Rule Conditions	2443
Security Zone Rule Conditions	2443
Security Zone Conditions and Multitenancy	2444
Network Rule Conditions	2444
Redirect to Host Name Network Rule Conditions	2444
VLAN Tags Rule Conditions	2445
Port Rule Conditions	2445
Port, Protocol, and ICMP Code Rule Conditions	2446
Realm & Settings Rule Conditions	2447
Create an Identity Rule	2449
Identity Rule Fields	2450
Sample Identity Policies and Rules	2451
Create an Identity Policy with a Passive Authentication Rule	2452
Create a Sample Identity Policy with an Active Authentication Rule	2454
Active Authentication Using a Realm	2456

Active Authentication Using a Realm Sequence	2457
Manage an Identity Policy	2458
Manage an Identity Rule	2459
Troubleshoot User Control	2459

PART XIII
Network Discovery 2463

CHAPTER 76
Network Discovery Overview 2465

About Detection of Host, Application, and User Data	2465
Host and Application Detection Fundamentals	2466
Passive Detection of Operating System and Host Data	2466
Active Detection of Operating System and Host Data	2466
Current Identities for Applications and Operating Systems	2467
Current User Identities	2468
Application and Operating System Identity Conflicts	2469
NetFlow Data	2469
Requirements for Using NetFlow Data	2470
Differences between NetFlow and Managed Device Data	2470

CHAPTER 77
Host Identity Sources 2473

Overview: Host Data Collection	2473
Requirements and Prerequisites for Host Identity Sources	2474
Determining Which Host Operating Systems the System Can Detect	2474
Identifying Host Operating Systems	2474
Custom Fingerprinting	2475
Managing Fingerprints	2476
Activating and Deactivating Fingerprints	2476
Editing an Active Fingerprint	2477
Editing an Inactive Fingerprint	2477
Creating a Custom Fingerprint for Clients	2478
Creating a Custom Fingerprint for Servers	2480
Host Input Data	2483
Requirements for Using Third-Party Data	2483
Third-Party Product Mappings	2484

Mapping Third-Party Products	2484
Mapping Third-Party Product Fixes	2485
Mapping Third-Party Vulnerabilities	2486
Custom Product Mappings	2487
Creating Custom Product Mappings	2487
Editing Custom Product Mapping Lists	2488
Activating and Deactivating Custom Product Mappings	2489
Configuring the Host Input Client	2489
Nmap Scanning	2490
Nmap Remediation Options	2491
Nmap Scanning Guidelines	2495
Example: Using Nmap to Resolve Unknown Operating Systems	2496
Example: Using Nmap to Respond to New Hosts	2497
Managing Nmap Scanning	2498
Adding an Nmap Scan Instance	2499
Editing an Nmap Scan Instance	2500
Adding an Nmap Scan Target	2501
Editing an Nmap Scan Target	2501
Creating an Nmap Remediation	2502
Editing an Nmap Remediation	2504
Running an On-Demand Nmap Scan	2504
Nmap Scan Results	2505
Viewing Nmap Scan Results	2505
Nmap Scan Results Fields	2506
Importing Nmap Scan Results	2507
History for Host Identity Sources	2508

CHAPTER 78**Application Detection 2509**

Overview: Application Detection	2509
Application Detector Fundamentals	2510
Identification of Application Protocols in the Web Interface	2511
Implied Application Protocol Detection from Client Detection	2512
Host Limits and Discovery Event Logging	2512
Special Considerations for Application Detection	2513

Application Detection in Snort 2 and Snort 3	2514
Requirements and Prerequisites for Application Detection	2515
Custom Application Detectors	2515
Custom Application Detector and User-Defined Application Fields	2515
Configuring Custom Application Detectors	2518
Creating a User-Defined Application	2519
Specifying Detection Patterns in Basic Detectors	2520
Specifying Detection Criteria in Advanced Detectors	2521
Specifying EVE Process Assignments	2522
Testing a Custom Application Protocol Detector	2523
Viewing or Downloading Detector Details	2524
Sorting the Detector List	2524
Filtering the Detector List	2525
Filter Groups for the Detector List	2525
Navigating to Other Detector Pages	2526
Activating and Deactivating Detectors	2526
Editing Custom Application Detectors	2527
Deleting Detectors	2528

CHAPTER 79
Network Discovery Policies 2529

Overview: Network Discovery Policies	2529
Requirements and Prerequisites for Network Discovery Policies	2530
Network Discovery Customization	2530
Configuring the Network Discovery Policy	2531
Network Discovery Rules	2531
Configuring Network Discovery Rules	2532
Actions and Discovered Assets	2532
Monitored Networks	2533
Port Exclusions	2535
Zones in Network Discovery Rules	2537
The Traffic-Based Detection Identity Source	2537
Configuring Advanced Network Discovery Options	2540
Network Discovery General Settings	2541
Configuring Network Discovery General Settings	2541

- Network Discovery Identity Conflict Settings 2541
 - Configuring Network Discovery Identity Conflict Resolution 2542
- Network Discovery Vulnerability Impact Assessment Options 2542
 - Enabling Network Discovery Vulnerability Impact Assessment 2543
- Indications of Compromise 2543
 - Enabling Indications of Compromise Rules 2544
- Adding NetFlow Exporters to a Network Discovery Policy 2544
- Network Discovery Data Storage Settings 2545
 - Configuring Network Discovery Data Storage 2546
 - Configuring Network Discovery Event Logging 2547
 - Adding Network Discovery OS and Server Identity Sources 2547
- Troubleshooting Your Network Discovery Strategy 2548

PART XIV

FlexConfig Policies 2551

CHAPTER 80

FlexConfig Policies 2553

- FlexConfig Policy Overview 2553
 - Recommended Usage for FlexConfig Policies 2554
 - CLI Commands in FlexConfig Objects 2554
 - Determine the ASA Software Version and Current CLI Configuration 2555
 - Prohibited CLI Commands 2555
 - Template Scripts 2557
 - FlexConfig Variables 2558
 - How to Process Variables 2558
 - How to See What a Variable Will Return for a Device 2561
 - FlexConfig Policy Object Variables 2562
 - FlexConfig System Variables 2563
 - Predefined FlexConfig Objects 2564
 - Predefined Text Objects 2569
- Requirements and Prerequisites for FlexConfig Policies 2573
- Guidelines and Limitations for FlexConfig 2573
- Customizing Device Configuration with FlexConfig Policies 2574
 - Configure FlexConfig Objects 2576
 - Add a Policy Object Variable to a FlexConfig Object 2578

Configure Secret Keys	2579
Configure FlexConfig Text Objects	2580
Configure the FlexConfig Policy	2581
Set Target Devices for a FlexConfig Policy	2582
Preview the FlexConfig Policy	2583
Verify the Deployed Configuration	2584
Remove Features Configured Using FlexConfig	2585
Convert from FlexConfig to Managed Feature	2587
Examples for FlexConfig	2587
How to Configure Precision Time Protocol (ISA 3000)	2587
How to Configure Automatic Hardware Bypass for Power Failure (ISA 3000)	2591
Migrating FlexConfig Policies	2594
History for FlexConfig	2595

PART XV
Advanced Network Analysis and Preprocessing 2599

CHAPTER 81
Advanced Access Control Settings for Network Analysis and Intrusion Policies 2601

About Advanced Access Control Settings for Network Analysis and Intrusion Policies	2601
Requirements and Prerequisites for Advanced Access Control Settings for Network Analysis and Intrusion Policies	2601
Inspection of Packets That Pass Before Traffic Is Identified	2602
Best Practices for Handling Packets That Pass Before Traffic Identification	2602
Specify a Policy to Handle Packets That Pass Before Traffic Identification	2602
Advanced Settings for Network Analysis Policies	2603
Setting the Default Network Analysis Policy	2604
Network Analysis Rules	2605
Network Analysis Policy Rule Conditions	2605
Configuring Network Analysis Rules	2606
Managing Network Analysis Rules	2607

CHAPTER 82
Getting Started with Network Analysis Policies 2609

Network Analysis Policy Basics	2609
License Requirements for Network Analysis Policies	2609

CHAPTER 1

Device Management

This guide applies to an *on-premises* Secure Firewall Management Center, either as your primary manager or as an analytics-only manager. When using the Cisco Defense Orchestrator (CDO) cloud-delivered Firewall Management Center as your primary manager, you can use an on-prem management center for analytics. Do not use this guide for cloud-delivered Firewall Management Center management; see [Managing Firewall Threat Defense with Cloud-Delivered Firewall Management Center in Cisco Defense Orchestrator](#).

You can add and manage devices in the Secure Firewall Management Center.

About Device Management

Use the management center to manage your devices.

About the Management Center and Device Management

When the management center manages a device, it sets up a two-way, SSL-encrypted communication channel between itself and the device. The management center uses this channel to send information to the device about how you want to analyze and manage your network traffic to the device. As the device evaluates the traffic, it generates events and sends them to the management center using the same channel.

By using the management center to manage devices, you can:

- configure policies for all your devices from a single location, making it easier to change configurations
- install various types of software updates on devices
- push health policies to your managed devices and monitor their health status from the management center

Note If you have a CDO-managed device and are using the on-prem management center for analytics only, then the on-prem management center does not support policy configuration or upgrading. Chapters and procedures in this guide related to device configuration and other unsupported features do not apply to devices whose primary manager is CDO.

The management center aggregates and correlates intrusion events, network discovery information, and device performance data, allowing you to monitor the information that your devices are reporting in relation to one another, and to assess the overall activity occurring on your network.

You can use the management center to manage nearly every aspect of a device's behavior.

Note Although the management center can manage devices running certain previous releases as specified in the compatibility matrix available at <http://www.cisco.com/c/en/us/support/security/defense-center/products-device-support-tables-list.html>, new features that require the latest version of threat defense software are not available to these previous-release devices. Some management center features may be available for earlier versions.

What Can Be Managed by a Secure Firewall Management Center?

You can use the Secure Firewall Management Center as a central management point to manage threat defense devices.

When you manage a device, information is transmitted between the management center and the device over a secure, TLS-1.3-encrypted communication channel. You do not need to run this traffic over an additional encrypted tunnel such as Site-to-Site VPN for security purposes. If the VPN goes down, for example, you will lose your management connection, so we recommend a simple management path.

The following illustration lists what is transmitted between the management center and its managed devices. Note that the types of events and policies that are sent between the appliances are based on the device type.

About the Management Connection

After you configure the device with the management center information and after you add the device to the management center, either the device or the management center can establish the management connection. Depending on initial setup:

- Either the device or the management center can initiate.
- Only the device can initiate.
- Only the management center can initiate.

Initiation always originates with eth0 on the management center or with the lowest-numbered management interface on the device. Additional management interfaces are tried if the connection is not established. Multiple management interfaces on the management center let you connect to discrete networks or to segregate management and event traffic. However, the initiator does not choose the best interface based on the routing table.

Make sure the management connection is stable, without excessive packet loss, with at least 5 Mbps throughput.

Note The management connection is a secure, TLS-1.3-encrypted communication channel between itself and the device. You do not need to run this traffic over an additional encrypted tunnel such as Site-to-Site VPN for security purposes. If the VPN goes down, for example, you will lose your management connection, so we recommend a simple management path.

Beyond Policies and Events

In addition to deploying policies to devices and receiving events from them, you can also perform other device-related tasks on the management center.

Backing Up a Device

You cannot backup a physical managed device from the FTD CLI. To back up configuration data, and, optionally, unified files, perform a backup of the device using the management center that is managing the device.

To back up event data, perform a backup of the management center that is managing the device.

Updating Devices

From time to time, Cisco releases updates to the Firepower System, including:

- intrusion rule updates, which may contain new and updated intrusion rules
- vulnerability database (VDB) updates
- geolocation updates
- software patches and updates

You can use the management center to install an update on the devices it manages.

About Device Management Interfaces

Each device includes a single dedicated Management interface for communicating with the management center. You can optionally configure the device to use a data interface for management instead of the dedicated Management interface.

You can perform initial setup on the management interface, or on the console port.

Management interfaces are also used to communicate with the Smart Licensing server, to download updates, and to perform other management functions.

Management and Event Interfaces on the Threat Defense

When you set up your device, you specify the management center IP address or hostname that you want to connect to, if known. In this case, the device initiates the connection, and both management and event traffic go to this address at initial registration. If the management center is not known, then the management center establishes the initial connection. In this case, it might initially connect from a different management center management interface than specified on the threat defense. Subsequent connections should use the management center management interface with the specified IP address.

If the management center has a separate event-only interface, the managed device sends subsequent event traffic to the management center event-only interface if the network allows. In addition, some managed-device models include an additional management interface that you can configure for event-only traffic. Note that if you configure a data interface for management, you cannot use separate management and event interfaces. If the event network goes down, then event traffic reverts to the regular management interfaces on the management center and/or on the managed device.

Using the Threat Defense Data Interface for Management

You can use either the dedicated Management interface or a regular data interface for communication with the management center. Manager access on a data interface is useful if you want to manage the threat defense remotely from the outside interface, or you do not have a separate management network. Moreover, using a data interface lets you configure a redundant secondary interface to take over management functions if the primary interface goes down.

Manager Access Requirements

Manager access from a data interface has the following requirements.

- You can only enable manager access on a physical, data interface. You cannot use a subinterface or EtherChannel, nor can you create a subinterface on the manager access interface. You can also use the management center to enable manager access on a single secondary interface for redundancy.
- This interface cannot be management-only.
- Routed firewall mode only, using a routed interface.
- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the threat defense and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using the management center. Because the Management interface gateway will be changed to be the data interfaces, you also cannot SSH to the Management interface from a remote network unless you add a static route for the Management interface using the **configure network static-routes** command. For threat defense virtual on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the Management interface: add a static route for Management before you continue with your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface for manager access and you are disconnected.
- You cannot use separate management and event-only interfaces.
- Clustering is not supported. You must use the Management interface in this case.

High Availability Requirements

When using a data interface with device high availability, see the following requirements.

- Use the same data interface on both devices for manager access.
- Redundant manager access data interface is not supported.
- You cannot use DHCP; only a static IP address is supported. Features that rely on DHCP cannot be used, including DDNS and zero-touch provisioning.
- Have different static IP addresses in the same subnet.
- Use either IPv4 or IPv6; you cannot set both.
- Use the same manager configuration (**configure manager add** command) to ensure that the connectivity is the same.
- You cannot use the data interface as the failover or state link.

Management Interface Support Per Device Model

See the hardware installation guide for your model for the management interface locations.

Note For the Firepower 4100/9300, the MGMT interface is for *chassis* management, not for threat defense logical device management. You must configure a separate interface to be of type mgmt (and/or firepower-eventing), and then assign it to the threat defense logical device.

See the following table for supported management interfaces on each managed device model.

Table 1: Management Interface Support on Managed Devices

Model	Management Interface	Optional Event Interface
Firepower 1000	management0 Note management0 is the internal name of the Management 1/1 interface.	No Support
Secure Firewall 3100	management0 Note management0 is the internal name of the Management 1/1 interface.	No Support
Secure Firewall 4200	management0 Note management0 is the internal name of the Management 1/1 interface.	management1 Note management1 is the internal name of the Management 1/2 interface.
Firepower 4100 and 9300	management0 Note management0 is the internal name of this interface, regardless of the physical interface ID.	management1 Note management1 is the internal name of this interface, regardless of the physical interface ID.
ISA 3000	br1 Note br1 is the internal name of the Management 1/1 interface.	No support
Secure Firewall Threat Defense Virtual	eth0	No support

Network Routes on Device Management Interfaces

Management interfaces (including event-only interfaces) support only static routes to reach remote networks. When you set up your managed device, the setup process creates a default route to the gateway IP address that you specify. You cannot delete this route; you can only modify the gateway address.

Note The routing for management interfaces is completely separate from routing that you configure for data interfaces. If you configure a data interface for management instead of using the dedicated Management interface, traffic is routed over the backplane to use the data routing table. The information in this section does not apply.

You can configure multiple management interfaces on some platforms (a management interface and an event-only interface). The default route does not include an egress interface, so the interface chosen depends on the gateway address you specify, and which interface's network the gateway belongs to. In the case of multiple interfaces on the default network, the device uses the lower-numbered interface as the egress interface.

At least one static route is recommended per management interface to access remote networks. We recommend placing each interface on a separate network to avoid potential routing problems, including routing problems from other devices to the threat defense.

Note The interface used for management connections is not determined by the routing table. Connections are always tried using the lowest-numbered interface first.

NAT Environments

Network address translation (NAT) is a method of transmitting and receiving network traffic through a router that involves reassigning the source or destination IP address. The most common use for NAT is to allow private networks to communicate with the internet. Static NAT performs a 1:1 translation, which does not pose a problem for management center communication with devices, but port address translation (PAT) is more common. PAT lets you use a single public IP address and unique ports to access the public network; these ports are dynamically assigned as needed, so you cannot initiate a connection to a device behind a PAT router.

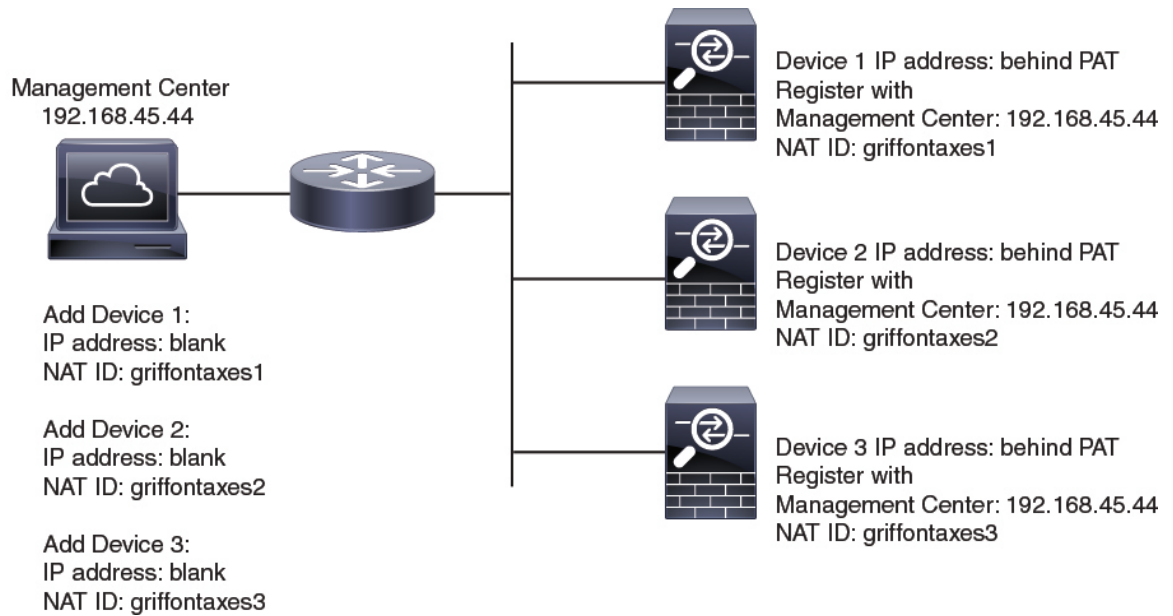

Normally, you need both IP addresses (along with a registration key) for both routing purposes and for authentication: the management center specifies the device IP address when you add a device, and the device specifies the management center IP address. However, if you only know one of the IP addresses, which is the minimum requirement for routing purposes, then you must also specify a unique NAT ID on both sides of the connection to establish trust for the initial communication and to look up the correct registration key. The management center and device use the registration key and NAT ID (instead of IP addresses) to authenticate and authorize for initial registration.

For example, you add a device to the management center, and you do not know the device IP address (for example, the device is behind a PAT router), so you specify only the NAT ID and the registration key on the management center; leave the IP address blank. On the device, you specify the management center IP address, the same NAT ID, and the same registration key. The device registers to the management center's IP address. At this point, the management center uses the NAT ID instead of IP address to authenticate the device.

Although the use of a NAT ID is most common for NAT environments, you might choose to use the NAT ID to simplify adding many devices to the management center. On the management center, specify a unique NAT ID for each device you want to add while leaving the IP address blank, and then on each device, specify both the management center IP address and the NAT ID. Note: The NAT ID must be unique per device.

The following example shows three devices behind a PAT IP address. In this case, specify a unique NAT ID per device on both the management center and the devices, and specify the management center IP address on the devices.

Figure 1: NAT ID for Managed Devices Behind PAT

The following example shows the management center behind a PAT IP address. In this case, specify a unique NAT ID per device on both the management center and the devices, and specify the device IP addresses on the management center.

Figure 2: NAT ID for Management Center Behind PAT

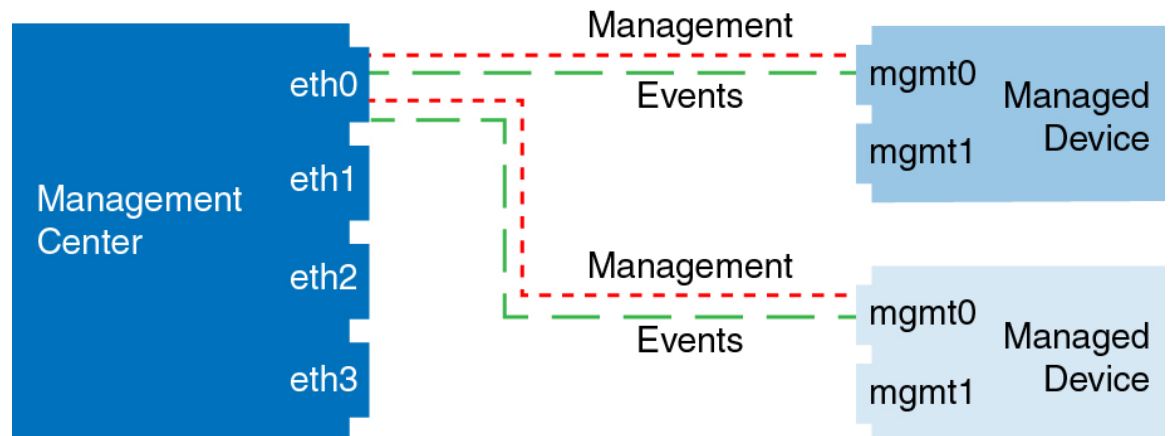

Management and Event Traffic Channel Examples

Note If you use a data interface for management on a threat defense, you cannot use separate management and event interfaces for that device.

The following example shows the management center and managed devices using only the default management interfaces.

Figure 3: Single Management Interface on the Secure Firewall Management Center

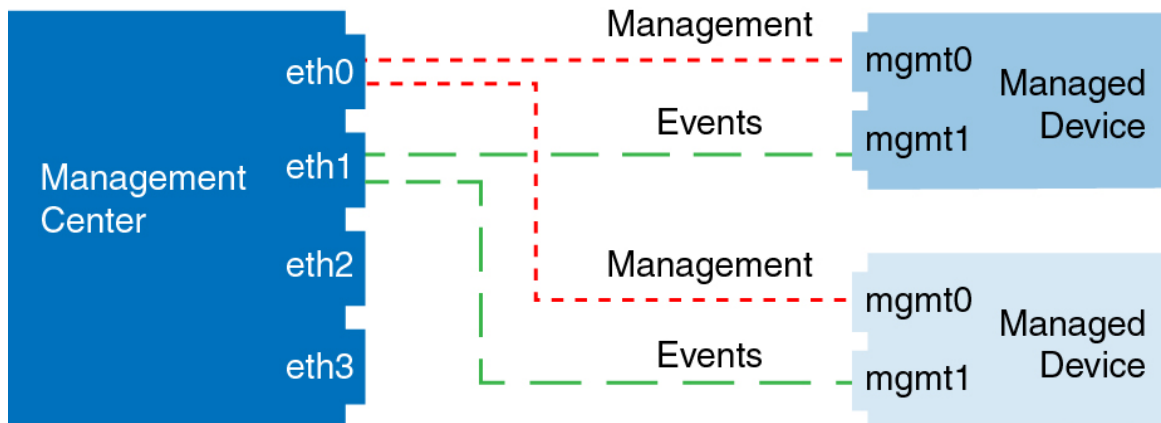

The following example shows the management center using separate management interfaces for devices; and each managed device using 1 management interface.

Figure 4: Multiple Management Interfaces on the Secure Firewall Management Center

The following example shows the management center and managed devices using a separate event interface.

Figure 5: Separate Event Interface on the Secure Firewall Management Center and Managed Devices

The following example shows a mix of multiple management interfaces and a separate event interface on the management center and a mix of managed devices using a separate event interface, or using a single management interface.

Figure 6: Mixed Management and Event Interface Usage

Requirements and Prerequisites for Device Management

Supported Domains

The domain in which the device resides.

User Roles

- Admin
- Network Admin

Management Connection

Make sure the management connection is stable, without excessive packet loss, with at least 5Mbps throughput.

Log Into the Command Line Interface on the Device

You can log directly into the command line interface on threat defense devices. If this is your first time logging in, complete the initial setup process using the default **admin** user; see [Complete the Threat Defense Initial Configuration Using the CLI, on page 19](#).

Note If a user makes three consecutive failed attempts to log into the CLI via SSH, the system terminates the SSH connection.

Before you begin

Create additional user accounts that can log into the CLI using the **configure user add** command.

Procedure

Step 1 Connect to the threat defense CLI, either from the console port or using SSH.

You can SSH to the management interface of the threat defense device. You can also connect to the address on a data interface if you open the interface for SSH connections. SSH access to data interfaces is disabled by default. See [SSH Access, on page 881](#) to allow SSH connections to specific data interfaces.

For physical devices, you can directly connect to the console port on the device. See the hardware guide for your device for more information about the console cable. Use the following serial settings:

- 9600 baud
- 8 data bits
- No parity
- 1 stop bit

The CLI on the console port is FXOS (with the exception of the ISA 3000, where it is the regular threat defense CLI). Use the threat defense CLI for basic configuration, monitoring, and normal system troubleshooting. See the FXOS documentation for information on FXOS commands.

For a chassis in multi-instance mode, you can connect to FXOS on the console port, or you can enable SSH for the Management interface according to [Configure SSH and SSH Access List, on page 353](#). SSH is disabled by default.

Step 2 Log in with the **admin** username and password.

Example:

```
firepower login: admin
Password:
Last login: Thu May 16 14:01:03 UTC 2019 on ttyS0
Successful login attempts for user 'admin' : 1

firepower#
```

Step 3 If you used the console port, access the threat defense CLI.

connect ftd

Multi-instance mode:

connect ftd *name*

To view the instance names, enter the command without a name.

Note This step does not apply to the ISA 3000.

Example:

```
firepower# connect ftd
>
```

Step 4 At the CLI prompt (>), use any of the commands allowed by your level of command line access.

To return to FXOS on the console port, enter **exit**.

Step 5 (Optional) If you used SSH, you can connect to FXOS.

connect fxos

To return to the threat defense CLI, enter **exit**.

Step 6 (Optional) Access the diagnostic CLI:

system support diagnostic-cli

Use this CLI for advanced troubleshooting. This CLI includes additional **show** and other commands.

This CLI has two sub-modes: user EXEC and privileged EXEC mode. More commands are available in privileged EXEC mode. To enter privileged EXEC mode, enter the **enable** command; press enter without entering a password when prompted.

Example:

```
> system support diagnostic-cli
firepower> enable
Password:
firepower#
```

To return to the regular CLI, type **Ctrl-a, d**.

Complete the Threat Defense Initial Configuration for Manual Registration

You can complete the threat defense initial configuration using the CLI or the device manager for all models except for the Firepower 4100/9300. For the Firepower 4100/9300, you complete initial configuration when you deploy the logical device. See [Logical Devices on the Firepower 4100/9300, on page 255](#).

For zero-touch provisioning (serial number registration), you should not log into the device or perform initial setup. See [Add a Device to the Management Center Using the Serial Number \(Zero-Touch Provisioning\)](#), on page 31.

Complete the Threat Defense Initial Configuration Using the Device Manager

When you use the device manager for initial setup, the following interfaces are preconfigured in addition to the Management interface and manager access settings:

- Ethernet 1/1—"outside", IP address from DHCP, IPv6 autoconfiguration
- Ethernet 1/2 (or for the Firepower 1010, the VLAN1 interface)— "inside", 192.168.95.1/24
- Default route—Obtained through DHCP on the outside interface

Note that other settings, such as the DHCP server on inside, access control policy, or security zones, are not configured.

If you perform additional interface-specific configuration within device manager before registering with the management center, then that configuration is preserved.

When you use the CLI, only the Management interface and manager access settings are retained (for example, the default inside interface configuration is not retained).

- The Secure Firewall 4200 does not support the device manager. You need to use the CLI procedure: [Complete the Threat Defense Initial Configuration Using the CLI, on page 19](#).
- This procedure does not apply for CDO-managed devices for which you want to use an on-prem management center *for analytics only*. The device manager configuration is meant to configure the primary manager. See [Complete the Threat Defense Initial Configuration Using the CLI, on page 19](#) for more information about configuring the device for analytics.
- This procedure applies to all other devices except for the Firepower 4100/9300 and the ISA 3000. You can use the device manager to onboard these devices to the management center, but because they have different default configurations than other platforms, the details in this procedure may not apply to these platforms.

Procedure

Step 1

Log into the device manager.

a) Enter the following URL in your browser.

- Inside—<https://192.168.95.1>.
- Management—https://management_ip. The Management interface is a DHCP client, so the IP address depends on your DHCP server. You will have to set the Management IP address to a static address as part of this procedure, so we recommend that you use the inside interface so you do not become disconnected.

b) Log in with the username **admin**, and the default password **Admin123**.

c) You are prompted to read and accept the End User License Agreement and change the admin password.

Step 2

Use the setup wizard when you first log into the device manager to complete the initial configuration. You can optionally skip the setup wizard by clicking **Skip device setup** at the bottom of the page.

After you complete the setup wizard, in addition to the default configuration for the inside interface, you will have configuration for an outside (Ethernet1/1) interface that will be maintained when you switch to the management center management.

a) Configure the following options for the outside and management interfaces, and click **Next**.

1. **Outside Interface Address**—This interface is typically the internet gateway, and might be used as your manager access interface. You cannot select an alternative outside interface during initial device setup. The first data interface is the default outside interface.

If you want to use a different interface from outside (or inside) for manager access, you will have to configure it manually after completing the setup wizard.

Configure IPv4—The IPv4 address for the outside interface. You can use DHCP or manually enter a static IP address, subnet mask, and gateway. You can also select **Off** to not configure an IPv4 address. You cannot configure PPPoE using the setup wizard. PPPoE may be required if the interface is connected to a DSL modem, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address. You can configure PPPoE after you complete the wizard.

Configure IPv6—The IPv6 address for the outside interface. You can use DHCP or manually enter a static IP address, prefix, and gateway. You can also select **Off** to not configure an IPv6 address.

2. **Management Interface**

You will not see Management Interface settings if you performed initial setup at the CLI.

The Management interface settings are used even if you enable manager access on a data interface. For example, the management traffic that is routed over the backplane through the data interface will resolve FQDNs using the Management interface DNS servers, and not the data interface DNS servers.

DNS Servers—The DNS server for the system's management address. Enter one or more addresses of DNS servers for name resolution. The default is the OpenDNS public DNS servers. If you edit the fields and want to return to the default, click **Use OpenDNS** to reload the appropriate IP addresses into the fields.

Firewall Hostname—The hostname for the system's management address.

b) Configure the **Time Setting (NTP)** and click **Next**.

1. **Time Zone**—Select the time zone for the system.
2. **NTP Time Server**—Select whether to use the default NTP servers or to manually enter the addresses of your NTP servers. You can add multiple servers to provide backups.

c) Select **Start 90 day evaluation period without registration**.

Do not register the threat defense with the Smart Software Manager; all licensing is performed on the management center.

d) Click **Finish**.

e) You are prompted to choose **Cloud Management** or **Standalone**. For management center management, choose **Standalone**, and then **Got It**.

Step 3

(Might be required) Configure the Management interface.

You may need to change the Management interface configuration, even if you intend to use a data interface for manager access. You will have to reconnect to the device manager if you were using the Management interface for the device manager connection.

- Data interface for manager access—The Management interface must have the gateway set to data interfaces. By default, the Management interface receives an IP address and gateway from DHCP. If you do not receive a gateway from DHCP (for example, you did not connect this interface to a network), then the gateway will default to data interfaces, and you do not need to configure anything. If you did receive a gateway from DHCP, then you need to instead configure this interface with a static IP address and set the gateway to data interfaces.
- Management interface for manager access—If you want to configure a static IP address, be sure to also set the default gateway to be a unique gateway instead of the data interfaces. If you use DHCP, then you do not need to configure anything assuming you successfully get the gateway from DHCP.

Step 4 If you want to configure additional interfaces, including an interface other than outside or inside that you want to use for manager access, choose **Device**, and then click the link in the **Interfaces** summary.

Other device manager configuration will not be retained when you register the device to management center.

Step 5 Choose **Device > System Settings > Central Management**, and click **Proceed** to set up the management center management.

Step 6 Configure the **Management Center/CDO Details**.

Figure 7: Management Center/CDO Details

Configure Connection to Management Center or CDO

Provide details to register to the management center/CDO.

Management Center/CDO Details

Do you know the Management Center/CDO hostname or IP address?

Management Center/CDO Access Interface

Data Interface

Please select an interface

Management Interface [View details](#)

- a) For **Do you know the Management Center/CDO hostname or IP address**, click **Yes** if you can reach the management center using an IP address or hostname, or **No** if the management center is behind NAT or does not have a public IP address or hostname.

At least one of the devices, either the management center or the threat defense device, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices.

- b) If you chose **Yes**, then enter the **Management Center/CDO Hostname/IP Address**.
- c) Specify the **Management Center/CDO Registration Key**.

This key is a one-time registration key of your choice that you will also specify on the management center when you register the threat defense device. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID can be used for multiple devices registering to the management center.

- d) Specify a **NAT ID**.

This ID is a unique, one-time string of your choice that you will also specify on the management center. This field is required if you only specify the IP address on one of the devices; but we recommend that you specify the NAT ID even if you know the IP addresses of both devices. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID *cannot* be used for any other devices registering to the management center. The NAT ID is used in combination with the IP address to verify that the connection is coming from the correct device; only after authentication of the IP address/NAT ID will the registration key be checked.

Step 7 Configure the **Connectivity Configuration**.

- a) Specify the **FTD Hostname**.

If you use a data interface for the **Management Center/CDO Access Interface** access, then this FQDN will be used for this interface.

- b) Specify the **DNS Server Group**.

Choose an existing group, or create a new one. The default DNS group is called **CiscoUmbrellaDNSServerGroup**, which includes the OpenDNS servers.

If you intend to choose a data interface for the **Management Center/CDO Access Interface**, then this setting sets the *data* interface DNS server. The Management DNS server that you set with the setup wizard is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface. You are likely to choose the same DNS server group that you used for Management, because both management and data traffic reach the DNS server through the outside interface.

On the management center, the data interface DNS servers are configured in the Platform Settings policy that you assign to this threat defense device. When you add the threat defense device to the management center, the local setting is maintained, and the DNS servers are *not* added to a Platform Settings policy. However, if you later assign a Platform Settings policy to the threat defense device that includes a DNS configuration, then that configuration will overwrite the local setting. We suggest that you actively configure the DNS Platform Settings to match this setting to bring the management center and the threat defense device into sync.

Also, local DNS servers are only retained by the management center if the DNS servers were discovered at initial registration.

If you intend to choose the Management interface for the **CDOFMC Access Interface**, then this setting configures the Management DNS server.

- c) For the **Management Center/CDO Access Interface**, choose any configured interface.

You can change the manager interface after you register the threat defense device to the management center, to either the Management interface or another data interface.

Step 8 (Optional) If you chose a data interface, and it was not the outside interface, then add a default route.

You will see a message telling you to check that you have a default route through the interface. If you chose outside, you already configured this route as part of the setup wizard. If you chose a different interface, then you need to manually configure a default route before you connect to the management center.

If you chose the Management interface, then you need to configure the gateway to be a unique gateway before you can proceed on this screen.

Step 9 (Optional) If you chose a data interface, click **Add a Dynamic DNS (DDNS) method**.

DDNS ensures the management center can reach the threat defense device at its Fully-Qualified Domain Name (FQDN) if the IP address changes. See **Device > System Settings > DDNS Service** to configure DDNS.

If you configure DDNS before you add the threat defense device to the management center, the threat defense device automatically adds certificates for all of the major CAs from the Cisco Trusted Root CA bundle so that the threat defense device can validate the DDNS server certificate for the HTTPS connection. Threat Defense supports any DDNS server that uses the DynDNS Remote API specification (<https://help.dyn.com/remote-access-api/>).

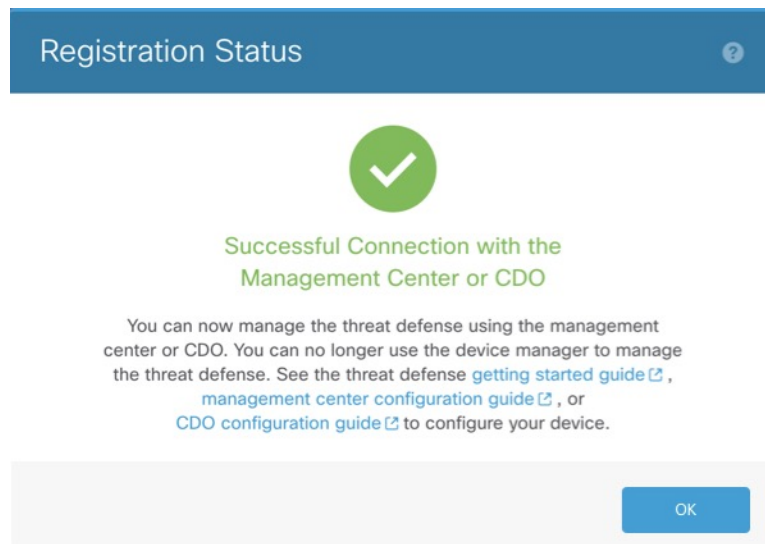

DDNS is not supported when using the Management interface for manager access.

Step 10 Click **Connect**. The **Registration Status** dialog box shows the current status of the switch to the management center. After the **Saving Management Center/CDO Registration Settings** step, go to the management center, and add the firewall.

If you want to cancel the switch to the management center, click **Cancel Registration**. Otherwise, do not close the device manager browser window until after the **Saving Management Center/CDO Registration Settings** step. If you do, the process will be paused, and will only resume when you reconnect to the device manager.

If you remain connected to the device manager after the **Saving Management Center/CDO Registration Settings** step, you will eventually see the **Successful Connection with Management Center or CDO** dialog box, after which you will be disconnected from the device manager.

Figure 8: Successful Connection

Complete the Threat Defense Initial Configuration Using the CLI

Connect to the threat defense CLI to perform initial setup, including setting the Management IP address, gateway, and other basic networking settings using the setup wizard. The dedicated Management interface is a special interface with its own network settings. If you do not want to use the Management interface for manager access, you can use the CLI to configure a data interface instead. You will also configure management center communication settings. When you perform initial setup using the device manager, *all* interface configuration completed in the device manager is retained when you switch to the management center for management, in addition to the Management interface and manager access interface settings. Note that other default configuration settings, such as the access control policy, are not retained.

This procedure applies to all models except for the Firepower 4100/9300. To deploy a logical device and complete initial configuration on the Firepower 4100/9300, see [Logical Devices on the Firepower 4100/9300, on page 255](#).

Procedure

Step 1 Connect to the threat defense CLI, either from the console port or using SSH to the Management interface, which obtains an IP address from a DHCP server by default. If you intend to change the network settings, we recommend using the console port so you do not get disconnected.

(Firepower and Secure Firewall hardware models) The console port connects to the FXOS CLI. The SSH session connects directly to the threat defense CLI.

Step 2 Log in with the username **admin** and the password **Admin123**.

(Firepower and Secure Firewall hardware models) At the console port, you connect to the FXOS CLI. The first time you log in to FXOS, you are prompted to change the password. This password is also used for the threat defense login for SSH.

Note If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default.

For Firepower and Secure Firewall hardware, see the [Reimage Procedures](#) in the [Cisco FXOS Troubleshooting Guide for the Firepower 1000/2100 and Secure Firewall 3100/4200 with Threat Defense](#).

For the ISA 3000, see the [Cisco Secure Firewall ASA and Secure Firewall Threat Defense Reimage Guide](#).

Example:

```
firepower login: admin
Password: Admin123
Successful login attempts for user 'admin' : 1
```

[...]

```
Hello admin. You must change your password.
Enter new password: *****
Confirm new password: *****
Your password was updated successfully.
```

[...]

```
firepower#
```

Step 3 (Firepower and Secure Firewall hardware models) If you connected to FXOS on the console port, connect to the threat defense CLI.

connect ftd

Example:

```
firepower# connect ftd
>
```

Step 4 The first time you log in to the threat defense, you are prompted to accept the End User License Agreement (EULA) and, if using an SSH connection, to change the admin password. You are then presented with the CLI setup script.

Note You cannot repeat the CLI setup wizard unless you clear the configuration; for example, by reimaging. However, all of these settings can be changed later at the CLI using **configure network** commands. See the [threat defense command reference](#).

Defaults or previously entered values appear in brackets. To accept previously entered values, press **Enter**.

Note The Management interface settings are used even when you enable manager access on a data interface. For example, the management traffic that is routed over the backplane through the data interface will resolve FQDNs using the Management interface DNS servers, and not the data interface DNS servers.

See the following guidelines:

- **Do you want to configure IPv4?** and/or **Do you want to configure IPv6?**—Enter **y** for at least one of these types of addresses.
- **Enter the IPv4 default gateway for the management interface** and/or **Enter the IPv6 gateway for the management interface**—If you want to use a data interface for manager access instead of the Management interface, choose **manual**. Although you do not plan to use the Management interface, you must set an IP address, for example, a private address. Make sure this interface is on a different subnet from the manager access interface to prevent routing issues. You cannot configure a data interface for management if the management interface is set to DHCP, because the default route, which must be **data-interfaces** (see the next bullet), might be overwritten with one received from the DHCP server.
- **Enter the IPv4 default gateway for the management interface** and/or **Configure IPv6 via DHCP, router, or manually?**—If you want to use a data interface for manager access instead of the management interface, set the gateway to be **data-interfaces**. This setting forwards management traffic over the backplane so it can be routed through the manager access data interface. If you want to use the Management interface for manager access, you should set a gateway IP address on the Management 1/1 network.
- **If your networking information has changed, you will need to reconnect**—If you are connected with SSH but you change the IP address at initial setup, you will be disconnected. Reconnect with the new IP address and password. Console connections are not affected.
- **Manage the device locally?**—Enter **no** to use the management center. A **yes** answer means you will use Firepower Device Manager instead.
- **Configure firewall mode?**—We recommend that you set the firewall mode at initial configuration. Changing the firewall mode after initial setup erases your running configuration. Note that data interface manager access is only supported in routed firewall mode.

Example:

```

You must accept the EULA to continue.
Press <ENTER> to display the EULA:
Cisco General Terms
[...]

Please enter 'YES' or press <ENTER> to AGREE to the EULA:

System initialization in progress. Please stand by.
You must configure the network to continue.
Configure at least one of IPv4 or IPv6 unless managing via data interfaces.
Do you want to configure IPv4? (y/n) [y]:
Do you want to configure IPv6? (y/n) [y]: n
Configure IPv4 via DHCP or manually? (dhcp/manual) [manual]:
Enter an IPv4 address for the management interface [192.168.45.61]: 10.89.5.17
Enter an IPv4 netmask for the management interface [255.255.255.0]: 255.255.255.192
Enter the IPv4 default gateway for the management interface [data-interfaces]: 10.89.5.1
Enter a fully qualified hostname for this system [firepower]: 1010-3
Enter a comma-separated list of DNS servers or 'none'
[208.67.222.222,208.67.220.220,2620:119:35::35]:

Configure firewall mode? (routed/transparent) [routed]:
Configuring firewall mode ...

Device is in OffBox mode - disabling/removing port 443 from iptables.
Update policy deployment information
- add device configuration
- add network discovery
- add system policy

You can register the sensor to a Firepower Management Center and use the
Firepower Management Center to manage it. Note that registering the sensor
to a Firepower Management Center disables on-sensor Firepower Services
management capabilities.

When registering the sensor to a Firepower Management Center, a unique
alphanumeric registration key is always required. In most cases, to register
a sensor to a Firepower Management Center, you must provide the hostname or
the IP address along with the registration key.
'configure manager add [hostname | ip address ] [registration key ]'

However, if the sensor and the Firepower Management Center are separated by a
NAT device, you must enter a unique NAT ID, along with the unique registration
key.
'configure manager add DONTRESOLVE [registration key ] [ NAT ID ]'

```

Later, using the web interface on the Firepower Management Center, you must use the same registration key and, if necessary, the same NAT ID when you add this sensor to the Firepower Management Center.

Step 5 Identify the management center that will manage this threat defense.

```
configure manager add {hostname | IPv4_address | IPv6_address | DONTRESOLVE} reg_key [nat_id]
[display_name]
```

Note If you are using CDO for management, use the CDO-generated **configure manager add** command for this step.

- {hostname | IPv4_address | IPv6_address | **DONTRESOLVE**}—Specifies either the FQDN or IP address of the management center. If the management center is not directly addressable, use **DONTRESOLVE** and also specify the *nat_id*. At least one of the devices, either the management center or the threat defense, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices. If you specify **DONTRESOLVE** in this command, then the FTD must have a reachable IP address or hostname.
- *reg_key*—Specifies a one-time registration key of your choice that you will also specify on the management center when you register the threat defense. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).
- *nat_id*—Specifies a unique, one-time string of your choice that you will also specify on the management center when you register the threat defense when one side does not specify a reachable IP address or hostname. For example, it is required if you set the management center to **DONTRESOLVE**. It is also required if you use the data interface for management, even if you specify IP addresses. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the management center.

Note If you use a data interface for management, then you must specify the NAT ID on both the threat defense and management center, even if you specify both IP addresses.

- *display_name*—Provide a display name for showing this manager with the **show managers** command. This option is useful if you are identifying CDO as the primary manager and an on-prem management center for analytics only. If you don't specify this argument, the firewall auto-generates a display name using one of the following methods:

- *hostname* | *IP_address* (if you don't use the **DONTRESOLVE** keyword)
- **manager-timestamp**

Example:

```
> configure manager add MC.example.com 123456
Manager successfully configured.
```

Example:

If the management center is behind a NAT device, enter a unique NAT ID along with the registration key, and specify **DONTRESOLVE** instead of the hostname, for example:

```
> configure manager add DONTRESOLVE regk3y78 natid90
Manager successfully configured.
```

Example:

If the threat defense is behind a NAT device, enter a unique NAT ID along with the management center IP address or hostname, for example:

```
> configure manager add 10.70.45.5 regk3y78 natid56
Manager successfully configured.
```

Step 6 If you are using CDO as your primary manager and want to use an on-prem management center for analytics only, identify the on-prem management center.

```
configure manager add {hostname | IPv4_address | IPv6_address | DONTRESOLVE} reg_key [nat_id]
[display_name]
```

Example:

The following example uses the generated command for CDO with a CDO-generated display name and then specifies an on-prem management center for analytics only with the "analytics-FMC" display name.

```
> configure manager add account1.app.us.cdo.cisco.com KPOOP0rgWzaHrnj1V5ha2q5Rf8pKFX9E
LzmlHOynhVUWhXYWz2swmkj2ZWsn3Lb account1.app.us.cdo.cisco.com
Manager successfully configured.
> configure manager add 10.70.45.5 regk3y78 natid56 analytics-FMC
Manager successfully configured.
```

Step 7 (Optional) Configure a data interface for manager access.

configure network management-data-interface

You are then prompted to configure basic network settings for the data interface.

Note You should use the console port when using this command. If you use SSH to the Management interface, you might get disconnected and have to reconnect to the console port. See below for more information about SSH usage.

See the following details for using this command. See also [Using the Threat Defense Data Interface for Management, on page 4](#).

- The original Management interface cannot use DHCP if you want to use a data interface for management. If you did not set the IP address manually during initial setup, you can set it now using the **configure network {ipv4 | ipv6} manual** command. Make sure this interface is on a different subnet from the manager access interface to prevent routing issues. If you did not already set the Management interface gateway to **data-interfaces**, this command will set it now.
- When you add the threat defense to the management center, the management center discovers and maintains the interface configuration, including the following settings: interface name and IP address, static route to the gateway, DNS servers, and DDNS server. For more information about the DNS server configuration, see below. In the management center, you can later make changes to the manager access interface configuration, but make sure you don't make changes that can prevent the threat defense or management center from re-establishing the management connection. If the management connection is disrupted, the threat defense includes the **configure policy rollback** command to restore the previous deployment.
- If you configure a DDNS server update URL, the threat defense automatically adds certificates for all of the major CAs from the Cisco Trusted Root CA bundle so that the threat defense can validate the DDNS server certificate for the HTTPS connection. The threat defense supports any DDNS server that uses the DynDNS Remote API specification (<https://help.dyn.com/remote-access-api/>).

- This command sets the *data* interface DNS server. The Management DNS server that you set with the setup script (or using the **configure network dns servers** command) is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface.

On the management center, the data interface DNS servers are configured in the Platform Settings policy that you assign to this threat defense. When you add the threat defense to the management center, the local setting is maintained, and the DNS servers are *not* added to a Platform Settings policy. However, if you later assign a Platform Settings policy to the threat defense that includes a DNS configuration, then that configuration will overwrite the local setting. We suggest that you actively configure the DNS Platform Settings to match this setting to bring the management center and the threat defense into sync.

Also, local DNS servers are only retained by the management center if the DNS servers were discovered at initial registration. For example, if you registered the device using the Management interface, but then later configure a data interface using the **configure network management-data-interface** command, then you must manually configure all of these settings in the management center, including the DNS servers, to match the FTD configuration.

- You can change the management interface after you register the threat defense to the management center, to either the Management interface or another data interface.
- The FQDN that you set in the setup wizard will be used for this interface.
- You can clear the entire device configuration as part of the command; you might use this option in a recovery scenario, but we do not suggest you use it for initial setup or normal operation.
- To disable data management, enter the **configure network management-data-interface disable** command.

Example:

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]:
IP address (manual / dhcp) [dhcp]:
DDNS server update URL [none]:
https://dwinchester:pa$$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>
Do you wish to clear all the device configuration before applying ? (y/n) [n]:

Configuration done with option to allow manager access from any network, if you wish to
change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.
```

>

Example:

```
> configure network management-data-interface
Data interface to use for management: ethernet1/1
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]:
```

```
Configuration done with option to allow manager access from any network, if you wish to
change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.
```

```
Setting IPv4 network configuration.
Network settings changed.
```

```
>
```

Step 8 (Optional) Limit data interface access to a manager on a specific network.

```
configure network management-data-interface client ip_address netmask
```

By default, all networks are allowed.

What to do next

Register your device to a management center.

Configure an Event Interface

You always need a management interface for management traffic. If your device has a second management interface, for example, the Firepower 4100/9300 and Secure Firewall 4200, you can enable it for event-only traffic.

Before you begin

To use a separate event interface, you also need to enable an event interface on the management center. See the [Cisco Secure Firewall Management Center Administration Guide](#).

Procedure

Step 1 Enable the second management interface as an event-only interface.

```
configure network management-interface enable management1
```

```
configure network management-interface disable-management-channel management1
```

You can optionally disable events for the main management interface using the **configure network management-interface disable-events-channel** command. In either case, the device will try to send events on the event-only interface, and if that interface is down, it will send events on the management interface even if you disable the event channel.

You cannot disable both event and management channels on an interface.

Example:

```
> configure network management-interface enable management1
Configuration updated successfully
```

```
> configure network management-interface disable-management-channel management1
Configuration updated successfully
```

>

Step 2 Configure the IP address of the event interface.

The event interface can be on a separate network from the management interface, or on the same network.

a) Configure the IPv4 address:

configure network ipv4 manual *ip_address netmask gateway_ip* management1

Note that the *gateway_ip* in this command is used to create the default route for the device, so you should enter the value you already set for the management0 interface. It does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you create a static route separately for the event-only interface.

Example:

```
> configure network ipv4 manual 10.10.10.45 255.255.255.0 10.10.10.1 management1
Setting IPv4 network configuration.
Network settings changed.
```

>

b) Configure the IPv6 address:

- Stateless autoconfiguration:

configure network ipv6 router management1

Example:

```
> configure network ipv6 router management1
Setting IPv6 network configuration.
Network settings changed.
```

>

- Manual configuration:

configure network ipv6 manual *ip6_address ip6_prefix_length* management1

Example:

```
> configure network ipv6 manual 2001:0DB8:BA98::3210 64 management1
Setting IPv6 network configuration.
Network settings changed.
```

>

Step 3 Add a static route for the event-only interface if the management center is on a remote network; otherwise, all traffic will match the default route through the management interface.

configure network static-routes {ipv4 | ipv6} add management1 *destination_ip netmask_or_prefix gateway_ip*

For the *default* route, do not use this command; you can only change the default route gateway IP address when you use the **configure network ipv4** or **ipv6** commands (see, [Step 2, on page 26](#)).

Example:

```
> configure network static-routes ipv4 add management1 192.168.6.0 255.255.255.0 10.10.10.1
Configuration updated successfully

> configure network static-routes ipv6 add management1 2001:0DB8:AA89::5110 64
2001:0DB8:BA98::3211
Configuration updated successfully

>
```

To display static routes, enter **show network-static-routes** (the default route is not shown):

```

Netmask            : 255.255.255.0
[...]
```

Add a Device to the Management Center Using a Registration Key

Use this procedure to add a single device to the management center using a registration key. If you plan to link devices for high availability, you must still use this procedure; see [Add a High Availability Pair, on page 395](#). For clustering, see the clustering chapter for your model.

You can also add a cloud-managed device for which you want to use the on-prem management center for event logging and analytics purposes.

To add one or more devices using a template, see [Device Management Using Device Templates, on page 131](#).

If you have established or will establish management center high availability, add devices *only* to the active (or intended active) management center. When you establish high availability, devices registered to the active management center are automatically registered to the standby.

Before you begin

- Set up the device to be managed by the management center. See:
 - [Complete the Threat Defense Initial Configuration for Manual Registration, on page 12](#)
 - The getting started guide for your model
- The management center must be registered to the Smart Software Manager. A valid evaluation license is sufficient, but if it expires, you will not be able to add new devices until you successfully register.
- If you registered a device using IPv4 and want to convert it to IPv6, you must unregister and reregister the device.

Procedure

Step 1

Choose **Devices > Device Management**.

Step 2

From the **Add** drop-down menu, choose **Device**.

Figure 9: Add Device Using a Registration Key

Add Device ?

CDO Managed Device

Host:†

Display Name:

Registration Key:*

Group:

Access Control Policy:*

Smart Licensing
 Note: All virtual Firewall Threat Defense devices require a performance tier license. Make sure your Smart Licensing account contains the available licenses you need. It's important to choose the tier that matches the license you have in your account. Click [here](#) for information about the Firewall Threat Defense performance-tiered licensing. Until you choose a tier, your Firewall Threat Defense virtual defaults to the FTDv50 selection.

Performance Tier (only for Firewall Threat Defense virtual 7.0 and above):

Carrier
 Malware Defense
 IPS
 URL

Advanced
Unique NAT ID:†

Transfer Packets

[Cancel](#) [Register](#)

Step 3

If you want to add a cloud-managed device to your on-prem management center for analytics only, check **CDO Managed Device**.

The system hides licensing and packet transfer settings because they are managed by CDO. You can skip those steps.

Figure 10: Add Device for CDO

Add Device ⓘ

CDO Managed Device

Host:

Display Name:

Registration Key:*

Group:

Advanced

Unique NAT ID:

Transfer Packets is configured in CDO

[Cancel](#) [Register](#)

- Step 4** In the **Host** field, enter the IP address or the hostname of the device you want to add.
- The hostname of the device is the fully qualified domain name or the name that resolves through the local DNS to a valid IP address. Use a hostname rather than an IP address if your network uses DHCP to assign IP addresses.
- In a NAT environment, you may not need to specify the IP address or hostname of the device, if you already specified the IP address or hostname of the management center when you configured the device to be managed by the management center. For more information, see [NAT Environments, on page 7](#).
- Note** In a management center high availability environment, when both the management centers are behind NAT, to register the device on the secondary management center, you must specify a value in the **Host** field.
- Step 5** In the **Display Name** field, enter a name for the device as you want it to display in the management center.
- Step 6** In the **Registration Key** field, enter the same registration key that you used when you configured the device to be managed by the management center. The registration key is a one-time-use shared secret. The key can include alphanumeric characters and hyphens (-).
- Step 7** (Optional) Add the device to a device **Group**.
- Step 8** Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If the device is incompatible with the policy you choose, deploying will fail. This incompatibility could occur for multiple reasons, including licensing mismatches, model restrictions, passive vs inline issues, and other misconfigurations. After you resolve the issue that caused the failure, manually deploy configurations to the device.

Step 9 Choose licenses to apply to the device.

You can also apply licenses after you add the device, from the **System > Licenses > Smart Licenses** page.

For threat defense virtual, you must also select the **Performance Tier**. It's important to choose the tier that matches the license you have in your account. Until you choose a tier, your device defaults to the FTDv50 selection. For more information about the performance-tiered license entitlements available for threat defense virtual, see *FTDv Licenses* in the [Cisco Secure Firewall Management Center Administration Guide](#).

Note If you are upgrading your threat defense virtual to Version 7.0+, you can choose **FTDv - Variable** to maintain your current license compliance.

Step 10 If you used a NAT ID during device setup, in the **Advanced** section enter the same NAT ID in the **Unique NAT ID** field.

The **Unique NAT ID** specifies a unique, one-time string of your choice that you will also specify on the device during initial setup when one side does not specify a reachable IP address or hostname. For example, it is required if you left the **Host** field blank. It is also required if you use the device's data interface for management, even if you specify IP addresses. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the management center.

Note If you use a data interface on the device for management, then you must specify the NAT ID on both the device and management center, even if you specify both IP addresses.

Step 11 Check the **Transfer Packets** check box to allow the device to transfer packets to the management center.

This option is enabled by default. When events like IPS or Snort are triggered with this option enabled, the device sends event metadata information and packet data to the management center for inspection. If you disable it, only event information will be sent to the management center but packet data is not sent.

Step 12 Click **Register**.

It may take up to two minutes for the management center to verify the device's heartbeat and establish communication. If the registration succeeds, the device is added to the list. If it fails, you will see an error message. If the device fails to register, check the following items:

- Ping—Access the device CLI, and ping the management center IP address using the following command:

```
ping system ip_address
```

If the ping is not successful, check your network settings using the **show network** command. If you need to change the device IP address, use the **configure network {ipv4 | ipv6} manual** command.

- Registration key, NAT ID, and management center IP address—Make sure you are using the same registration key, and if used, NAT ID, on both devices. You can set the registration key and NAT ID on the device using the **configure manager add** command.

For more troubleshooting information, see <https://cisco.com/go/fmc-reg-error>.

Add a Device to the Management Center Using the Serial Number (Zero-Touch Provisioning)

Zero-Touch Provisioning lets you register devices to the management center by serial number without having to perform any initial setup on the device. The management center integrates with the Cisco Security Cloud and Cisco Defense Orchestrator (CDO) for this functionality.

When you use zero-touch provisioning, the following interfaces are preconfigured. Note that other settings, such as the DHCP server on inside, access control policy, or security zones, are not configured.

- Ethernet 1/1—"outside", IP address from DHCP, IPv6 autoconfiguration
- Ethernet 1/2 (or for the Firepower 1010 and , the VLAN1 interface)— "inside", 192.168.95.1/24
- Default route—Obtained through DHCP on the outside interface

Use this procedure to add a single device to the management center. To add one or more devices using a template, see [Device Management Using Device Templates, on page 131](#)

Zero-Touch Provisioning is not supported with clustering or multi-instance mode.

High availability is only supported when you use the Management interface because zero-touch provisioning uses DHCP, which is not supported for data interfaces and high availability.

Zero-Touch Provisioning is only supported on the following models using 7.2 and 7.4 or later; prior to 7.2.4, the management center must be publicly reachable.

- Firepower 1010
- Firepower 1100
- Firepower 2100 (on supported versions)
- Secure Firewall 3100

Before you begin

- Make sure the device is unconfigured or a fresh install. Zero-Touch Provisioning is meant for new devices only. Pre-configuration can disable zero-touch provisioning, depending on how you configure the device.
- Cable the outside interface or Management interface so it can reach the internet. If you use the outside interface for zero-touch provisioning, do not also cable the Management interface; if the Management interface gets an IP address from DHCP, the routing will be incorrect for the outside interface.
- If the device does not have a public IP address or FQDN, or you use the Management interface, set a public IP address/FQDN for the management center (for example, if it is behind NAT), so the device can initiate the management connection. See **System > Configuration > Manager Remote Access**.
- The management center must be registered to the Smart Software Manager. A valid evaluation license is sufficient, but if it expires, you will not be able to add new devices until you successfully register.
- If you registered a device using IPv4 and want to convert it to IPv6, you must unregister and reregister the device.

Procedure

Step 1 The first time you add a device using a serial number, integrate the management center with Cisco Security Cloud.

Note For a management center high-availability pair, you also need to integrate the secondary management center with Cisco Security Cloud.

- a) Choose **Integration > Cisco Security Cloud**.
- b) Click **Enable Cisco Security Cloud** to open a separate browser tab to log you into your Cisco Security Cloud account and confirm the displayed code.

Make sure this page is not blocked by a pop-up blocker. If you do not already have a Cisco Security Cloud and CDO account, you can add one during this procedure.

For detailed information about this integration, see the "System Configuration" chapter in the [Cisco Secure Firewall Management Center Administration Guide](#).

CDO onboards the on-prem management center after you integrate the management center with Cisco Security Cloud. CDO needs the management center in its inventory for zero-touch provisioning to operate. However, you do not need to use CDO directly. If you do use CDO, its management center support is limited to device onboarding, viewing its managed devices, viewing objects associated with the management center, and cross-launching the management center.

- c) Make sure **Enable Zero-Touch Provisioning** is checked.
- d) Click **Save**.

Step 2 Choose **Devices > Device Management**.

Step 3 From the **Add** drop-down menu, choose **Device (Wizard)**.

Step 4 Click **Use Serial Number**, and then click **Next**.

Figure 11: Device Registration Method

Step 5 For the **Initial device configuration**, click the **Basic** radio button.

Previous Next

Cancel Add Device

- a) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.
If the device is incompatible with the policy you choose, deploying will fail. This incompatibility could occur for multiple reasons, including licensing mismatches, model restrictions, passive vs inline issues, and other misconfigurations. After you resolve the issue that caused the failure, manually deploy configurations to the device.
- b) Choose **Smart licensing** licenses to apply to the device.
You can also apply licenses after you add the device, from the **System > Licenses > Smart Licenses** page.
- c) Click **Next**.

Step 6 Configure the **Device details**.

Figure 13: Device details

Add Device

1 Device registration method
Device registration method **Serial Number**

2 Initial device configuration
Access control policy **wfx_automationPolicy123**

3 Device details

Configure the public IP address or FQDN for the Management Center, except in scenarios where the Threat Defense device is publicly reachable, running a version earlier than 7.4, and is connected to the data interface. To configure the public IP address or FQDN, go to [Configuration > Manager Remote Access](#).

Serial number Display name

Device group

Set the device password
Enter a new password if you have not previously changed the device's default password.

New password Confirm password

Skip this field if you already changed the password on the device. If you provide a new password in this case, registration will fail.

[Previous](#)

[Cancel](#) [Add Device](#)

- Enter the **Serial number**.
- Enter the **Display name** as you want it to display in the management center
- (Optional) Choose the **Device Group**.
- Set the device password**.

If this device is unconfigured or a fresh install, then you need to set a new password. If you already logged in and changed the password, then leave this field blank. Otherwise, registration will fail.

Step 7 Click **Add Device**.

It may take up to two minutes for the management center to verify the device's heartbeat and establish communication. If the registration succeeds, the device is added to the list.

If the device fails to register, see [Resolve Serial Number \(Zero-Touch Provisioning\) Registration Issues](#), on page 111.

Add a Chassis to the Management Center

You can add a Firepower 4100/9300 chassis to the management center. The management center and the chassis share a separate management connection using the chassis MGMT interface. The management center offers chassis-level health alerts. For configuration, you still need to use the Secure Firewall chassis manager or FXOS CLI.

Note For the Secure Firewall 3100/4200, the chassis is added to the management center as part of the conversion to multi-instance mode. See [Convert a Device to Multi-Instance Mode, on page 328](#). However, if you used the CLI to convert to multi-instance mode ([Enable Multi-Instance Mode at the CLI, on page 366](#)), skip to [Step 3, on page 36](#) of this procedure to add the chassis to the management center.

Procedure

Step 1 Connect to the chassis FXOS CLI, either using the console port or SSH.

Step 2 Configure the management center.

```
create device-manager manager_name [hostname {hostname | ipv4_address | ipv6_address}] [nat-id nat_id]
```

You are prompted for the registration key.

You can enter this command from any scope. This command is accepted immediately without using **commit-buffer**.

- **hostname** {*hostname* | *ipv4_address* | *ipv6_address*}—Specifies either the FQDN or IP address of the management center. At least one of the devices, either the management center or the chassis, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices. If you do not specify a **hostname**, then the chassis must have a reachable IP address or hostname and you must specify the **nat-id**.
- **nat-id** *nat_id*—Specifies a unique, one-time string of your choice that you will also specify on the management center when you register the chassis when one side does not specify a reachable IP address or hostname. It is required if you do not specify a **hostname**, however we recommend that you always set the NAT ID even when you specify a hostname or IP address. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the management center.
- **Registration Key:** *reg_key*—You will be prompted for a one-time registration key of your choice that you will also specify on the management center when you register the chassis. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).

Example:

```
firepower# create device-manager boulder_fmc hostname 10.89.5.35 nat-id 93002
(Valid registration key characters: [a-z],[A-Z],[0-9],[ -]. Length: [2-36])
```

Registration Key: Impala67

Step 3 In the management center, add the chassis using the chassis management IP address or hostname.

- a) Choose **Device > Device Management**, and then **Add > Chassis**.

Figure 14: Add Chassis

Figure 15: Add Chassis

 A screenshot of the 'Add Chassis' form in a management center. The form has a title bar with a question mark icon and a close 'X' icon. Below the title bar is a warning message in a blue box: 'This operation is only supported on 3100, 4100 & 9300 chassis'. The form contains several input fields:

- 'Hostname/IP Address†' with the value '10.89.5.9'
- 'Chassis name' with the value 'eng1'
- 'Registration key*' with a masked value '....'
- 'Device Group' with a dropdown menu showing 'Select...'
- 'Unique NAT ID†' with the value 'winchester'

 At the bottom of the form, there is a note: '† Either host or NAT ID is required.' and two buttons: 'Cancel' and 'Submit'.

- b) In the **Hostname/IP Address** field, enter the IP address or the hostname of the chassis you want to add. If you don't know the hostname or IP address, you can leave this field blank specify the **Unique NAT ID**.
- c) In the **Chassis Name** field, enter a name for the chassis as you want it to display in the management center.
- d) In the **Registration Key** field, enter the same registration key that you used when you configured the chassis to be managed by the management center.

The registration key is a one-time-use shared secret. The key can include alphanumeric characters and hyphens (-).

- e) In a multidomain deployment, regardless of your current domain, assign the chassis to a leaf **Domain**.
If your current domain is a leaf domain, the chassis is automatically added to the current domain. If your current domain is not a leaf domain, post-registration, you must switch to the leaf domain to configure the chassis. A chassis can only belong to one domain.
 - f) (Optional) Add the chassis to a **Device Group**.
 - g) If you used a NAT ID during chassis setup, expand enter the same NAT ID in the **Unique NAT ID** field.
The NAT ID can include alphanumeric characters and hyphens (-).
 - h) Click **Submit**.
The chassis is added to the **Device > Device Management** page.
-

Unregister a Device from the Management Center

If you no longer want to manage a device, you can unregister it from the management center.

To unregister a cluster, cluster node, or high availability pair, see the chapters for those deployments.

Unregistering a device:

- Severs all communication between the management center and the device.
- Removes the device from the **Device Management** page.
- Returns the device to local time management if the device's platform settings policy is configured to receive time from the management center using NTP.
- Leaves the configuration intact, so the device continues to process traffic.
Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the device again to the same or a different management center causes the configuration to be removed, so the device will stop processing traffic at that point.

Before you unregister the device, be sure to export the configuration or create a template so you can re-apply the device-level configuration (interfaces, routing, and so on) when you re-register it. If you do not have a saved configuration or template, you will have to re-configure device settings.

After you re-add the device and either import a saved configuration, use a template, or re-configure your settings, you need to deploy the configuration before it starts passing traffic again.

Before you begin

To re-apply the device-level configuration if you re-add it to the management center, do one of the following:

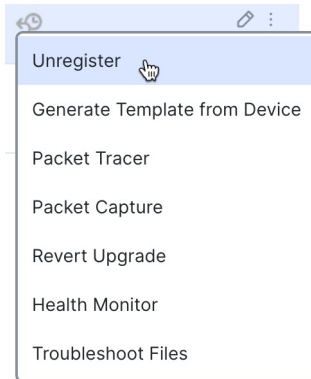

- Export the device configuration. See [Export and Import the Device Configuration, on page 48](#).
- Create a template for the device.

Procedure

Step 1 Choose **Devices > Device Management**.

Step 2 Next to the device you want to unregister, click **More** (⋮), and then click **Unregister**.

Figure 16: Unregister

Step 3 Confirm that you want to unregister the device.

Step 4 You can now change your manager.

- Re-register the device to this management center—If you know the registration key and NAT ID, you can [Add a Device to the Management Center Using a Registration Key, on page 27](#). If you need to reset them, you can reconfigure the manager as though it's new. See [Identify a New Management Center, on page 104](#).
 - Register to a new management center—[Identify a New Management Center, on page 104](#).
 - Change to the device manager—[Switch from Management Center to Device Manager, on page 110](#).
 - Delete the manager without specifying a new one—To sever the management connection on the threat defense without identifying a new manager (no manager mode), from the threat defense CLI use the **configure manager delete** command.
-

Add a Device Group

The management center allows you to group devices so you can easily deploy policies and install updates on multiple devices. You can expand and collapse the list of devices in the group.

If you add the primary device in a high-availability pair to a group, both devices are added to the group. If you break the high-availability pair, both devices remain in that group.

Procedure

Step 1 Choose **Devices > Device Management**.

- Step 2** From the **Add** drop-down menu, choose **Add Group**.
- To edit an existing group, click **Edit** (✎) for the group you want to edit.
- Step 3** Enter a **Name**.
- Step 4** Under **Available Devices**, choose one or more devices to add to the device group. Use Ctrl or Shift while clicking to choose multiple devices.
- Step 5** Click **Add** to include the devices you chose in the device group.
- Step 6** Optionally, to remove a device from the device group, click **Delete** (🗑) next to the device you want to remove.
- Step 7** Click **OK** to add the device group.
-

Shut Down or Restart the Device

It's important that you shut down your system properly. Simply unplugging the power or pressing the power switch can cause serious file system damage. Remember that there are many processes running in the background all the time, and unplugging or shutting off the power does not allow the graceful shutdown of your firewall.

See the following task to shut down or restart your system properly.

Note After restarting your device, you may see an error that the management connection could not be reestablished. In some cases, the connection is attempted before the Management interface on the device is ready. The connection will be retried automatically and should come up within 15 minutes.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device that you want to restart, click **Edit** (✎).
- Step 3** Click **Device**.
- Step 4** To restart the device:
- Click **Restart Device** (🔄).
 - When prompted, confirm that you want to restart the device.
- Step 5** To shut down the device:
- Click **Shut Down Device** (⊗) in the **System** section.
 - When prompted, confirm that you want to shut down the device.
 - If you have a console connection to the firewall, monitor the system prompts as the firewall shuts down. You will see the following prompt:

```
System is stopped.  
It is safe to power off now.  
Do you want to reboot instead? [y/N]
```

If you do not have a console connection, wait approximately 3 minutes to ensure the system has shut down.

For the ISA 3000, when shutdown is complete, the System LED will turn off. Wait at least 10 seconds before you remove the power.

Download the Managed Device List

You can download a report of all the managed devices.

Before you begin

To perform the following task, you must be an Admin user.

Procedure

-
- Step 1** Choose **Devices > Device Management**.
 - Step 2** Click the **Download Device List Report** link.
 - Step 3** You can download the device list in CSV or PDF format. Choose **Download CSV** or **Download PDF** to download the report.
-

Configure Device Settings

The **Devices > Device Management** page provides you with range of information and options:

- **View By**—Use this option to view the devices based on group, licenses, model, version, or access control policy.
- **Device State**—You can also view the devices based on its state. You can click on a state icon to view the devices belonging to it. The number of devices belonging to the states are provided within brackets.
- **Search**—You can search for a configured device by providing the device name, host name, or the IP address.
- **Add options**—You can add devices, high availability pairs, clusters and groups.
- **Edit and other actions**—Against each configured device, use the **Edit** (✎) icon to edit the device parameters and attributes. Click the **More** (⋮) icon and execute other actions:
 - **Access Control Policy**—Click on the link in the Access Control Policy column to view the policy that is deployed to the device.
 - **Unregister**—To unregister the device.
 - **Packet Tracer**—To navigate to the packet tracer page for examining policy configuration on the device by injecting a model packet into the system.

- Packet Capture—To navigate to the packet capture page, where, you can view the verdicts and actions the system takes while processing a packet.
- Revert Upgrade—To revert the upgrade and configuration changes that were made after the last upgrade. This action results in restoring the device to the version that was before the upgrade.
- Health Monitor—To navigate to the device's health monitoring page.
- Troubleshooting Files—Generate troubleshooting files, where you can choose the type of data to be included in the report.
- For Firepower 4100/9300 series devices, a link to the chassis manager web interface.

When you click on the device, the device properties page appears with several tabs. You can use the tabs to view the device information, and configure routing, interfaces, inline sets, and DHCP.

Edit General Settings

The **General** section of the **Device** page displays the settings described in the table below.

Figure 17: General

General	
Name:	10.10.0.6
Transfer Packets:	Yes
Troubleshoot:	Logs CLI Download
Mode:	Routed
Compliance Mode:	None
Performance Profile:	Default
TLS Crypto Acceleration:	Disabled
Device Configuration:	Import Export Download
OnBoarding Method:	Registration Key

Table 2: General Section Table Fields

Field	Description
Name	The display name of the device on the management center.
Transfer Packets	This displays whether or not the managed device sends packet data with the events to the management center.
Troubleshoot	Lets you generate and download troubleshooting files and also see CLI command output. See Generate Troubleshooting Files, on page 42 and View CLI Output, on page 45 .
Mode	The displays the mode of the management interface for the device: routed or transparent .

Field	Description
Compliance Mode	This displays the security certifications compliance for a device. Valid values are CC, UCAPL and None.
Performance Profile	This displays the core allocation performance profile for the device, as configured in the platform settings policy.
TLS Crypto Acceleration:	Shows whether TLS crypto acceleration is enabled or disabled.
Device Configuration	Lets you copy, export, or import a configuration. See Copy a Configuration to Another Device, on page 47 and Export and Import the Device Configuration, on page 48 .
OnBoarding Method	Shows whether the device was registered using a registration key or using the serial number (zero-touch provisioning).

You can edit some of these settings from this section.

Procedure

Step 1 Choose **Devices > Device Management**.

Step 2 Next to the device you want to modify, click **Edit** (✎).

Step 3 Click **Device**.

Step 4 In the **General** section, click **Edit** (✎).

- a) Enter a **Name** for the managed device.
- b) Check **Transfer Packets** to allow packet data to be stored with events on the management center.
- c) Click **Force Deploy** to force deployment of current policies and device configuration to the device.

Note Force-deploy consumes more time than the regular deployment since it involves the complete generation of the policy rules to be deployed on the threat defense.

Step 5 For **Troubleshoot** actions, see [Generate Troubleshooting Files, on page 42](#) and [View CLI Output, on page 45](#).

Step 6 For **Device Configuration** actions, see [Copy a Configuration to Another Device, on page 47](#) and [Export and Import the Device Configuration, on page 48](#).

Step 7 Click **Deploy**.

What to do next

- Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

Generate Troubleshooting Files

You can generate and download troubleshooting files for each device and also for all cluster nodes. For a cluster, you can download all files as a single compressed file. You can also include cluster logs for the cluster for cluster nodes.

You can alternatively trigger file generation from the **Devices > Device Management > More (⋮) > Troubleshoot Files** menu.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device or cluster you want to view, click **Edit (✎)**.
In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.
- Step 3** Click **Device** or **Cluster**.
- Step 4** Generate logs for the device or for all cluster nodes.
 - a) On the **General > Troubleshoot** section, click **Logs**.

Figure 18: Logs

- b) You are prompted to choose the logs you want to include. For a cluster, under **Device**, you can choose **All Devices** or an individual node. A cluster also has the **Cluster Logs** available.

Figure 19: Generate Troubleshoot Files

Generate Troubleshoot Files - 10.10.0.6

This operation may take several minutes to complete, the status can be tracked in Message Center Tasks.

Please select the data to include:

- All Data
 - Snort Performance and Configuration
 - Hardware Performance and Logs
 - System Configuration, Policy, and Logs
 - Detection Configuration, Policy, and Logs
 - Interface and Network Related Data
 - Discovery, Awareness, VDB Data, and Logs
 - Upgrade Data and Logs
 - All Database Data
 - All Log Data
 - Network Map Information
 - Deployment Logs

Cancel Generate

c) Click **Generate**.

Step 5 To download the generated logs, on the **General > Troubleshoot** section, click **Download**.

Figure 20: Download

General

Name: 10.10.0.6

Transfer Packets: Yes

Troubleshoot: Logs CLI Download

Mode: Routed

Compliance Mode: None

Performance Profile: Default

TLS Crypto Acceleration: Disabled

Device Configuration: Import Export Download

OnBoarding Method: Registration Key

The logs are downloaded to your computer.

View CLI Output

You can view a set of pre-defined CLI outputs that can help you troubleshoot the device or cluster. You can also enter any **show** command and see the output.

For a device, the following commands are executed:

- **show version**
- **show asp drop**
- **show counters**
- **show int ip brief**
- **show blocks**
- **show cpu detailed**

For a cluster or cluster node:

- **show running-config cluster**
- **show cluster info**
- **show cluster info health**
- **show cluster info transport cp**
- **show version**
- **show asp drop**
- **show counters**
- **show arp**
- **show int ip brief**
- **show blocks**
- **show cpu detailed**
- **show interface *ccl_interface***
- **ping *ccl_ip* size *ccl_mtu* repeat 2**

Procedure

Step 1 Choose **Devices > Device Management**.

Step 2 Next to the device or cluster you want to view, click **Edit** (🔗).

In a multidomain deployment, if you are not in a leaf domain, the system prompts you to switch.

Step 3 Click **Device** or **Cluster**.

Step 4 In the **General > Troubleshoot** section, click **CLI**.

Figure 21: CLI

The **CLI Troubleshoot** dialog box appears with the pre-defined CLIs executed.

Figure 22: CLI Troubleshoot

Step 5 On the **CLI Troubleshoot** dialog box, you can perform the following tasks.

- Enter a **show** command in the **Command** field, and click **Execute**. The new command output will be added to the window.
- Click **Refresh** to re-run the predefined CLIs.
- Click **Copy** to copy the output to your clipboard.
- For a cluster, choose a different node from the **Device** drop down list.

Step 6 Click **Close**.

Copy a Configuration to Another Device

When a new device is deployed in the network you can easily copy configurations and policies from a pre-configured device, instead of manually reconfiguring the new device.

Before you begin

Confirm that:

- The source and destination threat defense devices are the same model and are running the same version of the software.
- The source is either a standalone Secure Firewall Threat Defense device or a Secure Firewall Threat Defense high availability pair.
- The destination device is a standalone threat defense device.
- The source and destination threat defense devices have the same number of physical interfaces.
- The source and destination threat defense devices are in the same firewall mode - routed or transparent.
- The source and destination threat defense devices are in the same security certifications compliance mode.
- The source and destination threat defense devices are in the same domain.
- Configuration deployment is not in progress on either the source or the destination threat defense devices.

Procedure

Step 1 Choose **Devices > Device Management**.

Step 2 Next to the device you want to modify, click **Edit** (✎).

Step 3 Click **Device**.

Step 4 In the **General** section, do one of the following:

- Click **Get Device Configuration** (↓) to copy device configuration from another device to the new device. On the **Get Device Configuration** page, select the source device in the **Select Device** drop-down list.

- Click **Push Device Configuration** (↑) to copy device configuration from the current device to the new device. On the **Push Device Configuration** page, select the destination to which configuration is to be copied in the **Target Device** drop-down list.

Step 5 (Optional) Check **Include shared policies configuration** check box to copy policies.

Shared policies like AC policy, NAT, Platform Settings and FlexConfig policies can be shared across multiple devices.

Step 6 Click **OK**.

You can monitor the status of the copy device configuration task on **Tasks** in the Message Center.

When the copy device configuration task is initiated, it erases the configuration on the target device and copies the configuration of the source device to the destination device.

Warning When you have completed the copy device configuration task, you cannot revert the target device to its original configuration.

Export and Import the Device Configuration

You can export all of the the device-specific configuration configurable on the Device pages, including:

- Interfaces
- Inline Sets
- Routing
- DHCP
- VTEP
- Associated objects

You can then import the saved configuration for the same device in the following use cases:

- Moving the device to a different management center—First unregister the device from the original management center, then add the device to the new management center. Then you can import the saved configuration.
- Moving the device between domains—When you move a device between domains, some device-specific configuration is not retained because supporting objects (such as interface groups for security zones) do not exist in the new domain. By importing the configuration after the domain move, any necessary objects are created for that domain, and the device configuration is restored.
- Restore an old configuration—If you deployed changes that negatively impacted the operation of the device, you can import a backup copy of a known working configuration to restore a previous operational state.
- Reregistering a device—If you unregister a device from the management center, but then want to add it back, you can import the saved configuration.

See the following guidelines:

- You can only import the configuration to the same device (the UUID must match). You cannot import a configuration to a different device, even if it is the same model.
- Do not change the version running on the device between exporting and importing; the version must match.
- When moving the device to a different management center, the target management center version must be the same as the source version.
- If an object doesn't exist, it will be created. If an object exists, but the value is different, see below:

Table 3: Object Import Action

Scenario	Import Action
Object exists with the same name and value.	Reuse existing objects.
Object exists with the same name but different value.	Network and Port objects: Create object overrides for this device. See Object Overrides, on page 1260 . Interface objects: Create new objects. For example, if both the type (security zone or interface group) and the interface type (routed or switched, for example) do not match, then a new object is created. All other objects: Reuse existing objects even though the values are different.
Object doesn't exist.	Create new object.s

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device you want to edit, click **Edit** (✎).
- Step 3** Click **Device**.
- Step 4** Export the configuration.
 - a) In the **General** area, click **Export**.

Figure 23: Export Device Configuration

You are prompted to acknowledge the export; click **OK**.

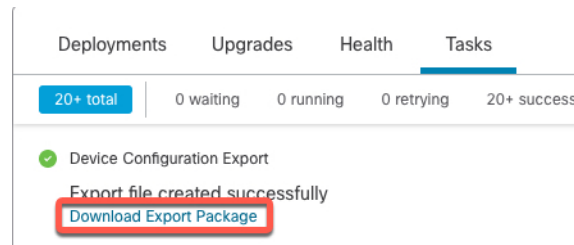

Figure 24: Acknowledge Export

You can view the export progress in the **Tasks** page.

- b) On the **Notifications > Tasks** page, ensure that the export has completed; click **Download Export Package**. Alternatively, you can click the **Download** button in the **General** area.

Figure 25: Export Task

You are prompted to download the package; click **Click here to download the package** to save the file locally, and then click **OK** to exit the dialog box.

Figure 26: Download Package

Step 5 Import the configuration.

- a) In the **General** area, click **Import**.

Figure 27: Import Device Configuration

General ✎ ↓ ↕	
Name:	192.168.0.197 FTDv
Transfer Packets:	Yes
Mode:	Routed
Compliance Mode:	None
TLS Crypto Acceleration:	Disabled
Device Configuration:	<input type="button" value="Import"/> <input type="button" value="Export"/> <input type="button" value="Download"/>

You are prompted to acknowledge that the current configuration will be replaced. Click **Yes**, and then navigate to the configuration package (with the suffix `.sfo`; note that this file is different from the Backup/Restore files).

Figure 28: Import Package

Device Configuration Import

This will replace current device configuration with new configuration from imported file. Do you want to continue?

Figure 29: Navigate to Package

Name
 [Redacted]
 DeviceExport-0434ef00-15bb-11ec-bb94-93bde3ad19d.sfo
 [Redacted]

You are prompted to acknowledge the import; click **OK**.

Figure 30: Acknowledge Import

Device Configuration Import

Device configuration import task initiated. View the progress of task from Tasks view.

You can view the import progress in the **Tasks** page.

- b) View the import reports so you can see what was imported. On the **Notifications > Tasks** page for the import task, click **View Import Report**.

Figure 31: View Import Report

The **Device Configuration Import Reports** page provides links to available reports.

Cisco Firepower Management Center

Device Configuration Import Reports

Device	Shared Policies	Device Configurations
0434ef00-15bb-11ec-bb94-93bdde3ad19d	Report does not exist	Device configurations import report

Edit License Settings

The **License** section of the **Device** page displays the licenses enabled for the device.

You can enable licenses on your device if you have available licenses on your management center.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device where you want to enable or disable licenses, click **Edit** (🔗).
- Step 3** Click **Device**.
- Step 4** In the **License** section, click **Edit** (🔗).
- Step 5** Check or clear the check box next to the license you want to enable or disable for the managed device.
- Step 6** Click **Save**.

What to do next

- Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

View System Information

The **System** section of the **Device** page displays a read-only table of system information, as described in the following table.

You can also shut down or restart the device.

Table 4: System Section Table Fields

Field	Description
Model	The model name and number for the managed device.
Serial	The serial number of the chassis of the managed device.
Time	The current system time of the device.
Time Zone	Shows the time zone.
Version	The version of the software currently installed on the managed device.
Time Zone setting for time-based rules	The current system time of the device, in the time zone specified in device platform settings.

View the Inspection Engine

The Inspection Engine section of the **Device** page shows whether your device uses Snort2 or Snort3. To switch the inspection engine, see [Cisco Secure Firewall Management Center Snort 3 Configuration Guide](#).

View Health Information

The **Health** section of the **Device** page displays the information described in the table below.

Table 5: Health Section Table Fields

Field	Description
Status	An icon that represents the current health status of the device. Clicking the icon displays the Health Monitor for the appliance.
Policy	A link to a read-only version of the health policy currently deployed at the device.
Excluded	A link to the Health Exclude page, where you can enable and disable health exclusion modules.

Edit Management Settings

You can edit management settings in the **Management** area.

Update the Hostname or IP Address in the Management Center

If you edit the hostname or IP address of a device after you added it to the management center (using the device's CLI, for example), you need to use the procedure below to manually update the hostname or IP address on the managing management center.

To change the device management IP address on the device, see [Modify Threat Defense Management Interfaces at the CLI, on page 75](#).

If you used only the NAT ID when registering the device, then the IP shows as **NO-IP** on this page, and you do not need to update the IP address/hostname.

If you used zero-touch provisioning to register the device on the outside interface, the hostname is automatically generated along with a matching DDNS configuration; you cannot edit the hostname in this case.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device where you want to modify management options, click **Edit** (✎).
- Step 3** Click **Device**, and view the **Management** area.
- Step 4** Disable management temporarily by clicking the slider so it is disabled (🔴).

Figure 32: Disable Management

You are prompted to proceed with disabling management; click **Yes**.

Disabling management blocks the connection between the management center and the device, but does **not** unregister the device from the management center.

- Step 5** Edit the **Remote Host Address** IP address and optional **Secondary Address** (when using a redundant data interface) or hostname by clicking **Edit** (✎).

Figure 33: Edit Management Address

Management	
Remote Host Address:	10.89.5.29
Secondary Address:	
Status:	✔
Manager Access Interface:	Data Interface
Manager Access Details:	Configuration

Step 6 In the **Management** dialog box, modify the name or IP address in the **Remote Host Address** field and the optional **Secondary Address** field, and click **Save**.

For information about using a secondary manager access data interface, see [Configure a Redundant Manager Access Data Interface, on page 65](#).

Figure 34: Management IP Address

Management	
Remote Host Address:	<input type="text" value="10.89.5.29"/>
Secondary Address:	<input type="text" value="10.99.11.6"/>
<input type="button" value="Cancel"/> <input type="button" value="Save"/>	

Step 7 Reenable management by clicking the slider so it is enabled (.

Figure 35: Enable Management Connection

Management	
Remote Host Address:	10.89.5.4
Secondary Address:	
Status:	✔
Manager Access Interface:	Management Interface

Change Both Management Center and Threat Defense IP Addresses

You might want to change both management center and threat defense IP addresses if you need to move them to a new network.

Procedure

Step 1

Disable the management connection.

For a high-availability pair or cluster, perform these steps on all units.

- Choose **Devices > Device Management**.
- Next to the device, click **Edit** (✎).
- Click **Device**, and view the **Management** area.
- Disable management temporarily by clicking the slider so it is disabled (☐).

Figure 36: Disable Management

You are prompted to proceed with disabling management; click **Yes**.

Step 2

Change the device IP address in the management center to the new device IP address.

You will change the IP address on the device later.

For a high-availability pair or cluster, perform these steps on all units.

- Edit the **Remote Host Address** IP address and optional **Secondary Address** (when using a redundant data interface) or hostname by clicking **Edit** (✎).

Figure 37: Edit Management Address

Management	
Remote Host Address:	10.89.5.29
Secondary Address:	
Status:	✔
Manager Access Interface:	Data Interface
Manager Access Details:	Configuration

- b) In the **Management** dialog box, modify the name or IP address in the **Remote Host Address** field and the optional **Secondary Address** field, and click **Save**.

Figure 38: Management IP Address

Management	
Remote Host Address:	<input type="text" value="10.89.5.29"/>
Secondary Address:	<input type="text" value="10.99.11.6"/>
<input type="button" value="Cancel"/> <input type="button" value="Save"/>	

Step 3 Change the management center IP address.

Caution Be careful when making changes to the management center interface to which you are connected; if you cannot re-connect because of a configuration error, you need to access the management center console port to re-configure the network settings in the Linux shell. You must contact Cisco TAC to guide you in this operation.

- Choose **System** (⚙) > **Configuration**, and then choose **Management Interfaces**.
- In the **Interfaces** area, click **Edit** next to the interface that you want to configure.
- Change the IP address, and click **Save**.

Step 4 Change the manager IP address on the device.

For a high-availability pair or cluster, perform these steps on all units.

- At the threat defense CLI, view the management center identifier.

show managers

Example:

```
> show managers
Type                : Manager
Host                : 10.10.1.4
Display name       : 10.10.1.4
Identifier          : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration       : Completed
Management type    : Configuration
```

- b) Edit the management center IP address or hostname.

```
configure manager edit identifier {hostname {ip_address | hostname} | displayname display_name}
```

If the management center was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

Example:

```
> configure manager edit f7ffad78-bf16-11ec-a737-baa2f76ef602 hostname 10.10.5.1
```

- Step 5** Change the IP address of the manager access interface at the console port.

For a high-availability pair or cluster, perform these steps on all units.

If you use the dedicated Management interface:

```
configure network ipv4
```

```
configure network ipv6
```

If you use the dedicated Management interface:

```
configure network management-data-interface disable
```

```
configure network management-data-interface
```

- Step 6** Reenable management by clicking the slider so it is enabled ()

For a high-availability pair or cluster, perform these steps on all units.

Figure 39: Enable Management Connection

- Step 7** (If using a data interface for manager access) Refresh the data interface settings in the management center.

For a high-availability pair, perform this step on both units.

- Choose **Devices > Device Management > Device > Management > Manager Access - Configuration Details**, and click **Refresh**.
- Choose **Devices > Device Management > Interfaces**, and set the IP address to match the new address.
- Return to the **Manager Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.

- Step 8** Ensure the management connection is reestablished.

In the management center, check the management connection status on the **Devices > Device Management > Device > Management > Manager Access - Configuration Details > Connection Status** page.

At the threat defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 40: Connection Status

The screenshot shows the 'Manager access - Configuration Details' page. At the top, it states 'Manager access configuration on device is in sync with the manager.' Below this are three tabs: 'Configuration', 'CLI Output', and 'Connection Status', with 'Connection Status' being the active tab. The main content area displays the output of the 'sftunnel-status-brief' command from the Firewall Threat Defense CLI. The output shows a successful connection to peer '10.89.5.35' via '169.254.1.3' using 'tap_nlp' interfaces. It includes details for Channel-A (CONTROL) and Channel-B (EVENT), registration completion, and connection timestamps. A 'Refresh' link is visible in the top right of the output area, and a 'Close' button is at the bottom right.

```
> sftunnel-status-brief
PEER:10.89.5.35
Peer channel Channel-A is valid type (CONTROL), using 'tap_nlp', connected to '10.89.5.35' via '169.254.1.3'
Peer channel Channel-B is valid type (EVENT), using 'tap_nlp', connected to '10.89.5.35' via '169.254.1.3'
Registration: Completed.
IPv4 Connection to peer '10.89.5.35' Start Time: Mon May 23 22:55:01 2022 UTC
Heartbeat Send Time:      Mon May 23 22:56:21 2022 UTC
Heartbeat Received Time: Mon May 23 22:55:58 2022 UTC
Last disconnect time   : Mon May 23 22:54:39 2022 UTC
Last disconnect reason : Both control and event channel connections with peer went down
```

Step 9 (For a high-availability management center pair) Repeat configuration changes on the secondary management center.

- a) Change the secondary management center IP address.
- b) Specify the new peer addresses on both units.
- c) Make the secondary unit the active unit.
- d) Disable the device management connection.
- e) Change the device IP address in the management center.
- f) Reenable the management connection.

Change the Manager Access Interface from Management to Data

You can manage the threat defense from either the dedicated Management interface, or from a data interface. If you want to change the manager access interface after you added the device to the management center, follow these steps to migrate from the Management interface to a data interface. To migrate the other direction, see [Change the Manager Access Interface from Data to Management, on page 63](#).

Initiating the manager access migration from Management to data causes the management center to apply a block on deployment to the threat defense. To remove the block, enable manager access on the data interface.

See the following steps to enable manager access on a data interface, and also configure other required settings.

Before you begin

For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

Procedure

Step 1

Initiate the interface migration.

- a) On the **Devices > Device Management** page, click **Edit** (✎) for the device.
- b) Go to the **Device > Management** section, and click the link for **Manager Access Interface**.

The **Manager Access Interface** field shows the current Management interface. When you click the link, choose the new interface type, **Data Interface**, in the **Manage device by** drop-down list.

Figure 41: Manager Access Interface

Manager Access Interface

This is an advanced setting and need to be configured only if needed.
See the [online help](#) for detailed steps.

Manage device by

Data Interface

Switching the manager access interface from Management to Data interface causes the deployment to be blocked. To unblock the deploy, pick a data interface and enable it for manager Access. See the [online help](#) for detailed steps.

Close Save

- c) Click **Save**.

You must now complete the remaining steps in this procedure to enable manager access on the data interface. The **Management** area now shows **Manager Access Interface: Data Interface**, and **Manager Access Details: Configuration**.

Figure 42: Manager Access

If you click **Configuration**, the **Manager Access - Configuration Details** dialog box opens. The **Manager Access Mode** shows a Deploy pending state.

Step 2 Enable manager access on a data interface on the **Devices > Device Management > Interfaces > Edit Physical Interface > Manager Access** page.

See [Configure Routed Mode Interfaces, on page 778](#). You can enable manager access on one routed data interface, plus an optional secondary interface. Make sure these interfaces are fully configured with a name and IP address and that they are enabled.

If you use a secondary interface for redundancy, see [Configure a Redundant Manager Access Data Interface, on page 65](#) for additional required configuration.

Step 3 (Optional) If you use DHCP for the interface, enable the web type DDNS method on the **Devices > Device Management > DHCP > DDNS** page.

See [Configure Dynamic DNS, on page 837](#). DDNS ensures the management center can reach the threat defense at its Fully-Qualified Domain Name (FQDN) if the FTD's IP address changes.

Step 4 Make sure the threat defense can route to the management center through the data interface; add a static route if necessary on **Devices > Device Management > Routing > Static Route**.

See [Add a Static Route, on page 1064](#).

Step 5 (Optional) Configure DNS in a Platform Settings policy, and apply it to this device at **Devices > Platform Settings > DNS**.

See [DNS, on page 867](#). DNS is required if you use DDNS. You may also use DNS for FQDNs in your security policies.

Step 6 (Optional) Enable SSH for the data interface in a Platform Settings policy, and apply it to this device at **Devices > Platform Settings > Secure Shell**.

See [SSH Access, on page 881](#). SSH is not enabled by default on the data interfaces, so if you want to manage the threat defense using SSH, you need to explicitly allow it.

Step 7 Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

The management center will deploy the configuration changes over the current Management interface. After the deployment, the data interface is now ready for use, but the original management connection to Management is still active.

Step 8 At the threat defense CLI (preferably from the console port), set the Management interface to use a static IP address and set the gateway to use the data interfaces. For high availability, perform this step on both units.

```
configure network {ipv4 | ipv6} manual ip_address netmask data-interfaces
```

- *ip_address netmask*—Although you do not plan to use the Management interface, you must set a static IP address, for example, a private address so that you can set the gateway to **data-interfaces** (see the next bullet). You cannot use DHCP because the default route, which must be **data-interfaces**, might be overwritten with one received from the DHCP server.
- **data-interfaces**—This setting forwards management traffic over the backplane so it can be routed through the manager access data interface.

We recommend that you use the console port instead of an SSH connection because when you change the Management interface network settings, your SSH session will be disconnected.

Step 9 If necessary, re-cable the threat defense so it can reach the management center on the data interface. For high availability, perform this step on both units.

Step 10 In the management center, disable the management connection, update the **Remote Host Address** IP address and optional **Secondary Address** for the threat defense in the **Devices > Device Management > Device > Management** section, and reenoble the connection.

See [Update the Hostname or IP Address in the Management Center, on page 53](#). If you used the threat defense hostname or just the NAT ID when you added the threat defense to the management center, you do not need to update the value; however, you need to disable and reenoble the management connection to restart the connection.

Step 11 Ensure the management connection is reestablished.

In the management center, check the management connection status on the **Devices > Device Management > Device > Management > Manager Access - Configuration Details > Connection Status** page.

At the threat defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

The following status shows a successful connection for a data interface, showing the internal "tap_nlp" interface.

Figure 43: Connection Status

Manager access - Configuration Details

Manager access configuration on device is in sync with the manager.

Configuration CLI Output **Connection Status**

sftunnel-status-brief command output from Firewall Threat Defense [Refresh]

```

> sftunnel-status-brief
PEER:10.89.5.35
Peer channel Channel-A is valid type (CONTROL), using 'tap_nlp', connected to '10.89.5.35' via '169.254.1.3'
Peer channel Channel-B is valid type (EVENT), using 'tap_nlp', connected to '10.89.5.35' via '169.254.1.3'
Registration: Completed.
IPv4 Connection to peer '10.89.5.35' Start Time: Mon May 23 22:55:01 2022 UTC
Heartbeat Send Time: Mon May 23 22:56:21 2022 UTC
Heartbeat Received Time: Mon May 23 22:55:58 2022 UTC
Last disconnect time : Mon May 23 22:54:39 2022 UTC
Last disconnect reason : Both control and event channel connections with peer went down

```

[Close](#)

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See [Troubleshoot Management Connectivity on a Data Interface, on page 85](#).

Change the Manager Access Interface from Data to Management

You can manage the threat defense from either the dedicated Management interface, or from a data interface. If you want to change the manager access interface after you added the device to the management center, follow these steps to migrate from a data interface to the Management interface. To migrate the other direction, see [Change the Manager Access Interface from Management to Data, on page 59](#).

Initiating the manager access migration from data to Management causes the management center to apply a block on deployment to the threat defense. You must disable manager access on the data interface to remove the block.

See the following steps to disable manager access on a data interface, and also configure other required settings.

Before you begin

For high-availability pairs, unless stated otherwise, perform all steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

Procedure

Step 1 Initiate the interface migration.

- a) On the **Devices > Device Management** page, click **Edit** (✎) for the device.
- b) Go to the **Device > Management** section, and click the link for **Manager Access Interface**.

The **Manager Access Interface** field shows the current management interface as data. When you click the link, choose the new interface type, **Management Interface**, in the **Manage device by** drop-down list.

Figure 44: Manager Access Interface

- c) Click **Save**.

You must now complete the remaining steps in this procedure to enable manager access on the Management interface. The **Management** area now shows the **Manager Access Interface: Management Interface**, and **Manager Access Details: Configuration**.

Figure 45: Manager Access

If you click **Configuration**, the **Manager Access - Configuration Details** dialog box opens. The **Manager Access Mode** shows a Deploy pending state.

- Step 2** Disable manager access on the data interface(s) on the **Devices > Device Management > Interfaces > Edit Physical Interface > Manager Access** page.

See [Configure Routed Mode Interfaces, on page 778](#). This step removes the block on deployment.

- Step 3** If you have not already done so, configure DNS settings for the data interface in a Platform Setting policy, and apply it to this device at **Devices > Platform Settings > DNS**.
- See [DNS, on page 867](#). The management center deployment that disables manager access on the data interface will remove any local DNS configuration. If that DNS server is used in any security policy, such as an FQDN in an Access Rule, then you must re-apply the DNS configuration using the management center.
- Step 4** Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).
- The management center will deploy the configuration changes over the current data interface.
- Step 5** If necessary, re-cable the threat defense so it can reach the management center on the Management interface. For High Availability, perform this step on both units.
- Step 6** At the threat defense CLI, configure the Management interface IP address and gateway using a static IP address or DHCP. For high availability, perform this step on both units.

When you originally configured the data interface for manager access, the Management gateway was set to data-interfaces, which forwarded management traffic over the backplane so it could be routed through the manager access data interface. You now need to set an IP address for the gateway on the management network.

Static IP address:

```
configure network {ipv4 | ipv6} manual ip_address netmask gateway_ip
```

DHCP:

```
configure network {ipv4 | ipv6} dhcp
```

- Step 7** In the management center, disable the management connection, update the **Remote Host Address** IP address and remove the optional **Secondary Address** for the threat defense in the **Devices > Device Management > Device > Management** section, and reenable the connection.

See [Update the Hostname or IP Address in the Management Center, on page 53](#). If you used the threat defense hostname or just the NAT ID when you added the threat defense to the management center, you do not need to update the value; however, you need to disable and re-enable the management connection to restart the connection.

- Step 8** Ensure the management connection is reestablished.

In the management center, check the management connection status on the **Devices > Device Management > Device > Management > Status** field or view notifications in the management center.

At the threat defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See [Troubleshoot Management Connectivity on a Data Interface, on page 85](#).

Configure a Redundant Manager Access Data Interface

When you use a data interface for manager access, you can configure a secondary data interface to take over management functions if the primary interface goes down. You can configure only one secondary interface. The device uses SLA monitoring to track the viability of the static routes and an ECMP zone that contains both interfaces so management traffic can use both interfaces.

High availability is not supported.

Before you begin

- The secondary interface needs to be in a separate security zone from the primary interface.
- All of the same requirements apply to the secondary interface as apply to the primary interface. See [Using the Threat Defense Data Interface for Management, on page 4](#).

Procedure

Step 1 On the **Devices > Device Management** page, click **Edit** (🔗) for the device.

Step 2 Enable manager access for the secondary interface.

This setting is in addition to standard interface settings such as enabling the interface, setting the name, setting the security zone, and setting a static IPv4 address.

- Choose **Interfaces > Edit Physical Interface > Manager Access**.
- Check **Enable management on this interface for the Manager**.
- Click **OK**.

Both interfaces show (**Manager Access**) in the interface listing.

Figure 46: Interface Listing

Interface	Logical Name	Type	Security Zones
Diagnostic1/1	diagnostic	Physical	
Ethernet1/1 (Manager Access)	outside	Physical	outside
Ethernet1/2		Physical	
Ethernet1/3		Physical	
Ethernet1/4		Physical	
Ethernet1/5		Physical	
Ethernet1/6		Physical	
Ethernet1/7		Physical	
Ethernet1/8 (Manager Access)	redundant	Physical	mgmt

Step 3 Add the secondary address to the **Management** settings.

- Click **Device**, and view the **Management** area.
- Click **Edit** (🔗).

Figure 47: Edit Management Address

The screenshot shows a 'Management' dialog box with the following fields and values:

Remote Host Address:	10.89.5.29
Secondary Address:	
Status:	✓
Manager Access Interface:	Data Interface
Manager Access Details:	Configuration

- c) In the **Management** dialog box, modify the name or IP address in the **Secondary Address** field

Figure 48: Management IP Address

The screenshot shows the 'Management' dialog box with the following fields and values:

Remote Host Address:	10.89.5.29
Secondary Address:	10.99.11.6

Buttons: Cancel, Save

- d) Click **Save**.

Step 4 Create an ECMP zone with both interfaces.

- Click **Routing**.
- From the virtual router drop-down, choose the virtual router in which the primary and secondary interfaces reside.
- Click **ECMP**, and then click **Add**.
- Enter a **Name** for the ECMP zone.
- Select the primary and secondary interfaces under the **Available Interfaces** box, and then click **Add**.

Figure 49: Add an ECMP Zone

The screenshot shows a dialog box titled "Add ECMP". At the top right of the dialog are a help icon (question mark) and a close icon (X). Below the title bar is a text input field labeled "Name" containing the text "redundant-mgmt". The main area of the dialog is divided into two columns. The left column is titled "Available Interfaces" and is currently empty. The right column is titled "Selected Interfaces" and contains two entries: "outside" and "redundant", each with a trash can icon to its right. A blue "Add" button is located between the two columns. At the bottom of the dialog are two buttons: "Cancel" and "OK".

f) Click **OK**, and then **Save**.

Step 5

Add equal-cost default static routes for both interfaces and enable SLA tracking on both.

The routes should be identical except for the gateway and should both have metric 1. The primary interface should already have a default route that you can edit.

Figure 50: Add/Edit Static Route

Edit Static Route Configuration

Type: IPv4 IPv6

Interface*

(Interface starting with this icon signifies it is available for route leak)

Available Network

- 10.99.11.1
- any-ipv4
- IPv4-Benchmark-Tests
- IPv4-Link-Local
- IPv4-Multicast
- IPv4-Private-10.0.0.0-8

Selected Network

any-ipv4

Ensure that egress virtualrouter has route to that destination

Gateway

Metric:

(1 - 254)

Tunneled: (Used only for default Route)

Route Tracking:

- Click **Static Route**.
- Either click **Add Route** to add a new route, or click **Edit** () for an existing route.
- From the **Interface** drop-down, choose the interface.
- For the destination network, select **any-ipv4** from the **Available Networks** box and click **Add**.
- Enter the default **Gateway**.
- For **Route Tracking**, click **Add** () to add a new SLA monitor object.
- Enter the required parameters including the following:
 - The **Monitor Address** as the management center IP address.
 - The zone for the primary or secondary management interface in **Available Zones**; for example, choose the outside zone for the primary interface object, and the mgmt zone for the secondary interface object.

See [SLA Monitor](#), on page 1338 for more information.

Figure 51: Add SLA Monitor

New SLA Monitor Object ?

Cancel Save

- h) Click **Save**, then choose the SLA object you just created in the **Route Tracking** drop-down list.
- i) Click **OK**, and then **Save**.
- j) Repeat for the default route for the other management interface.

Step 6

Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

As part of the deployment for this feature, the management center enables the secondary interface for management traffic, including auto-generated policy-based routing configuration for management traffic to get to the right data interface. The management center also deploys a second instance of the **configure network management-data-interface** command. Note that if you edit the secondary interface at the CLI, you cannot configure the gateway or otherwise alter the default route, because the static route for this interface can only be edited in the management center.

View Manager Access Details for Data Interface Management

Model Support—Threat Defense

When you use a data interface for management center management instead of using the dedicated Management interface, you must be careful about changing the interface and network settings for the device in the management center so you do not disrupt the connection. You can also change the data interface settings locally on the device, which requires you to reconcile those changes in the management center manually. The **Devices > Device Management > Device > Management > Manager Access - Configuration Details** dialog box helps you resolve any discrepancies between the management center and the threat defense local configuration.

Normally, you configure the manager access data interface as part of initial threat defense setup before you add the threat defense to the management center. When you add the threat defense to the management center, the management center discovers and maintains the interface configuration, including the following settings: interface name and IP address, static route to the gateway, DNS servers, and DDNS server. For the DNS server, the configuration is maintained locally if it is discovered during registration, but it is not added to the Platform Settings policy in management center.

After you add the threat defense to the management center, if you change the data interface settings on the threat defense locally using the **configure network management-data-interface** command, then the management center detects the configuration changes, and blocks deployment to the threat defense. The management center detects the configuration changes using one of the following methods:

- Deploy to the threat defense. Before the management center deploys, it will detect the configuration differences and stop the deployment.
- The **Sync** button in the **Interfaces** page.
- The **Refresh** button on the **Manager Access - Configuration Details** dialog box.

To remove the block, you must go to the **Manager Access - Configuration Details** dialog box and click **Acknowledge**. The next time you deploy, the management center configuration will overwrite any remaining conflicting settings on the threat defense. It is your responsibility to manually fix the configuration in the management center before you re-deploy.

See the following pages on this dialog box.

Configuration

View the configuration comparison of the manager access data interface on the management center and the threat defense.

The following example shows the configuration details of the threat defense where the **configure network management-data-interface** command was entered on the threat defense. The pink highlights show that if you **Acknowledge** the differences but do not match the configuration in the management center, then the threat defense configuration will be removed. The blue highlights show configurations that will be modified on the threat defense. The green highlights show configurations that will be added to the threat defense.

Manager access - Configuration Details

Manager access configuration on device have been updated outside of Manager. Review the differences and update Manager values accordingly.

Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

Modify Threat Defense Management Interfaces at the CLI

Modify the management interface settings on the managed device using the CLI. Many of these settings are ones that you set when you performed the initial setup; this procedure lets you change those settings, and set additional settings such as enabling an event interface if your model supports it, or adding static routes.

Note This topic applies to the dedicated Management interface. You can alternatively configure a data interface for management. If you want to change network settings for that interface, you should do so within management center and not at the CLI. If you need to troubleshoot a disrupted management connection, and need to make changes directly on the threat defense, see [Modify the Threat Defense Data Interface Used for Management at the CLI, on page 81](#).

For information about the threat defense CLI, see the [Cisco Secure Firewall Threat Defense Command Reference](#).

Note When using SSH, be careful when making changes to the management interface; if you cannot re-connect because of a configuration error, you will need to access the device console port.

Note If you change the device management IP address, then see the following tasks for management center connectivity depending on how you identified the management center during initial device setup using the **configure manager add** command (see [Identify a New Management Center, on page 104](#)):

- **IP address—No action.** If you identified the management center using a reachable IP address, then the management connection will be reestablished automatically after several minutes. We recommend that you also change the device IP address shown in management center to keep the information in sync; see [Update the Hostname or IP Address in the Management Center, on page 53](#). This action can help the connection reestablish faster. **Note:** If you specified an unreachable management center IP address, then see the procedure for NAT ID below.
- **NAT ID only—Manually reestablish the connection.** If you identified the management center using only the NAT ID, then the connection cannot be automatically reestablished. In this case, change the device management IP address in management center according to [Update the Hostname or IP Address in the Management Center, on page 53](#).

Note In a High Availability management center configuration, when you modify the management IP address from the device CLI or from the management center, the secondary management center does not reflect the changes even after an HA synchronization. To ensure that the secondary management center is also updated, switch roles between the two management centers, making the secondary management center the active unit. Modify the management IP address of the registered device on the device management page of the now active management center.

Before you begin

- You can create user accounts that can log into the CLI using the **configure user add** command; see [Add an Internal User at the CLI, on page 175](#). You can also configure AAA users according to [External Authentication, on page 870](#).

Procedure

- Step 1** Connect to the device CLI, either from the console port or using SSH.
See [Log Into the Command Line Interface on the Device, on page 11](#).
- Step 2** Log in with the Admin username and password.
- Step 3** (Firepower 4100/9300/Secure Firewall 4200 only) Enable the second management interface as an event-only interface.

configure network management-interface enable management1

configure network management-interface disable-management-channel management1

You always need a management interface for management traffic. If your device has a second management interface, you can enable it for event-only traffic.

You can optionally disable events for the main management interface using the **configure network management-interface disable-events-channel** command. In either case, the device will try to send events

on the event-only interface, and if that interface is down, it will send events on the management interface even if you disable the event channel.

You cannot disable both event and management channels on an interface.

To use a separate event interface, you also need to enable an event interface on the management center. See the [Cisco Secure Firewall Management Center Administration Guide](#).

Example:

```
> configure network management-interface enable management1
Configuration updated successfully

> configure network management-interface disable-management-channel management1
Configuration updated successfully

>
```

Step 4

Configure the IP address of the management interface and/or event interface:

If you do not specify the *management_interface* argument, then you change the network settings for the default management interface. When configuring an event interface, be sure to specify the *management_interface* argument. The event interface can be on a separate network from the management interface, or on the same network. If you are connected to the interface you are configuring, you will be disconnected. You can re-connect to the new IP address.

a) Configure the IPv4 address:

- Manual configuration:

```
configure network ipv4 manual ip_address netmask gateway_ip [management_interface]
```

Note that the *gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *gateway_ip* for use with the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

Example:

```
> configure network ipv4 manual 10.10.10.45 255.255.255.0 10.10.10.1 management1
Setting IPv4 network configuration.
Network settings changed.

>
```

- DHCP (supported on the default management interface only):

```
configure network ipv4 dhcp
```

b) Configure the IPv6 address:

- Stateless autoconfiguration:

```
configure network ipv6 router [management_interface]
```

Example:

```
> configure network ipv6 router management0
Setting IPv6 network configuration.
Network settings changed.

>
```

- Manual configuration:

```
configure network ipv6 manual ip6_address ip6_prefix_length [ip6_gateway_ip]
[management_interface]
```

Note that the *ip6_gateway_ip* in this command is used to create the default route for the device. If you configure an event-only interface, then you must enter the *ip6_gateway_ip* as part of the command; however, this entry just configures the default route to the value you specify and does not create a separate static route for the eventing interface. If you are using an event-only interface on a different network from the management interface, we recommend that you set the *ip6_gateway_ip* for use with the management interface, and then create a static route separately for the event-only interface using the **configure network static-routes** command.

Example:

```
> configure network ipv6 manual 2001:0DB8:BA98::3210 64 management1
Setting IPv6 network configuration.
Network settings changed.

>
```

- DHCPv6 (supported on the default management interface only):

```
configure network ipv6 dhcp
```

Step 5

For IPv6, enable or disable ICMPv6 Echo Replies and Destination Unreachable messages. These messages are enabled by default.

```
configure network ipv6 destination-unreachable {enable | disable}
```

```
configure network ipv6 echo-reply {enable | disable}
```

You might want to disable these packets to guard against potential denial of service attacks. Disabling Echo Reply packets means you cannot use IPv6 ping to the device management interfaces for testing purposes.

Example:

```
> configure network ipv6 destination-unreachable disable
> configure network ipv6 echo-reply disable
```

Step 6

Enable a DHCP server on the default management interface to provide IP addresses to connected hosts:

```
configure network ipv4 dhcp-server-enable start_ip_address end_ip_address
```

Example:

```
> configure network ipv4 dhcp-server-enable 10.10.10.200 10.10.10.254
DHCP Server Enabled
```

```
>
```

You can only configure a DHCP server when you set the management interface IP address manually. This command is not supported on the management center virtual. To display the status of the DHCP server, enter **show network-dhcp-server**:

```
> show network-dhcp-server
DHCP Server Enabled
10.10.10.200-10.10.10.254
```

Step 7

Add a static route for the event-only interface if the management center is on a remote network; otherwise, all traffic will match the default route through the management interface.

configure network static-routes {*ipv4* | *ipv6*} **add** *management_interface destination_ip netmask_or_prefix gateway_ip*

For the *default* route, do not use this command; you can only change the default route gateway IP address when you use the **configure network ipv4** or **ipv6** commands (see [Step 4, on page 77](#)).

Example:

```
> configure network static-routes ipv4 add management1 192.168.6.0 255.255.255.0 10.10.10.1
Configuration updated successfully
```

```
> configure network static-routes ipv6 add management1 2001:0DB8:AA89::5110 64
2001:0DB8:BA98::3211
Configuration updated successfully
```

```
>
```

To display static routes, enter **show network-static-routes** (the default route is not shown):

```
> show network-static-routes
-----[ IPv4 Static Routes ]-----
Interface           : management1
Destination         : 192.168.6.0
Gateway             : 10.10.10.1
Netmask             : 255.255.255.0
[...]
```

Step 8

Set the hostname:

configure network hostname *name*

Example:

```
> configure network hostname farscape1.cisco.com
```

Syslog messages do not reflect a new hostname until after a reboot.

Step 9

Set the search domains:

configure network dns searchdomains *domain_list*

Example:

```
> configure network dns searchdomains example.com,cisco.com
```

Set the search domain(s) for the device, separated by commas. These domains are added to hostnames when you do not specify a fully-qualified domain name in a command, for example, **ping system**. The domains are used only on the management interface, or for commands that go through the management interface.

Step 10 Set up to 3 DNS servers, separated by commas:

```
configure network dns servers dns_ip_list
```

Example:

```
> configure network dns servers 10.10.6.5,10.20.89.2,10.80.54.3
```

Step 11 Set the remote management port for communication with the management center:

```
configure network management-interface tcpport number
```

Example:

```
> configure network management-interface tcpport 8555
```

The management center and managed devices communicate using a two-way, TLS-1.3-encrypted communication channel, which by default is on port 8305.

Note Cisco **strongly** recommends that you keep the default settings for the remote management port, but if the management port conflicts with other communications on your network, you can choose a different port. If you change the management port, you must change it for **all** devices in your deployment that need to communicate with each other.

Step 12 (Threat Defense only) Set the management or eventing interface MTU. The MTU is 1500 bytes by default.

```
configure network mtu [bytes] [interface_id]
```

- *bytes*—Sets the MTU in bytes. For the management interface, the value can be between 64 and 1500 if you enable IPv4, and 1280 to 1500 if you enable IPv6. For the eventing interface, the value can be between 64 and 9000 if you enable IPv4, and 1280 to 9000 if you enable IPv6. If you enable both IPv4 and IPv6, then the minimum is 1280. If you do not enter the *bytes*, you are prompted for a value.
- *interface_id*—Specifies the interface ID on which to set the MTU. Use the **show network** command to see available interface IDs, for example management0, management1, br1, and eth0, depending on the platform. If you do not specify an interface, then the management interface is used.

Example:

```
> configure network mtu 8192 management1
MTU set successfully to 1500 from 8192 for management1
Refreshing Network Config...
NetworkSettings::refreshNetworkConfig MTU value at start 8192

Interface management1 speed is set to '10000baseT/Full'
NetworkSettings::refreshNetworkConfig MTU value at end 8192
>
```

Step 13 Configure an HTTP proxy. The device is configured to directly-connect to the internet on ports TCP/443 (HTTPS) and TCP/80 (HTTP). You can use a proxy server, to which you can authenticate via HTTP Digest. After issuing the command, you are prompted for the HTTP proxy address and port, whether proxy authentication is required, and if it is required, the proxy username, proxy password, and confirmation of the proxy password.

Note For proxy password on threat defense, you can use A-Z, a-z, and 0-9 characters only.

configure network http-proxy

Example:

```
> configure network http-proxy
Manual proxy configuration
Enter HTTP Proxy address: 10.100.10.10
Enter HTTP Proxy Port: 80
Use Proxy Authentication? (y/n) [n]: Y
Enter Proxy Username: proxyuser
Enter Proxy Password: proxypassword
Confirm Proxy Password: proxypassword
```

Step 14 If you change the device management IP address, then see the following tasks for management center connectivity depending on how you identified the management center during initial device setup using the **configure manager add** command (see [Identify a New Management Center, on page 104](#)):

- **IP address—No action.** If you identified the management center using a reachable IP address, then the management connection will be reestablished automatically after several minutes. We recommend that you also change the device IP address shown in management center to keep the information in sync; see [Update the Hostname or IP Address in the Management Center, on page 53](#). This action can help the connection reestablish faster. **Note:** If you specified an unreachable management center IP address, then you must manually reestablish the connection using [Update the Hostname or IP Address in the Management Center, on page 53](#).
- **NAT ID only—Manually reestablish the connection.** If you identified the management center using only the NAT ID, then the connection cannot be automatically reestablished. In this case, change the device management IP address in management center according to [Update the Hostname or IP Address in the Management Center, on page 53](#).

Modify the Threat Defense Data Interface Used for Management at the CLI

If the management connection between the threat defense and the management center was disrupted, and you want to specify a new data interface to replace the old interface, use the threat defense CLI to configure the new interface. This procedure assumes you want to replace the old interface with a new interface on the same network. If the management connection is active, then you should make any changes to an existing data interface using the management center. For initial setup of the data management interface, see the **configure network management-data-interface** command in [Complete the Threat Defense Initial Configuration Using the CLI, on page 19](#).

For high-availability pairs, perform all CLI steps on both units. Within the management center, perform steps only on the active unit. Once the configuration changes are deployed, the standby unit synchronizes configuration and other state information from the active unit.

Note This topic applies to the data interface that you configured for Management, not the dedicated Management interface. If you want to change network settings for the Management interface, see [Modify Threat Defense Management Interfaces at the CLI, on page 75](#).

For information about the threat defense CLI, see the [Cisco Secure Firewall Threat Defense Command Reference](#).

Before you begin

You can create user accounts that can log into the CLI using the **configure user add** command; see [Add an Internal User at the CLI, on page 175](#). You can also configure AAA users according to [External Authentication, on page 870](#).

Procedure

Step 1 If you are changing the data management interface to a new interface, move the current interface cable to the new interface.

Step 2 Connect to the device CLI.

You should use the console port when using these commands. If you are performing initial setup, then you may be disconnected from the Management interface. If you are editing the configuration due to a disrupted management connection, and you have SSH access to the dedicated Management interface, then you can use that SSH connection.

See [Log Into the Command Line Interface on the Device, on page 11](#).

Step 3 Log in with the Admin username and password.

Step 4 Disable the interface so you can reconfigure its settings.

configure network management-data-interface disable

Example:

```
> configure network management-data-interface disable
Configuration updated successfully..!!
```

```
Configuration disable was successful, please update the default route to point to a gateway
on management interface using the command 'configure network'
```

Step 5 Configure the new data interface for manager access.

configure network management-data-interface

You are then prompted to configure basic network settings for the data interface.

When you change the data management interface to a new interface on the same network, use the same settings as for the previous interface except the interface ID. In addition, for the **Do you wish to clear all the device configuration before applying ? (y/n) [n]:** option, choose **y**. This choice will clear the old data management interface configuration, so that you can successfully reuse the IP address and interface name on the new interface.

```

> configure network management-data-interface
Data interface to use for management: ethernet1/4
Specify a name for the interface [outside]: internet
IP address (manual / dhcp) [dhcp]: manual
IPv4/IPv6 address: 10.10.6.7
Netmask/IPv6 Prefix: 255.255.255.0
Default Gateway: 10.10.6.1
Comma-separated list of DNS servers [none]: 208.67.222.222,208.67.220.220
DDNS server update URL [none]:
Do you wish to clear all the device configuration before applying ? (y/n) [n]: y

Configuration done with option to allow manager access from any network, if you wish to
change the manager access network
use the 'client' option in the command 'configure network management-data-interface'.

Setting IPv4 network configuration.
Network settings changed.

>

```

Step 6 (Optional) Limit data interface access to the management center on a specific network.

```
configure network management-data-interface client ip_address netmask
```

By default, all networks are allowed.

Step 7 The connection will be reestablished automatically, but disabling and reenabling the connection in the management center will help the connection reestablish faster. See [Update the Hostname or IP Address in the Management Center, on page 53](#).

Step 8 Check that the management connection was reestablished.

```
sftunnel-status-brief
```

See the following sample output for a connection that is up, with peer channel and heartbeat information shown:

```

> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202' via
'10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC

```

Step 9 In the management center, choose **Devices > Device Management > Device > Management > Manager Access - Configuration Details**, and click **Refresh**.

The management center detects the interface and default route configuration changes, and blocks deployment to the threat defense. When you change the data interface settings locally on the device, you must reconcile those changes in the management center manually. You can view the discrepancies between the management center and the threat defense on the **Configuration** tab.

Step 10 Choose **Devices > Device Management > Interfaces**, and make the following changes.

- a) Remove the IP address and name from the old data management interface, and disable manager access for this interface.

- b) Configure the new data management interface with the settings of the old interface (the ones you used at the CLI), and enable manager access for it.

Step 11 Choose **Devices > Device Management > Routing > Static Route** and change the default route from the old data management interface to the new one.

Step 12 Return to the **Manager Access - Configuration Details** dialog box, and click **Acknowledge** to remove the deployment block.

The next time you deploy, the management center configuration will overwrite any remaining conflicting settings on the threat defense. It is your responsibility to manually fix the configuration in the management center before you re-deploy.

You will see expected messages of "Config was cleared" and "Manager access changed and acknowledged."

Manually Roll Back the Configuration if the Management Center Loses Connectivity

If you use a data interface on the threat defense for manager access, and you deploy a configuration change from the management center that affects the network connectivity, you can roll back the configuration on the threat defense to the last-deployed configuration so you can restore management connectivity. You can then adjust the configuration settings in management center so that the network connectivity is maintained, and re-deploy. You can use the rollback feature even if you do not lose connectivity; it is not limited to this troubleshooting situation.

Alternatively, you can enable auto rollback of the configuration if you lose connectivity after a deployment; see [Edit Deployment Settings, on page 96](#).

See the following guidelines:

- Only the previous deployment is available locally on the threat defense; you cannot roll back to any earlier deployments.
- Rollback is supported for high availability but not supported for clustering deployments.
- The rollback only affects configurations that you can set in the management center. For example, the rollback does not affect any local configuration related to the dedicated Management interface, which you can only configure at the threat defense CLI. Note that if you changed data interface settings after the last management center deployment using the **configure network management-data-interface** command, and then you use the rollback command, those settings will not be preserved; they will roll back to the last-deployed management center settings.
- UCAPL/CC mode cannot be rolled back.
- Out-of-band SCEP certificate data that was updated during the previous deployment cannot be rolled back.
- During the rollback, connections will drop because the current configuration will be cleared.

Procedure

Step 1 At the threat defense CLI, roll back to the previous configuration.

configure policy rollback

After the rollback, the threat defense notifies the management center that the rollback was completed successfully. In the management center, the deployment screen will show a banner stating that the configuration was rolled back.

Note If the rollback failed and the management center management is restored, refer to <https://www.cisco.com/c/en/us/support/docs/security/firepower-ngfw-virtual/215258-troubleshooting-firepower-threat-defense.html> for common deployment problems. In some cases, the rollback can fail after the management center management access is restored; in this case, you can resolve the management center configuration issues, and redeploy from the management center.

Example:

For the threat defense that uses a data interface for manager access:

```
> configure policy rollback
```

```
The last deployment to this FTD was on June 1, 2020 and its status was Successful.
Do you want to continue [Y/N]?
```

```
Y
```

```
Rolling back complete configuration on the FTD. This will take time.
```

```
.....
```

```
Policy rollback was successful on the FTD.
```

```
Configuration has been reverted back to transaction id:
```

```
Following is the rollback summary:
```

```
.....
```

```
.....
```

```
>
```

Step 2 Check that the management connection was reestablished.

In management center, check the management connection status on the **Devices > Device Management > Device > Management > Manager Access - Configuration Details > Connection Status** page.

At the threat defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See [Troubleshoot Management Connectivity on a Data Interface, on page 85](#).

Troubleshoot Management Connectivity on a Data Interface

When you use a data interface for manager access instead of using the dedicated Management interface, you must be careful about changing the interface and network settings for the threat defense in the management center so you do not disrupt the connection. If you change the management interface type after you add the threat defense to the management center (from data to Management, or from Management to data), if the interfaces and network settings are not configured correctly, you can lose management connectivity.

This topic helps you troubleshoot the loss of management connectivity.

View management connection status

In the management center, check the management connection status on the **Devices > Device Management > Device > Management > Manager Access - Configuration Details > Connection Status** page.

At the threat defense CLI, enter the **sftunnel-status-brief** command to view the management connection status. You can also use **sftunnel-status** to view more complete information.

See the following sample output for a connection that is down; there is no peer channel "connected to" information, nor heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Registration: Completed.
Connection to peer '10.10.17.202' Attempted at Mon Jun 15 09:21:57 2020 UTC
Last disconnect time : Mon Jun 15 09:19:09 2020 UTC
Last disconnect reason : Both control and event channel connections with peer went down
```

See the following sample output for a connection that is up, with peer channel and heartbeat information shown:

```
> sftunnel-status-brief
PEER:10.10.17.202
Peer channel Channel-A is valid type (CONTROL), using 'eth0', connected to '10.10.17.202'
via '10.10.17.222'
Peer channel Channel-B is valid type (EVENT), using 'eth0', connected to '10.10.17.202'
via '10.10.17.222'
Registration: Completed.
IPv4 Connection to peer '10.10.17.202' Start Time: Wed Jun 10 14:27:12 2020 UTC
Heartbeat Send Time: Mon Jun 15 09:02:08 2020 UTC
Heartbeat Received Time: Mon Jun 15 09:02:16 2020 UTC
```

View the threat defense network information

At the threat defense CLI, view the Management and manager access data interface network settings:

show network

```
> show network

Version            : 7.6.0 (Build 1385)
Identifier         : a904b8b2-ca9a-11ee-a583-5e804c16b2fd
Registration       : Completed
Management type    : Configuration and analytics

```

Ping the management center

At the threat defense CLI, use the following command to ping the management center from the data interfaces:

ping *fmc_ip*

At the threat defense CLI, use the following command to ping the management center from the Management interface, which should route over the backplane to the data interfaces:

ping system *fmc_ip*

Capture packets on the threat defense internal interface

At the threat defense CLI, capture packets on the internal backplane interface (*nlp_int_tap*) to see if management packets are being sent:

capture *name* interface *nlp_int_tap* trace detail match ip any any

show capture *name* trace detail

Check the internal interface status, statistics, and packet count

At the threat defense CLI, see information about the internal backplane interface, `nlp_int_tap`:

show interface detail

```
> show interface detail
[...]
Interface Internal-Data0/1 "nlp_int_tap", is up, line protocol is up
  Hardware is en_vtun rev00, BW Unknown Speed-Capability, DLY 1000 usec
  (Full-duplex), (1000 Mbps)
  Input flow control is unsupported, output flow control is unsupported
  MAC address 0000.0100.0001, MTU 1500
  IP address 169.254.1.1, subnet mask 255.255.255.248
  37 packets input, 2822 bytes, 0 no buffer

  translate_hits = 0, untranslate_hits = 0
>
```

Check other settings

See the following commands to check that all other settings are present. You can also see many of these commands on the management center's **Devices > Device Management > Device > Management > Manager Access - Configuration Details > CLI Output** page.

show running-config sftunnel

```
> show running-config sftunnel
sftunnel interface outside
sftunnel port 8305
```

show running-config ip-client

```
> show running-config ip-client
ip-client outside
```

show conn address *fmc_ip*

```
> show conn address 10.89.5.35
5 in use, 16 most used
Inspect Snort:
  preserve-connection: 0 enabled, 0 in effect, 0 most enabled, 0 most in effect

TCP nlp_int_tap 10.89.5.29(169.254.1.2):51231 outside 10.89.5.35:8305, idle 0:00:04,
  bytes 86684, flags UxIO
TCP nlp_int_tap 10.89.5.29(169.254.1.2):8305 outside 10.89.5.35:52019, idle 0:00:02,
  bytes 1630834, flags UIO
>
```

Check for a successful DDNS update

At the threat defense CLI, check for a successful DDNS update:

debug ddns

```
> debug ddns
DDNS update request = /v3/update?hostname=domain.example.org&myip=209.165.200.225
Successfully updated the DDNS sever with current IP addresses
DDNS: Another update completed, outstanding = 0
DDNS: IDB SB total = 0
```

If the update failed, use the **debug http** and **debug ssl** commands. For certificate validation failures, check that the root certificates are installed on the device:

show crypto ca certificates *trustpoint_name*

To check the DDNS operation:

show ddns update interface *fmc_access_ifc_name*

```
> show ddns update interface outside

Dynamic DNS Update on outside:
  Update Method Name Update Destination
  RBD_DDNS not available

Last Update attempted on 04:11:58.083 UTC Thu Jun 11 2020
Status : Success
FQDN : domain.example.org
IP addresses : 209.165.200.225
```

Check management center log files

See <https://cisco.com/go/fmc-reg-error>.

View Inventory Details

The **Inventory Details** section of the **Device** page shows chassis details such as the CPU and memory.

Figure 55: Inventory Details

Inventory Details 	
CPU Type:	CPU Xeon E5 series 2300 MHz
CPU Cores:	1 CPU (4 cores)
Memory:	8192 MB RAM
Storage:	N/A
Chassis URL:	N/A
Chassis Serial Number:	N/A
Chassis Module Number:	N/A
Chassis Module Serial Number:	N/A

To update information, click **Refresh** .

Edit Applied Policies

The **Applied Policies** section of the **Device** page displays the following policies applied to your firewall:

Figure 56: Applied Policies

For policies with links, you can click the link to view the policy.

For the Access Control Policy, view the **Access Policy Information for Troubleshooting** dialog box by clicking the **Exclamation** (ⓘ) icon. This dialog box shows how access rules are expanded into access control entries (ACEs).

Figure 57: Access Policy Information for Troubleshooting

You can assign policies to an individual device from the **Device Management** page.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device where you want to assign policies, click **Edit** (✎).
- Step 3** Click **Device**.
- Step 4** In the **Applied Policies** section, click **Edit** (✎).

Figure 58: Policy Assignments

Policy Assignments ?

Access Control Policy: Initial AC Policy

NAT Policy: None

Platform Settings Policy: None

QoS Policy: None

FlexConfig Policy: None

Cancel Save

- Step 5** For each policy type, choose a policy from the drop-down menu. Only existing policies are listed.
- Step 6** Click **Save**.

What to do next

- Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

Edit Advanced Settings

The **Advanced Settings** section of the **Device** page displays a table of advanced configuration settings, as described below. You can edit any of these settings.

Table 6: Advanced Section Table Fields

Field	Description
Application Bypass	The state of Automatic Application Bypass on the device.
Bypass Threshold	The Automatic Application Bypass threshold, in milliseconds.

Field	Description
Object Group Search	<p>The state of object group search on the device. While operating, the FTD device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in Firepower Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules.</p> <p>Note By default, the Object Group Search is enabled when you add threat defense for the first time in the management center.</p>
Interface Object Optimization	<p>The state of interface object optimization on the device. During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the Object Group Search option to reduce memory usage on the device.</p>

The following topics explain how to edit the advanced device settings.

Note For information about the Transfer Packets setting, see [Edit General Settings, on page 41](#).

Configure Automatic Application Bypass

Automatic Application Bypass (AAB) allows packets to bypass detection if Snort is down or, for a Classic device, if a packet takes too long to process. AAB causes Snort to restart within ten minutes of the failure, and generates troubleshooting data that can be analyzed to investigate the cause of the Snort failure.

Caution AAB activation partially restarts the Snort process, which temporarily interrupts the inspection of a few packets. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) for more information.

See the following behavior:

Threat Defense Behavior: If Snort is down, then AAB is triggered after the specified timer duration. If Snort is up, then AAB is never triggered, even if packet processing exceeds the configured timer.

Classic Device Behavior: AAB limits the time allowed to process packets through an interface. You balance packet processing delays with your network's tolerance for packet latency.

The feature functions with any deployment; however, it is most valuable in inline deployments.

Typically, you use Rule Latency Thresholding in the intrusion policy to fast-path packets after the latency threshold value is exceeded. Rule Latency Thresholding does not shut down the engine or generate troubleshooting data.

If detection is bypassed, the device generates a health monitoring alert.

By default the AAB is disabled; to enable AAB follow the steps described.

Procedure

- Step 1** Choose **Devices > Device Management**.
 - Step 2** Next to the device where you want to edit advanced device settings, click **Edit** (✎).
 - Step 3** Click **Device**, then click **Edit** (✎) in the **Advanced Settings** section.
 - Step 4** Check **Automatic Application Bypass**.
 - Step 5** Enter a **Bypass Threshold** from 250 ms to 60,000 ms. The default setting is 3000 milliseconds (ms).
 - Step 6** Click **Save**.
-

What to do next

- Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

Configure Object Group Search

While operating, the threat defense device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in management center. It impacts only how the device interprets and processes them while matching connections to access control rules.

Enabling object group search reduces memory requirements for access control policies that include network or interface objects. However, it is important to note that object group search might also decrease rule lookup performance and thus increase CPU utilization. You should balance the CPU impact against the reduced memory requirements for your specific access control policy. In most cases, enabling object group search provides a net operational improvement.

By default, the object group search is enabled for the threat defense devices that are added for the first time in the management center. In the case of upgraded devices, if the device is configured with disabled object group search, then you need to manually enable it. You can enable it on one device at a time; you cannot enable it globally. We recommend that you enable it on any device to which you deploy access rules that use network or interface objects.

Note If you enable object group search and then configure and operate the device for a while, be aware that subsequently disabling the feature might lead to undesirable results. When you disable object group search, your existing access control rules will be expanded in the device's running configuration. If the expansion requires more memory than is available on the device, your device can be left in an inconsistent state and you might see a performance impact. If your device is operating normally, you should not disable object group search once you have enabled it.

Before you begin

- Model Support—Threat Defense
- We recommend that you also enable transactional commit on each device. From the device CLI, enter the **asp rule-engine transactional-commit access-group** command.
- Changing this setting can be disruptive to system operation while the device recompiles the ACLs. We recommend that you change this setting during a maintenance window.
- You can use FlexConfig to configure the **object-group-search threshold** command to enable a threshold to help prevent performance degradation. When operating with a threshold, for each connection, both the source and destination IP addresses are matched against network objects. If the number of objects matched by the source address times the number matched by the destination address exceeds 10,000, the connection is dropped. Configure your rules to prevent an excessive number of matches.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the threat defense device where you want to configure the rule, click the **Edit** (✎).
- Step 3** Click the **Device** tab, then click the **Edit** (✎) in the **Advanced Settings** section.
- Step 4** Check **Object Group Search**.
- Step 5** To have object group search work on interface objects in addition to network objects, check **Interface Object Optimization**.
- If you do not select **Interface Object Optimization**, the system deploys separate rules for each source/interface pair, rather than use the security zones and interface groups used in the rules. This means the interface groups are not available for object group search processing.
- Step 6** Click **Save**.
-

Configure Interface Object Optimization

During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the **Object Group Search** option to reduce memory usage on the device.

Interface object optimization is disabled by default. You can enable it on one device at a time; you cannot enable it globally.

Note If you disable interface object optimization, your existing access control rules will be deployed without using interface objects, which might make deployment take longer. In addition, if object group search is enabled, its benefits will not apply to interface objects, and you might see expansion in the access control rules in the device's running configuration. If the expansion requires more memory than is available on the device, your device can be left in an inconsistent state and you might see a performance impact.

Before you begin

Model Support—Threat Defense

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the threat defense device where you want to configure the rule, click the **Edit** (✎).
- Step 3** Click the **Device** tab, then click **Edit** (✎) in the **Advanced Settings** section.
- Step 4** Check **Interface Object Optimization**.
- Step 5** Click **Save**.

Edit Deployment Settings

The **Deployment Settings** section of the **Device** page displays the information described in the table below.

Figure 59: Deployment Settings

Deployment Settings 	
Auto Rollback Deployment if Connectivity fails	Disabled
Connectivity Monitor Interval (in Minutes) 	20 Mins.

Table 7: Deployment Settings

Field	Description
Auto Rollback Deployment if Connectivity Fails	Enabled or Disabled. You can enable auto rollback if the management connection fails as a result of the deployment; specifically if you use data for management center access, and then you misconfigure the data interface.
Connectivity Monitor Interval (in Minutes)	Shows the amount of time to wait before rolling back the configuration.

You can set deployment settings from the **Device Management** page. Deployment settings include enabling auto rollback of the deployment if the management connection fails as a result of the deployment; specifically if you use data for management center access, and then you misconfigure the data interface. You can alternatively manually roll back the configuration using the **configure policy rollback** command (see [Manually Roll Back the Configuration if the Management Center Loses Connectivity, on page 84](#)).

See the following guidelines:

- Only the previous deployment is available locally on the threat defense; you cannot roll back to any earlier deployments.
- Rollback is supported for high availability but not supported for clustering deployments.
- The rollback only affects configurations that you can set in the management center. For example, the rollback does not affect any local configuration related to the dedicated Management interface, which you can only configure at the threat defense CLI. Note that if you changed data interface settings after the last management center deployment using the **configure network management-data-interface** command, and then you use the rollback command, those settings will not be preserved; they will roll back to the last-deployed management center settings.
- UCAPL/CC mode cannot be rolled back.
- Out-of-band SCEP certificate data that was updated during the previous deployment cannot be rolled back.
- During the rollback, connections will drop because the current configuration will be cleared.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device where you want to assign policies, click **Edit** (✎).
- Step 3** Click **Device**.
- Step 4** In the **Deployment Settings** section, click **Edit** (✎).

Figure 60: Deployment Settings

Deployment Settings

Auto Rollback Deployment if Connectivity Fails:

Connectivity Monitor Interval (in Minutes): 20

The connectivity failure timeout will be applicable from next deployment incase, the deployment for this device is already in progress.

Cancel Save

- Step 5** Check **Auto Rollback Deployment if Connectivity Fails** to enable auto rollback.

Step 6 Set the **Connectivity Monitor Interval (in Minutes)** to set the amount of time to wait before rolling back the configuration. The default is 20 minutes.

Step 7 If a rollback occurs, see the following for next steps.

- If the auto rollback was successful, you see a success message instructing you to do a full deployment.
- You can also go to the **Deploy > Advanced Deploy** screen and click the **Preview** (📄) icon to view the parts of the configuration that were rolled back (see [Deploy Configuration Changes, on page 218](#)). Click **Show Rollback Changes** to view the changes, and **Hide Rollback Changes** to hide the changes.

Figure 61: Rollback Changes

Change Log: 10.10.35.97

⚠ This device requires a full deployment as auto rollback operation is performed in the device. [see more](#)
[Hide Rollback Changes](#)

Download as PDF OK

- In the Deployment History Preview, you can view the rollback changes. See [View Deployment History, on page 225](#).

Step 8 Check that the management connection was reestablished.

In management center, check the management connection status on the **Devices > Device Management > Device > Management > FMC Access Details > Connection Status** page.

At the threat defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.

If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See [Troubleshoot Management Connectivity on a Data Interface, on page 85](#).

Edit Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 62: Cluster Health Monitor Settings

Cluster Health Monitor Settings 			
Timeouts			
Hold Time			3 s
Interface Debounce Time			9000 ms
Monitored Interfaces			
Service Application			Enabled
Unmonitored Interfaces			None
Auto-Rejoin Settings			
	Attempts	Interval Between Attempts	Interval Variation
Cluster Interface	-1	5	1
Data Interface	3	5	2
System	3	5	2

Table 8: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.

Field	Description
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.
<i>Attempts</i>	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
<i>Interval Between Attempts</i>	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
<i>Interval Variation</i>	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
<i>Attempts</i>	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
<i>Interval Between Attempts</i>	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
<i>Interval Variation</i>	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
<i>Attempts</i>	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
<i>Interval Between Attempts</i>	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
<i>Interval Variation</i>	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

-
- Step 1** Choose **Devices > Device Management**.
 - Step 2** Next to the cluster you want to modify, click **Edit** (✎).
 - Step 3** Click **Cluster**.

Step 4 In the **Cluster Health Monitor Settings** section, click **Edit** (✎).

Step 5 Disable the system health check by clicking the **Health Check** slider.

Figure 63: Disable the System Health Check

The screenshot shows a dialog box titled "Edit Cluster Health Monitor Settings". At the top right is a close button (X). Below the title bar, there is a "Health Check" section with a toggle switch that is currently turned off (to the left) and an information icon (i) to its right. Below this is a "Timeouts" section with a downward arrow. Under "Timeouts", there are two input fields: "Hold Time" with a value of "3" and a range of "0.3 to 45 seconds", and "Interface Debounce Time" with a value of "9000" and a range of "300 to 9000 milliseconds". Below these are two expandable sections: "Auto-Rejoin Settings" and "Monitored Interfaces", each with a right-pointing arrow. At the bottom of the dialog, there are three buttons: "Reset to Defaults" (light blue), "Cancel" (light blue), and "Save" (dark blue).

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 64: Configure Auto-Rejoin Settings

▼ Auto-Rejoin Settings

Cluster Interface

Attempts Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts Range: 2-60 minutes between rejoin attempts

Interval Variation Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

Data Interface

Attempts Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts Range: 2-60 minutes between rejoin attempts

Interval Variation Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

System

Attempts Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts Range: 2-60 minutes between rejoin attempts

Interval Variation Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8

Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 65: Configure Monitored Interfaces

▼ Monitored Interfaces

Unmonitored Interfaces 0

[Add](#)

Enable Service Application Monitoring

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Step 10 Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

Change the Management Settings for the Device

You might need to change the manager, change the manager IP address, or perform other management tasks.

Edit the Management Center IP Address or Hostname on the Device

If you change the management center IP address or hostname, you should also change the value at the device CLI so the configurations match. Although in most cases, the management connection will be reestablished without changing the management center IP address or hostname on the device, in at least one case, you must perform this task for the connection to be reestablished: when you added the device to the management center

and you specified the NAT ID only. Even in other cases, we recommend keeping the management center IP address or hostname up to date for extra network resiliency.

Procedure

Step 1 At the threat defense CLI, view the management center identifier.

show managers

Example:

```
> show managers
Type                : Manager
Host                : 10.10.1.4
Display name       : 10.10.1.4
Identifier          : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration        : Completed
Management type    : Configuration
```

Step 2 At the threat defense CLI, edit the management center IP address or hostname.

configure manager edit identifier {hostname {ip_address | hostname} | displayname display_name}

If the management center was originally identified by **DONTRESOLVE** and a NAT ID, you can change the value to a hostname or IP address using this command. You cannot change an IP address or hostname to **DONTRESOLVE**.

The management connection will go down, and then reestablish. You can monitor the state of the connection using the **sftunnel-status** command.

Example:

```
> configure manager edit f7ffad78-bf16-11ec-a737-baa2f76ef602 hostname 10.10.5.1
```

Identify a New Management Center

This procedure shows how to identify a new management center for the managed device. You should perform these steps even if the new management center uses the old management center's IP address.

Procedure

Step 1 On the old management center, if present, unregister the managed device. See [Unregister a Device from the Management Center, on page 37](#).

You cannot change the management center IP address if you have an active connection with the management center.

Step 2 Connect to the device CLI, for example using SSH.

Step 3 Configure the new management center.

configure manager add {*hostname* | *IPv4_address* | *IPv6_address* | **DONTRESOLVE** } *regkey* [*nat_id*] [*display_name*]

- {*hostname* | *IPv4_address* | *IPv6_address*}—Sets the management center hostname, IPv4 address, or IPv6 address.
- **DONTRESOLVE**—If the management center is not directly addressable, use **DONTRESOLVE** instead of a hostname or IP address. If you use **DONTRESOLVE**, then a *nat_id* is required. When you add this device to the management center, make sure that you specify both the device IP address and the *nat_id*; one side of the connection needs to specify an IP address, and both sides need to specify the same, unique NAT ID.
- *regkey*—Make up a registration key to be shared between the management center and the device during registration. You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the management center when you add the threat defense.
- *nat_id*—Make up an alphanumeric string from 1 to 37 characters used only during the registration process between the management center and the device when one side does not specify an IP address. This NAT ID is a one-time password used only during registration. Make sure the NAT ID is unique, and not used by any other devices awaiting registration. Specify the same NAT ID on the management center when you add the threat defense.
- *display_name*—Provide a display name for showing this manager with the **show managers** command. This option is useful if you are identifying CDO as the primary manager and an on-prem management center for analytics only. If you don't specify this argument, the firewall auto-generates a display name using one of the following methods:
 - *hostname* | *IP_address* (if you don't use the **DONTRESOLVE** keyword)
 - **manager-timestamp**

Example:

```
> configure manager add DONTRESOLVE abc123 efg456
Manager successfully configured.
Please make note of reg_key as this will be required while adding Device in FMC.
>
```

- Step 4** Add the device to the management center. See [Add a Device to the Management Center Using a Registration Key, on page 27](#).

Switch from the Device Manager to the Management Center

When you switch from the device manager to the management center, all interface configuration is retained, in addition to the Management interface and the manager access settings. Note that other configuration settings, such as the access control policy or security zones, are not retained.

After you switch to the management center, you can no longer use the device manager to manage the threat defense device.

Before you begin

If the firewall is configured for high availability, you must first break the high availability configuration using the device manager (if possible) or the **configure high-availability disable** command. Ideally, break high availability from the active unit.

Procedure

Step 1 In the device manager, unregister the device from the Cisco Smart Software Manager.

Step 2 (Might be required) Configure the Management interface.

You may need to change the Management interface configuration, even if you intend to use a data interface for manager access. You will have to reconnect to the device manager if you were using the Management interface for the device manager connection.

- Data interface for manager access—The Management interface must have the gateway set to data interfaces. By default, the Management interface receives an IP address and gateway from DHCP. If you do not receive a gateway from DHCP (for example, you did not connect this interface to a network), then the gateway will default to data interfaces, and you do not need to configure anything. If you did receive a gateway from DHCP, then you need to instead configure this interface with a static IP address and set the gateway to data interfaces.
- Management interface for manager access—If you want to configure a static IP address, be sure to also set the default gateway to be a unique gateway instead of the data interfaces. If you use DHCP, then you do not need to configure anything assuming you successfully get the gateway from DHCP.

Step 3 Choose **Device > System Settings > Central Management**, and click **Proceed** to set up the management center management.

Step 4 Configure the **Management Center/CDO Details**.

Figure 66: Management Center/CDO Details

Configure Connection to Management Center or CDO

Please select an interface

Management Interface [View details](#)

- a) For **Do you know the Management Center/CDO hostname or IP address**, click **Yes** if you can reach the management center using an IP address or hostname, or **No** if the management center is behind NAT or does not have a public IP address or hostname.

At least one of the devices, either the management center or the threat defense device, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices.

- b) If you chose **Yes**, then enter the **Management Center/CDO Hostname/IP Address**.
- c) Specify the **Management Center/CDO Registration Key**.

This key is a one-time registration key of your choice that you will also specify on the management center when you register the threat defense device. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID can be used for multiple devices registering to the management center.

- d) Specify a **NAT ID**.

This ID is a unique, one-time string of your choice that you will also specify on the management center. This field is required if you only specify the IP address on one of the devices; but we recommend that you specify the NAT ID even if you know the IP addresses of both devices. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID *cannot* be used for any other devices registering to the management center. The NAT ID is used in combination with the IP address to verify that the connection is coming from the correct device; only after authentication of the IP address/NAT ID will the registration key be checked.

Step 5 Configure the **Connectivity Configuration**.

- a) Specify the **FTD Hostname**.

If you use a data interface for the **Management Center/CDO Access Interface** access, then this FQDN will be used for this interface.

- b) Specify the **DNS Server Group**.

Choose an existing group, or create a new one. The default DNS group is called **CiscoUmbrellaDNSServerGroup**, which includes the OpenDNS servers.

If you intend to choose a data interface for the **Management Center/CDO Access Interface**, then this setting sets the *data* interface DNS server. The Management DNS server that you set with the setup wizard is used for management traffic. The data DNS server is used for DDNS (if configured) or for security policies applied to this interface. You are likely to choose the same DNS server group that you used for Management, because both management and data traffic reach the DNS server through the outside interface.

On the management center, the data interface DNS servers are configured in the Platform Settings policy that you assign to this threat defense device. When you add the threat defense device to the management center, the local setting is maintained, and the DNS servers are *not* added to a Platform Settings policy. However, if you later assign a Platform Settings policy to the threat defense device that includes a DNS configuration, then that configuration will overwrite the local setting. We suggest that you actively configure the DNS Platform Settings to match this setting to bring the management center and the threat defense device into sync.

Also, local DNS servers are only retained by the management center if the DNS servers were discovered at initial registration.

If you intend to choose the Management interface for the **CDOFMC Access Interface**, then this setting configures the Management DNS server.

- c) For the **Management Center/CDO Access Interface**, choose any configured interface.

You can change the manager interface after you register the threat defense device to the management center, to either the Management interface or another data interface.

- Step 6** (Optional) If you chose a data interface, and it was not the outside interface, then add a default route. You will see a message telling you to check that you have a default route through the interface. If you chose outside, you already configured this route as part of the setup wizard. If you chose a different interface, then you need to manually configure a default route before you connect to the management center. If you chose the Management interface, then you need to configure the gateway to be a unique gateway before you can proceed on this screen.
- Step 7** (Optional) If you chose a data interface, click **Add a Dynamic DNS (DDNS) method**. DDNS ensures the management center can reach the threat defense device at its Fully-Qualified Domain Name (FQDN) if the IP address changes. See **Device > System Settings > DDNS Service** to configure DDNS. If you configure DDNS before you add the threat defense device to the management center, the threat defense device automatically adds certificates for all of the major CAs from the Cisco Trusted Root CA bundle so that the threat defense device can validate the DDNS server certificate for the HTTPS connection. Threat Defense supports any DDNS server that uses the DynDNS Remote API specification (<https://help.dyn.com/remote-access-api/>). DDNS is not supported when using the Management interface for manager access.
- Step 8** Click **Connect**. The **Registration Status** dialog box shows the current status of the switch to the management center. After the **Saving Management Center/CDO Registration Settings** step, go to the management center, and add the firewall. If you want to cancel the switch to the management center, click **Cancel Registration**. Otherwise, do not close the device manager browser window until after the **Saving Management Center/CDO Registration Settings** step. If you do, the process will be paused, and will only resume when you reconnect to the device manager. If you remain connected to the device manager after the **Saving Management Center/CDO Registration Settings** step, you will eventually see the **Successful Connection with Management Center or CDO** dialog box, after which you will be disconnected from the device manager.

Figure 67: Successful Connection

Switch from Management Center to Device Manager

You can configure the threat defense device currently being managed by the on-premises or cloud-delivered management center to use the device manager instead.

You can switch from the management center to the device manager without reinstalling the software. Before switching from the management center to the device manager, verify that the device manager meets all of your configuration requirements. If you want to switch from the device manager to the management center, see [Switch from the Device Manager to the Management Center, on page 105](#).

Caution Switching to the device manager erases the device configuration and returns the system to the default configuration. However, the Management IP address and hostname are preserved.

Procedure

Step 1 In the management center, unregister the firewall from the **Devices > Device Management** page.

Step 2 Connect to the threat defense CLI using SSH or the console port. For SSH, open a connection to the **management IP address**, and log into the threat defense CLI with the **admin** username (or any other user with admin privileges).

The console port defaults to the FXOS CLI. Connect to the threat defense CLI using the **connect ftd** command. The SSH session connects directly to the threat defense CLI.

If you cannot connect to the management IP address, do one of the following:

- Ensure that the Management physical port is wired to a functioning network.
- Ensure that the management IP address and gateway are configured for the management network. Use the **configure network ipv4/ipv6 manual** command.

Step 3 Verify you are currently in remote management mode.

show managers

Example:

```
> show managers
Type           : Manager
Host           : 10.89.5.35
Display name   : 10.89.5.35
Identifier     : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration   : Completed
```

Step 4 Delete the remote manager and go into no manager mode.

configure manager delete uuid

You cannot go directly from remote management to local management. If you have more than one manager defined, you need to specify the identifier (also known as the UUID; see the **show managers** command). Delete each manager entry separately.

Example:

```
> configure manager delete
Deleting task list
Manager successfully deleted.

>
> show managers
No managers configured.
```

Step 5 Configure the local manager.

configure manager local

You can now use a web browser to open the local manager at <https://management-IP-address>.

Example:

```
> configure manager local
Deleting task list

> show managers
Managed locally.
```

Resolve Serial Number (Zero-Touch Provisioning) Registration Issues

If the device fails to register using the serial number, the device may not have successfully connected to the cloud. To confirm the cloud connection, check that the Managed Status LED is flashing green. If it is not flashing green, this failure might occur because:

- You performed initial configuration at the CLI or the device manager and disabled low-touch provisioning
- The serial number was already claimed by another manager

For other requirements for serial number registration, see [Add a Device to the Management Center Using the Serial Number \(Zero-Touch Provisioning\)](#), on page 31.

To work around a registration failure, do one of the following tasks.

Reset the Device

Supported for the following models:

- Firepower 1010
- Firepower 1100
- Secure Firewall 3100

If you do not have access to the CLI and want to make sure your device is unconfigured and ready for zero-touch provisioning, reset the device to its default state by press the small, recessed Reset button for longer than five seconds. See your hardware installation guide for more information.

Use Manual Registration and a Registration Key

If low-touch provisioning fails, the easiest way to complete registration is to use the registration key method.

1. See [Complete the Threat Defense Initial Configuration for Manual Registration, on page 12](#) or [Complete the Threat Defense Initial Configuration Using the Device Manager, on page 13](#).
2. If you are not presented with the initial setup tasks, it's possible your device was successfully registered to another management center. You must first delete the management connection and then re-register with the correct manager.
 - a. First, check if registration has completed:

```
> show managers
Type                : Manager
Host                : 10.10.1.4
Display name        : 10.10.1.4
Identifier           : f7ffad78-bf16-11ec-a737-baa2f76ef602
Registration         : Completed
Management type     : Configuration
```

- b. If **Registration** shows **Completed**, you need to delete the manager:
configure manager delete
 - c. You can then register the device at the CLI using **configure manager add**.

Restart Low-Touch Provisioning at the CLI

If the device was previously registered using low-touch provisioning, reregistration will fail, and you will see a **Serial Number Already Claimed** error in CDO.

You can unregister the serial number, clear the configuration and any existing management connection, and start the process over.

1. Connect to the FXOS CLI using SSH or the console port.

If you used SSH, you connect to the threat defense CLI. In this case, enter **connect fxos**. If you used the console port, you connect directly to FXOS.

```
> connect fxos
firepower#
```

2. Enter local management.

connect local-mgmt

```
firepower# connect local-mgmt
firepower(local-mgmt)#
```

3. Deregister the device from the Cisco cloud.

cloud deregister

```
firepower(local-mgmt)# cloud deregister
Release Image Detected RESULT=success MESSAGE=SUCCESS 10, X-Flow-Id:
```

```
2b3c9e8b-76c3-4764-91e4-cfd9828e73f9
```

4. Erase the configuration to restore cloud connectivity.

erase configuration

```
firepower(local-mgmt)# erase configuration
All configurations will be erased and system will reboot. Are you sure? (yes/no):yes
Removing all the configuration. Please wait....
Configurations are cleaned up. Rebooting....
```

5. [Add a Device to the Management Center Using the Serial Number \(Zero-Touch Provisioning\)](#), on page 31

Restart Low-Touch Provisioning Using the Device Manager

You can accidentally disable low-touch provisioning if you log into the device manager. In this case, you can restart low-touch provisioning within the device manager.

Note If the serial number was already claimed, see [Restart Low-Touch Provisioning at the CLI](#), on page 112 instead.

1. In the device manager, click **Device**, then click the **System Settings > Cloud Services**.
2. Check **Auto-enroll with Cisco Defense Orchestrator or Secure Firewall Management Center**.
3. Click **Register**.
4. [Add a Device to the Management Center Using the Serial Number \(Zero-Touch Provisioning\)](#), on page 31

Hot Swap an SSD on the Secure Firewall 3100/4200

If you have two SSDs, they form a RAID when you boot up. You can perform the following tasks at the threat defense CLI while the firewall is powered up:

- Hot swap one of the SSDs—If an SSD is faulty, you can replace it. Note that if you only have one SSD, you cannot remove it while the firewall is powered on.
- Remove one of the SSDs—If you have two SSDs, you can remove one.
- Add a second SSD—If you have one SSD, you can add a second SSD and form a RAID.

Caution Do not remove an SSD without first removing it from the RAID using this procedure. You can cause data loss.

Procedure

Step 1

Remove one of the SSDs.

- a) Remove the SSD from the RAID.

configure raid remove-secure local-disk {1 | 2}

The **remove-secure** keyword removes the SSD from the RAID, disables the self-encrypting disk feature, and performs a secure erase of the SSD. If you only want to remove the SSD from the RAID and want to keep the data intact, you can use the **remove** keyword.

Example:

```
> configure raid remove-secure local-disk 2
```

- b) Monitor the RAID status until the SSD no longer shows in the inventory.

show raid

After the SSD is removed from the RAID, the **Operability** and **Drive State** will show as **degraded**. The second drive will no longer be listed as a member disk.

Example:

```
> show raid
Virtual Drive
ID: 1
Size (MB): 858306
Operability: operable
Presence: equipped
Lifecycle: available
Drive State: optimal
Type: raid
Level: raid1
Max Disks: 2
Meta Version: 1.0
Array State: active
Sync Action: idle
Sync Completed: unknown
Degraded: 0
Sync Speed: none

RAID member Disk:
Device Name: nvme0n1
Disk State: in-sync
Disk Slot: 1
Read Errors: 0
Recovery Start: none
Bad Blocks:
Unacknowledged Bad Blocks:

Device Name: nvme1n1
Disk State: in-sync
Disk Slot: 2
Read Errors: 0
Recovery Start: none
Bad Blocks:
Unacknowledged Bad Blocks:

> show raid
```

```

Virtual Drive
ID: 1
Size (MB): 858306
Operability: degraded
Presence: equipped
Lifecycle: available
Drive State: degraded
Type: raid
Level: raid1
Max Disks: 2
Meta Version: 1.0
Array State: active
Sync Action: idle
Sync Completed: unknown
Degraded: 1
Sync Speed: none

RAID member Disk:
Device Name: nvme0n1
Disk State: in-sync
Disk Slot: 1
Read Errors: 0
Recovery Start: none
Bad Blocks:
Unacknowledged Bad Blocks:

```

c) Physically remove the SSD from the chassis.

Step 2

Add an SSD.

- a) Physically add the SSD to the empty slot.
- b) Add the SSD to the RAID.

```
configure raid add local-disk {1 | 2}
```

It can take several hours to complete syncing the new SSD to the RAID, during which the firewall is completely operational. You can even reboot, and the sync will continue after it powers up. Use the **show raid** command to show the status.

If you install an SSD that was previously used on another system, and is still locked, enter the following command:

```
configure raid add local-disk {1 | 2} psid
```

The *psid* is printed on the label attached to the back of the SSD. Alternatively, you can reboot the system, and the SSD will be reformatted and added to the RAID.

Disable the USB Port

By default, the type-A USB port is enabled. You might want to disable USB port access for security purposes. Disabling USB is supported on the following models:

- Firepower 1000 Series
- Secure Firewall 3100
- Secure Firewall 4200

Guidelines

- Enabling or disabling the USB port requires a reboot.
- If the USB port is disabled and you downgrade to a version that does not support this feature, the port will remain disabled, and you cannot re-enable it without erasing the NVRAM (the FXOS local-mgmt **erase secure all** command).
- If you perform a ROMMON **factory-reset** or FXOS local-mgmt **erase secure**, the USB port will be re-enabled.
- For high availability or clustering, you must disable or re-enable the port individually on each unit.

Note This feature does not affect the USB console port, if present.

Disable the USB Port on a Device

To disable the USB port on a device, you can do so at the threat defense CLI.

Procedure

Step 1 Disable the USB port.

```
system support usb configure disable
reboot
```

To re-enable the USB port, enter **system support usb configure enable**.

Example:

```
>system support usb configure disable
USB Port Admin State set to 'disabled'.
Please reboot the system to apply any control state changes.

>reboot
This command will reboot the system. Continue?
Please enter 'YES' or 'NO': YES
```

Step 2 View the port status.

```
system support usb show
```

The Admin State shows the USB port configuration. The Oper State shows the current operation. For example, if you disable the USB port but do not reload, the Admin State will show disabled while the Oper State would be enabled.

Example:

```
>system support usb show
USB Port Info
-----
```

```
Admin State: disabled
Oper State: disabled
```

Disable the USB Port in Multi-Instance Mode

To disable the USB port in multi-instance mode, you can do so at the FXOS CLI.

Procedure

Step 1 Disable the USB port and reboot for the change to take effect.

a) Disable the USB port.

```
scope fabric-interconnect
```

```
disable usb-port
```

```
commit buffer
```

b) Reboot the chassis.

```
connect local-mgmt
```

```
reboot
```

Example:

```
firepower-4245 /fabric-interconnect # disable usb-port
Note: USB enablement or disablement changes are effected only after FXOS reboot.
Confirm change? (yes/no) [yes]:
device /fabric-interconnect* # commit buffer
Note: USB enablement or disablement changes are effected only after FXOS reboot.
Confirm change? (yes/no) [yes]:yes
firepower-4245 /fabric-interconnect # connect local-mgmt
firepower-4245(local-mgmt)# reboot
Before rebooting, please take a configuration backup.
Do you still want to reboot? (yes/no):yes
Broadcast message from admin@firepower-4245 (Wed Feb 21 05:59:55 2024):
All shells being terminated due to system /sbin/reboot
```

Step 2 Enable the USB port and reboot for the change to take effect.

a) Enable the USB port.

```
scope fabric-interconnect
```

```
enable usb-port
```

```
commit buffer
```

b) Reboot the chassis.

```
connect local-mgmt
```

```
reboot
```

Example:

```

firepower-4245 /fabric-interconnect # enable usb-port
Note: USB enablement or disablement changes are effected only after FXOS reboot.
Confirm change? (yes/no) [yes]:
device /fabric-interconnect* # commit buffer
Note: USB enablement or disablement changes are effected only after FXOS reboot.
Confirm change? (yes/no) [yes]:yes
firepower-4245 /fabric-interconnect # connect local-mgmt
firepower-4245(local-mgmt)# reboot
Before rebooting, please take a configuration backup.
Do you still want to reboot? (yes/no):yes
Broadcast message from admin@firepower-4245 (Wed Feb 21 05:59:55 2024):
All shells being terminated due to system /sbin/reboot

```

Step 3 View the USB port status.

scope fabric-interconnect

show usb-port

The Admin State shows the USB port configuration. The Oper State shows the current operation. For example, if you disable the USB port but do not reload, the Admin State will show Disabled while the Oper State would will Enabled.

Example:

```

firepower-4245# scope fabric-interconnect
firepower-4245 /fabric-interconnect # show usb-port
usb Port:
Equipment          Admin State Oper State
-----
A                   Disabled   Disabled

```

Migrate the Configuration to a New Model

The Firewall Threat Defense model migration wizard enables you to migrate configurations from an old threat defense model to a new model. You can map source device interfaces to target device interfaces. Before the migration, the source and target devices are locked.

Supported Devices for Migration

Supported Source Devices

- Cisco Firepower 1120
- Cisco Firepower 1140
- Cisco Firepower 1150
- Cisco Firepower 2110
- Cisco Firepower 2120
- Cisco Firepower 2130

- Cisco Firepower 2140

Note The source devices must be version 7.0 or later.

Supported Target Devices

- Cisco Secure Firewall 3105
- Cisco Secure Firewall 3110
- Cisco Secure Firewall 3120
- Cisco Secure Firewall 3130
- Cisco Secure Firewall 3140

Note The Cisco Secure Firewall 3110, 3120, 3130, and 3140 devices must be version 7.1 or later. Cisco Secure Firewall 3105 must be version 7.3 or later.

License for Migration

You must register and enroll the device with the smart licensing account. The migration copies the source device licenses to the target device.

Prerequisites for Migration

- You must register the source and the target devices to the management center.
- Your Smart Licensing account must have the license entitlements for the target device.
- We recommend that the target device is a freshly registered device without any configurations.
- Source and target devices must be in the same:
 - Domain
 - Firewall mode: Routed or Transparent
 - Compliance mode
- The target device must not be:
 - In a multi-instance mode
 - Part of a cluster
- The user must have modify permissions on the device.
- The configurations on the source device must be valid and have no errors.

- The source device can have pending deployments. However, deployment, import, or export tasks must not run on either of the devices during the migration.
- If the source device is part of an HA pair, the target device need not be part of an HA pair and vice versa. The migration does not form or break the HA pair.

What Configurations Does the Wizard Migrate?

The migration wizard copies the following configurations from the source device to the target device:

- Licenses
- Interface configurations
- Inline sets configurations
- Routing configurations
- DHCP and DDNS configurations
- Virtual router configurations
- Policies
- Associated objects and object overrides
- Platform settings
- Remote branch deployment configurations

The migration wizard copies the following policy configurations from the source device to the target device:

- Health policies
- NAT policies
- QoS policies
- Remote access VPN policies
- FlexConfig policies
- Access control policies
- Prefilter policies
- IPS policies
- DNS policies
- SSL policies
- Malware and File policies
- Identity policies

The migration wizard copies the following routing configurations from the source device to the target device:

- ECMP

- BFD
- OSPFv2/v3
- EIGRP
- RIP
- BGP
- Policy Based Routing
- Static Route
- Multicast Routing
- Virtual Router

The migration wizard copies the following interfaces from the source device to the target device:

- Physical interfaces
- Sub-interfaces
- Etherchannel interfaces
- Bridge group interfaces
- VTI interfaces
- VNI interfaces
- Loopback interfaces

Limitations for Migration

- The wizard does not migrate:
 - Site-to-site VPN policies
 - SNMP configurations

After the migration, you can configure SNMP using the platform settings for the device.
- You can perform only one migration at a time.
- If the speed, auto-negotiation, and duplex settings of the source interface are valid for the mapped interface of the target device, the values are copied. If not, these parameters are set to the default values.
- Remote access VPN trustpoint certificates are not enrolled. You must manually enroll these certificates before the deployment.
- After migration, by default, the target device uses Snort 3 and not Snort 2, even if the source device uses Snort 2.
- For HA devices:
 - Target Device: You cannot map the interfaces that are part of the failover configuration. These interfaces are disabled in the wizard.

- **Source and Target Devices:** The wizard does not migrate HA configurations such as monitored interfaces, failover trigger criteria, and interface MAC addresses. You must manually configure these parameters after the migration if required.

Migrate the Secure Firewall Threat Defense

Before you begin

Review the prerequisites and limitations for the migration.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Click **Migrate** on the top-right of the page.
- Step 3** Click **Start** on the welcome screen.
- Step 4** From the **Source Device** drop-down list, choose a device.
If the device is part of an HA pair, only the container name of the HA pair appears.
- Step 5** Click **Next**.
- Step 6** From the **Target Device** drop-down list, choose a device.
If the device is part of an HA pair, only the container name of the HA pair appears.
- Step 7** Click **Next**.
- Step 8** In the **Configure Interfaces** step, map the physical interfaces of the source device with those of the target device.
Mapping of all interfaces is not mandatory. You must map all named interfaces and interfaces that are part of other interfaces. You cannot map interfaces that are part of an HA failover configuration. These interfaces are disabled in the wizard. The wizard creates the logical interfaces according to the interface mapping provided by the user.
- Click **Map Default** to configure default interface mappings.
For example, Ethernet1/1 in the source device will be mapped to Ethernet1/1 in the target device.
 - Click **Clear All** to clear all the mappings.
- Step 9** Click **Next**.
- Step 10** Click **View Mappings** to verify the interface mappings.
- Step 11** Click **Submit** to start the migration.
- Step 12** View the migration status in the **Notifications > Tasks** page.
-

What to do next

After a successful migration, you can deploy the device.

Deployment is not mandatory, you can validate the configurations and deploy as required. However, before the deployment ensure that you perform the actions mentioned in [Best Practices for Migration, on page 123](#).

Best Practices for Migration

After a successful migration, we recommend that you perform the following actions before the deployment:

- Change the IP addresses of the interfaces if the source device is live, as they are copied to the target device from the source device.
- Ensure that you update your NAT policies with the modified IP addresses.
- Configure the interface speeds if they are set to default values after migration.
- Re-enroll the device certificates, if any, on the target device.
- If you have a HA setup, configure HA parameters such as monitored interfaces, failover trigger criteria, and interface MAC addresses.
- Configure the diagnostic interface as it gets reset after migration.
- (Optional) Configure SNMP using the platform settings for the device.
- (Optional) Configure remote branch deployment configurations.

If the source or target device had manager access through a data interface, after the migration, the manager access will be lost. Update the manager access configuration on the target device. For more information, see the *Change the Manager Access Interface from Management to Data* topic in the Cisco Secure Firewall Management Center Device Configuration Guide or the Online Help.

- (Optional) Configure site-to-site VPN if required. These configurations are not migrated from the source device.
- View the deployment preview before the deployment. Choose **Deploy > Advanced Deploy** and click the **Preview** (🔍) icon for the device.

History for Device Management Basics

Feature	Minimum Management Center	Minimum Threat Defense	Details
Serial-number registration (zero-touch provisioning) supported from an on-prem management center.	7.6.0	Mgmt. center must be publicly reachable: 7.2.0 Restriction removed: 7.2.4/7.4.0	You can now register a device using its serial number from an on-prem management center. With templates (requires threat defense 7.4.1+ on the device), you can register multiple devices at once. This feature was previously known as low-touch provisioning. Requires Cisco Security Cloud. For upgraded management centers, your existing CDO integration continues to work until you enable Cisco Security Cloud. New/modified screens: Devices > Device Management > Add > Device (Wizard) Supported platforms: Firepower 1000/2100, Secure Firewall 3100. Note that Firepower 2100 support is for threat defense 7.4.1–7.4.x only; those devices cannot run Version 7.6.0.
Delete menu item renamed to Unregister	7.6.0	Any	The Delete menu choice was renamed to Unregister to better indicate that the device, high-availability pair, or cluster is being unregistered from the management center and not deleted from the high availability pair or cluster or having its configuration erased. The device, high-availability pair, or cluster continues to pass traffic until it is re-registered. New/modified screens: Devices > Device Management > More (☰)
Disable the front panel USB-A port on the Firepower 1000 and Secure Firewall 3100/4200.	7.6.0	7.6.0	You can now disable the front panel USB-A port on the Firepower 1000 and Secure Firewall 3100/4200. By default, the port is enabled. New/modified threat defense CLI commands: system support usb show , system support usb port disable , system support usb port enable New/modified FXOS CLI commands for the Secure Firewall 3100/4200 in multi-instance mode: show usb-port , disable USB port , enable usb-port See: Cisco Secure Firewall Threat Defense Command Reference and Cisco Firepower 4100/9300 FXOS Command Reference
Chassis-level health alerts for the Firepower 4100/9300.	7.4.1	7.4.1	You can now view chassis-level health alerts for Firepower 4100/9300 by registering the chassis to the management center as a read-only device. You must also enable the Firewall Threat Defense Platform Faults health module and apply the health policy. The alerts appear in the Message Center, the health monitor (in the left pane, under Devices, select the chassis), and in the health events view. You can also add a chassis (and view health alerts for) the Secure Firewall 3100 in multi-instance mode. For those devices, you use the management center to manage the chassis. But for the Firepower 4100/9300 chassis, you still must use the chassis manager or the FXOS CLI. New/modified screens: Devices > Device Management > Add > Chassis

Feature	Minimum Management Center	Minimum Threat Defense	Details
View CLI output for a device or device cluster.	7.4.1	Any	You can view a set of pre-defined CLI outputs that can help you troubleshoot the device or cluster. You can also enter any show command and see the output. New/modified screens: Devices > Device Management > Cluster > General
Troubleshooting file generation and download available from Device and Cluster pages.	7.4.1	7.4.1	You can generate and download troubleshooting files for each device on the Device page and also for all cluster nodes on the Cluster page. For a cluster, you can download all files as a single compressed file. You can also include cluster logs for the cluster for cluster nodes. You can alternatively trigger file generation from the Devices > Device Management > More (⋮) > Troubleshoot Files menu. New/modified screens: <ul style="list-style-type: none"> • Devices > Device Management > Device > General • Devices > Device Management > Cluster > General
Zero-Touch Provisioning to register the Firepower 1000/2100 and Secure Firewall 3100 to the management center using a serial number.	7.4.0	Mgmt. center <i>is</i> publicly reachable: 7.2.0 Mgmt. center <i>is not</i> publicly reachable: 7.2.4/7.4.0	Zero-Touch Provisioning (also called low-touch provisioning) lets you register Firepower 1000/2100 and Secure Firewall 3100 devices to the management center by serial number without having to perform any initial setup on the device. The management center integrates with SecureX and Cisco Defense Orchestrator for this functionality. New/modified screens: Devices > Device Management > Add > Device > Serial Number Other version restrictions: This feature is not supported on Version 7.3.x or 7.4.0 threat defense devices when the management center is not publicly reachable. Support returns in Version 7.4.1.

Feature	Minimum Management Center	Minimum Threat Defense	Details
Merged management and diagnostic interfaces.	7.4.0	7.4.0	<p>Upgrade impact. Merge interfaces after upgrade.</p> <p>For new devices using 7.4 and later, you cannot use the legacy diagnostic interface. Only the merged management interface is available.</p> <p>If you upgraded to 7.4 or later and:</p> <ul style="list-style-type: none"> You did not have any configuration for the diagnostic interface, then the interfaces will merge automatically. You have configuration for the diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate diagnostic interface. Note that support for the diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. <p>Merged mode also changes the behavior of AAA traffic to use the data routing table by default. The management-only routing table can now only be used if you specify the management-only interface (including Management) in the configuration.</p> <p>For platform settings, this means:</p> <ul style="list-style-type: none"> You can no longer enable HTTP, ICMP, or SMTP for diagnostic. For SNMP, you can allow hosts on management instead of diagnostic. For Syslog servers, you can reach them on management instead of diagnostic. If Platform Settings for syslog servers or SNMP hosts specify the diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices. DNS lookups no longer fall back to the management-only routing table if you do not specify interfaces. <p>New/modified screens: Devices > Device Management > Interfaces</p> <p>New/modified commands: show management-interface convergence</p>
Migrate from Firepower 1000/2100 to Secure Firewall 3100.	7.4.0	Any	<p>You can now easily migrate configurations from the Firepower 1000/2100 to the Secure Firewall 3100.</p> <p>New/modified screens: Devices > Device Management > Migrate</p> <p>Platform restrictions: Migration not supported from the Firepower 1010 or 1010E.</p>
Download a report of all registered devices.	7.4.0	Any	<p>You can now download a report of all registered devices. On Devices > Device Management, click the new Download Device List Report link, at the top right of the page.</p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Manage threat defense high availability pairs using a data interface.	7.4.0	7.4.0	Threat defense high availability now supports using a regular data interface for communication with the management center. Previously, only standalone devices supported this feature. See: Using the Threat Defense Data Interface for Management
Cluster health monitor settings.	7.3.0	Any	You can now edit cluster health monitor settings. New/modified screens: Devices > Device Management > Cluster > Cluster Health Monitor Settings Note If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.
Redundant manager access data interface.	7.3.0	7.3.0	When you use a data interface for manager access, you can configure a secondary data interface to take over management functions if the primary interface goes down. The device uses SLA monitoring to track the viability of the static routes and an ECMP zone that contains both interfaces so management traffic can use both interfaces. New/modified screens: <ul style="list-style-type: none">• Devices > Device Management > Device > Management• Devices > Device Management > Device > Interfaces > Manager Access
ISA 3000 System LED support for shutting down.	7.0.5/7.3.0	7.0.5/7.3.0	When you shut down the ISA 3000, the System LED will turn off. You should wait at least 10 seconds before removing the power.
ISA 3000 support for shutting down.	7.0.2/7.2.0	7.0.2/7.2.0	You can now shut down the ISA 3000; previously, you could only reboot the device.
Policy rollback support for high availability devices.	7.2.0	7.2.0	The configure policy rollback command is supported for high availability devices.

Feature	Minimum Management Center	Minimum Threat Defense	Details
Multi-manager support.	7.2.0	7.2.0	<p>We introduced the cloud-delivered management center. The cloud-delivered management center uses the Cisco Defense Orchestrator (CDO) platform and unites management across multiple Cisco security solutions. We take care of manager updates.</p> <p>Hardware or virtual management centers running Version 7.2+ can "co-manage" cloud-managed devices, but for event logging and analytics purposes only. You cannot deploy policy to these devices from the hardware or virtual management center.</p> <p>New/modified commands: configure manager add, configure manager delete, configure manager edit, show managers</p> <p>New/modified screens:</p> <ul style="list-style-type: none"> • When you add a cloud-managed device to a hardware or virtual management center, use the new CDO Managed Device check box to specify that it is analytics-only. • View which devices are analytics-only on Devices > Device Management. <p>For more information, see CDO documentation.</p>
Object group search is enabled by default for access control rules.	7.2.0	7.2.0	<p>The Object Group Search setting is enabled by default for managed devices starting with Version 7.2.0. This option is in the Advanced Settings section when editing device settings on the Device Management page.</p>
Auto rollback of a deployment that causes a loss of management connectivity.	7.2.0	7.2.0	<p>You can now enable auto rollback of the configuration if a deployment causes the management connection between the management center and the threat defense to go down. Previously, you could only manually rollback a configuration using the configure policy rollback command.</p> <p>New/modified screens:</p> <ul style="list-style-type: none"> • Devices > Device Management > Device > Deployment Settings • Deploy > Advanced Deploy > Preview • Deploy > Deployment History > Preview
RAID support for SSDs on the Secure Firewall 3100.	7.1.0	7.1.0	<p>The SSDs are self-encrypting drives (SEDs), and if you have 2 SSDs, they form a software RAID.</p> <p>New/modified commands: configure raid, show raid, show ssd</p>
Support for TLS 1.3 for the management connection.	7.1.0	7.1.0	<p>The FMC-device management connection now uses TLS 1.3. Previously, TLS 1.2 was supported.</p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Import and export device configurations.	7.1.0	7.1.0	<p>You can export the device-specific configuration, and you can then import the saved configuration for the same device in the following use cases:</p> <ul style="list-style-type: none"> • Moving the device to a different FMC. • Restore an old configuration. • Reregistering a device. <p>New/modified screens: Devices > Device Management > Device > General</p>
Use FDM to configure FTD for management by the FMC.	7.1.0	7.1.0	<p>When you perform initial setup using FDM, all interface configuration completed in FDM is retained when you switch to FMC for management, in addition to the Management and manager access settings. Note that other default configuration settings, such as the access control policy or security zones, are not retained. When you use the FMC CLI, only the Management and manager access settings are retained (for example, the default inside interface configuration is not retained).</p> <p>After you switch to FMC, you can no longer use FDM to manage FTD.</p> <p>New/modified FDM screens: System Settings > Management Center</p>
Filter devices by upgrade status.	6.7.0	6.7.0	<p>The Device Management page now provides upgrade information about your managed devices, including whether a device is upgrading (and what its upgrade path is), and whether its last upgrade succeeded or failed.</p> <p>New/modified screens: Devices > Device Management</p>
Update the FMC IP address on FTD.	6.7.0	6.7.0	<p>If you change the FMC IP address, you can now use the FTD CLI to update the device.</p> <p>New/modified commands: configure manager edit</p>
One-click access to the Firepower Chassis Manager.	6.4.0	6.4.0	<p>For Firepower 4100/9300 series devices, the Device Management page provides a link to the Firepower Chassis Manager web interface.</p> <p>New/modified screens: Devices > Device Management</p>
Filter devices by health and deployment status; view version information.	6.2.3	6.2.3	<p>The Device Management page now provides version information for managed devices, as well as the ability to filter devices by health and deployment status.</p> <p>New/modified screens: Devices > Device Management</p>

CHAPTER 2

Device Management Using Device Templates

You can add devices to the management center using device templates.

About Device Management using Device Templates

Device templates enable deployment of multiple branch devices with pre-provisioned initial device configurations. You can use device templates to perform bulk zero-touch provisioning of multiple devices, apply day 2 configuration changes to multiple devices with different interface configurations, and clone configuration parameters from existing devices. You can also register more than one device at a time with the Management Center using serial numbers.

When you register a device using basic initial configuration, you can apply limited configurations such as the access control policy and licenses. You must then configure other device settings such as interfaces, routing, and site-to-site VPN configurations individually after device registration. Device templates let you pre-configure these settings and more so you can apply them at the time of registration. Values that need to be unique per

device, such as IP addresses, can be defined using variables and network object overrides that you define at registration.

You can also configure Site-to-site VPN connections in a device template. These configurations define the site-to-site VPN topologies that a device should be a part of. The VPN configurations along with the other device template policies and configurations enable easy deployment of the branch device to your network. Device templates support the configuration of a device only as a spoke. A device can be part of multiple hub and spoke site-to-site VPN topologies.

After the configured device template is applied to a device, the variables are resolved, the protected network overrides are configured, and the device is added as a spoke in the specified VPN topology.

Methods to Register Devices using Templates

You can use device templates with the following methods to register the device on the management center and set up day 0 configuration:

- **Registration Key** - You can register a single device by specifying the registration key and defining variables in the management center.
- **Serial Number** - You can use zero-touch provisioning to register one or more devices by serial number. For serial number registration, define all variables and overrides in a CSV file that you upload.

Variables and Network Object Overrides

You can parameterize template configurations using variables and network object overrides.

A variable is an object type that is supported for template configurations. A variable in a template defines specific configuration values for a device. You can define values for these variables during device registration and during application of the template on the device. You can see the variable icon (x) for the fields that use a variable. The variables are displayed with a \$ prefix to distinguish these values from the other values.

For information on supported variable types and creating variables, see [Supported Variables](#) and [Add a Variable](#).

Network object overrides are similar to variables. But, these are used to provide override values for a network object. You can declare a list of network objects in the template and create network object overrides for these objects. You can then provide values for these network object overrides during the application of the template on the device. For example, if you define a host network object in a template, you can add a network object override before the application of the template on the device and then provide a relevant value during the application of the template on the device.

For more information on supported network objects and adding a network object override, see [Supported Network Object Overrides](#) and [Add a Network Object Override](#).

Model Mapping

As interface configurations vary for different device models, the interface configurations in the template have to be copied to the target interfaces on the device. Model mapping enables you to define mapping of interfaces defined in the template to the interfaces of the required Threat Defense model. During application of the template on the device, the variables in the interface configurations are replaced with the values that you provide and copied to the mapped interfaces on the device. Note that you have to create the model mappings

in the template before initiating application of the template on the device. For more information on setting up model mapping, see [Add Model Mapping](#).

Requirements and Prerequisites for Device Management using Device Templates

Model Support

Device templates are supported on On-Prem Management Center, cloud-delivered Firewall Management Center (cdFMC), with the following models running Secure Firewall version 7.4.1 and later versions:

- Firepower 1000 series
- Firepower 2100 series (7.4.x only)
- Secure Firewall 3100 series

Supported Domains

Any

User Roles

- To create, modify, or delete templates:
 - Admin
 - Network Admin
- To view the created templates:
 - Any

Prerequisites for VPN Connections in Device Templates

- Configure site-to-site VPN topologies that must be used in the device template.
- Ensure that you have configured all hub and VPN topology-related configurations such as authentication methods, IKE and IPsec policies.
- Supported types of VPN hub and spoke topologies are:
 - Policy-based
 - Route-based
 - SD-WAN
- Assign appropriate logical names and IP addresses to the interfaces of the threat defense devices. For example, use *inside* for the interface connected to the LAN, and *outside* for the interface connected to the internet or WAN.
- Spoke devices must be version 7.4.1 and later.

Licenses for Device Management using Device Templates

- Device templates does not have any specific license requirements.
- License entitlements for the target device must be present in the Smart Licensing account.
- To configure VPN connections in the template, the Essentials license must allow export-controlled functionality. Choose **System > Licenses > Smart Licenses** to verify this functionality in the management center.
- When you apply a template on a device, note the following conditions for Secure Client licensing:

Device with Secure Client License	Template with Secure Client License	Secure Client License after Device Template Application
Yes	Yes	Template License
Yes	No	Device License
No	Yes	Template License

Guidelines and Limitations for Device Management using Device Templates

General Guidelines for Device Templates

- All device configurations other than VNI and VTEP are supported.
- You can attach shared policies and S2S VPN policies to a template. These policies are assigned during template application.
- Templates can be applied on HA devices. However, application of device templates during HA device pair registration is not supported. You also cannot manage HA-related configurations such as failover links, standby IP addresses, and so on. For more information, see [Device Template Operations on Threat Defense HA Devices](#).
- Device template operations are supported only on the active Management Center. The standby peer does not support device template operations.
- Ensure that the template names and device display names are not the same.
- Ensure that you do not create or delete a template during device backup or restore operations.
- After application of the template on the device, if the manager access is changed from management to data interface or vice-versa, you must re-establish the management connection with the device. Note that you cannot change the manager access interface during template application.
- You can add a maximum of 250 device templates to the Management Center.

- Templates that are created and configured for devices that are managed through the data interface cannot be used to register and apply to devices that are managed through the management interface.
- Device registration and application of template does not come under the Change Management workflow. Only approved data, such as access policies, templates, template variables, network overrides declared in template, and template configurations used in the template application operation are used.
- Device registration with serial number and access control policy is supported for only one device at a time.
- Devices with IPv6 DHCP discoverability are not supported when you add devices using serial numbers.
- Any change in model mapping causes the device to be marked as 'Out of Sync'. Consider reapplying the template to the devices if you have made changes to the interface mapping in the corresponding model mapping or if you have made any configuration changes after the previous application of the template.
- Template configuration updates are supported by change management. Creation and application of device templates is not supported by change management.
- You cannot sync configuration changes from a device to the template. A few sample scenarios during which you may want to make changes to the device configuration using a template along with recommended solutions are given below:
 - If you want to test the new configuration changes on one device before propagating the changes to multiple devices, we recommend that you make the changes in the template and apply the template to one device. Validate the changes on that device and then apply the template to the other devices.
 - If you want to make a large number of changes resulting in a significant deviation from the current configuration on a device, and then propagate those changes to other devices, you may choose one of the following options:
 - Export the current template to get a copy of the template. You can then make the required changes in the template and apply to a single device. Validate the changes on that device and then apply the template to the other devices.
 - You can also make the required changes on the device and create a template from that device. You can then apply and validate the changes on the other devices. However, we do not recommend this as template parameters such as variables and network object overrides will not be present in the created template.
 - If the configuration on a particular device starts to differ significantly from the configuration in the template, you may also choose to not use the template for this device and delete the device-template association from the **Associated Devices** window.

Guidelines for VPN Connections in Device Templates

- Supported interfaces for VPN topologies are:

Topology Type	Interface Type
Policy-Based and SD-WAN	<ul style="list-style-type: none"> • Physical interfaces <ul style="list-style-type: none"> • Non-management • Interface Mode must be either Routed or None • Subinterfaces • Redundant interfaces • Etherchannel interfaces • VLAN interfaces
Route-Based	Static Virtual Tunnel Interfaces

- When you apply a template on a device that is part of a VPN topology, you must ensure that the template includes interface configurations for all interfaces used in the topology.
- When you apply a template with VPN connections to multiple devices, note the following:
A template is applied to multiple devices in the order in which you have selected the devices. If the template has VPN connections, the corresponding VPN topology is locked.
- For SD-WAN topology VPN connections: Ensure that IP address subnet of the interface does not conflict with the subnet of the IP address pool of the SD-WAN hub.
- Domain:
 - You can define a template in a global or leaf domain. However, you can define a VPN topology only in a leaf domain.
 - You can configure VPN connections in a template for all domains. During template application, VPN connections are applied to the device only if the device is in the same domain as the VPN topology.

For more information, see [Device Templates in Domains, on page 167](#).

- Change management: Before you apply a device template to a device, ensure that the VPN topology is not locked by a Change management ticket.

Limitations for Device Templates

- The following features and configurations are not supported using device templates:
 - Multi-instance mode
 - Clustering
 - Non-converged management interface
 - Transparent mode
 - HA failover configurations

- Chassis configurations
- Logical devices
- Variables for nested objects
- Override support for network groups and other object types

Limitations for VPN Connections

- When you create a template from a device that is part of a VPN topology (**Devices > Device Management > More**  > **Generate Template from Device**), VPN configurations are not part of the template. You must reconfigure the VPN configurations on the template.
- When you export a device template with one or more VPN connections (**Template Settings > General > General** pane > **Export**), the VPN connections are not exported. You must reconfigure the VPN connections on the imported template.
- Certificate-based authentication:
 - Device templates do not support automatic certificate enrolment of a device.
 - When you onboard a device using a template with VPN configurations, if the VPN topology uses certificate-based authentication, the first deployment to the device will fail. Ensure that you manually enroll the device certificate after the device registration and deploy the configurations on the device again.

Template Management

Choose **Devices > Template Management** to bring up the Template Management window. This window provides you with a range of information and options to manage templates. All the created device templates are listed on this window.

Information on each template is provided under the following columns:

- **Name** - Displays the name of the template.
- **Domain** - Displays the domain in which the template is present.
- **Variables** - Displays the variables and network object overrides in the template.
- **Access Control Policy** - Click the link in the Access Control Policy column to view the policy that is deployed on the device.
- **Model Interface Mapping** – Displays the device model interfaces that are mapped to the template interfaces.

Against each template, there is an **Edit**  icon and a **More**  icon. When you click the **Edit**  icon, the **Device Management** window appears with several tabs. You can use the tabs to configure interfaces, inline sets, routing, DHCP, VPN, and template settings.

Click the **More**  icon for the following options:.

- **Apply:** To apply the template on a device. See [Apply a Template](#).
- **Delete:** To delete a template. See [Delete Device Template](#).
- **Export and Import:** To import or export a template. See [Import a Device Template](#).

Workflow for Device Management using Device Templates

Add a Device Template

You can add a new device template with the required configuration or generate a device template from an existing device.

Create a New Device Template

You can specify the device template name, description, access control policy, and routing mode. You can add more configurations after the template has been created. Perform the procedure given below to create a device template.

Procedure

- Step 1** Choose **Devices > Template Management**.
- Step 2** Click **Add Device Template**.
- Step 3** In the **Add Device Template** window, enter a **Name** for the template.
- Step 4** (Optional) Enter a **Description** for the template.
- Step 5** Choose an **Access Control Policy** from the drop-down list.

- Step 6** Choose a **Mode** from the drop-down list.
- Step 7** Click **OK**.
-

Generate a New Device Template from an Existing Device

You can generate a new device template from a device that is registered with the Management Center. The new template has the same configuration as the device from which it is generated. You can generate a new device template from standalone and HA devices. However, if you generate a template from HA devices, the new template will not contain the failover configurations.

Perform the procedure given below to generate a new device template from an existing device.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Click the **More** (⋮) icon, and click **Generate Template from Device**.
- Step 3** In the **Generate template from device** window, enter a **Name** for the template.
- Step 4** (Optional) Enter a **Description** for the template.
- Step 5** Choose an **Access Control Policy** from the drop-down list.
- Note** This policy is assigned to the generated template. Any other shared policies that are associated with the device from which the template is generated are assigned to the generated template only if these policies are visible in the domain in which the template is being generated.
- Step 6** Click **OK**. You can view the status of template creation in the **Notifications > Tasks** window.
- Step 7** Choose **Devices > Template Management** to view the newly created template.
-

Import a Device Template

You can import a template into the management center or export a template to your local system. This feature is useful in the following scenarios:

- Generate a copy of the template from a device, export it, and import that template into another Management Center or cloud delivered Management Center.
- Generate a copy of the template, export it, modify as required to create a variation of the existing template, and import the template into the management center.
- Generate a copy of the template, export it, and import that template into another domain in which the source template is not visible.

When you import a template into a domain, any objects that are part of the configuration are either newly created or reused if the objects with the same name are visible in the domain into which the template is imported. Any object with matching names that is not visible, due to domain hierarchy, is imported as a new object with the name suffixed with a `_x`.

If there is a mismatch in the variable names when you want to onboard devices in a domain using the cloned template from another domain, you must specify the new variable names in the .csv file to onboard the devices.

Perform the procedure given below to import a device template into the Management Center from your local system.

Procedure

- Step 1** Choose **Devices > Template Management**.
- Step 2** Click the **More** (⋮) icon for the template that you want to replace with an imported template.
- Step 3** Click **Import** and click **Import** again.
- If you want to export a template, click **Export** and click **OK**.
- Step 4** View the status of the import task in the **Notifications > Tasks** window.
- Step 5** Choose the template SFO file on your local system and click **Open**. This template SFO file that you import can be newly created, generated from a device, or cloned from an existing template.
- Step 6** View the status of the import task in the **Notifications > Tasks** window. You will see a notification informing you that the import or export task is successfully completed. If you are exporting a template, click **Download Export Package** in the **Notifications > Tasks** window to download the template configuration as an SFO file.

Note Alternatively, you can also go to the **Template Management** window and click the **Edit** (✎) icon of the template. Then, go to **Template Settings > General**, and click **Import** or **Export** in the **General** tile to import or export the template.

Configure a Device Template

After creating the template, you can set up device configurations and configure settings that you want to apply on the device by editing the template.

Add a Physical Interface

By default, a device template will enable the device to come up with the following physical interfaces:

- Management interface
- Inside interface
- Outside interface

Perform the procedure given below to create a physical interface.

Procedure

- Step 1** Choose **Devices > Template Management**.

- Step 2** Click the **Edit** (✎) icon of the template in which you want to add the physical interface.
- Step 3** In the **Interfaces** tab, click **Add Physical Interface**.
- Step 4** Choose a **Slot** and **Port Index** number from the drop-down list.
- Step 5** Click **Create Interface**.
-

Add a Logical Interface

You can create a logical interface in the same way as you do on the Management Center without using the template. Perform the procedure given below to create a logical interface.

Procedure

- Step 1** Choose **Devices > Template Management**.
- Step 2** Click the **Edit** (✎) icon of the template in which you want to add the logical interface.
- Step 3** In the **Interfaces** tab, click **Add Interface**, and choose the type of interface that you want to create from the drop-down list. You can create the following types of interfaces:
- Sub-interface
 - Ether channel interface
 - Bridge group interface
 - VLAN interface
 - Virtual tunnel interface
 - Loopback interface

For more information, see [Interface overview](#) and [Regular Firewall Interfaces](#).

Edit an Interface

You can edit an interface in the same way as you do on the Management Center without using the template. Use template variables to set up the IPv4 and IPv6 addresses. The device template supports the configurations that are supported on Firepower 1000, 2100, and Secure Firewall 3100 Threat Defense devices. Perform the procedure given below to edit an interface.

Procedure

- Step 1** Choose **Devices > Template Management**.
- Step 2** Click the **Edit** (✎) icon of the template in which you want to edit the physical interface.
- Step 3** In the **Interfaces** tab, click the **Edit** icon for the interface that you want to edit.

Step 4 In the **Edit Physical Interface** window, you can edit any of the following settings:

- General
- PoE
- IPv4
- IPv6
- Path Monitoring
- Hardware Configuration
- Manager Access
- Advanced

Note Use variables to configure IPv4 and IPv6 addresses. For more information on templating variables, see [Configure Template Parameters](#).

For more information on editing the settings mentioned above, see [Interface overview](#) and [Regular Firewall Interfaces](#).

Configure Other Device Settings

Configure the other device settings in the same way as you do on the Management Center without using the template.

Procedure

Step 1 Choose **Devices > Template Management**.

Step 2 Click the **Edit** (✎) icon for the template in which you want to configure the settings.

Step 3 Click the tabs at the top of the window to configure any of the following settings:

- Inline Sets
 - Routing
 - DHCP
 - VPN
 - Template Settings
-

Configure Template Settings

These are template-specific settings that are copied to the device when the template is applied on the device. In the **Template Settings** window, you can configure the following template settings:

- General
 - [Edit General Settings](#)
 - [Edit Licenses](#)
 - [Edit Applied Policies](#)
 - [Edit Advanced Settings](#)
 - [Edit Deployment Settings](#)
- Template Parameters
 - [Add a Variable](#)
 - [Add a Network Object Override](#)
- [Add Model Mapping](#)

Edit General Settings

In the **General** tile, you see the following fields:

- **Template Name** – The name of the template.
- **Transfer Packets** – Displays whether or not the managed device sends packet data with the events to the management center.
- **Mode** – Displays the mode of the management interface for the device: routed.
- **Configuration** – Click **Export** to export the template configurations as an SFO file. Click **Import** to import an SFO file that has the template configurations that you require.
- **Manage device by Data Interface** – Toggle the button to enable or disable management of the device using the data interface.

Perform the procedure given below to edit the name of the device, and to enable or disable packet transfer.

Procedure

- Step 1** Click the **Edit** () icon in the **General** tile.
 - Step 2** Change the **Template Name** as per your requirement.
 - Step 3** Check the **Transfer Packets** checkbox to allow packet data to be stored with events on the management center.
 - Step 4** Click **Save**.
-

Edit Licenses

In the **License** tile, you can see the **License types** that are required based on the configurations used in the template. Choosing a license here does not consume that license on the device. The license is consumed only when you apply the template to a device.

Perform the procedure given below to edit the license types as per your requirement.

Procedure

- Step 1** Click the **Edit** (✎) icon in the **License** tile.
 - Step 2** Check or clear the check box next to the license you want to enable or disable for the managed device.
 - Step 3** Click **Save**.
-

Edit Applied Policies

In the **Applied Policies** tile, you can see the access control policies that are associated with the template.

For policies with links, you can click the link to view the policy.

Perform the procedure given below to edit the policy assignments as per your requirement.

Procedure

- Step 1** Click the **Edit** (✎) icon in the **Applied Policies** tile.
 - Step 2** For each policy type, choose a policy from the drop-down list. Only existing policies are listed.
 - Step 3** Click **Save**.
-

Edit Advanced Settings

The **Advanced Settings** tile displays the advanced configuration settings, as described below. You can edit any of these settings.

Table 9: Advanced Section Table Fields

Field	Description
Application Bypass	The state of Automatic Application Bypass on the device.
Bypass Threshold	The Automatic Application Bypass threshold, in milliseconds.

Field	Description
Object Group Search	<p>The state of object group search on the device. While operating, the FTD device expands access control rules into multiple access control list entries based on the contents of any network or interface objects used in the access rule. You can reduce the memory required to search access control rules by enabling object group search. With object group search enabled, the system does not expand network or interface objects, but instead searches access rules for matches based on those group definitions. Object group search does not impact how your access rules are defined or how they appear in Firepower Management Center. It impacts only how the device interprets and processes them while matching connections to access control rules.</p> <p>Note By default, the Object Group Search is enabled when you add threat defense for the first time in the management center.</p>
Interface Object Optimization	<p>The state of interface object optimization on the device. During deployment, interface groups and security zones used in the access control and prefilter policies generate separate rules for each source/destination interface pair. If you enable interface object optimization, the system will instead deploy a single rule per access control/prefilter rule, which can simplify the device configuration and improve deployment performance. If you select this option, also select the Object Group Search option to reduce memory usage on the device.</p>

Perform the procedure given below to edit the advanced settings.

Procedure

-
- Step 1** Click the **Edit** (✎) icon in the **Advanced Settings** tile.
- Step 2** You can change the settings as per your requirement. For more information, see the following sections:
- [Configure Automatic Application Bypass](#)
 - [Configure Object Group Search](#)
 - [Configure Interface Object Optimization](#)
- Step 3** Click **Save**.
-

Edit Deployment Settings

The **Deployment Settings** tile displays the information described in the table below.

Table 10: Deployment Settings

Field	Description
Auto Rollback Deployment if Connectivity Fails	Enabled or Disabled. You can enable auto rollback if the management connection fails as a result of the deployment; specifically if you use data for management center access, and then you misconfigure the data interface.
Connectivity Monitor Interval (in Minutes)	Shows the amount of time to wait before rolling back the configuration.

Deployment settings include enabling auto rollback of the deployment if the management connection fails as a result of the deployment; specifically if you use data for management center access, and then you misconfigure the data interface. You can alternatively manually roll back the configuration using the **configure policy rollback** command.

Perform the procedure given below to edit the deployment settings.

Procedure

-
- Step 1** Click the **Edit** icon in the **Deployment Settings** tile.
- Step 2** Set the **Connectivity Monitor Interval (in Minutes)** to set the amount of time to wait before rolling back the configuration. The default is 20 minutes.
- Step 3** If a rollback occurs, see the following for next steps.
- If the auto rollback was successful, you see a success message instructing you to do a full deployment.
 - You can also go to the **Deploy > Advanced Deploy** screen and click the **Preview** icon to view the parts of the configuration that were rolled back (see [Deploy Configuration Changes](#)). Click **Show Rollback Changes** to view the changes, and **Hide Rollback Changes** to hide the changes.
 - In the Deployment History Preview, you can view the rollback changes.
- Step 4** Check that the management connection was reestablished.
- In management center, check the management connection status on the **Devices > Device Management > Device > Management > FMC Access Details > Connection Status** page.
- At the threat defense CLI, enter the **sftunnel-status-brief** command to view the management connection status.
- If it takes more than 10 minutes to reestablish the connection, you should troubleshoot the connection. See [Troubleshoot Management Connectivity on a Data Interface](#).
-

Configure Template Parameters

You can templatize configurations using template parameters such as variables and network object overrides.

Supported Variables

The following variable types are supported in device templates.

Variable Name	Description	Type
AS Number	Defines the unique Autonomous System (AS) number.	Integer Example: 2
FQDN	Defines a single Fully Qualified Domain Name (FQDN).	String Example: abc.example.com
IPv4 Host	Defines the IPv4 address of the host.	String Example: 209.165.201.8
IPv4 Network	Defines the IPv4 network address block.	String Example: 209.165.200.224/27
IPv4 Range	Defines the range of IPv4 addresses.	String Example: 209.165.200.225-209.165.200.250
IPv6 Host	Defines the IPv6 address of the host.	String Example: 2001:DB8::1
IPv6 Network	Defines the IPv6 network address block.	String Example: 2001:DB8:0:CD30::/60
Password	Defines a password string.	String Example: E28@20iUrhx!
Router ID	Defines an identifier for the router.	Integer Example: 21
String	Defines a custom string.	String Example: testvalue2

Add a Variable

Perform the procedure given below to add a variable.

Procedure

-
- Step 1** Choose **Objects > Object Management**.
 - Step 2** Choose **Variable** from the list of object types.
 - Step 3** Click **Add Variable**.
 - Step 4** Enter a **Name**.

In a multidomain deployment, object names must be unique within the domain hierarchy. The system may identify a conflict with the name of an object you cannot view in your current domain.

Step 5 Choose a **Variable Type** from the drop-down list.

Step 6 (Optional) Enter a **Description**.

Step 7 Click **Save**.

Supported Network Object Overrides

The following network objects are supported.

Network Object Name	Description	Type
Network	An address block, also known as a subnet.	String Example: IPv4 - 209.165.200.224/27 IPv6 - 2001:DB8::/48
Host	The IP address of the host.	String Example: IPv4 - 209.165.200.225 IPv6 - 2001:DB8:1::1
Range	A range of IP addresses.	String Example: IPv4 - 209.165.200.225-209.165.200.250 IPv6 - 2001:DB8::1 - 2001:DB8:FFFFFFFFFFFFFFFFFFFFFFFF
FQDN	A single fully-qualified domain name (FQDN).	String Example: abc.example.com

Add a Network Object Override

Perform the procedure given below to add a network object override.

Procedure

Step 1 Choose **Devices > Template Management**.

Step 2 Click the **Edit** (✎) icon of the template in which you want to add the network object override.

Step 3 Choose **Template Settings > Template Parameters**.

Step 4 In the **Network Object Overrides** section, click **Add or Remove Network Object Overrides**.

- Step 5** In the **Add or Remove Network Object Overrides** window, choose the network objects for which you want to create network object overrides from the **Available Networks** window and click the > button.
- Step 6** Click **Save**.
-

Add Model Mapping

For each model, you can specify which template interface corresponds with which model interface. You can map a template to one or more models as long as the interface configurations are valid for all mapped models. For example, if the template includes switch ports and VLAN interfaces, then that template can only be applied to a Firepower 1010.

Perform the procedure given below to add model mapping.

Procedure

- Step 1** Choose **Devices > Template Management**.
- Step 2** Click **Add Model Mapping** for the template in which you want to create the model mapping. Alternatively, you can click the **Edit** (✎) icon of the template and choose **Template Settings > Model Mapping**.
- Step 3** Click **Add Model Mapping**.
- Step 4** Choose the **Device Model** from the drop-down list.
- Step 5** Map the template interfaces to the device model interfaces by choosing the interface from the **Model Interface** drop-down list.
- Note** You can click **Clear Mapping** to remove the defined model mapping. Click **Reset Mappings** for default interface mapping in which the mapping is done based on the slot and port index order of the interface names.
- Step 6** Click **Save**. The interface mappings are listed along with the device model and mapping status on the **Model Mapping** window.
- Note** Some configurations in the template may not be supported on all device models. Unsupported configurations, if any, are not applied to the device. The Device Template Apply Report provides details about such configurations.
-

Invalid Model Mappings

Some configurations in the template may not be supported on all device models. Unsupported configurations, if any, are not applied to the device. Valid model mappings can also become invalid when you modify template configurations. For example, when you add a new interface on the template and assign a name to it, the new interface must be mapped to the appropriate interface on the device model.

Model mapping can also be invalidated due to any of the following reasons:

- Number of configured VRF instances exceeds the limit for a specific model.
- Interfaces mapped to incompatible models, versions, or interfaces. See [Requirements and Prerequisites for Device Management using Device Templates](#) for more information.

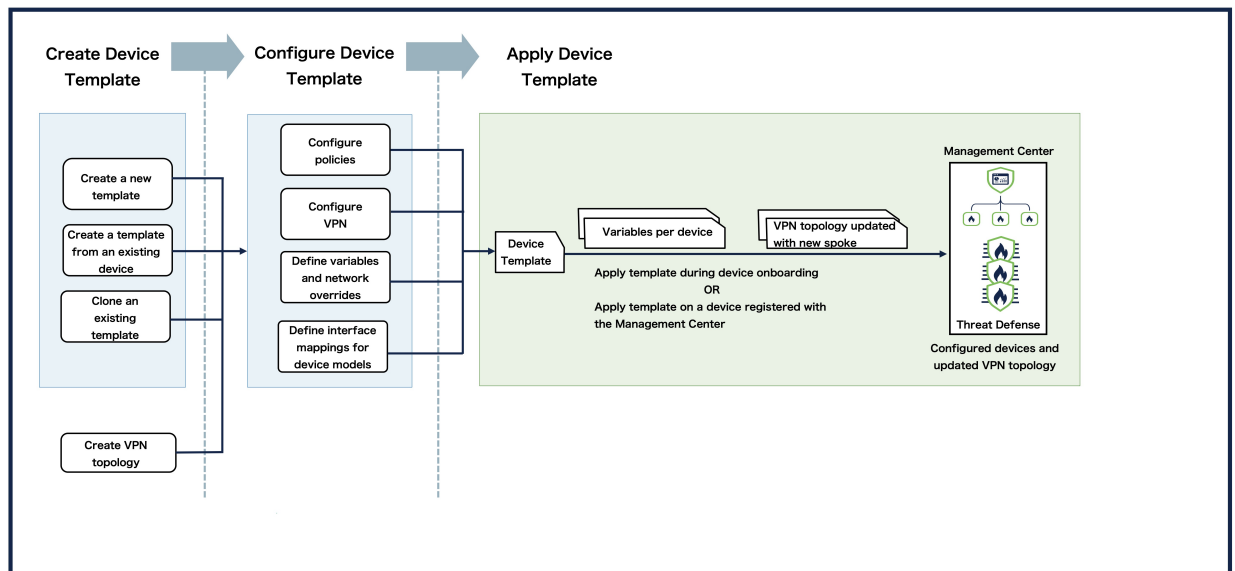

- Number of interfaces exceeds the model limit.
- Deleted an interface that was mapped.
- Newly added physical interfaces are not mapped to a compatible model interface.
- Model mapping is not done for a named interface.
- Model mapping is not done for an interface related to other logical interfaces, such as sub-interfaces, PC interfaces, and so on.
- Making policy or configuration changes that are unsupported on some device models. For example, enabling switch port configuration on interfaces.

You can also save a template with invalid model mappings. However, you must review and fix the model mapping before initiating application of the template on the device.

You can hover over **Invalid** under **Mapping Status** to view the errors that caused the invalid mapping status. Fix the errors before initiating application of the template on the device.

Configure Site-to-Site VPN Connections in a Device Template

Device Template with Site-to-Site VPN Connections Workflow

Configure an SD-WAN VPN Connection

You can configure an SD-WAN VPN connection to add spokes to SD-WAN topologies using the device template.

Before you begin

- Configure a minimum of one SD-WAN topology (**Devices > VPN > Site To Site**).
- Review [Requirements and Prerequisites for Device Management using Device Templates](#) and [Guidelines and Limitations for Device Management using Device Templates](#).

Procedure

-
- Step 1** Choose **Devices > Template Management**.
- Step 2** Click the edit icon adjacent to the device template that you want to edit.
- Step 3** Click the **VPN** tab.
- Step 4** Click **Add VPN Connection**.
- Step 5** Choose an SD-WAN topology from the **VPN Topology** drop-down list.

The **Add VPN Connection** dialog box expands and you can configure the following parameters:

- a) From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface to establish a VPN connection with the hub.

This list contains all the interfaces configured on the device template.
- b) **Use IP Address from the VPN Interface**—This drop-down list is auto populated with the IP address variable. For IPv6 addresses, choose an IPv6 address from the drop-down list.
- c) Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from the spoke to a remote peer.
- d) **Identity Type**—Key ID is the only supported identity type. Choose a key ID variable from the drop-down list or click + to create a new key ID variable.
- e) Click **OK**.

You can view the VPN connection in the **Site-to-Site VPN Connections** table.

- Step 6** Click **Save**.
-

What to do next

1. Configure the routing policy for the spoke in the device template.
2. Map the device interfaces to the template interfaces (Model Mapping).
3. Apply the template to a device.

Configure a Route-Based Site-to-Site VPN Connection

You can configure a route-based site-to-site VPN connection to add spokes to route-based site-to-site VPN topologies using the device template.

Before you begin

- Configure a minimum of one route-based site-to-site VPN topology (**Devices > VPN > Site To Site**).

- Review [Requirements and Prerequisites for Device Management using Device Templates](#) and [Guidelines and Limitations for Device Management using Device Templates](#).

Procedure

- Step 1** Choose **Devices > Template Management**.
- Step 2** Click the edit icon adjacent to the device template that you want to edit.
- Step 3** Click the **VPN** tab.
- Step 4** Click **Add VPN Connection**.
- Step 5** Choose a route-based site-to-site VPN topology from the **VPN Topology** drop-down list.

The **Add VPN Connection** dialog box expands and you can configure the following parameters:

- From the **Virtual Tunnel Interface (VTI)** drop-down list, choose a VTI interface or click + to create a new VTI.

VTI is a virtual interface used to establish a route-based VPN tunnel. You must configure routing policies for a VTI to set up a VPN tunnel. This list contains all the VTIs configured on the device template. For more information on creating a VTI, see [Add a VTI Interface, on page 1432](#).
- Check the **Use Public IP Address** check box to override the tunnel source IP address and configure a public IP address variable for the VTI. Click + to create a new public IP address variable.

This IP address is the source IP address for the VPN tunnel. By default, this is the IP address of the VPN interface. However, if the device is behind NAT, the VPN interface has a private address, but the post-NAT public IP address should be configured.
- Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from the spoke to a remote peer.
- Identity Type:** Key ID is the only supported identity type. Choose a key ID variable from the drop-down list or click + to create a new key ID variable.
- (Optional) Check the **Enable Secondary VPN Tunnel** check box to configure the parameters for the secondary VPN tunnel.
- Click **OK**.

You can view the VPN connection in the **Site-to-Site VPN Connections** table.

- Step 6** Click **Save**.
-

What to do next

1. Configure the routing policy for the spoke in the device template.
2. Map the device interfaces to the template interfaces (Model Mapping).
3. Apply the template to a device.

Configure a Policy-Based Site-to-Site VPN Connection

You can configure a policy-based site-to-site VPN connection to add spokes to policy-based site-to-site VPN topologies using the device template.

Before you begin

- Configure a minimum of one policy-based site-to-site VPN (**Devices > VPN > Site To Site**).
- Review [Requirements and Prerequisites for Device Management using Device Templates](#) and [Guidelines and Limitations for Device Management using Device Templates](#).

Procedure

-
- Step 1** Choose **Devices > Template Management**.
- Step 2** Click the edit icon adjacent to the device template that you want to edit.
- Step 3** Click the **VPN** tab.
- Step 4** Click **Add VPN Connection**.
- Step 5** Choose a policy-based site-to-site VPN topology from the **VPN Topology** drop-down list.

The **Add VPN Connection** dialog box expands and you can configure the following parameters:

- a) From the **VPN Interface** drop-down list, choose a WAN-facing or internet-facing physical interface to establish a VPN connection with the hub.

This list contains all the interfaces configured on the device template.

Do one of the following to configure the IP address of the VPN interface:

- Click the **Use IP Address from the VPN Interface** radio button to use the IP address of the VPN interface.

This IP address is auto populated. For IPv6 addresses, choose an IPv6 address from the drop-down list.
- Click the **Use Public IP Address** radio button to configure a public IP address for the VPN interface.

Choose an IP address variable from the drop-down list or click + to add an IP address variable.

- b) Check the **Local Tunnel (IKE) Identity** check box to enable a unique and configurable identity for the VPN tunnel from the spoke to a remote peer.
- c) **Identity Type**: Key ID is the only supported identity type. Choose a key ID variable from the drop-down list or click + to add a new key ID variable.
- d) **Protected Networks**: Click + to configure a protected network for the VPN connection.

Do one of the following:

- Choose a protected network and click **OK**.
- Click **Add** to configure a network object and click **Save**.

When you create a protected network object, note the following:

- Click either the **Host** or the **Network** radio button.

- Check the **Allow Overrides** check box.

e) Click **OK**.

You can view the VPN connection in the **Site-to-Site VPN Connections** table.

Step 6 Click **Save**.

What to do next

1. Note that before you apply a template to a device, to configure device-specific values for the protected networks, add these objects in **Template Settings > Template Parameters > Add Network Objects Overrides**.
2. Map the device interfaces to the template interfaces (Model Mapping).
3. Apply the template to a device.

Register a Device Using Device Template and Add it to a Route-Based VPN Topology

This section provides instructions to register a device using device template and add it to a route-based VPN topology.

Before you begin

Ensure that you have a route-based VPN topology.

Step	Task	GUI Path	More Information
1	Create a device template.	Devices > Template Management > Add Device Template	Create a New Device Template, on page 138
2	Configure interfaces in the template.	Devices > Template Management > Interfaces	Edit an Interface, on page 141
3	Configure a route-based VPN connection in the template.	Devices > Template Management > VPN > Add VPN Connection	Configure a Route-Based Site-to-Site VPN Connection, on page 151
4	Configure routing policies in the template.	Devices > Template Management > Routing	—

Step	Task	GUI Path	More Information
5	Add a model mapping for the device model in the template.	Devices > Template Management > Template Settings > Model Mapping	Add Model Mapping, on page 149
6	Register the device using a device template.	Devices > Device Management > Add > Device (Wizard)	Add a Device Using a Registration Key and a Device Template, on page 157
7	Deploy configurations on the hub of the VPN topology.	Deploy	—

Add a Device to an SD-WAN Topology in a Dual ISP Deployment

This section provides instructions to add a device to an SD-WAN topology in a dual ISP deployment using a device template.

Before you begin

Ensure that you have two SD-WAN VPN topologies with the same hub. For more information about configuring SD-WAN topologies, see [Configure an SD-WAN Topology Using the SD-WAN Wizard, on page 1885](#).

Step	Task	GUI Path	More Information
1	Create a device template.	Devices > Template Management > Add Device Template	Create a New Device Template, on page 138
2	Add a physical interface in the template. By default, a template has only one outside interface. Rename the outside interfaces, for example, ISP1, ISP2.	Devices > Template Management > Interfaces > Add Physical Interface	Add a Physical Interface, on page 140
3	Configure an SD-WAN VPN connection using ISP1 interface.	Devices > Template Management > VPN > Add VPN Connection	Configure an SD-WAN VPN Connection, on page 150
4	Configure an SD-WAN VPN connection using ISP2 interface.		
5	Add static routes from ISP1 and ISP2 interfaces to the SD-WAN hub network.	Devices > Template Management > Routing > Static Route	-

Step	Task	GUI Path	More Information
6	Add the ISP1 and ISP2 interfaces to an ECMP zone.	Devices > Template Management > Routing > ECMP	-
7	Configure the network object overrides.	Devices > Template Management > Template Settings > Template Parameters > Add Network Objects Overrides	Add a Network Object Override, on page 148
8	Map the template interfaces to the device model interfaces (Model Mapping).	Devices > Template Management > Template Settings > Model Mapping	Add Model Mapping, on page 149
9	Apply template to the device.	Devices > Template Management >	Apply a Template, on page 161
10	Deploy configurations on the device.	Deploy	—
11	Deploy configurations on the hubs of the SD-WAN topologies.	Deploy	—

For more information about dual ISP deployment using the SD-WAN wizard, see [Sample Configurations for Dual ISP Deployment Using SD-WAN Wizard, on page 1890](#).

Add a Device to the Management Center

You can add a device to the management center using any of the following options:

- [Add a Device Using a Registration Key and a Device Template](#)
- Use Zero-Touch Provisioning to add a device using one of the following options:
 - [Add a Device to the Management Center Using the Serial Number \(Zero-Touch Provisioning\)](#)
 - [Add Devices Using Serial Numbers and a Device Template \(Zero-Touch Provisioning\)](#)

Note Any change management tickets related to template configurations must be approved for the corresponding changes to be incorporated into the template application workflow. Only approved template configurations are used during template application.

Add a Device Using a Registration Key and a Device Template

You can use a template to add a device, register the device with the Management Center, and bring up the device with the given template configurations. Before initiating application of the template on the device, you must specify any required variables and network object overrides for each device and ensure that model mapping is done for the target Threat Defense device model.

We recommend that you create a checklist to ensure that all configurations in the template have been entered correctly before applying the template on the device.

A sample checklist is given below.

- Check version, model, operation modes.
- Check list of variables and overrides.
- Check sanity of variable and override values.
- Check if the required Model Mappings exist.
- Check if parallel device template operations are in progress.

Note If you are adding a Threat Defense device that will be managed by a data interface for Management Center connectivity, ensure that you configure the template to be compatible with the connectivity parameters of the device. For more information, see [Configure a Template for Threat Defense Devices Managed Using the Data Interface](#).

Perform the procedure given below to add a device using a registration key and a device template.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Click **Add > Device (Wizard)**.
- Step 3** On the **Add Device (Wizard)** window, choose **Registration Key** to register a device using registration key.
- Step 4** Choose a template from the **Device template** drop-down list.
- Step 5** In the **Host** field, enter the IP address or the hostname of the device you want to add.
- The hostname of the device is the fully qualified domain name or the name that resolves through the local DNS to a valid IP address. Use a hostname rather than an IP address if your network uses DHCP to assign IP addresses.
- Step 6** In the **Display name** field, enter a name for the device as you want it to display in the management center.

- Step 7** In the **Registration key** field, enter the same registration key that you used when you configured the device to be managed by the management center. The registration key is a one-time-use shared secret. The key can include alphanumeric characters and hyphens (-).
- Step 8** From the **Device group** drop-down list, choose a device group in which the device is added.
- Step 9** Enter values for the **Variables** and **Network object overrides**.
- Step 10** Click **Add Device** to initiate device registration. The template configurations are applied after the device is successfully registered with the Management Center.
-

Zero-Touch Provisioning

Zero-Touch Provisioning lets you register devices to the management center by serial number without having to perform any initial setup on the device. The management center integrates with the Cisco Security Cloud and Cisco Defense Orchestrator (CDO) for this functionality.

ZTP is only supported on the following device models:

- Firepower 1000 series
- Firepower 2100 series (7.4.x only)
- Secure Firewall 3100 series

You can use the ZTP method to add devices to the management center using any of the following options:

- [Add a Device to the Management Center Using the Serial Number \(Zero-Touch Provisioning\)](#)
- [Add Devices Using Serial Numbers and a Device Template \(Zero-Touch Provisioning\)](#)

Add Devices Using Serial Numbers and a Device Template (Zero-Touch Provisioning)

You can use a template to add a device, register the device with the Management Center, and bring up the device with the given template configurations. Before initiating application of the template on the device, you must specify any required variables and network object overrides for each device and ensure that model mapping is done for the target Threat Defense device model.

Use this procedure to add devices to the management center using serial numbers and a device template. To add a device without using a template, see [Add a Device to the Management Center Using the Serial Number \(Zero-Touch Provisioning\)](#), on page 31.

We recommend that you create a checklist to ensure that all configurations in the template have been entered correctly before applying the template on the device.

A sample checklist is given below.

- Check version, model, operation modes.
- Check list of variables and overrides.
- Check sanity of variable and override values.
- Check if the required model mappings exist.

- Check if parallel device template operations are in progress.

Note If you are adding a Threat Defense device that will be managed by a data interface for Management Center connectivity, ensure that you configure the template to be compatible with the connectivity parameters of the device. For more information, see [Configure a Template for Threat Defense Devices Managed Using the Data Interface](#).

Perform the procedure given below to add devices using serial numbers and a device template.

Before you begin

Ensure that you read the following prerequisites before you perform the procedure to add devices using serial numbers and a template:

- Cisco Security Cloud integration must be enabled if you want to add devices using serial numbers.
- Threat Defense device must be in factory-shipped state, or must have been reset or reimaged. This means that there must be no configuration done using FDM, and the device must be in on-box mode in the CLI.
- The first data interface or the management interface on the Threat Defense device must have internet connectivity and must be able to get an IPv4 DHCP lease.
- If data interface is used for connectivity, do not plug in the management interface. Usually, the first data interface, Ethernet1/1, is used for Manager Access.

Procedure

Step 1

The first time you add a device using a serial number, integrate the management center with Cisco Security Cloud.

Note For a management center high-availability pair, you also need to integrate the secondary management center with Cisco Security Cloud.

- a) Choose **Integration > Cisco Security Cloud**.
- b) Click **Enable Cisco Security Cloud** to open a separate browser tab to log you into your Cisco Security Cloud account and confirm the displayed code.

Make sure this page is not blocked by a pop-up blocker. If you do not already have a Cisco Security Cloud and CDO account, you can add one during this procedure.

For detailed information about this integration, see the "System Configuration" chapter in the [Cisco Secure Firewall Management Center Administration Guide](#).

CDO onboards the on-prem management center after you integrate the management center with Cisco Security Cloud. CDO needs the management center in its inventory for zero-touch provisioning to operate. However, you do not need to use CDO directly. If you do use CDO, its management center support is limited to device onboarding, viewing its managed devices, viewing objects associated with the management center, and cross-launching the management center.

- c) Make sure **Enable Zero-Touch Provisioning** is checked.
- d) Click **Save**.

- Step 2** Choose **Devices > Device Management**.
- Step 3** Click **Add > Device (Wizard)**.
- Step 4** On the **Add Device (Wizard)** window, choose **Serial Number** to register one or more devices using the serial number. This is the Zero-Touch Provisioning (ZTP) method.
- Step 5** Choose **Device Template** as the **Initial device configuration** method to use a device template with preconfigured settings.
- Step 6** Choose the **Device Template** from the drop-down list. After choosing the device template, the access control policy that is assigned to the template and the device models supported with the template are displayed on the window.
- Step 7** Verify the details and click **Next**.
- Step 8** Download the **CSV Sample Template File** to have a look at the required header details that have to be used in the template. For more information on the CSV template file fields, see [CSV Template File](#).
- Step 9** **Drag & drop** your CSV template file or **Browse** to select the CSV template file that you want to upload. A validation check is done on the file after you upload it.
- After the CSV template file has been uploaded successfully, the content of the CSV template file is displayed in a table format.
- Step 10** Click **Add Device** to register the device with the Management Center.
- When device registration is completed on the Management Center, the device hostname is displayed as *{serialNumber}.local*. In the **General** tile under the **Device** tab, the **Onboarding Method** is shown as **Serial Number**.

CSV Template File

The CSV template file must be less than 2 MB in size. The filename must satisfy the following criteria:

- Can have a maximum of 64 characters.
- Only alphanumeric characters and special characters such as dash (-), period (.), and underscore (_) are allowed.
- Must not contain any spaces.

A properly formatted .csv file has the following fields:

Mandatory fields

- Display Name - Name of the device. Type: string. Example: test1
- Serial Number - Serial number of the device. Type: string, Example: JADX345670EG

Optional fields

- Device Group - Name of the device group, Type: string, Example: testgroup
- Admin Password - Password for admin access, Type: string, Example: E28@20iUrhx

Variables

Use the following format: `$(varName)`.

Sample variable: `$(LAN-Devices-IPv4Address)` - IPv4 address of the LAN device. Type: string. Example: 1.2.3.4.

Network object overrides

Use the following format: `<objType>:<objName>`.

Sample network object override: `Network:LAN-Devices-Network` - IP address of the network of LAN devices. Type: string. Example: 1.2.3.4

FQDNs

Fully Qualified Domain Name (FQDN) variables are populated automatically if they are used in the hostname for the Manager access interface and the FMC-Only DDNS update method is used.

Value for the variable used in the **Hostname** field of **DDNS settings on Manager access interface** must be given as `$(serial-number).local.`

A sample CSV template file containing configuration for two devices is as given below.

DisplayName	SerialNumber	AdminPassword	\$WANLinkIP	Host:gateway
Branch A FTD	JADX345410AB	C15c05n0rt#	10.20.30.1	10.2.3.1
Branch B FTD	JADX345670CE	Admin123!	10.20.30.5	10.2.3.1

Apply Templates to Existing Devices

You can apply or reapply a template to existing devices.

Apply a Template

You can apply a template to devices that are already registered with the Management Center. Application of a template on a device clears existing configurations and applies configurations from the template. However, the Threat Defense HA failover configurations are not cleared.

Application of a template changes device configurations only on the Management Center. You must explicitly deploy these device configuration changes to the Threat Defense device. You cannot roll back the applied configuration changes. However, you can apply another template with the required configurations.

Note Any change management tickets related to template configurations must be approved for the corresponding changes to be incorporated into the template application workflow. Only approved template configurations are used during template application.

Perform the procedure given below to apply the template on existing devices.

Procedure

- Step 1** To apply the template from the **Template Management** window, choose **Devices > Template Management**.
- Click the **More** (⋮) icon next to the template that you want to apply, and click **Apply**.
 - From the **Device** dropdown list, choose the **Device** on which you want to apply the template.
 - Click **Confirm** to initiate application of template on the device.
- Step 2** (Optional) To apply the template from the **Associated Devices** window, choose **Devices > Template Management**.
- Click the **Edit** (✎) icon of the template that you want to apply to a device.
 - Click **Associated Devices**.
 - In the **Associated Devices** window, click **Apply Template**.
 - From the **Device** drop-down list, choose the **Device** on which you want to apply the template.
 - Enter values for the **Variables** and **Network object overrides** fields.
 - Click **Apply** to initiate application of template on the device.
-

Reapply a Template

If you make any changes to the device or template that results in the configuration being out-of-sync, you can reapply the template to make the configuration in sync with the template.

Perform the procedure given below to reapply the template on a device.

Procedure

- Step 1** Choose **Devices > Template Management**.
- Step 2** Click the **Edit** (✎) icon of the template that you want to reapply to a device.
- Step 3** Click **Associated Devices**.
- Step 4** In the **Associated Devices** window, click **Reapply Template** for the device on which you want to reapply the template.
- Note** If you want to reapply the template on all the associated devices in the template, click **Bulk Reapply** and click **Confirm**.
- Step 5** On the **Reapply template** window, you can reuse the autopopulated **Variables** and **Network object overrides** values or enter new values.
- Step 6** Click **Confirm** to initiate reapplication of the template on the device.
-

Validation of Template Configuration Before and After Application of Template on Device

Validation of template configuration is done before and after application of the template on the device.

The following validation checks are performed at the start of the task to apply the template on the device:

- Ensure that the target device model and version are supported.
- Cluster and container checks -The device must not be part of a cluster or multi-instance.
- Model mapping validation - Model mapping for the target device model exists and is valid.
- Sanity check of template parameter values. For example, two variables used as IP addresses of interfaces must not have the same value.

The following validation checks are performed at the end of the task to apply the template on the device to ensure that the applied configurations are valid:

- Interface configuration validation. For example, variables used for the IP address fields of two or more interfaces must not have the same IP address values.
- Routing policy validation. For example, the IPv4 address in BGP neighbor configurations must not overlap with the IP address of any interface.

If the validation checks that are done at the end of the task to apply the template on the device fail, any applied configurations are rolled back and the device is restored to its original state.

Monitoring Device Templates

You can monitor and verify the application of templates by viewing the devices listed in the **Associated Devices** window and by viewing the **Template Apply Report**.

Viewing Associated Devices

The devices that are associated with the templates are listed in the **Associated Devices** window. Each device row displays the **Device Name**, **Sync Status**, **Apply Status**, and **Applied Date**. You can also click **Re-apply template** to reapply the template, and click the **View** icon display template configuration details. Click the **Delete** icon to remove the template from the device.

The **Sync Status** can be either **Sync** or **Out-of-Sync**. If the status is displayed as **Sync**, it indicates that the template and device configurations are the same or in sync. If the status is displayed as **Out-of-Sync**, it indicates that there has been a change in configuration either on the device or in the template since the last time that the template was applied..

The association of the device with the template is not altered by the following conditions:

- Pending configuration changes on the device – The **Sync Status** does not change if there are pending configuration changes that have to applied on the device.

- Deployment of pending configuration changes on the device – The **Sync Status** does not change after deployment of pending configuration changes on the device.

The table below shows the **Sync** and **Out-of-Sync** scenarios that may occur.

Device Configurations Modified After Application of Template on Device	Template Configurations Modified After Application of Template on Device	Association Status
No	No	In Sync
Yes	No	Out of Sync
No	Yes	Out of Sync
Yes	Yes	Out of Sync

Generating a Template Apply Report

A **Template Apply Report** PDF is generated after the task to apply the template is completed. This report is generated on both successful and unsuccessful application of the template on the device. You will see a link to this report in the **Notifications > Tasks** window.

The **Template Apply Report** contains the following details:

- Template name
- Device model name
- Domain from which the template was applied
- Start and end time
- Status of the application of the template on the device
- Interface mapping information
- Variable values

There may be some configurations on the template that are not applied to the device due to incompatible device model or version. The report also contains details about such configurations. The report also contains any errors that are encountered when the application of the template fails. Application of a template on a device may fail due to any of the following reasons:

- Model mapping does not exist for the device model that is used.
- Values used for variables and network object overrides do not conform to routing policy or interface configuration rules. For example, the same IPv4 address has been used for two IPv4 address interface variables.
- Device or template is locked due to some other task that is being executed, such as application or modification of the template.

Delete Device Template

Note that you cannot recover a template after deleting it. To backup template configurations, use the **Export** option explained in the [Import a Device Template, on page 139](#) section. To delete a device template, perform the procedure given below.

Procedure

-
- Step 1** Choose **Devices > Template Management**.
 - Step 2** Click the **More** (⋮) icon of the template that you want to delete.
 - Step 3** Click **Delete**.
 - Step 4** Click **Delete** again in the **Confirm Deletion** window.
-

Configure a Template for Threat Defense Devices Managed Using the Data Interface

To configure a template that you want to apply to a Threat Defense device that is managed using a data interface for Management Center connectivity, ensure that the connectivity parameters of the device match the template. This ensures that the Threat Defense device does not lose connectivity with the Management Center after application of the template. A template that you configure for Threat Defense devices managed using the data interface cannot be applied on devices that are not managed by the data interface.

The following is a list of connectivity parameters:

- Data interface used to manage the Threat Defense device. For example, **Ethernet1/1**.
- Name of the interface. For example, **outside**.
- IP address configured on the data interface. For example, DHCP or static IP.
- Route configured for the data interface. This can be a default or specific route defined on the data interface used for connectivity between the Threat Defense device and the Management Center.
- DDNS hostname configuration on the data interface.

If the connectivity parameters on the template do not match with the ones on the device, the template validation checks that are done to ensure that the template is successfully applied on the device will fail. The template is then not applied on the device. The template validation checks do not enforce an exact match for some parameters such as IP address or DDNS hostname. However, ensure that you configure such parameters to maintain connectivity between the Threat Defense device and the Management Center after deployment.

The following is a list of template validation checks done to ensure sanity of configurations that are required to manage the Threat Defense device using the data interface:

- You cannot apply a template in which manager access to the device is configured with the management interface to a device in which manager access to the device is configured with the data interface.

- You cannot apply a template in which manager access to the device is configured with the data interface to a device in which manager access to the device is configured with the management interface.
- You cannot apply a template in which manager access to the device is configured with the single WAN data interface to a device in which manager access to the device is configured with the dual WAN data interface.
- If any of the connectivity parameters do not match, you cannot apply a template in which manager access to the device is configured with the data interface to a device in which manager access to the device is configured with the data interface.

Perform the procedure given below to configure the template to manage Threat Defense devices through the data interface.

Procedure

-
- Step 1** Choose **Devices > Template Management**.
- Step 2** Click the **Edit** (✎) icon of the template that you want to configure to manage Threat Defense devices through the data interface.
- Step 3** Click the **Template Settings** tab.
- Step 4** In the **General** tile, toggle the **Manage device by Data Interface** button.
- Step 5** You will see a popup asking you to pick a data interface for manager access. Click **OK**.
- Step 6** Click the **Interfaces** tab.
- Step 7** Click the **Edit** icon of the data interface that you want to use for manager access. The first data interface – Ethernet1/1 (outside interface), is the data interface that is most commonly used for manager access.
- Step 8** In the **Edit Physical Interface** window, click the **Manager Access** tab.
- Step 9** Check the **Enable management access** checkbox.
- Step 10** Click **OK**. You will see that the interface that you selected for manager access has been marked with **Manager Access**.
- Step 11** Click the **DHCP** tab.
- Step 12** Click the **DDNS Update Methods** tab.
- Step 13** Click **+Add** to add a DDNS update method.
- Step 14** In the **Add DDNS Update Method** window, enter a **Method Name** and choose **FMC only**.
- Step 15** Set the **Update Interval** as per your requirement.
- Step 16** Click **OK**. You will see the method that you created in the **DDNS Update Methods** table.
- Step 17** Click the **DDNS Interface Settings** tab.
- Step 18** Click **+Add** to add dynamic DNS configuration.
- Step 19** In the **Add Dynamic DNS** configuration window, choose values for the following fields:
- **Interface** – Choose the interface enabled for manager access
 - **Method Name** – Choose the method that you created.
 - **Host Name** – Choose a variable for the hostname.

Do not edit the rest of the fields in this window.

- Step 20** Click **OK**. The **DDNS Interface Settings** table is populated with the entry that you created.
- Step 21** To configure the model mapping to ensure that the data interface set for manager access in the template matches the data interface selected for manager access on the device, click the **Template Settings** tab and click **Model Mapping**.
- Step 22** Click **Add Model Mapping**.
- Step 23** Choose the **Device Model** from the drop-down list.
- Step 24** Map the data interface that is set for manager access in the template to the appropriate data interface on the device by choosing the interface from the **Model Interface** drop-down list.
- Step 25** Click **Save**. The interface mappings are listed along with the device model and mapping status on the **Model Mapping** window. You can now apply the template on a device that is managed using the data interface.
-

Device Template Operations on Threat Defense HA Devices

You can apply device templates on Threat Defense HA devices after device registration. Failover configurations are not supported in device templates. Any failover configurations and monitored interfaces that are already part of the target HA device pair configurations are not modified. You cannot map any template interfaces to failover interfaces.

You can generate a device template from a HA device pair. Template operations such as application of template on device, template generation, import, and export of template, can be performed only on primary or active HA devices. You cannot perform these operations on secondary or standby devices.

Audit Logs

Logs related to application of the device template, configuration updates, device template creation, and deletion, are logged under audit logs. The device template audit logs are added to the log both at the start and at the end of the task to apply the template on the device.

An audit diff file is also generated that enables you to view configuration changes that have been done during application of the template on the device. Perform the procedure given below to view the diff file.

Procedure

- Step 1** Choose **System > Monitoring > Audit**.
- Step 2** The device template logs are logged under the subsystem **Devices > Template Management**. Click the **diff** icon to open a new window that displays the configuration changes that have been done during the application of the template on the device.
-

Device Templates in Domains

Device templates can exist in any domain. If you are in the child domain, you have read-only access to the templates above you in the domain hierarchy. You can apply a template to a device from its domain or its

parent domains. You can generate a template from a device and apply that template to a device in any domain in the domain hierarchy.

A domain hierarchy sample is given below along with a table displaying the supported device template application and generation scenarios.

Consider the following scenario:

- Domain A and B are child domains of the Global domain.
- Domain A1 is the child domain of Domain A.

Template Domain	Device Domain	Device Template Application/Generation Supported
Global	A1	Yes
Global	B	Yes
A	A1	Yes
A	B	No
B	A1	No
B	B	Yes
A1	A1	Yes
A1	B	No

Domains and VPN Connections

- You can define a template in a global or child/leaf domain. However, you can define a VPN topology only in a leaf domain.
- You can configure VPN connections in a template for all domains. During template application, VPN connections are applied to the device only if the device is in the same domain as the VPN topology.

A domain hierarchy sample is given below along with a table displaying the supported device template application and generation scenarios.

Consider the following scenario:

- Domain A and B are child domains of the Global domain.
- Domain A1 is the child domain of Domain A.
- VPN A is part of Domain A1.
- VPN B is part of Domain B.

Template Domain	VPN Topology in the Template	Device Domain	Device Template Application/Generation Supported
Global	VPN A VPN B	A1	No
Global	VPN B	B	Yes
A	VPN A	A1	Yes
B	VPN B	A1	No
B	VPN B	B	Yes
A1	VPN A	A1	Yes

Troubleshooting Device Templates

Initial Troubleshooting

For initial troubleshooting, we recommend looking at the information in the Template Apply Report and notifications that come up on the Management Center UI when you run into an error. The Management Center log files also contain detailed debugging and troubleshooting info.

Follow the procedure given below for initial troubleshooting.

1. Check the errors mentioned in the **Template Apply Report**. For more information, see [Generating a Template Apply Report](#).
2. Review variable values and check for overlaps and incompatibilities.
3. Check model mappings to ensure if the correct model mappings exist. Delete or add mappings accordingly.
4. See the Management Center audit logs to find any other issues and resolve them.

Consider the following error scenario. In a device template, the inside interface is configured with a static IPv4 variable - `$insideIPv4`.

The BGP IPv4 address is configured with an IPv4 BGP neighbor.

An overlapping IPv4 address is configured for the BGP neighbor and an interface.

Due to the issues mentioned above, the application of the device template fails and an error is displayed.

To troubleshoot this error, identify the error from the notification displayed on the UI.

```
IP Address 192.168.10.1 same as ip address of interface - 'inside'(Ethernet1/1)
```

Check the **Template Apply Report** for more information.

Enter correct values for the variables and apply the template again to ensure successful application of the template on the device.

Troubleshoot Device Registration

- Issue: Admin Password is incorrect or not provided during registration

Scenario: If the admin password is not set on the device and if you have not provided the admin password during registration, the Threat Defense device provisioning will fail. In such a scenario, a *Provision Error* along with an **Enter Password** link is displayed.

Workaround: Click **Enter Password** to enter a new password and click **Save**. Click **Confirm and Proceed** to trigger the onboarding again.

- If the admin password is already set on the device and you provide another admin password during registration, device provisioning will fail.
- Issue: Device registration in Management Center fails

Workaround: Follow existing device registration troubleshooting steps. For more information, see [Configure, Verify, and Troubleshoot Firepower Device Registration](#).

- Issue: Bulk Registration Request Fails in Management Center

Scenario: The bulk registration request can fail due to a few scenarios:

- You do not have the required permissions to perform template-related operations
- Template is not visible from the request domain
- Invalid CSV file provided

Workaround: You can see logs for these errors in the VMS Shared and USM Shared log files. Fix the errors and initiate registration again.

- Issue: Device provisioning fails in CDO due to some generic errors, such as communication with the device fails

Workaround: Click Retry in the Provision Error to trigger the onboarding in CDO again. You can also see the CDO workflows for more information on the error and troubleshooting information.

Troubleshoot Cisco Security Cloud Integration

Issue: Cisco Security cloud integration not successful

Workaround: Follow Cisco Security Cloud integration troubleshooting steps. For more information, see [Cisco Security Cloud Integration](#).

Troubleshoot Device Template Configuration Issues

Issue: Device template misconfigurations causing deployment failures after registration

Workaround: Follow the steps given below for initial troubleshooting.

1. Check the errors mentioned in the Template Apply Report.
2. Review variable values and check for overlaps and incompatibilities.
3. Check model mappings to ensure if the correct model mappings exist. Delete or add mappings accordingly.
4. See the Management Center audit logs to find any other issues and resolve them.

Troubleshoot CDO Issues

- Issue: Device with serial number already claimed

Workaround: Verify serial number and reinitiate onboarding.

- Issue: CDO fails to claim devices

Workaround: Select the device in the CDO Inventory window for more details on the error. You can see logs related to device claim issues in the VMS Shared and USM Shared log files. Click **Retry** to initiate registration again.

- Issue: Communication failures between Management Center and CDO

Scenario: Communication failures between Management Center and CDO can cause failures during the Zero-Touch Provisioning (ZTP) device registration request.

Workaround: Refresh the ZTP device status, retry ZTP registration, and delete the ZTP device. You can see logs regarding communication failure between the Management Center and CDO in the Auth Daemon logs. For operational failures related to ZTP, you can see the logs in the VMS Shared and USM Shared log files.

History for Device Management using Device Templates

Feature	Minimum Management Center	Minimum Threat Defense	Details
Device management using device templates	7.6.0	7.4.1	<p>Device templates enable deployment of multiple branch devices with pre-provisioned initial device configurations. You can use device templates to perform bulk zero-touch provisioning of multiple devices, apply day 2 configuration changes to multiple devices with different interface configurations, and clone configuration parameters from existing devices.</p> <p>New/modified screens:</p> <ul style="list-style-type: none"> • Devices > Device Management > Add > Device (Wizard) • Devices > Template Management > Add Device Template • Devices > Template Management > Add Model Mapping • Devices > Template Management > Edit a template > Template Settings • Integration > Cisco Security Cloud

CHAPTER 3

Users

Managed devices include a default **admin** account for CLI access. This chapter discusses how to create custom user accounts.

- [About Users, on page 173](#)
- [Requirements and Prerequisites for User Accounts for Devices, on page 174](#)
- [Guidelines and Limitations for User Accounts for Devices, on page 175](#)
- [Add an Internal User at the CLI, on page 175](#)
- [Configure External Authentication for the Threat Defense, on page 177](#)
- [Troubleshooting LDAP Authentication Connections, on page 189](#)
- [History for Users, on page 191](#)

About Users

You can add custom user accounts on managed devices, either as internal users or as external users on a LDAP or RADIUS server. Each managed device maintains separate user accounts. For example, when you add a user to the management center, that user only has access to the management center; you cannot then use that username to log directly into a managed device. You must separately add a user on the managed device.

Internal and External Users

Managed devices support two types of users:

- Internal user—The device checks a local database for user authentication.
- External user—If the user is not present in the local database, the system queries an external LDAP or RADIUS authentication server.

CLI Access

Firepower devices include a Firepower CLI that runs on top of Linux. You can create internal users on devices using the CLI. You can establish external users on threat defense devices using the management center.

Caution Users with CLI Config level access can access the Linux shell using the **expert** command, and obtain `sudoers` privileges in the Linux shell, which can present a security risk. For system security reasons, we strongly recommend:

- Only use the Linux shell under TAC supervision or when explicitly instructed by Firepower user documentation.
- Make sure that you restrict the list of users with CLI access appropriately.
- When granting CLI access privileges, restrict the list of users with Config level access.
- Do not add users directly in the Linux shell; only use the procedures in this chapter.
- Do not access Firepower devices using CLI expert mode unless directed by Cisco TAC or by explicit instructions in the Firepower user documentation.

CLI User Roles

On managed devices, user access to commands in the CLI depends on the role you assign.

None

The user cannot log into the device on the command line.

Config

The user can access all commands, including configuration commands. Exercise caution in assigning this level of access to users.

Basic

The user can access non-configuration commands only. Only internal users and threat defense external RADIUS users support the Basic role.

Requirements and Prerequisites for User Accounts for Devices

Model Support

- Threat Defense—Internal and external users

Supported Domains

Any

User Roles

Configure external users—Admin FMC user

Configure internal users—Config CLI user

Guidelines and Limitations for User Accounts for Devices

Username

- You cannot add the same username for both internal and external users. If the external server uses a duplicate username, the deployment to the device fails.
- The username must be Linux-valid:
 - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
 - All lowercase
 - Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Defaults

All devices include an **admin** user as a local user account; you cannot delete the **admin** user. The default initial password is **Admin123**; the system forces you to change this during the initialization process. See the getting started guide for your model for more information about system initialization.

Number of User Accounts

You can create a maximum of 43 user accounts for the Firepower 1000.

Add an Internal User at the CLI

Use the CLI to create internal users on the threat defense.

Procedure

Step 1 Log into the device CLI using an account with Config privileges.

The **admin** user account has the required privileges, but any account with Config privileges will work. You can use an SSH session or the Console port.

For certain threat defense models, the Console port puts you into the FXOS CLI. Use the **connect ftd** command to get to the threat defense CLI.

Step 2 Create the user account.

configure user add *username* {**basic** | **config**}

- *username*—Sets the username. The username must be Linux-valid:
 - Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
 - All lowercase

- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)
- **basic**—Gives the user basic access. This role does not allow the user to enter configuration commands.
- **config**—Gives the user configuration access. This role gives the user full administrator rights to all commands.

Example:

The following example adds a user account named johnrichton with Config access rights. The password is not shown as you type it.

```
> configure user add johnrichton config
Enter new password for user johnrichton: newpassword
Confirm new password for user johnrichton: newpassword
> show user
Login          UID   Auth Access  Enabled Reset   Exp Warn  Str Lock Max
admin          1000 Local Config Enabled No   Never N/A  Dis No  N/A
johnrichton    1001 Local Config Enabled No   Never N/A  Dis No   5
```

Note Tell users they can change their own passwords using the **configure password** command.

Step 3 (Optional) Adjust the characteristics of the account to meet your security requirements.

You can use the following commands to change the default account behavior.

- **configure user aging** *username max_days warn_days*
Sets an expiration date for the user's password. Specify the maximum number of days for the password to be valid followed by the number of days before expiration the user will be warned about the upcoming expiration. Both values are 1 to 9999, but the warning days must be less than the maximum days. When you create the account, there is no expiration date for the password.
- **configure user forcereset** *username*
Forces the user to change the password on the next login.
- **configure user maxfailedlogins** *username number*
Sets the maximum number of consecutive failed logins you will allow before locking the account, from 1 to 9999. Use the **configure user unlock** command to unlock accounts. The default for new accounts is 5 consecutive failed logins.
- **configure user minpasswdlen** *username number*
Sets a minimum password length, which can be from 1 to 127.
- **configure user strengthcheck** *username {enable | disable}*
Enables or disables password strength checking, which requires a user to meet specific password criteria when changing their password. When a user's password expires or if the **configure user forcereset** command is used, this requirement is automatically enabled the next time the user logs in.

Step 4 Manage user accounts as necessary.

Users can get locked out of their accounts, or you might need to remove accounts or fix other issues. Use the following commands to manage the user accounts on the system.

- **configure user access** *username* {**basic** | **config**}
Changes the privileges for a user account.
- **configure user delete** *username*
Deletes the specified account.
- **configure user disable** *username*
Disables the specified account without deleting it. The user cannot log in until you enable the account.
- **configure user enable** *username*
Enables the specified account.
- **configure user password** *username*
Changes the password for the specified user. Users should normally change their own password using the **configure password** command.
- **configure user unlock** *username*
Unlocks a user account that was locked due to exceeding the maximum number of consecutive failed login attempts.

Configure External Authentication for the Threat Defense

To enable external authentication for threat defense devices, you need to add one or more external authentication objects.

About External Authentication for the Threat Defense

When you enable external authentication for threat defense users, the threat defense verifies the user credentials with an LDAP or RADIUS server as specified in an *external authentication object*.

External authentication objects can be used by the management center and threat defense devices. You can share the same object between the different appliance/device types or create separate objects. For the threat defense, you can only activate one external authentication object in the platform settings that you deploy to the devices.

Note The timeout range is different for the threat defense and the management center, so if you share an object, be sure not to exceed the threat defense's smaller timeout range (1-30 seconds for LDAP, and 1-300 seconds for RADIUS). If you set the timeout to a higher value, the threat defense external authentication configuration will not work.

Only a subset of fields in the external authentication object are used for threat defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for other device types, those fields will be used.

LDAP users always have Config privileges. RADIUS users can be defined as either Config or Basic users.

You can either define users on the RADIUS server (with the Service-Type attribute), or you can pre-define the user list in the external authentication object. For LDAP, you can specify a filter to match CLI users on the LDAP server.

Note Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you:

- Restrict the list of users with Linux shell access.
 - Do not create Linux shell users.
-

About LDAP

The Lightweight Directory Access Protocol (LDAP) allows you to set up a directory on your network that organizes objects, such as user credentials, in a centralized location. Multiple applications can then access those credentials and the information used to describe them. If you ever need to change a user's credentials, you can change them in one place.

Microsoft has announced that Active Directory servers will start enforcing LDAP binding and LDAP signing in 2020. Microsoft is making these a requirement because when using default settings, an elevation of privilege vulnerability exists in Microsoft Windows that could allow a man-in-the-middle attacker to successfully forward an authentication request to a Windows LDAP server. For more information, see [2020 LDAP channel binding and LDAP signing requirement for Windows](#) on the Microsoft support site.

If you have not done so already, we recommend you start using TLS/SSL encryption to authenticate with an Active Directory server.

About RADIUS

Remote Authentication Dial In User Service (RADIUS) is an authentication protocol used to authenticate, authorize, and account for user access to network resources. You can create an authentication object for any RADIUS server that conforms to [RFC 2865](#).

Secure Firewall devices support the use of SecurID tokens. When you configure authentication by a server using SecurID, users authenticated against that server append the SecurID token to the end of their SecurID PIN and use that as their password when they log in. You do not need to configure anything extra on the Secure Firewall device to support SecurID.

Add an LDAP External Authentication Object for Threat Defense

Add an LDAP server to support external users for threat defense management.

In a multidomain deployment, external authentication objects are only available in the domain in which they are created.

Sharing External Authentication Objects

External LDAP objects can be used by the management center and threat defense devices. You can share the same object between the management center and devices or create separate objects. Be sure that both the threat defense and the management center can reach the LDAP server, even if you are not sharing the object. The management center is essential to retrieving the user list and downloading it to the device.

Note For LDAP, the timeout range is different for the threat defense and the management center, so if you share an object, be sure not to exceed the threat defense's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the deployment to the threat defense will fail.

Threat Defense Supported Fields

Only a subset of fields in the LDAP object are used for threat defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for the management center, those fields will be used. This procedure only covers the supported fields for the threat defense. For other fields, see [Add an LDAP External Authentication Object for the Management Center](#).

Username

Username must be Linux-valid usernames and be lower-case only, using alphanumeric characters plus period (.) or hyphen (-). Other special characters such as at sign (@) and slash (/) are not supported. You cannot add the **admin** user for external authentication. You can only add external users (as part of the External Authentication object) in the management center; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the management center.

If you previously configured the same username for an internal user using the **configure user add** command, the threat defense first checks the password against the internal user, and if that fails, it checks the LDAP server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported.

Privilege Level

LDAP users always have Config privileges.

Before you begin

You must specify DNS server(s) for domain name lookup on your device. Even if you specify an IP address and not a hostname for the LDAP server on this procedure, the LDAP server may return a URI for authentication that can include a hostname. A DNS lookup is required to resolve the hostname. See [Modify Threat Defense Management Interfaces at the CLI, on page 75](#) to add DNS servers.

Procedure

- Step 1** Choose **System** (⚙) > **Users**.
- Step 2** Click the **External Authentication** tab.
- Step 3** Click (+) **Add External Authentication Object**.
- Step 4** Set the **Authentication Method** to **LDAP**.
- Step 5** Enter a **Name** and optional **Description**.
- Step 6** Choose a **Server Type** from the drop-down list.
- Step 7** For the **Primary Server**, enter a **Host Name/IP Address**.

If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.
- Step 8** (Optional) Change the **Port** from the default.

Step 9 (Optional) Enter the **Backup Server** parameters.

Step 10 Enter **LDAP-Specific Parameters**.

- a) Enter the **Base DN** for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs**, and choose the appropriate base distinguished name from the drop-down list.
- b) (Optional) Enter the **Base Filter**. For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.
- c) Enter a **User Name** for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at your example company has a `uid` value of `NetworkAdmin`, you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.
- d) Enter the user password in the **Password** and the **Confirm Password** fields.
- e) (Optional) Click **Show Advanced Options** to configure the following advanced options.

- **Encryption**—Click **None**, **TLS**, or **SSL**.

If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS**, the port resets to the default value of 389. If you choose **SSL** encryption, the port resets to 636.

- **SSL Certificate Upload Path**—For **SSL** or **TLS** encryption, you must choose a certificate by clicking **Choose File**.

If you previously uploaded a certificate and want to replace it, upload the new certificate and redeploy the configuration to your devices to copy over the new certificate.

Note TLS encryption requires a certificate on all platforms. For **SSL**, the threat defense also requires a certificate. For other platforms, **SSL** does not require a certificate. However, we recommend that you *always* upload a certificate for **SSL** to prevent man-in-the-middle attacks.

- (Not Used) **User Name Template**—Not used by the threat defense.
- **Timeout (Seconds)**—Enter the number of seconds before rolling over to the backup connection, between 1 and 30. The default is 30.

Note The timeout range is different for the threat defense and the management center, so if you share an object, be sure not to exceed the threat defense's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the threat defense LDAP configuration will not work.

Step 11 Configure **Attribute Mapping** to retrieve users based on an attribute.

- Enter a **UI Access Attribute**. **Note:** This field is not used for device CLI access; however, it is a required field, so you need to enter a value. You can just enter the same value that you enter for the **CLI Access Attribute**.
- Set the **CLI Access Attribute** if you want to use a CLI access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` CLI access attribute to retrieve CLI access users by typing `sAMAccountName`.

Note Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you restrict the list of users with CLI or Linux shell access.

Note Deploying an external authentication object that allows a large number of users with CLI access may cause deployments to time out and fail while waiting for the users to be created.

Step 12 Set the **CLI Access Filter**.

Choose one of the following methods:

- To use the same filter you specified when configuring authentication settings, check the check box of **Same as Base Filter**.
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.

The usernames must be Linux-valid:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Note If you previously configured the same username for an internal user, the threat defense first checks the password against the internal user, and if that fails, it checks the LDAP server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported.

Step 13 Click **Save**.

Step 14 Enable use of this server. See [External Authentication, on page 870](#).

Step 15 If you later add or delete users on the LDAP server, you must refresh the user list and redeploy the Platform Settings on managed devices.

- a) Click **Refresh** (🔄) next to each LDAP server.

If the user list changed, you will see a message advising you to deploy configuration changes for your device.

- b) Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

Examples

Basic Example

The following figures illustrate a basic configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 389 for access.

▸ Group Controlled Access Roles (Optional)

CLI Access Filter

CLI Access Filter Same as Base Filter ex. (cn=*smith), (cn=smith), (&(cn=*smith)(!(cn=borith)(cn=csmith)))

(Mandatory for FTD devices)

Additional Test Parameters

User Name

Password

*Required Field

A **CLI Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into the threat defense.

Note that because no base filter is applied to this server, the threat defense checks attributes for all objects in the directory indicated by the base distinguished name. Connections to the server time out after the default time period (or the timeout period set on the LDAP server).

Advanced Example

This example illustrates an advanced configuration of an LDAP login authentication object for a Microsoft Active Directory Server. The LDAP server in this example has an IP address of 10.11.3.4. The connection uses port 636 for access.

External Authentication Object

Authentication Method

CAC Use for CAC authentication and authorization

Name *

Description

Server Type

Primary Server

Host Name/IP Address * ex. IP or hostname

Port *

This example shows a connection using a base distinguished name of `OU=security,DC=it,DC=example,DC=com` for the security organization in the information technology domain of the Example company. However, note that this server has a base filter of `(cn=*smith)`. The filter restricts the users retrieved from the server to those with a common name ending in `smith`.

LDAP-Specific Parameters

Base DN * ex. dc=sourcefire,dc=com

Base Filter ex. (&(cn=smith), (&(cn=smith), (&(cn=smith))((cn=smith)(cn=csmith*)))

User Name * ex. cn=smith,dc=sourcefire,dc=com

Password *

Confirm Password *

▼ Show Advanced Options

Encryption SSL TLS None

SSL Certificate Upload Path certificate.pem ex. PEM Format (base64 encoded version of DER)

User Name Template ex. cn=%s,dc=sourcefire,dc=com

Timeout (Seconds)

Attribute Mapping

UI Access Attribute *

CLI Access Attribute *

The connection to the server is encrypted using SSL and a certificate named `certificate.pem` is used for the connection. In addition, connections to the server time out after 60 seconds because of the **Timeout (Seconds)** setting.

Because this server is a Microsoft Active Directory server, it uses the `sAMAccountName` attribute to store user names rather than the `uid` attribute.

The **CLI Access Attribute** of `sAMAccountName` causes each `sAMAccountName` attribute to be checked for all objects in the directory for matches when a user logs into the threat defense.

In the following example, the CLI access filter is set to be the same as the base filter.

CLI Access Filter

CLI Access Filter Same as Base Filter

(Mandatory for Firewall Threat Defense devices)

Additional Test Parameters

User Name

Password

*Required Field

Add a RADIUS External Authentication Object for Threat Defense

Add a RADIUS server to support external users for the threat defense.

Sharing External Authentication Objects

You can share the same object between the management center and devices or create separate objects. Note that the threat defense supports defining users on the RADIUS server, while the management center requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the threat defense, but if you want to define users on the RADIUS server, you must create separate objects for the threat defense and the management center.

Note The timeout range is different for the threat defense and the management center, so if you share an object, be sure not to exceed the threat defense's smaller timeout range (1-300 seconds). If you set the timeout to a higher value, the threat defense RADIUS configuration will not work.

threat defense Supported Fields

Only a subset of fields in the RADIUS object are used for threat defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for the management center, those fields will be used. This procedure only covers the supported fields for the threat defense. For other fields, see [Add a RADIUS External Authentication Object for Management Center in the Cisco Secure Firewall Management Center Administration Guide](#).

Username

You cannot add the **admin** user for external authentication. You can only add external users (as part of the External Authentication object) in the management center; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the management center.

If you previously configured the same username for an internal user using the **configure user add** command, the threat defense first checks the password against the internal user, and if that fails, it checks the RADIUS server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

Procedure

Step 1 Define users on the RADIUS server using the Service-Type attribute.

The following are supported values for the Service-Type attribute:

- Administrator (6)—Provides Config access authorization to the CLI. These users can use all commands in the CLI.
- NAS Prompt (7) or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as **show** commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a sign (@) or slash (/)

Alternatively, you can predefine users in the external authentication object (see, [Step 12, on page 186](#)). To use the same RADIUS server for the threat defense and management center while using the Service-Type attribute method for the threat defense, create two external authentication objects that identify the same RADIUS server: one object includes the predefined **CLI Access Filter** users (for use with the management center), and the other object leaves the **CLI Access Filter** empty (for use with threat defenses).

Step 2 In the management center, choose **System** (⚙) > **Users**.

Step 3 Click **External Authentication**.

Step 4 Click (+) **Add External Authentication Object**.

Step 5 Set the **Authentication Method** to **RADIUS**.

Step 6 Enter a **Name** and optional **Description**.

Step 7 For the **Primary Server**, enter a **Host Name/IP Address**.

Only IPv4 is supported.

Note If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field.

Step 8 (Optional) Change the **Port** from the default.

Step 9 Enter the **RADIUS Secret Key**.

Step 10 (Optional) Enter the **Backup Server** parameters.

Step 11 (Optional) Enter **RADIUS-Specific Parameters**.

a) Enter the **Timeout (Seconds)** in seconds before retrying the primary server, between 1 and 300. The default is 30.

Note The timeout range is different for the threat defense and the management center, so if you share an object, be sure not to exceed the threat defense's smaller timeout range (1-300 seconds). If you set the timeout to a higher value, the threat defense RADIUS configuration will not work.

b) Enter the **Retries** before rolling over to the backup server. The default is 3.

Step 12 (Optional) Instead of using RADIUS-defined users (see, [Step 1, on page 185](#)), in the **CLI Access Filter** area **Administrator CLI Access User List** field, enter the user names that should have CLI access, separated by commas. For example, enter **jchrichton, aerynsun, rygel**.

You may want to use the **CLI Access Filter** method for threat defense so you can use the same external authentication object with threat defense and other platform types.

Note If you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Note Users with CLI access can gain Linux shell access with the **expert** command. Linux shell users can obtain root privileges, which can present a security risk. Make sure that you restrict the list of users with CLI or Linux shell access.

Note Deploying an external authentication object that allows a large number of users with CLI access may cause deployments to time out and fail while waiting for the users to be created.

Step 13 (Optional) Click **Test** to test management center connectivity to the RADIUS server.

This function can only test management center connectivity to the RADIUS server; there is no test function for managed device connectivity to the RADIUS server.

Step 14 (Optional) You can also enter **Additional Test Parameters** to test user credentials for a user who should be able to authenticate: enter a **User Name** and **Password**, and then click **Test**.

Tip If you mistype the name or password of the test user, the test fails even if the server configuration is correct. To verify that the server configuration is correct, click **Test** without entering user information in the **Additional Test Parameters** field first. If that succeeds, supply a user name and password to test with the specific user.

Example:

To test if you can retrieve the `JSmith` user credentials at the Example company, enter `JSmith` and the correct password.

Step 15

Click **Save**.

Step 16

Enable use of this server. See [External Authentication, on page 870](#)

Examples**Simple User Role Assignments**

The following figure illustrates a sample RADIUS login authentication object for a server running Cisco Identity Services Engine (ISE) with an IP address of 10.10.10.98 on port 1812. No backup server is defined.

External Authentication Object

Authentication Method: RADIUS

Name: ISE_RADIUS

Description:

Primary Server

Host Name/IP Address: 10.10.10.98 ex. IP or hostname

Port: 1812

RADIUS Secret Key:

The following example shows RADIUS-specific parameters, including the timeout (30 seconds) and number of failed retries before the system attempts to contact the backup server, if any.

This example illustrates important aspects of RADIUS user role configuration:

Users `ewharton` and `gsand` are granted web interface Administrative access.

The user `cbronte` is granted web interface Maintenance User access.

The user `jausten` is granted web interface Security Analyst access.

The user `ewharton` can log into the device using a CLI account.

RADIUS-Specific Parameters

Timeout (Seconds)	<input type="text" value="30"/>	
Retries	<input type="text" value="3"/>	
Access Admin	<input type="text"/>	
Administrator	<input type="text" value="ewharton.gsand"/>	
Discovery Admin	<input type="text"/>	
External Database User	<input type="text"/>	
Intrusion Admin	<input type="text"/>	
Maintenance User	<input type="text" value="ehronte"/>	
Network Admin	<input type="text"/>	
Security Analyst	<input type="text" value="jswalton"/>	
Security Analyst (Read Only)	<input type="text"/>	
Security Approver	<input type="text"/>	
Threat Intelligence Director (TID) User	<input type="text"/>	
Default User Role	<div style="border: 1px solid gray; padding: 2px;"> Discovery Admin External Database User Intrusion Admin Maintenance User </div>	To specify the default user role if user is not found in any group

CLI Access Filter

(For FMC (all versions) and FTD (6.2.3 and 6.3), define users for CLI access. For FTD 6.4 and later, we recommend defining users on the RADIUS server. Click [here](#) for more information)

Administrator CLI Access User List	<input type="text" value="ewharton"/>	<small>ex. user1, user2, user3 (lowercase letters only)</small>
------------------------------------	---------------------------------------	---

The following graphic depicts the role configuration for the example:

Roles for Users Matching an Attribute-Value Pair

You can use an attribute-value pair to identify users who should receive a particular user role. If the attribute you use is a custom attribute, you must define the custom attribute.

The following figure illustrates the role configuration and custom attribute definition in a sample RADIUS login authentication object for the same ISE server as in the previous example.

In this example, however, the `MS-RAS-Version` custom attribute is returned for one or more of the users because a Microsoft remote access server is in use. Note the `MS-RAS-Version` custom attribute is a string. In this example, all users logging in to RADIUS through a Microsoft v. 5.00 remote access server should receive the Security Analyst (Read Only) role, so you enter the attribute-value pair of `MS-RAS-Version=MSRASV5.00` in the **Security Analyst (Read Only)** field.

The screenshot shows the configuration page for external authentication. It includes the following sections:

- Security Analyst (Read Only):** MS-RAS-Version=MSRASV5.00
- Security Approver:** (Empty text field)
- Threat Intelligence Director (TID) User:** (Empty text field)
- Default User Role:** A dropdown menu with options: External Database User, **Intrusion Admin** (selected), Maintenance User, and Network Admin. A note states: "To specify the default user role if user is not found in any group".
- CLI Access Filter:** (For FMC (all versions) and FTD (6.2.3 and 6.3), define users for CLI access. For FTD 6.4 and later, we recommend defining users on the RADIUS server. Click [here](#) for more information.)
 - Administrator CLI Access User List:** ewharton
 - Example: ex. user1, user2, user3 (lowercase letters only).
- Define Custom RADIUS Attributes:**

Attribute Name	Attribute ID	Attribute Type	
MS-Ras-Version	S	string	<input type="button" value="Add"/> <input type="button" value="Delete"/>

Enable External Authentication for Users on Threat Defense Devices

Enable External Authentication in the Threat Defense Platform Settings, and then deploy the settings to the managed devices. See [External Authentication, on page 870](#) for more information.

Troubleshooting LDAP Authentication Connections

If you create an LDAP authentication object and it either does not succeed in connecting to the server you select or does not retrieve the list of users you want, you can tune the settings in the object.

If the connection fails when you test it, try the following suggestions to troubleshoot your configuration:

- Use the messages displayed at the top of the web interface screen and in the test output to determine which areas of the object are causing the issue.
- Check that the user name and password you used for the object are valid:
 - Check that you have the rights to browse to the directory indicated in your base-distinguished name by connecting to the LDAP server using a third-party LDAP browser.
 - Check that the user name is unique to the directory information tree for the LDAP server.
 - If you see an LDAP bind error 49 in the test output, the user binding for the user failed. Try authenticating to the server through a third-party application to see if the binding fails through that connection as well.
- Check that you have correctly identified the server:
 - Check that the server IP address or host name is correct.
 - Check that you have TCP/IP access from your local appliance to the authentication server where you want to connect.

- Check that access to the server is not blocked by a firewall and that the port you have configured in the object is open.
- If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used for the server.
- Check that you have not used an IPv6 address for the server connection if you are authenticating CLI access.
- If you used server type defaults, check that you have the correct server type and click **Set Defaults** again to reset the default values.
- If you typed in your base-distinguished name, click **Fetch DNS** to retrieve all the available base distinguished names on the server, and select the name from the list.
- If you are using any filters, access attributes, or advanced settings, check that each is valid and typed correctly.
- If you are using any filters, access attributes, or advanced settings, try removing each setting and testing the object without it.
- If you are using a base filter or a CLI access filter, make sure that the filter is enclosed in parentheses and that you are using a valid comparison operator (maximum 450 characters, including the enclosing parentheses).
- To test a more restricted base filter, try setting it to the base distinguished name for the user to retrieve just that user.
- If you are using an encrypted connection:
 - Check that the name of the LDAP server in the certificate matches the host name that you use to connect.
 - Check that you have not used an IPv6 address with an encrypted server connection.
- If you are using a test user, make sure that the user name and password are typed correctly.
- If you are using a test user, remove the user credentials and test the object.
- Test the query that you are using by connecting to the LDAP server and using this syntax:

```
ldapsearch -x -b 'base_distinguished_name'
-h LDAPserver_ip_address -p port -v -D
'user_distinguished_name' -W 'base_filter'
```

For example, if you are trying to connect to the security domain on `myrtle.example.com` using the `domainadmin@myrtle.example.com` user and a base filter of `(cn=*)`, you could test the connection using this statement:

```
ldapsearch -x -b 'CN=security,DC=myrtle,DC=example,DC=com'
-h myrtle.example.com -p 389 -v -D
'domainadmin@myrtle.example.com' -W '(cn=*)'
```

If you can test your connection successfully but authentication does not work after you deploy a platform settings policy, check that authentication and the object you want to use are both enabled in the platform settings policy that is applied to the device.

If you connect successfully but want to adjust the list of users retrieved by your connection, you can add or change a base filter or CLI access filter or use a more restrictive or less restrictive base DN.

While authenticating a connection to Active Directory (AD) server, rarely the connection event log indicates blocked LDAP traffic although the connection to AD server is successful. This incorrect connection log occurs when the AD server sends a duplicate reset packet. The threat defense device identifies the second reset packet as part of a new connection request and logs the connection with Block action.

History for Users

Feature	Minimum Management Center	Minimum Threat Defense	Details
Support for the Service-Type attribute for threat defense users defined on the RADIUS server	6.4	Any	<p>For RADIUS authentication of threat defense CLI users, you used to have to pre-define the usernames in the RADIUS external authentication object and manually make sure that the list matched usernames defined on the RADIUS server. You can now define CLI users on the RADIUS server using the Service-Type attribute and also define both Basic and Config user roles. To use this method, be sure to leave the shell access filter blank in the external authentication object.</p> <p>New/Modified screens:</p> <p>System > Users > External Authentication (+) Add External Authentication Object > Shell Access Filter</p> <p>Supported platforms: threat defense</p>
External Authentication for threat defense SSH Access	6.2.3	Any	<p>You can now configure external authentication for SSH access to the threat defense using LDAP or RADIUS.</p> <p>New/Modified screens:</p> <p>Devices > Platform Settings > External Authentication</p> <p>Supported platforms: threat defense</p>

CHAPTER 4

Change Management

You can enable Change Management if your organization needs to implement more formal processes for configuration changes, including audit tracking and official approval before changes are deployed.

- [About Change Management, on page 193](#)
- [Requirements and Prerequisites for Change Management, on page 197](#)
- [Guidelines and Limitations for Change Management, on page 197](#)
- [Enabling or Disabling Change Management, on page 198](#)
- [Managing Tickets, on page 199](#)
- [History for Change Management, on page 204](#)

About Change Management

Some organizations need to implement a formal approach to deploying configuration changes. This might include more auditing, and an official approval process that must happen before configuration changes can be made to a device.

If your organization uses a more formal configuration change process, you can enable Change Management to enforce the process. With Change Management, administrators must open tickets before they can make configuration changes. Then, once the change is complete, they must submit the ticket for approval before they can deploy the proposed changes. This allows you to enforce your official approval process and ensure that the right employees make the final decisions.

When using Change Management, administrators can see their own changes within a ticket, but they cannot see changes anyone else has made within a ticket. Because a policy is locked once a user makes a change within a ticket, users should not be able to make interfering changes. However, users will not be able to make changes while another user has made a change that is pending approval.

Administrators can create multiple tickets so that a single ticket contains only logically-related policy changes. Tickets with a more limited scope are also easier to evaluate and approve quickly.

The following topics explain the Change Management Workflow and which policies and objects are subject to the ticketing and approval process.

How to Configure Devices in the Change Management Workflow

When you enable Change Management, users who configure devices need to change their approach slightly. Configuration specialists need to take the following approach when making configuration changes to supported policies and objects.

Procedure

Step 1 Create a ticket.

Step 2 Open the ticket.

Step 3 Make the configuration changes.

Note that the procedures explained in the online help and user guides assume that Change Management is not active, and omit any steps for creating, opening, or submitting tickets.

Step 4 Optionally, preview and validate the ticket to ensure the changes are complete and correct.

Step 5 Submit the ticket. At this point, the approver can either approve or reject the ticket.

- If the ticket is approved, deploy the changes.
 - If the ticket is rejected, address the issues, and resubmit the ticket.
-

Creating Separate Approver and Configuration Roles

Some system-defined roles have permissions to modify (create/open/discard) and review (approve/reject) tickets:

- To both modify and review tickets:
 - Admin
 - Network Admin
- To modify tickets only:
 - Access Admin
 - Intrusion Admin
- To review tickets only:
 - Security Approver

If you need more granular roles to separate these activities due to your organizational requirements, you can create separate roles to ensure that ticket approval is assigned only to those users who have the organizational authority to approve changes. To create new user roles, go to **System > Users**, and select the **User Roles** tab..

Following are the permissions, in the **System > Change Management** folder, relevant to ticket usage and approval. Note that these permissions are available only after you enable Change Management.

- **Modify Tickets**—To create tickets (for yourself), to use tickets for configuration changes, and to discard tickets.
- **Review Tickets**—To approve or reject tickets.
- **Both Modify and Review Tickets**—To create tickets for yourself and others, use tickets, and approve/reject tickets. You can also take over tickets assigned to other users.

The approach you take depends on your precise requirements. For example:

- If your approvers should also be allowed to make configuration changes, you can simply assign them the system-defined roles, such as Administrator. Then, create custom configuration-only roles that include the same permissions but not the Review Tickets permission.
- If you need complete separation between approvers and those who make configuration changes, create custom roles for both, limiting the roles to either the Modify Tickets or the Review Tickets permission plus all other needed permissions for viewing or changing the supported policies and objects.

Policies and Objects that Support Change Management

If a policy or object supports the change management workflow, then creating, editing, or deleting the policy or object, including assigning a policy to a device, must be done in an open ticket.

Any action, policy, or object that does not support the change management workflow can be created, edited, or deleted, and so forth, without an open ticket. Even if a ticket is open, the changes made to unsupported policies are not included in the ticketed changes and are available for deployment immediately.

The following lists include the policies and objects that are supported. Anything not listed is unsupported.

Supported Policies

- Access Control, including rules, references to other policies, and inheritance settings.
- Device Configuration policies:
 - Interfaces
 - Inline Sets
 - DHCP
 - VTEP
 - All Routing
- Decryption policy
- DNS policy
- FlexConfig
- Intrusion policy and Network Analysis Policy (NAP), Snort 3 only.
- Malware and File policy
- Network Address Translation (NAT)
- Network Discovery policy

- Platform Settings
- Prefilter
- QoS
- Umbrella SASE Topology
- VPN policies, both site-to-site and remote access
- Zero Trust Access

Supported Objects

- AAA Server
- Access List
- Address Pools
- AS Path
- Cipher suit lists
- Community List
- Distinguished Name objects
- DHCP IPv6 Pools
- DNS Server Group
- FlexConfig objects
- Group policy
- Interface
- Key Chain
- Network
- PKI certificates, all objects
- Policy List
- Port
- Prefix List
- Route Map
- Sinkhole
- SLA Monitor
- Time Range
- Time Zone
- Tunnel Zone

- URL
- Variable Set
- VLAN Tag
- VPN objects (IKEv1, IKEv2 IPSec and policy, PKI enrollment, certificate map)

Requirements and Prerequisites for Change Management

Model Support

Management Center

Supported Domains

Any

User Roles

- To enable or disable Change Management: Admin.
- To both modify and review tickets:
 - Admin
 - Network Admin
- To modify tickets only:
 - Access Admin
 - Intrusion Admin
- To review tickets only:
 - Security Approver

Guidelines and Limitations for Change Management

- When operating in change management mode, users can make changes to supported policies, but they cannot save the changes. For example, you could go through the dialog box to create a new Platform Settings policy without an open ticket, but when you click OK to actually create the policy, you will get an error and the policy will not be created.
- The following activities require that all tickets be in a terminal state, that is, approved or discarded: backup/restore, moving a device between domains, upgrading Management Center.
- Deleting a device from the inventory requires that all tickets involving that device be approved or discarded.

- Some processes, such as deployment and backup/restore, prevent you from changing the Change Management mode. Wait until the process completes to change the mode.
- Your ability to create objects while configuring a feature is constrained based on whether the feature and objects are all supported by change management. For example, importing a configuration is not supported by change management. Therefore, you cannot create security zone objects, which are supported, during the import. On the other hand, you can create new objects while configuring access control rules, because both are supported.
- When using cloud-delivered Firewall Management Center, a user defined in Cisco Defense Orchestrator is available to be assigned tickets only after the user cross-launches cdFMC at least once. Until the first cross-launch, the user does not exist in cdFMC.

Enabling or Disabling Change Management

The default is that the Change Management workflow is disabled. Users do not need to open tickets and get approval when making configuration changes. If you want to enforce the Change Management workflow, you must enable it globally for the system.

Before you begin

There are several system processes that prevent you from enabling/disabling change management. If any of the following are in process, you need to wait for them to complete before changing these settings: backup/restore; import/export; domain movement; upgrade; Flexconfig migration; device registration; high-availability registration, creation, break, or switch; cluster create, registration, break, edit, add or remove nodes; EPM break out or join.

An access control policy cannot be locked when you change these settings. If a policy is locked, you must wait for the lock to be released before enabling/disabling this feature.

Procedure

Step 1 Choose **System** (⚙️) > **Configuration**.

Step 2 Click **Change Management**.

Step 3 Select **Enable Change Management**.

To disable the feature, deselect the option. All tickets must be approved or discarded to disable Change Management. You cannot disable Change Management if any ticket is in the In Progress, On Hold, Rejected, or Pending Approval state.

Step 4 Select the **Number of approvals required**, which is how many administrators must approve the change for the ticket to be approved and deployable. The default is 1, but you can require up to 5 approvers per ticket. Users can override this number when creating tickets.

Step 5 Select the **Ticket Purge Duration**, which is the number of days to keep approved tickets, from 1-100 days. The default is 5 days.

Step 6 (Optional.) Enter the **Reply to Address** and the email addresses for the **List of Approver Addresses**. You must also configure the Email Notification system settings for email to work.

Step 7 Click **Save**.

The system adds the **Ticket** (📄) shortcut to the menu bar, and the **System** (⚙️) > **Change Management Workflow** command. Users can manage tickets using these methods.

Managing Tickets

When you enable Change Management, configuration changes for supported policies must be done within the context of a ticket. You open a ticket, make your changes, then submit the ticket for approval.

You can see a list of tickets, and create new ones, either on the Change Management page or through the Ticket quick-access menu. All ticket changes are synchronized in each menu, so you can switch back and forth at your convenience and use whichever method you prefer.

Note When you open a ticket and make a change to a supported policy, that policy is locked from changes by other users or through other tickets. The policy remains locked until the ticket is approved or discarded.

Procedure

Step 1

Do any of the following:

- Choose **System** (⚙️) > **Change Management Workflow** to open a page showing existing tickets.
- Click the **Ticket** (📄) quick-access menu. The icon can either be named Select a Ticket (if no ticket is opened), the ticket name if a ticket is opened, or unnamed if no tickets exist.

Both pages are organized the same. The **Ticket** tab lists all tickets, whereas the **Review** tab lists tickets that have been submitted for approval. The default view shows your tickets only.

Step 2

On the **Ticket** tab, take any of these actions:

- To create a new ticket, click **Add Ticket**.
- To view the details of a ticket, click the > next to the ticket name. The Details page includes UUID, name, description, user, last modified date, and comments. The History page includes the status changes for the ticket. The image at the top shows where the ticket stands in the overall workflow.
- To preview the configuration changes for an open ticket, click **Preview** (📄).
- To validate the configuration changes in an open ticket, click **Validate** (🔍) or **More** (⋮) > **Validate**. A dialog box opens showing error, warning, and informational messages, if there are any validation errors.
- To open a ticket, click **Open** (🔑) or **More** (⋮) > **Open**.
- To close an open ticket, click **Put Ticket on Hold** (X) or **More** (⋮) > **Put Ticket on Hold**. Closing a ticket does not submit it for review, nor does it release any locks placed on edited policies.
- To submit an open ticket for review and approval, click **Submit for Approval** (📄) or **More** (⋮) > **Submit for Approval**. The ticket must be open to be submitted.

- To discard a ticket, click **Discard** (🗑️) or **More** (⋮) > **Discard**.
- To take over or reassign a ticket, click **More** (⋮) > **Take Over Ticket** when viewing all tickets in the system.
- To search for a ticket, type a string in the search box. The search looks at ticket name, description, and responsible user.
- To filter the list by ticket status (on the Change Management Workflow page), click the status above the list: **New**, **Open**, **On Hold** (ticket was closed), **Rejected**, **Pending Approval**, **Approved**. Each status has a count of the number of tickets in that state. Click **All** under **My Tickets** to return to the default of showing all of your tickets, or **All** under **Tickets in System** to see everyone's tickets.

Step 3 On the **Reviews** tab, take any of these actions on submitted tickets. The list is empty if there are no submitted tickets. In addition, only users with Review Ticket permissions can see this tab.

- To preview the configuration changes for a ticket, click **Preview** (📄).
- To validate the configuration changes in an open ticket, click **Validate** (🔍) or **More** (⋮) > **Validate**.
- To approve the ticket, click **Approve** (✅) or **More** (⋮) > **Approve**.
- To disapprove the ticket, click **Reject** (❌) or **More** (⋮) > **Reject**.

Creating Change Management Tickets

When using the Change Management workflow, you must do all configuration changes within the context of an open ticket. If you do not already have a ticket, you must create a new one.

Procedure

Step 1 Choose **System** (⚙️) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.

Step 2 Click **Add Ticket**.

Step 3 Configure the ticket options:

- **Name**—The name of the ticket. The name can include letters, numbers, spaces, and the following special characters: #-_!
- **Description**—An optional description of what you intend to configure using this ticket. For example, if you have a case number related to what you intend to fix using this ticket, that would be useful information in a description.
- **Number of Approvers**—How many administrators must approve the change for the ticket to be approved and deployable. You can specify 1-5.
- **Assign to**—Select the user who will own the ticket and be responsible for implementing the changes. Choose **self** to assign it to yourself.

- Step 4** Click one of the following: .
- **Create**—The ticket is added to the list of tickets, but it is not opened. You need to open it before you can work within the context of the ticket.
 - **Create and Open**—The ticket is added to the list of tickets and also opened.
-

Opening a Ticket for Configuration Changes

Before you can make changes within a ticket, you must open the ticket.

If you have another ticket open, the system puts it on hold (closes it) for you before opening the new one.

Procedure

- Step 1** Choose **System** (⚙️) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.
- Step 2** On the **Tickets** tab, click **Open** (📄) or **More** (⋮) > **Open** for the ticket.
- Step 3** Optionally, enter a comment for the action.
- Step 4** Click **Open**.

You can now start your configuration changes. The name of the Ticket icon changes to the name of the open ticket.

Previewing a Ticket

You can preview a ticket while making your configuration changes, or before approving it. The preview shows all configuration changes made within the context of the ticket.

Procedure

- Step 1** Choose **System** (⚙️) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.
- Step 2** Click **Preview** (📄) for the ticket.
- The Preview dialog box opens. Changes are color coded according to the legend at the top of the dialog box.
- Step 3** Select the policy whose changes you want to view in the Changed Policies list.
- You are shown both the current version of the policy as it is defined in Secure Firewall Management Center (on the left) and the proposed changes defined within the ticket.
- For policies that contain pages, such as Platform Settings, you can select the overall policy to see all changes, or specific pages within the policy, in the Changed Policies list.
- You cannot alter the changes from within the preview. If you need to change something, you must close the preview and return to the policy you want to change.

- Step 4** Optionally, click **Download as PDF** to save the preview to a PDF file for offline viewing or archival purposes.
- Step 5** Click **OK**.
-

Submitting a Ticket

After you have completed the changes needed for a ticket, you can preview and validate the changes. Then, when you are satisfied with the changes, submit the ticket for review and approval.

Changes made within the ticket are not applied until you submit the ticket and the ticket is approved. Until approval happens, all policies modified within a ticket are locked to that ticket and cannot be changed by anyone else.

Procedure

- Step 1** Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.
- Step 2** Click **Submit for Approval** (📄) or **More** (⋮) > **Submit for Approval** for the open ticket.
- Step 3** Optionally, enter a comment for your action.
- Step 4** Click **Submit**.
-

Discarding a Ticket

If you no longer need to make the changes for which you created a ticket, you can discard the ticket. When you discard a ticket, any changes that you made within the ticket are removed.

You cannot undo this action and retrieve a ticket with its changes. If you need them, you must create a new ticket and start over.

You cannot discard a ticket after you submit it. However, if the approver rejects the ticket, you can then discard it.

- Note** If you have permission to modify tickets, you can discard tickets that belong to another user. This makes it possible to deal with situations where an admin is on vacation or otherwise unavailable to manage an in-process ticket. If you have Review Ticket permission, you can alternatively reassign or take over the ticket rather than discard it.
-

Procedure

- Step 1** Choose **System** (⚙) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.
- Step 2** Click **Discard** (🗑) or **More** (⋮) > **Discard** for the ticket.
- Step 3** Optionally, enter a comment for your action.

Step 4 Click **Discard**.

Approving or Rejecting a Ticket

When a user submits a ticket, it must be approved for the changes made within the ticket to become active and available for deployment.

Whether you can approve your own tickets, or there is a separate approver, depends on your workplace policies and how user roles are assigned, not on the management software.

The Details view includes a summary of how many approvers are required for the ticket, and who has approved the ticket.

If the changes are inadequate or undesirable, you can reject the ticket. Rejected tickets go back to the submitter, who can then make additional changes and resubmit the ticket, or simply discard the ticket and the configuration changes it contains.

Procedure

Step 1 Choose **System** (⚙️) > **Change Management Workflow**, or click the **Ticket** (📄) shortcut menu.

Step 2 On the **Review** tab, click **Preview** (🔍) for the ticket and evaluate the proposed changes.

You can also click **Validate** (🔍) or **More** (⋮) > **Validate** to check for errors.

Step 3 After completing your evaluation, do one of the following:

- To approve the ticket, click **Approve** (✅) or **More** (⋮) > **Approve**.
- To disapprove the ticket, click **Reject** (❌) or **More** (⋮) > **Reject**.

Step 4 Optionally, enter a comment for your action.

Step 5 Click **Approve** or **Reject**, as appropriate.

Taking Over or Reassigning Tickets

Sometimes it might be necessary to take over a ticket that someone else created. For example, the ticket owner might be on vacation or is otherwise unavailable, and the ticket is blocking updates that need to be deployed.

You can also use this procedure to reassign your own ticket to another person.

Before you begin

Following are the permissions required to take over tickets:

- Admin user—You can assign tickets to yourself or other users.
- Modify or Review ticket + System > User Management > Users (custom role)—You can assign tickets to yourself or other users.

However, you can assign a user only if the user has the same role as the current ticket owner, or the Admin role. This ensures that the new user has the permissions required to configure the features currently modified within the ticket.

You cannot reassign a ticket that has been submitted for approval.

Procedure

Step 1 Choose **System** (⚙) > **Change Management Workflow**.

Step 2 Click on **All** under **Tickets in System**.

Step 3 Click **More** (⋮) > **Take Over Ticket**.

Step 4 Select the user who should now own the ticket.

The list of users is restricted to those who have the permissions required to edit the policies already changed within the ticket. For example, if a ticket contains changes to the access control policy, the list of users contains only those users who are allowed to modify the access control policy.

Step 5 Enter an optional comment and click **Takeover**.

History for Change Management

Feature	Minimum Management Center	Minimum Threat Defense	Details
Taking over tickets and additional support for Change Management.	7.6.0	Any	You can take over another user's ticket. This is useful if a ticket is blocking other updates to a policy and the user is unavailable. In addition, the following features are now included in the Change Management approval workflow: Decryption policies, DNS policies, file and malware policies, network discovery, certificates and certificate groups, cipher suite lists, Distinguished Name objects, Sinkhole objects.
Change management.	7.4.1	Any	You can enable change management if your organization needs to implement more formal processes for configuration changes, including audit tracking and official approval before changes are deployed. We added the System (⚙) > Configuration > Change Management page to enable the feature. When enabled, there is a System (⚙) > Change Management Workflow page, and a new Ticket (📄) quick access icon in the menu.

CHAPTER 5

Configuration Deployment

This chapter describes how to download configuration changes to one or more managed devices.

- [About Configuration Deployment, on page 205](#)
- [Requirements and Prerequisites for Policy Management, on page 216](#)
- [Best Practices for Deploying Configuration Changes, on page 216](#)
- [Deploy the Configuration, on page 217](#)
- [Manage Deployments, on page 225](#)
- [History for Configuration Deployment, on page 237](#)

About Configuration Deployment

All device configuration is managed by the management center and then deployed to the managed devices.

Configuration Changes that Require Deployment

The system marks out-of-date policies with red status text that indicates how many of its targeted devices need a policy update. To clear this status, you must re-deploy the policy to the devices.

Deployment Required

Configuration changes that require a deployment include:

- Modifying an access control policy: any changes to access control rules, the default action, policy targets, Security Intelligence filtering, advanced options including preprocessing, and so on.
- Modifying any of the policies that the access control policy invokes: the SSL policy, network analysis policies, intrusion policies, file policies, identity policies, or DNS policies.
- Changing any reusable object or configuration used in an access control policy or policies it invokes:
 - network, port, VLAN tag, URL, and geolocation objects
 - Security Intelligence lists and feeds
 - application filters or detectors
 - intrusion policy variable sets
 - file lists

- decryption-related objects and security zones
- Updating the system software, intrusion rules, or the vulnerability database (VDB).

Keep in mind that you can change some of these configurations from multiple places in the web interface. For example, you can modify security zones using the object manager (**Objects > Object Management**), but modifying an interface type in a device's configuration (**Devices > Device Management**) can also change a zone and require a deployment.

Deployment Not Required

Note that the following updates do **not** require a deployment:

- automatic updates to Security Intelligence feeds and additions to the Security Intelligence global Block or Do Not Block list using the context menu
- automatic updates to URL filtering data
- scheduled geolocation database (GeoDB) updates

Deployment Preview

Preview provides a snapshot of all the policy and object changes to be deployed on the device. The policy changes include the new policies, changes in the existing policies, and the deleted policies. The object changes include the added and modified objects which are used in policies. The unused object changes are not displayed because they are not deployed on the device.

Click the **Preview** icon next to a deployment job to view the configuration change log for that are pending to be deployed on the device. The change log includes:

- **Comparison View:** Displays a side-by-side comparison of all the device configuration changes made since your last deployment.
- **Advanced View:** Displays the pending CLI commands to be applied to the device.

For more information about viewing the deployment preview, see [Deploy Configuration Changes, on page 218](#).

The preview shows all the default values, even when they are not altered, along with the other configured settings when an interface or a platform settings policy is added for the first time. Similarly, the high availability-related policies and default values for settings are shown, even when they are not altered, in the first preview after a high availability pair is configured or disrupted.

To view changes due to an auto rollback, see [Edit Deployment Settings, on page 96](#).

Unsupported Features

- Object additions and attribute changes are displayed in the preview only if the objects are associated with any device or interface. Object deletions are not displayed.
- Preview is not supported for the following policies:
 - High availability
 - Network discovery

- Network analysis
 - Device settings
- User information at the rule level is not available for intrusion policies.
 - The preview does not show the reordering of rules across policies.

For DNS policies, reordered rules appear in the preview list as rule additions and deletions. For example, moving a rule from position 1 to position 3 in the rule order is displayed as if the rule was deleted from position 1 and added as a new rule in position 3. Similarly, when a rule is deleted, the rules under it are listed as edited rules as they have changed their positions. The changes are displayed in the final order in which they appear in the policy.

- Preview is not supported in the following HA scenarios:
 - If a device was in standalone mode and if a chain is made, then an auto-deployment is triggered. For that particular job, preview is not supported. On hover over the **Preview** (🔍), a message is displayed that it is a HA bootstrap deployment, and no preview is supported.
 - **Configuration groups** - Consider a flow in which a device was initially standalone. Subsequently, three deployments took place. In the fourth deployment, the device was a HA bootstrap deployment. After these, the user deploys devices 5, 6, and 7. The deployment 7 is an HA break deployment, and the user deploys devices 8, 9, and 10.

In this flow, the preview between 3 and 5 is not supported because 4 was a HA deployment. Similarly, the preview between 8 and 3 is also not supported. Preview is supported only from 3 to 1, 7,6, 5, 4, and 10, 9, and 8.
 - If a device is broken (HA is broken) then the new device is considered as a fresh device.

Selective Policy Deployment

The management center allows you to select a specific policy within the list of all the changes on the device that are due for deployment and deploy only the selected policy. Selective deployment is available only for the following policies:

- Access control policies
- Intrusion policies
- Malware and file policies
- DNS policies
- Identity policies
- SSL policies
- QoS policies
- Prefilter policies
- Network discovery
- NAT policies

- Routing policies
- VPN policies

There are certain limitations to selectively deploying policies. Follow the contents in the table below to understand when selective policy deployment can be used.

Table 11: Limitations for Selective Deployment

Type	Description	Scenarios
Full deployment	Full deployment is necessary for specific deploy scenarios, and the management center does not support selective deployment in such scenarios. If you encounter an error in such scenarios, you may choose to proceed by selecting all the changes for deployment on the device.	Scenarios wherein a full deployment is required are: <ul style="list-style-type: none"> • The first deployment after you have upgraded the threat defense or the management center. • The first deployment after you have restored the threat defense. • The first deployment after modifications in the threat defense interface settings. • The first deployment after modifications in the virtual router settings. • When the threat defense device is moved to a new domain (global to sub-domain or sub-domain to global).
Associated policy deployment	The management center identifies interdependent policies which are interlinked. When one of the interlinked policies is selected, the remaining interlinked policies are automatically selected.	Scenarios wherein an associated policy is automatically selected: <ul style="list-style-type: none"> • When a new object is associated with an existing policy. • When an existing policy's object is modified. Scenarios wherein multiple policies are automatically selected: <ul style="list-style-type: none"> • When a new object is associated with an existing policy, and the same object is already associated with other policies, all the associated policies are automatically selected. • When a shared object is modified, all the associated policies are automatically selected.

Type	Description	Scenarios
Interdependent policy changes (shown using color-coded tags)	The management center dynamically detects dependencies in-between policies, and between the shared objects and the policies. The interdependency of the objects or policies is shown using color-coded tags.	<p>Scenarios wherein color-coded interdependent policies or objects are automatically selected:</p> <ul style="list-style-type: none"> • When all the out-of-date policies have interdependent changes. <p>For example, when an access control policy, an intrusion policy, and a NAT policy are out-of-date. Since access control policy and NAT policy share an object, all policies are selected together for deployment.</p> <ul style="list-style-type: none"> • When all out-of-date policies share an object, and the object is modified.
Access Policy Group specifications	Access Policy Group policies are listed together in the preview window under Access Policy Group when you click Show or Hide Policy (👁).	<p>The scenarios and the expected behavior for Access Policy Group policies are:</p> <ul style="list-style-type: none"> • If the access control policy is out-of-date, all other out-of-date policies under this group, except file policy and intrusion policy, are selected when the access control policy is selected for deployment. <p>However, if the access control policy is out-of-date, intrusion and file policies can be individually selected or deselected irrespective of whether the access control policy is selected or not, unless there are any dependent changes. For example, if a new intrusion policy is assigned to an access control rule, it indicates that there are dependent changes, then both the access control policy and the intrusion policy will be automatically selected when either of them is selected.</p> <ul style="list-style-type: none"> • If no access control policy is out-of-date, other out-of-date policies in this group can be selected and deployed individually.

System Username

The management center displays the username as **system** for the following operations:

- Rollback
- Upgrade
- Threat Defense backup and restore
- SRU update

- LSP update
- VDB update

Auto-Enabling of Application Detectors

If you are performing application control but disable required detectors, the system automatically enables the appropriate system-provided detectors upon policy deploy. If none exist, the system enables the most recently modified user-defined detector for the application.

Asset Rediscovery with Network Discovery Policy Changes

When you deploy changes to a network discovery policy, the system deletes and then rediscovers MAC address, TTL, and hops information from the network map for the hosts in your monitored networks. Also, the affected managed devices discard any discovery data that has not yet been sent to the management center.

Snort Restart Scenarios

When the traffic inspection engine referred to as *the Snort process* on a managed device restarts, inspection is interrupted until the process resumes. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) for more information. Additionally, resource demands may result in a small number of packets dropping without inspection when you deploy, regardless of whether the Snort process restarts.

Any of the scenarios in the following table cause the Snort process to restart.

Table 12: Snort Restart Scenarios

Restart Scenario	More Information
Deploying a specific configuration that requires the Snort process to restart.	Configurations that Restart the Snort Process When Deployed or Activated, on page 214
Modifying a configuration that immediately restarts the Snort process.	Changes that Immediately Restart the Snort Process, on page 215
Traffic-activation of the currently deployed Automatic Application Bypass (AAB) configuration.	Configure Automatic Application Bypass, on page 93
Enabling or disabling "Logging connection events to RAM disk" feature.	See the section Log to Ramdisk in Troubleshoot Drain of FMC Unprocessed Events .

[Configurations that Restart the Snort Process When Deployed or Activated, on page 214](#)

Restart Warnings for Devices

When you deploy, the **Inspect Interruption** column in the deploy page specifies whether a deployed configuration restarts the Snort process on the threat defense device. When the traffic inspection engine referred to as *the Snort process* restarts, inspection is interrupted until the process resumes. Whether traffic is interrupted

or passes without inspection during the interruption depends on how the device handles traffic. Note that you can proceed with the deployment, cancel the deployment and modify the configuration, or delay the deployment until a time when deploying would have the least impact on your network.

When the **Inspect Interruption** column indicates **Yes** and you expand the device configuration listing, the system indicates any specific configuration type that would restart the Snort process with an **Inspect Interruption** () **Yes**. When you hover your mouse over the icon, a message informs you that deploying the configuration may interrupt traffic.

The following table summarizes how the deploy page displays inspection interruption warnings.

Table 13: Inspection Interruption Indicators

Type	Inspect Interruption	Description
Threat Defense	Inspect Interruption () Yes	At least one configuration would interrupt inspection on the device if deployed, and might interrupt traffic depending on how the device handles traffic. You can expand the device configuration listing for more information.
	--	Deployed configurations will not interrupt traffic on the device.
	Undetermined	The system cannot determine if a deployed configuration may interrupt traffic on the device. Undetermined status is displayed before the first deployment after a software upgrade, or in some cases during a Support call.
	Errors ()	The system cannot determine the status due to an internal error. Cancel the operation and click Deploy again to allow the system to redetermine the Inspect Interruption status. If the problem persists, contact Support.
sensor	--	The device identified as <i>sensor</i> is not the threat defense device; the system does not determine if a deployed configuration may interrupt traffic on this device.

For information on all configurations that restart the Snort process for all device types, see [Configurations that Restart the Snort Process When Deployed or Activated](#), on page 214.

Inspect Traffic During Policy Apply

Inspect traffic during policy apply is an advanced access control policy general setting that allows managed devices to inspect traffic while deploying configuration changes; this is the case unless a configuration that you deploy requires the Snort process to restart. You can configure this option as follows:

- Enabled — Traffic is inspected during the deployment unless certain configurations require the Snort process to restart.

When the configurations you deploy do not require a Snort restart, the system initially uses the currently deployed access control policy to inspect traffic, and switches during deployment to the access control policy you are deploying.

- Disabled — Traffic is not inspected during the deployment. The Snort process always restarts when you deploy.

The following graphic illustrates how Snort restarts can occur when you enable or disable **Inspect traffic during policy apply**.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) and [Configurations that Restart the Snort Process When Deployed or Activated, on page 214](#).

Snort Restart Traffic Behavior

The following tables explain how different devices handle traffic when the Snort process restarts.

Table 14: The Threat Defense and the Threat Defense Virtual Restart Traffic Effects

Interface Configuration	Restart Traffic Behavior
inline: Snort Fail Open: Down: disabled	dropped
inline: Snort Fail Open: Down: enabled	passed without inspection Some packets can be delayed in buffer for several seconds before the system recognizes that Snort is down. This delay can vary depending upon the load distribution. However, the buffered packets are eventually passed.

Interface Configuration	Restart Traffic Behavior
routed, transparent (including EtherChannel, redundant, subinterface): preserve-connection enabled (configure snort preserve-connection enable ; default) For more information, see Cisco Secure Firewall Threat Defense Command Reference .	existing TCP/UDP flows: passed without inspection so long as at least one packet arrives while Snort is down new TCP/UDP flows and all non-TCP/UDP flows: dropped Note that the following traffic drops even when preserve-connection is enabled: <ul style="list-style-type: none"> • plaintext, passthrough prefilter tunnel traffic that matches an Analyze rule action or an Analyze all tunnel traffic default policy action • connections that do not match an access control rule and are instead handled by the default action. • decrypted TLS/SSL traffic • a safe search flow • a captive portal flow
routed, transparent (including EtherChannel, redundant, subinterface): preserve-connection disabled (configure snort preserve-connection disable)	dropped
inline: tap mode	egress packet immediately, copy bypasses Snort
passive	uninterrupted, not inspected

Note In addition to traffic handling when the Snort process is down while it restarts, traffic can also pass without inspection or drop when the Snort process is busy, depending on the configuration of the Snort Fail Open **Busy** option (see [Configure an Inline Set, on page 822](#)). A device supports either the Failsafe option or the Snort Fail Open option, but not both.

Note When the Snort process is busy but not down during configuration deployment, some packets may drop on routed, switched, or transparent interfaces if the total CPU load exceeds 60 percent.

Warning Do not reboot the system while the Snort Rule Update is in progress.

Snort-busy drops happen when snort is not able to process the packets fast enough. Lina does not know whether Snort is busy due to processing delay, or if is stuck or due to call blocking. When transmission queue is full, snort-busy drops occur. Based on Transmission queue utilization, Lina will try to access if the queue is being serviced smoothly.

Configurations that Restart the Snort Process When Deployed or Activated

Deploying any of the following configurations except AAB restarts the Snort process as described. Deploying AAB does not cause a restart, but excessive packet latency activates the currently deployed AAB configuration, causing a partial restart of the Snort process.

Access Control Policy Advanced Settings

- Deploy when **Inspect Traffic During Policy Apply** is disabled.
- Add or remove an SSL policy.

File Policy

Deploy the first or last of any one of the following configurations; note that while otherwise deploying these file policy configurations does not cause a restart, deploying non-file-policy configurations can cause restarts.

- Take either of the following actions:
 - Enable or disable **Inspect Archives** when the deployed access control policy includes at least one file policy.
 - Add the first or remove the last file policy rule when **Inspect Archives** is enabled (note that at least one rule is required for **Inspect Archives** to be meaningful).
- Enable or disable **Store files** in a **Detect Files** or **Block Files** rule.
- Add the first or remove the last active file rule that combines the **Malware Cloud Lookup** or **Block Malware** rule action with an analysis option (**Spero Analysis** or **MSEXE**, **Dynamic Analysis**, or **Local Malware Analysis**) or a store files option (**Malware**, **Unknown**, **Clean**, or **Custom**).

Note that access control rules that deploy these file policy configurations to security zones or tunnel zones cause a restart only when your configuration meets the following conditions:

- Source or destination security zones in your access control rule must match the security zones associated with interfaces on the target devices.
- Unless the destination zone in your access control rule is *any*, a source tunnel zone in the rule must match a tunnel zone assigned to a tunnel rule in the prefilter policy.

Identity Policy

- When SSL decryption is disabled (that is, when the access control policy does not include an SSL policy), add the first or remove the last active authentication rule.

An active authentication rule has either an **Active Authentication** rule action, or a **Passive Authentication** rule action with **Use active authentication if passive or VPN identity cannot be established** selected.

Network Discovery

- Enable or disable non-authoritative, traffic-based user detection over the HTTP, FTP, or MDNS protocols, using the network discovery policy.

Device Management

- **MTU:** Change the highest MTU value among all non-management interfaces on a device.
- **Automatic Application Bypass (AAB):** The currently deployed AAB configuration activates when a malfunction of the Snort process or a device misconfiguration causes a single packet to use an excessive amount of processing time. The result is a partial restart of the Snort process to alleviate extremely high latency or prevent a complete traffic stall. This partial restart causes a few packets to pass without inspection, or drop, depending on how the device handles traffic.

Updates

- **System update:** Deploy configurations the first time after a software update that includes a new version of the Snort binary or data acquisition library (DAQ).
- **VDB:** For managed devices running Snort 2, deploying configurations the first time after installing a vulnerability database (VDB) update that includes changes applicable to managed devices will require a detection engine restart and may result in a temporary traffic interruption. For these, a message warns you when you select the management center to begin installing. The deploy dialog provides additional warnings for the threat defense devices when VDB changes are pending. VDB updates that apply only to the management center do not cause detection engine restarts, and you cannot deploy them.

For managed devices running Snort 3, deploying configurations the first time after installing a vulnerability database (VDB) update may temporarily interrupt application detection, but there will be no traffic interruptions.

Changes that Immediately Restart the Snort Process

The following changes immediately restart the Snort process without going through the deploy process. How the restart affects traffic depends on how the target device handles traffic. See [Snort Restart Traffic Behavior](#), on page 212 for more information.

- Take any of the following actions involving applications or application detectors:
 - Activate or deactivate a system or custom application detector.
 - Delete an activated custom detector.
 - **Save and Reactivate** an activated custom detector.
 - Create a user-defined application.

A message warns you that continuing restarts the Snort process, and allows you to cancel; the restart occurs on any managed device in the current domain or in any of its child domains.

- Create or break a threat defense high availability pair.

A message warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

- Security Approver

Best Practices for Deploying Configuration Changes

The following are guidelines for deploying configuration changes.

Reliable Management Connection

The management connection between the management center and the device is a secure, TLS-1.3-encrypted communication channel between itself and the device.

You do not need to run this traffic over an additional encrypted tunnel such as Site-to-Site VPN for security purposes. If the VPN goes down, for example, you will lose your management connection, so we recommend a simple management path.

Caution We recommend against a device's management connection going through a VPN tunnel that terminates on the device itself. If you deploy a configuration change that causes the VPN to go down, the management connection will be disconnected and you will not have any way to recover the configuration without connecting directly to the device.

If management traffic exits a VPN-terminating interface, be sure to exclude the management traffic from the VPN tunnel.

Maximum Concurrent Deployments

You should not deploy to more than 25% of the maximum devices allowed for a management center in the same job. For example, for the FMCv300, the maximum job size should be 75 devices (25% of 300). Concurrent deployment to more devices can cause performance issues.

Deployment of Shared Policies

For best performance, deploy to devices that use the same policies. Create separate deployment jobs for each group of devices that share policies.

Time to Deploy and Memory Limitations

The time it takes to deploy depends on multiple factors, including (but not limited to):

- The configurations you send to the device. For example, if you dramatically increase the number of Security Intelligence entries you block, deployment can take longer.
- Device model and memory. On lower-memory devices, deploying can take longer.

Do not exceed the capability of your devices. If you exceed the maximum number of rules or policies supported by a target device, the system displays a warning. The maximum depends on a number of factors—not only memory and the number of processors on the device, but also on policy and rule complexity. For information on optimizing policies and rules, see [Best Practices for Access Control Rules, on page 1620](#).

Use a Maintenance Window to Lessen the Impact of Traffic Interruptions

We *strongly* recommend you deploy in a maintenance window or at a time when interruptions will have the least impact.

When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) and [Configurations that Restart the Snort Process When Deployed or Activated, on page 214](#).

For the threat defense devices, the **Inspect Interruption** column in the Deploy dialog warns you when deploying might interrupt traffic flow or inspection. You can either proceed with, cancel, or delay deployment; see [Restart Warnings for Devices, on page 210](#) for more information.

Related Topics

[Snort Restart Scenarios, on page 210](#)

Deploy the Configuration

After you configure your deployment, and any time you change that configuration, you must deploy the changes to affected devices. You can view deployment status in the Message Center.

Deploying updates the following components:

- Device and interface configurations
- Device-related policies: NAT, VPN, QoS, platform settings
- Access control and related policies: DNS, file, identity, intrusion, network analysis, prefilter, SSL
- Network discovery policy
- Intrusion rule updates
- Configurations and objects associated with any of these elements

You can configure the system to deploy automatically by scheduling a deploy task or by setting the system to deploy when importing intrusion rule updates. Automating policy deployment is especially useful if you allow intrusion rule updates to modify system-provided base policies for intrusion and network analysis. Intrusion rule updates can also modify default values for the advanced preprocessing and performance options in your access control policies.

Deploy Configuration Changes

After you change configurations, deploy them to the affected devices. We *strongly* recommend that you deploy in a maintenance window or at a time when any interruptions to traffic flow and inspection will have the least impact.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) and [Configurations that Restart the Snort Process When Deployed or Activated, on page 214](#).

Before you begin

- Be sure all managed devices use the same revision of the Security Zones object. If you have edited security zone objects: Do not deploy configuration changes to any device until you edit the zone setting for interfaces on *all* devices you want to sync. You must deploy to all managed devices at the same time.
- To preview the deployment changes, enable REST API access. To enable the REST API access, follow the steps in *Enabling REST API Access* in the [Cisco Secure Firewall Management Center Administration Guide](#).

Note The deployment process fails if the device configuration is being read at the device CLI during deployment. Do not execute commands such as **show running-config** during the deployment.

Procedure

-
- Step 1** On the management center menu bar, click **Deploy**.
- Step 2** For a quick deployment, check specific devices and then click **Deploy**, or click **Deploy All** to deploy to all devices. Otherwise, for additional deployment options, click **Advanced Deploy**.

The rest of this procedure applies to the **Advanced Deploy** screen.

Figure 68: Quick Deploy

Figure 69: Advanced Deploy

Step 3 Click **Expand Arrow** () to view device-specific configuration changes to be deployed.

Figure 70: Expand

- The **Modified By** column lists the users who have modified the policies or objects. On expanding the device listing, you can view the users who have modified the policies against each policy listing. For information about when the **System** user is shown (instead of the logged-in user), see [System Username, on page 209](#).

Note Usernames are not provided for deleted policies and objects.

- The **Inspect Interruption** column indicates if traffic inspection interruption may be caused in the device during deployment.

When the status indicates (Yes) that deploying will interrupt inspection, and perhaps traffic, on the threat defense device, the expanded list indicates the specific configurations causing the interruption with the

Inspect Interruption (🔥).

If the entry is blank in this column for a device, then it indicates that there will be no traffic inspection interruptions on that device during deployment.

See [Restart Warnings for Devices, on page 210](#) for information to help you identify configurations that interrupt traffic inspection and might interrupt traffic when deployed to the threat defense devices.

- The **Last Modified Time** column specifies when you last made the configuration changes.
- The **Preview** column allows you to preview the changes for the next deployment.
- The **Status** column provides the status for each deployment. For more information, see [View Deployment Status, on page 225](#).

Step 4 In the **Preview** column, click **Preview** (📄) to see the configuration changes that you can deploy.

Figure 71: Preview

Device	Modified by	Inspect Interruption	Type	Group	Last Deploy Time	Preview	Status
HA1	System, admin		FTD		-		Ready for Deployment
1120-4	System		FTD		Oct 17, 2023 10:47 ...		Ready for Deployment

Note If you change the management center name in **System** (⚙️) > **Configuration** > **Information**, the deployment preview does not specify this change, yet it requires a deployment.

For unsupported features for Preview, see [Deployment Preview, on page 206](#).

The **Comparison View** tab lists all the policy and object changes. The left pane lists all the different policy types that have changed on the device, organized in a tree structure.

Figure 72: Comparison View

Change Log: 1120-4

Comparison View | Advanced View

Legend: Added | Edited | Remove

Changed Policies	Deployed Version	Version on Firewall Management Center	Modified By
<ul style="list-style-type: none"> Access Control Policy Network Analysis Policy <ul style="list-style-type: none"> Balanced Security and Conne... 	Network Analysis Policy: Network Analysis Policy: Balanced Security and Co Network Analysis Policy: Balanced Security and C <pre> inspectorData: {"iec104":{"enabled":false,"instan {"imap":{"type":"multiton","enabled":true,"instanc </pre>		System

The **Filter** icon (⌵) lets you filter the policies at the user level and policy level.

The right pane lists all the additions, changes, or deletions in the policy, or the object selected in the left pane. The two columns on the right pane provide the last deployed configuration settings (in the **Deployed Version** column) versus the changes that are due for deployment (in the **Version on Firewall Management Center** column). The last-deployed configuration settings are derived from a snapshot of the last saved deployment in the management center and not from the device. The background colors of the settings are color-coded as per the legend available on the top-right of the page.

The **Modified By** column lists the users who have modified, or added the configuration settings. At the policy level, the management center displays all the users who have modified the policy, and at the rule level, the management center displays only the last user who has modified the rule.

You can download a copy of the change log by clicking the **Download Report** button.

The **Advanced View** tab shows the CLI commands that will be applied. This view is useful if you are familiar with ASA CLI, which is used on the back end of the threat defense.

Figure 73: Advanced View

Step 5 Use **Show or Hide Policy** (👁) to selectively view or hide the associated unmodified policies.

Figure 74: Show or Hide Policy

Step 6 Check the box next to the device name to deploy all configuration changes, or click **Policy selection** (👁) to select individual policies or configurations to deploy while withholding the remaining changes without deploying them.

You can also view the interdependent changes for a certain policy or configuration using this option. The management center dynamically detects dependencies between policies (for example, between an access control policy and an intrusion policy), and between the shared objects and the policies. Interdependent changes are indicated using color-coded tags to identify a set of interdependent deployment changes. When one of the deployment changes is selected, the interdependent changes are automatically selected.

For more details, see [Selective Policy Deployment, on page 207](#).

- Note**
- When the changes in shared objects are deployed, the impacted policies should also be deployed along with them. When you select a shared object during deployment, the impacted policies are automatically selected.
 - Selective deployment is not supported for scheduled deployments and deployments using REST APIs. You can only opt for complete deployment of all the changes in these cases.
 - The pre-deployment checks for warnings and errors are performed not only on the selected policies, but on all the policies that are out-of-date. Therefore, the warnings or errors list shows the deselected policies as well.
 - Similarly, the **Inspect Interruption** column indication on the Deployment page considers all out-of-date policies and not just the selected policies. For information on the **Inspect Interruption** column, see [Restart Warnings for Devices, on page 210](#).

Step 7 After you select the devices or policies to deploy, click **Estimate** to get a rough estimate of the deployment duration.

Figure 75: Estimate

Figure 76: Deploy Time

The time duration is a rough estimate (having around 70% accuracy), and the actual time taken for deployment may vary for a few scenarios. The estimate is dependable for deployments of up to 20 devices.

When an estimate is not available, it indicates that the data is not available, since the first successful deployment on the selected device is pending. This situation could occur after the management center reimage, version upgrade, or after a high availability failover.

- Note** The estimate is incorrect and unreliable for bulk policy changes (in case of bulk policy migrations), and selective deployments because the estimate is based on the heuristic technique.

Step 8 Click **Deploy**.

Step 9 If the system identifies errors or warnings in the changes to be deployed, it displays them in the **Validation Messages** window. To view complete details, click the arrow icon before the warnings or errors.

You have the following choices:

- Deploy—Continue deploying without resolving warning conditions. Check the **Ignore warnings** checkbox, to ignore warnings and deploy the changes. You cannot proceed if the system identifies errors.

- Close—Exit without deploying. Resolve the error and warning conditions, and attempt to deploy the configuration again.

What to do next

- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- If the deployment fails, see [Best Practices for Deploying Configuration Changes, on page 216](#).
- During deployment, if there are specific configuration changes in the deployment, the deployment failure may lead to traffic being interrupted. For example, in a cluster environment, an erroneous configuration of an IP address that is not in the same subnet as the Site IPs is configured on the interface. Due to this error, deployment fails and the device attempts to clear the configuration while the rollback operation is being processed. These events collectively lead to a deployment failure that interrupts the traffic.

See the following table to know what configuration changes may cause traffic interruption when deployment fails.

Configuration Changes	Exists?	Traffic Impacted?
Threat Defense Service changes in an access control policy	Yes	Yes
VRF	Yes	Yes
Interface	Yes	Yes
QoS	Yes	Yes

Note The configuration changes interrupting traffic during deployment is valid only if both the management center and the threat defense are of version 6.2.3 or higher.

[Snort Restart Scenarios, on page 210](#)

Redeploy Existing Configurations to a Device

You can force-deploy existing (unchanged) configurations to a single managed device. We *strongly* recommend you deploy in a maintenance window or at a time when any interruptions to traffic flow and inspection will have the least impact.

Caution When you deploy, resource demands may result in a small number of packets dropping without inspection. Additionally, deploying some configurations restarts the Snort process, which interrupts traffic inspection. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) and [Configurations that Restart the Snort Process When Deployed or Activated, on page 214](#).

Before you begin

Review the guidelines described in [Best Practices for Deploying Configuration Changes, on page 216](#).

Procedure

Step 1 Choose **Devices > Device Management**.

Step 2 Click **Edit** (✎) next to the device where you want to force deployment.

Step 3 Click **Device**.

Step 4 Click **Edit** (✎) next to the **General** section heading.

Step 5 Click **Force Deploy** (➔).

Note Force-deploy takes more time than the regular deployment because it involves the complete generation of the policy rules to be deployed on the threat defense.

Step 6 Click **Deploy**.

The system identifies any errors or warnings with the configurations you are deploying. You can click **Proceed** to continue without resolving warning conditions. However, you cannot proceed if the system identifies an error.

What to do next

- (Optional) Monitor deployment status; see *Viewing Deployment Messages* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- If deploy fails, see [Best Practices for Deploying Configuration Changes, on page 216](#).

Related Topics

[Snort Restart Scenarios, on page 210](#)

Manage Deployments

View Deployment Status

On the Deployment page, the **Status** column provides the deployment status for each device. If a deployment is in progress, then the live status of the deployment progress is displayed, else one of the following statuses is displayed:

- Pending—Indicates that there are changes in the device that are to be deployed.
- Warnings or errors—Indicates that the pre-deployment checks have identified warnings or errors for the deployment, and you have not proceeded with the deployment. You can continue with the deployment if there are any warnings, but not if there are any errors.

Note The status column provides the warning or error status only for a single user session on the deployment page. If you navigate away from the page or refresh the page, the status changes to pending.

- Failed—Indicates that the previous deployment attempt failed. Click on the status to view the details.
- In queue—Indicates that deployment is initiated, and the system is yet to start the deployment process.
- Completed—Indicates that deployment has completed successfully.

View Deployment History

In the deployment history, the last 10 successful deployments, the last 5 failed deployments, and last 5 rollback deployments are captured.

Procedure

- Step 1** On the management center menu bar, click **Deploy** and then click **Deployment History** (↻).

Figure 77: Deployment History Icon

A list of all the previous deployment and rollback jobs is displayed in reverse chronological order.

Figure 78: Deployment History Page

Job Name	Deployed by	Start Time	End Time	Status	Deployment Notes
> Deploy_Job_10	admin	Oct 25, 2023 12:59 PM	Oct 25, 2023 1:01 PM	Failed	
> Deploy_Job_9	admin	Oct 24, 2023 11:27 AM	Oct 24, 2023 11:30 AM	Completed	
> Certificate_Job_1	System	Oct 9, 2023 11:03 AM	Oct 9, 2023 11:03 AM	Failed	Certificate deployment

Step 2 Click **Expand Arrow** (>) next to the required deployment job to view the devices included in the job and their deployment statuses.

Figure 79: Expand

Job Name	Deployed by	Start Time	End Time	Status	Deployment Notes
▼ Deploy_Job_10	admin	Oct 25, 2023 12:59 PM	Oct 25, 2023 1:01 PM	Failed	
Device	Transcript	Preview	Status		
HA1			Failed		
1120-4			Completed		

- View notes in the **Deployment Notes** column.

Deployment notes are custom notes that a user can add as part of the deployment, and these notes are optional.

Step 3 (Optional) Click **Transcript Details** () to view the commands sent to the device, and the responses received.

Figure 80: Transcript Details Icon

Job Name	Deployed by	Start Time	End Time	Status	Deployment Notes
Deploy_Job_10	admin	Oct 25, 2023 12:59 PM	Oct 25, 2023 1:01 PM	Failed	
Device	Transcript	Preview	Status		
HA1			Failed		
1120-4			Completed		

Figure 81: Transcript Details

```

=====SNORT APPLY=====

===== CLI APPLY =====

FMC >> clear configuration session
FMC >> no strong-encryption-disable
FMC >> no dp-tcp-proxy
FMC >> policy-map global_policy
FMC >> class class-default
FMC >> class inspection_default
FMC >> exit
FMC >> vpn-addr-assign local
FMC >> access-group CSM_FW_ACL_ global
FMC >> clear configuration session

```

The transcript includes the following sections:

- **Snort Apply**—If there are any failures or responses from Snort-related policies, then the messages are displayed in this section. Normally, the section is empty.
- **CLI Apply**—This section covers features that are configured using commands that are sent to the device.
 - Note** The transcript for the rollback operation does not provide the CLI commands information. To view the rollback commands, see [View the Deployment Rollback Transcript, on page 233](#).
- **Infrastructure Messages**—This section shows the status of different deployment modules.

In the **CLI Apply** section, the deployment transcript includes commands that are sent to the device, and any responses returned from the device. These responses can be informative messages or error messages. For failed deployments, look for messages that indicate errors with the commands. Examining these errors can be particularly helpful if you are using FlexConfig policies to configure customized features. These errors can help you correct the script in the FlexConfig object that is trying to configure the commands.

Note There is no distinction that is made in the transcript between commands that are sent for managed features and those generated from FlexConfig policies.

For example, the following sequence shows that management center sent commands to configure GigabitEthernet0/0 with the logical name **outside**. The device responded that it automatically set the security level to 0. Threat Defense does not use the security level for anything.

```
===== CLI APPLY =====
```

```
FMC >> interface GigabitEthernet0/0
FMC >> nameif outside
FTDv 192.168.0.152 >> [info] : INFO: Security level for "outside" set to 0 by default.
```

Step 4 (Optional) Click **Preview** (📄) to view the policy and object changes deployed on the device versus the previously deployed version.

Figure 82: Preview Icon

Job Name	Deployed by	Start Time	End Time	Status	Deployment Notes
Deploy_Job_10	admin	Oct 25, 2023 12:59 PM	Oct 25, 2023 1:01 PM	Failed	
Device					
HA1	Transcript	Preview	Status	Failed	
1120-4			Completed		

- To compare any two versions and view the change log, choose the required versions in the drop-down boxes and click the **Show** button. The drop-down boxes show the deployment job name and the end time of the deployment.

Figure 83: Compare Versions

Note The drop-down boxes also show failed deployments.

- The **Modified By** column lists the users who have modified the policies or objects.
 - At the policy level, management center displays all the user names who have modified the policy.
 - At the rule level, management center displays the last user who has modified the rule.
- You can also download a copy of the change log by clicking **Download Report**.

Note

- Deployment history preview is not supported for certificate enrollments, HA operations, and failed deployments.
- When a device is registered, preview is not supported for the job history record that is created.

Step 5 (Optional) Against each deployment job, click the **More** (⋮) icon and execute other actions:

- **Bookmark**—To bookmark the deployment job.
- **Edit Deployment Notes**—To edit your custom deployment notes that you added for a deployment job.
- **Generate Report**—To generate a deployment report, which can be used for auditing. This report includes job properties with preview and transcript information, and the report can be downloaded as a PDF file.
 - a. Click **Generate Report** to generate a deployment report.

Figure 84: Generate Report

The screenshot shows a 'Generate Report' dialog box with the following fields and controls:

- Job Name: Deploy_Job_1
- Number of device(s): 1
- Email:
- Relay Host: No Relay Host (with an edit icon)
- Recipient List:
- Buttons: Cancel and Generate

- b. In the **Generate Report** popup window, check the **Email** checkbox.
- c. The report can also be sent through email if mail relay host is configured. If the mail relay host is not configured, use the **Edit** (✎) icon to configure or modify the mail relay host. For more information, see *Configuring a Mail Relay Host and Notification Address* in the [Cisco Secure Firewall Management Center Administration Guide](#).
- d. In the **Recipient List**, you can enter multiple email addresses, separated by semicolons.
- e. Click **Generate** to generate the report, and this report is emailed to the recipients.
- f. In the Notifications task tab, you can track the progress. After the report generation is complete, click the link in the notification task tab to download the PDF report.

Set the Number of Configuration Versions

The management center stores device configuration history files on the disk as configuration versions. You can specify the number of configuration versions that you want to retain for a device. This setting allows you to estimate the size of the device configuration files on the disk and keep it within the allowed limit. Reducing the number of configuration versions can reduce the backup size and improve the high-availability synchronization speed of the management center.

In a management center high-availability deployment, configuration version setting is available only on the active management center.

Before you begin

This feature is not supported in Version 7.4.0.

Procedure

-
- Step 1** On the management center menu bar, choose **Deploy > Deployment History** (📄).
- Step 2** Click **Deployment Setting**.
- Step 3** Choose the number of configuration versions that you want to retain for a device from the **Number of Versions to Retain** drop-down list.
- Note** Reducing the number of versions removes the oldest configuration versions to match the version size you have selected. You cannot roll back or preview the removed versions.
- **Maximum Permitted Disk Size:** The maximum size for storing configuration versions is 20 GB. The management center calculates the size of configuration versions periodically and sends a health alert if the size of the configuration versions exceeds 20 GB. To resolve the health alert, choose a **Number of Versions to Retain** for which the estimated configuration version size is less than 20 GB.
 - **Current Configuration Version Size:** The size of the configuration files on the management center for the previous deployment.
 - **Estimated Configuration Version Size:** The approximate size of the configuration files on the management center. It is calculated based on the number of configuration versions you chose to retain.
- Step 4** Click **Save**.
-

Roll Back a Deployment

You can roll back a device to a previously deployed configuration. After a policy deployment, if the traffic through the device is affected in an unintended way, rollback provides an option to revert the device to the earlier state, which existed before the faulty deployment.

Rollback is a disruptive operation: all the existing connections and routes are dropped, and the traffic is disrupted.

Identifying the Disruptive Configuration

When a deployment has gone awry and caused traffic interruption in an unintended way, you should identify the change in the deployment that caused the condition and fix it so your next deployment will be successful.

See the following ways to compare configurations.

Before a Rollback

1. Choose **Deploy > Deployment History**, expand the last deployed job (that caused the traffic disruption), and click the preview icon (📄).

The preview page provides an option to compare deployments, which can be useful to identify specific changes for a deployment compared to a previous deployment.
2. After identifying the change causing the problem, rectify the configuration, and redeploy it on the device.

After a Rollback

1. After a successful rollback operation, choose **Deploy > Deployment**, and click the **Preview** icon next to the rolled back device.
2. View the changes between the rolled back configuration and the current changes in the management center that are pending deployment.
3. After identifying the change causing the problem, rectify the configuration, and redeploy it on the device.

Rollback Guidelines and Limitations

- You can roll back to any one of the last 10 versions before the currently deployed version. Rollback to versions prior to these are not supported. The rollback icon is greyed out for unsupported versions.
- You have to perform a deployment before you can roll back again.
- After you perform a rollback, the rolled back devices are marked as out-of-date on the management center. The changes you made to the configuration are still pending for the next deployment. To see the pending changes, choose **Deploy > Deployment**, and click the **Preview** icon next to the rolled back device.
- For devices with very large access lists, if the **Object Group Search** setting is disabled, then the rollback operation may take a longer duration to complete. To verify the **Object Group Search** setting, choose **Devices > Device Management**, and then select the device and click **Edit Advanced Settings**.
- For the Firepower 4100/9300, make sure your current chassis manager interface configuration is the same for any rollback versions. Otherwise, the rollback interface configuration may not match your actual interfaces.
- Rollback is not supported if the manager access interface (Manager or data interface) is different between the rollback version and the current version.
- Independent certificate enrollments are also listed as deployment jobs in the Deployment History page. However, you cannot roll back to these versions. A rollback from a deployment version created after certificate enrollments reverts the certificate associations as well. In the next deployment after a rollback, manually associate the certificates before proceeding with the deployment.
- If you upgrade the management center, all rollback versions from the previous software release will no longer be available for devices, even if you did not upgrade the devices.
- If you upgrade the device, you can only roll back to versions on the current software release.
- If a deployment for a device with a FlexConfig object configured with a deployment frequency set to **Once** is rolled back, then you will not be able to redeploy the object even though it is displayed as out-of-date on the Preview page. After a rollback, you will have to manually unassign and then reassign the FlexConfig object to the device before the next deployment.
- For High Availability, rollback is not supported in the following scenarios:
 - When the version you want to roll back to contains the high-availability bootstrap configuration. In other words, the deployment when you first formed high availability for the standalone devices.
 - When a device that is currently in standalone mode was part of a high availability pair in the previous deployment version.
- For clustering, see the following guidelines:

- Rollback is not supported when a device that is currently in standalone mode was part of a cluster in the previous deployment version.
- (Secure Firewall 3100/4200 and threat defense virtual in a private cloud) If you change the clustering bootstrap configuration or add or delete nodes, you cannot roll back to a version prior to those changes.

Configurations Not Reverted After a Rollback

Rollback reverts all the configurations on the device except a few. See the table below for details.

Configurations that are reverted during a rollback	Configurations that are not reverted during a rollback
<ul style="list-style-type: none"> • All policy configurations • Interface configurations • SRU configurations • VDB configurations • LSP configurations • VPN configurations • FXOS configurations 	<ul style="list-style-type: none"> • Snort binaries <p>Note Rollback from Snort 3 to Snort 2 version policies and vice versa are supported.</p> <ul style="list-style-type: none"> • Geo DB

Perform a Rollback

You can roll back a device to a previously deployed configuration. After a policy deployment, if the traffic through the device is affected in an unintended way, rollback provides an option to revert the device to the earlier state, which existed before the faulty deployment.

Rollback reverts the configuration only on the selected devices.

Procedure

-
- Step 1** Choose **Deploy >Deployment History** (↻).
- A list of all the previous deployment jobs is displayed in reverse chronological order.
- Step 2** Click **Rollback**.
- Step 3** Filter the list of devices displayed by either clicking **Job** and choosing a job from the **Selected Job** drop-down list, or by clicking **Device List**.
- Step 4** (Optional) Enter the device name in the **Search Device** search box to filter the device list.
- Step 5** Check the box next to the devices you want to roll back and choose the version for each device from the **Rollback Version** drop-down list.

Figure 85: Selected Job List

Rollback

▲ Rollback is the last resort for disaster recovery. Use rollback only if a deployment has caused a data

<input checked="" type="checkbox"/>	1120-4	Aug 2, 2023 7:16 PM ▼	
<input type="checkbox"/>	HA1 ▲		

The job names and associated deployment notes are also listed for a particular rollback version.

Step 6 (Optional) Click the preview icon () to view the changes deployed in the selected version.

Step 7 Click **Rollback**.

What to do next

To know the status of the rollback, choose **Deploy > Deployment**. You can view the rollback status next to the device name.

View the Deployment Rollback Transcript

Rollback transcript is a written version of the commands that are sent to the device, along with the responses returned from the device. If a rollback operation has failed, the transcript in the **Deploy > Deployment History**

page provides the reason for the failure. However, to know the CLI commands executed for a successful rollback operation, follow the steps given below after a rollback operation has completed. Note that this information is available only until the next deployment.

Note The CLI command information is available after a rollback is complete and is available only until the next deployment. The first deployment after a rollback operation erases all the rollback-related information.

Note For any rollback deployment, the Deployment Notes are updated automatically as Rollback Job. In the **Deployment History** page, the user can filter the Rollback Jobs easily using the Search option.

Procedure

- Step 1** On the Secure Firewall Management Center menu bar, choose **System > Health > Monitor**.
 - Step 2** Select the device, which was rolled back, from the left pane.
 - Step 3** Click **View System & Troubleshooting Details** link.
 - Step 4** Click **Advanced Troubleshooting**.
 - Step 5** Click **Threat Defense CLI**.
 - Step 6** Select **show** from the **Command** drop-down box.
 - Step 7** Enter **running** in the **Parameter** field.
 - Step 8** Click **Execute**.
-

Download Policy Changes Report for Multiple Devices

Download reports on the policy and object changes made since your last deployment for multiple threat defense devices. You can download the reports in the form of a zip file that contains the following reports:

- A pending changes report for each device, that previews the additions, updates, or deletions in the policy, or the objects that are to be deployed on the device. For more information, see [Deploy Configuration Changes, on page 218](#) and [Deployment Preview](#).
- A consolidated report that categorizes each device based on the report status.

Procedure

- Step 1** Choose **Deploy > Advanced Deploy**.
- Step 2** Check the check box next to the devices for which you want to generate a pending policy changes report, and then click **Pending Changes Reports**.
- Step 3** Click **Pending Changes Reports**. Reports are generated in the background.
- Step 4** On the management center menu bar, choose **Notifications > Tasks** to view the report generation task.

When the report request task is complete, the download link appears within the task notification.

Step 5 Click the **Download Report(s)** link to download the reports.

Compare Policies

To review policy changes for compliance with your organization's standards or to optimize system performance, you can examine the differences between two policies or between a saved policy and the running configuration.

You can compare the following policy types:

- DNS
- File
- Health
- Identity
- Intrusion (Only Snort 2 policies)
- Network Analysis
- SSL

The comparison view displays both policies in a side-by-side format. Differences between the two policies are highlighted:

- Blue indicates that the highlighted setting is different in the two policies, and the difference is noted in red text.
- Green indicates that the highlighted setting appears in one policy but not the other.

Before you begin

You can compare policies only if you have access rights and any required licenses for the specific policy, and you are in the correct domain for configuring the policy.

Procedure

Step 1 Access the management page for the policy you want to compare:

- DNS—**Policies > Access Control > DNS**
- File—**Policies > Access Control > Malware & File**
- Health—**System (⚙️) > Health > Policy**
- Identity—**Policies > Access Control > Identity**
- Intrusion—**Policies > Access Control > Intrusion**

Note You can compare only Snort 2 policies.

- Network Analysis—**Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**

Note If your custom user role limits access to the first path listed here, use the second path to access the policy.

- **SSL—Policies > Access Control > Decryption**

Step 2 Click **Compare Policies**.

Step 3 From the **Compare Against** drop-down list, choose the type of comparison you want to make:

- To compare two different policies, choose **Other Policy**.
- To compare two revisions of the same policy, choose **Other Revision**.
- To compare another policy to the currently active policy, choose **Running Configuration**.

Step 4 Depending on the comparison type you choose, you have the following choices:

- If you are comparing two different policies, choose the policies you want to compare from the **Policy A** and **Policy B** drop-down lists.
- If you are comparing the running configuration to another policy, choose the second policy from the **Policy B** drop-down list.

Step 5 Click **OK**.

Step 6 Review the comparison results:

- Comparison Viewer—To use the comparison viewer to navigate individually through policy differences, click **Previous** or **Next** above the title bar.
- Comparison Report—To generate a PDF report that lists the differences between the two policies, click **Comparison Report**.

Generate Current Policy Reports

For most policies, you can generate two kinds of reports. A report on a single policy provides details on the policy's current saved configuration, while a comparison report lists only the differences between two policies. You can generate a single-policy report for all policy types except health.

Note Intrusion policy reports combine the settings in the base policy with the settings of the policy layers, and make no distinction between which settings originated in the base policy or policy layer.

Before you begin

You can generate policy reports only if you have access rights and any required licenses for the specific policy, and you are in the correct domain for configuring the policy.

Procedure

Step 1 Access the management page for the policy for which you want to generate a report:

- Access Control—**Policies > Access Control**

- DNS—**Policies > Access Control > DNS**
- File—**Policies > Access Control > Malware & File**
- Health—**System (⚙️) > Health > Policy**
- Identity—**Policies > Access Control > Identity**
- Intrusion—**Policies > Access Control > Intrusion**
- NAT—**Devices > NAT**
- Network Analysis—**Policies > Access Control**, then click **Network Analysis Policy** or **Policies > Access Control > Intrusion**, then click **Network Analysis Policies**

Note If your custom user role limits access to the first path listed here, use the second path to access the policy.

- SSL—**Policies > Access Control > Decryption**

Step 2 Click **Report** (📄) next to the policy for which you want to generate a report.

History for Configuration Deployment

Feature	Minimum Management Center	Minimum Threat Defense	Details
Set the number of deployment history files to retain for device rollback.	Any	Any	<p>You can now set the number of deployment history files to retain for device rollback, up to ten (the default). CHAPTER 6

Transparent or Routed Firewall Mode

This chapter describes how to set the firewall mode to routed or transparent, as well as how the firewall works in each firewall mode.

Note The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes. See [Inline Sets and Passive Interfaces, on page 815](#) for more information about IPS-only interfaces. Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode described in this chapter or the firewall-type interfaces.

Caution

- Use FTD CLI commands to set "Firewall Mode."

- [About the Firewall Mode, on page 243](#)
- [Default Settings, on page 251](#)
- [Guidelines for Firewall Mode, on page 251](#)
- [Set the Firewall Mode, on page 252](#)

About the Firewall Mode

The threat defense supports two firewall modes for regular firewall interfaces: Routed Firewall mode and Transparent Firewall mode.

About Routed Firewall Mode

In routed mode, the threat defense device is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet.

With Integrated Routing and Bridging, you can use a "bridge group" where you group together multiple interfaces on a network, and the threat defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. The threat defense device routes between BVIs and regular routed interfaces. If you do not need clustering or EtherChannel member interfaces, you might consider using routed mode instead of transparent

mode. In routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.

About Transparent Firewall Mode

Traditionally, a firewall is a routed hop and acts as a default gateway for hosts that connect to one of its screened subnets. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices. However, like any other firewall, access control between interfaces is controlled, and all of the usual firewall checks are in place.

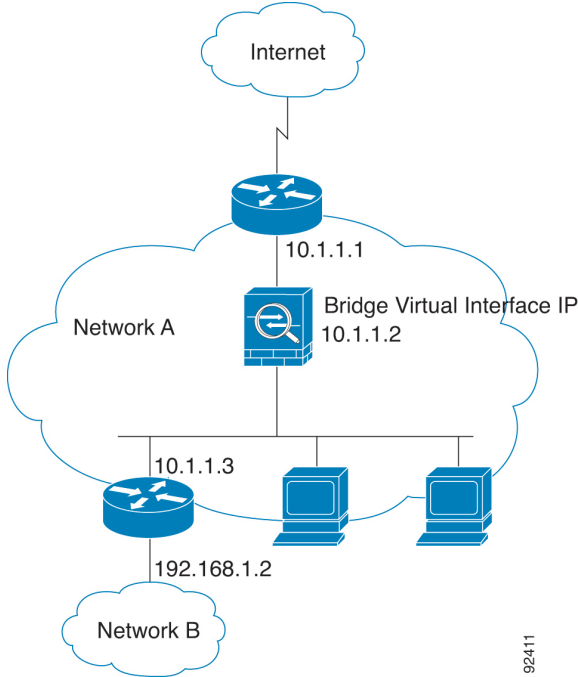

Layer 2 connectivity is achieved by using a "bridge group" where you group together the inside and outside interfaces for a network, and the threat defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. You can have multiple bridge groups for multiple networks. In transparent mode, these bridge groups cannot communicate with each other.

Using the Transparent Firewall in Your Network

The threat defense device connects the same network between its interfaces. Because the firewall is not a routed hop, you can easily introduce a transparent firewall into an existing network.

The following figure shows a typical transparent firewall network where the outside devices are on the same subnet as the inside devices. The inside router and hosts appear to be directly connected to the outside router.

Figure 87: Transparent Firewall Network

92411

Passing Traffic For Routed-Mode Features

For features that are not directly supported on the transparent firewall, you can allow traffic to pass through so that upstream and downstream routers can support the functionality. For example, by using an access rule,

you can allow DHCP traffic (instead of the unsupported DHCP relay feature) or multicast traffic such as that created by IP/TV. You can also establish routing protocol adjacencies through a transparent firewall; you can allow OSPF, RIP, EIGRP, or BGP traffic through based on an access rule. Likewise, protocols like HSRP or VRRP can pass through the threat defense device.

About Bridge Groups

A bridge group is a group of interfaces that the threat defense device bridges instead of routes. Bridge groups are supported in both transparent and routed firewall mode. Like any other firewall interfaces, access control between interfaces is controlled, and all of the usual firewall checks are in place.

Bridge Virtual Interface (BVI)

Each bridge group includes a Bridge Virtual Interface (BVI). The threat defense device uses the BVI IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the bridge group member interfaces. The BVI does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.

In transparent mode: Only bridge group member interfaces are named and can be used with interface-based features.

In routed mode: The BVI acts as the gateway between the bridge group and other routed interfaces. To route between bridge groups/routed interfaces, you must name the BVI. For some interface-based features, you can use the BVI itself:

- DHCPv4 server—Only the BVI supports the DHCPv4 server configuration.
- Static routes—You can configure static routes for the BVI; you cannot configure static routes for the member interfaces.
- Syslog server and other traffic sourced from the threat defense device—When specifying a syslog server (or SNMP server, or other service where the traffic is sourced from the threat defense device), you can specify either the BVI or a member interface.

If you do not name the BVI in routed mode, then the threat defense device does not route bridge group traffic. This configuration replicates transparent firewall mode for the bridge group. If you do not need clustering or EtherChannel member interfaces, you might consider using routed mode instead. In routed mode, you can have one or more isolated bridge groups like in transparent mode, but also have normal routed interfaces as well for a mixed deployment.

Bridge Groups in Transparent Firewall Mode

Bridge group traffic is isolated from other bridge groups; traffic is not routed to another bridge group within the threat defense device, and traffic must exit the threat defense device before it is routed by an external router back to another bridge group in the threat defense device. Although the bridging functions are separate for each bridge group, many other functions are shared between all bridge groups. For example, all bridge groups share a syslog server or AAA server configuration.

You can include multiple interfaces per bridge group. See [Guidelines for Firewall Mode, on page 251](#) for the exact number of bridge groups and interfaces supported. If you use more than 2 interfaces per bridge group, you can control communication between multiple segments on the same network, and not just between inside and outside. For example, if you have three inside segments that you do not want to communicate with each other, you can put each segment on a separate interface, and only allow them to communicate with the outside interface. Or you can customize the access rules between interfaces to allow only as much access as desired.

The following figure shows two networks connected to the threat defense device, which has two bridge groups.

Figure 88: Transparent Firewall Network with Two Bridge Groups

Bridge Groups in Routed Firewall Mode

Bridge group traffic can be routed to other bridge groups or routed interfaces. You can choose to isolate bridge group traffic by not assigning a name to the BVI interface for the bridge group. If you name the BVI, then the BVI participates in routing like any other regular interface.

One use for a bridge group in routed mode is to use extra interfaces on the threat defense instead of an external switch. For example, the default configuration for some devices include an outside interface as a regular interface, and then all other interfaces assigned to the inside bridge group. Because the purpose of this bridge group is to replace an external switch, you need to configure an access policy so all bridge group interfaces can freely communicate.

Figure 89: Routed Firewall Network with an Inside Bridge Group and an Outside Routed Interface

Allowing Layer 3 Traffic

- Unicast IPv4 and IPv6 traffic requires an access rule to be allowed through the bridge group.
- ARPs are allowed through the bridge group in both directions without an access rule. ARP traffic can be controlled by ARP inspection.
- IPv6 neighbor discovery and router solicitation packets can be passed using access rules.
- Broadcast and multicast traffic can be passed using access rules.

Allowed MAC Addresses

The following destination MAC addresses are allowed through the bridge group if allowed by your access policy (see [Allowing Layer 3 Traffic](#), on page 247). Any MAC address not on this list is dropped.

- TRUE broadcast destination MAC address equal to FFFF.FFFF.FFFF
- IPv4 multicast MAC addresses from 0100.5E00.0000 to 0100.5EFE.FFFF
- IPv6 multicast MAC addresses from 3333.0000.0000 to 3333.FFFF.FFFF
- BPDU multicast address equal to 0100.0CCC.CCCD

BPDU Handling

To prevent loops using the Spanning Tree Protocol, BPDUs are passed by default.

By default BPDUs are also forwarded for advanced inspection, which is unnecessary for this type of packet, and which can cause problems if they are blocked due to an inspection restart, for example. We recommend

that you always exempt BPDUs from advanced inspection. To do so, use FlexConfig to configure an EtherType ACL that trusts BPDUs and exempts them from advanced inspection on each member interface. See [#unique_236](#).

The FlexConfig object should deploy the following commands, where you replace <if-name> with an interface name. Add as many access-group commands as needed to cover each bridge group member interface on the device. You can also choose a different name for the ACL.

```
access-list permit-bpdu ethertype trust bpdu
access-group permit-bpdu in interface <if-name>
```

MAC Address vs. Route Lookups

For traffic within a bridge group, the outgoing interface of a packet is determined by performing a destination MAC address lookup instead of a route lookup.

Route lookups, however, are necessary for the following situations:

- Traffic originating on the threat defense device—Add a default/static route on the threat defense device for traffic destined for a remote network where a syslog server, for example, is located.
- Voice over IP (VoIP) and TFTP traffic, and the endpoint is at least one hop away—Add a static route on the threat defense device for traffic destined for the remote endpoint so that secondary connections are successful. The threat defense device creates a temporary "pinhole" in the access control policy to allow the secondary connection; and because the connection might use a different set of IP addresses than the primary connection, the threat defense device needs to perform a route lookup to install the pinhole on the correct interface.

Affected applications include:

- H.323
 - RTSP
 - SIP
 - Skinny (SCCP)
 - SQL*Net
 - SunRPC
 - TFTP
- Traffic at least one hop away for which the threat defense device performs NAT—Configure a static route on the threat defense device for traffic destined for the remote network. You also need a static route on the upstream router for traffic destined for the mapped addresses to be sent to the threat defense device.

This routing requirement is also true for embedded IP addresses for VoIP and DNS with NAT enabled, and the embedded IP addresses are at least one hop away. The threat defense device needs to identify the correct egress interface so it can perform the translation.

Figure 90: NAT Example: NAT within a Bridge Group

Unsupported Features for Bridge Groups in Transparent Mode

The following table lists the features are not supported in bridge groups in transparent mode.

Table 15: Unsupported Features in Transparent Mode

Feature	Description
Dynamic DNS	—
DHCP relay	The transparent firewall can act as a DHCPv4 server, but it does not support DHCP relay. DHCP relay is not required because you can allow DHCP traffic to pass through using two access rules: one that allows DCHP requests from the inside interface to the outside, and one that allows the replies from the server in the other direction.

Feature	Description
Dynamic routing protocols	You can, however, add static routes for traffic originating on the threat defense device for bridge group member interfaces. You can also allow dynamic routing protocols through the threat defense device using an access rule.
Multicast IP routing	You can allow multicast traffic through the threat defense device by allowing it in an access rule.
QoS	—
VPN termination for through traffic	The transparent firewall supports site-to-site VPN tunnels for management connections only on bridge group member interfaces. It does not terminate VPN connections for traffic through the threat defense device. You can pass VPN traffic through the ASA using an access rule, but it does not terminate non-management connections.

Unsupported Features for Bridge Groups in Routed Mode

The following table lists the features are not supported in bridge groups in routed mode.

Table 16: Unsupported Features in Routed Mode

Feature	Description
EtherChannel member interfaces	Only physical interfaces, redundant interfaces, and subinterfaces are supported as bridge group member interfaces. Management interfaces are also not supported.
Clustering	Bridge groups are not supported in clustering.
Dynamic DNS	—
DHCP relay	The routed firewall can act as a DHCPv4 server, but it does not support DHCP relay on BVIs or bridge group member interfaces.
Dynamic routing protocols	You can, however, add static routes for BVIs. You can also allow dynamic routing protocols through the threat defense device using an access rule. Non-bridge group interfaces support dynamic routing.
Multicast IP routing	You can allow multicast traffic through the threat defense device by allowing it in an access rule. Non-bridge group interfaces support multicast routing.
QoS	Non-bridge group interfaces support QoS.

Feature	Description
VPN termination for through traffic	<p>You cannot terminate a VPN connection on the BVI. Non-bridge group interfaces support VPN.</p> <p>Bridge group member interfaces support site-to-site VPN tunnels for management connections only. It does not terminate VPN connections for traffic through the threat defense device. You can pass VPN traffic through the bridge group using an access rule, but it does not terminate non-management connections.</p>

Default Settings

Bridge Group Defaults

By default, all ARP packets are passed within the bridge group.

Guidelines for Firewall Mode

Bridge Group Guidelines (Transparent and Routed Mode)

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The threat defense device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.
- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the threat defense device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).
- Management interfaces are not supported as bridge group members.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the threat defense virtual on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
- For the Firepower 1010, you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.
- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.

- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the threat defense as the default gateway.
- In transparent mode, the *default* route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.
- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, threat defense-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the threat defense when using bridge group members. If there are two neighbors on either side of the threat defense running BFD, then the threat defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

Set the Firewall Mode

You can set the firewall mode when you perform the initial system setup at the CLI. We recommend setting the firewall mode during setup because changing the firewall mode erases your configuration to ensure you do not have incompatible settings. If you need to change the firewall mode later, you must do so from the CLI.

Procedure

Step 1 Unregister the threat defense device from the management center.

You cannot change the mode until you deregister the device.

- Choose **Devices > Device Management**.
- Next to the device you want to unregister, click **More** (⋮), and then click **Delete**.

Step 2 Access the threat defense device CLI, preferably from the console port.

Step 3 Change the firewall mode:

configure firewall [routed | transparent]

Example:

```
> configure firewall transparent
This will destroy the current interface configurations, are you sure that you want to
proceed? [y/N] y
The firewall mode was changed successfully.
```

- Step 4** Re-register with the management center. See [Complete the Threat Defense Initial Configuration Using the CLI, on page 19](#) and [Add a Device to the Management Center Using a Registration Key, on page 27](#).
-

CHAPTER 7

Logical Devices on the Firepower 4100/9300

The Firepower 4100/9300 is a flexible security platform on which you can install one or more *logical devices*. Before you can add the threat defense to the management center, you must configure chassis interfaces, add a logical device, and assign interfaces to the device on the Firepower 4100/9300 chassis using the Secure Firewall chassis manager or the FXOS CLI. This chapter describes basic interface configuration and how to add a standalone or High Availability logical device using the Secure Firewall chassis manager. To add a clustered logical device, see [Clustering for the Firepower 4100/9300, on page 623](#). To use the FXOS CLI, see the FXOS CLI configuration guide. For more advanced FXOS procedures and troubleshooting, see the FXOS configuration guide.

- [About Interfaces, on page 255](#)
- [About Logical Devices, on page 269](#)
- [Licenses for Container Instances, on page 278](#)
- [Requirements and Prerequisites for Logical Devices, on page 279](#)
- [Guidelines and Limitations for Logical Devices, on page 286](#)
- [Configure Interfaces, on page 289](#)
- [Configure Logical Devices, on page 294](#)
- [History for Logical Devices, on page 306](#)

About Interfaces

The Firepower 4100/9300 chassis supports physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces. EtherChannel interfaces can include up to 16 member interfaces of the same type.

Chassis Management Interface

The chassis management interface is used for management of the FXOS Chassis by SSH or chassis manager. This interface appears at the top of the **Interfaces** tab as **MGMT**, and you can only enable or disable this interface on the **Interfaces** tab. This interface is separate from the mgmt-type interface that you assign to the logical devices for application management.

To configure parameters for this interface, you must configure them from the CLI. To view information about this interface in the FXOS CLI, connect to local management and show the management port:

```
Firepower # connect local-mgmt
```

```
Firepower(local-mgmt) # show mgmt-port
```

Note that the chassis management interface remains up even if the physical cable or SFP module are unplugged, or if the **mgmt-port shut** command is performed.

Note The chassis management interface does not support jumbo frames.

Interface Types

Physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces can be one of the following types:

- **Data**—Use for regular data. Data interfaces cannot be shared between logical devices, and logical devices cannot communicate over the backplane to other logical devices. For traffic on Data interfaces, all traffic must exit the chassis on one interface and return on another interface to reach another logical device.
- **Data-sharing**—Use for regular data. Only supported with container instances, these data interfaces can be shared by one or more logical devices/container instances (threat defense-using-management center only). Each container instance can communicate over the backplane with all other instances that share this interface. Shared interfaces can affect the number of container instances you can deploy. Shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode), inline sets, passive interfaces, clusters, or failover links.
- **Mgmt**—Use to manage application instances. These interfaces can be shared by one or more logical devices to access external hosts; logical devices cannot communicate over this interface with other logical devices that share the interface. You can only assign one management interface per logical device. Depending on your application and manager, you can later enable management from a data interface; but you must assign a Management interface to the logical device even if you don't intend to use it after you enable data management. For information about the separate chassis management interface, see [Chassis Management Interface, on page 255](#).

Note Mgmt interface change will cause reboot of the logical device, for example one change mgmt from e1/1 to e1/2 will cause the logical device to reboot to apply the new management.

- **Eventing**—Use as a secondary management interface for threat defense-using-management center devices. To use this interface, you must configure its IP address and other parameters at the threat defense CLI. For example, you can separate management traffic from events (such as web events). See the [management center configuration guide](#) for more information. Eventing interfaces can be shared by one or more logical devices to access external hosts; logical devices cannot communicate over this interface with other logical devices that share the interface. If you later configure a data interface for management, you cannot use a separate eventing interface.

Note A virtual Ethernet interface is allocated when each application instance is installed. If the application does not use an eventing interface, then the virtual interface will be in an admin down state.

```
Firepower # show interface Vethernet775
Firepower # Vethernet775 is down (Administratively down)
Bound Interface is Ethernet1/10
Port description is server 1/1, VNIC ext-mgmt-nic5
```

- **Cluster**—Use as the cluster control link for a clustered logical device. By default, the cluster control link is automatically created on Port-channel 48. The Cluster type is only supported on EtherChannel interfaces. For multi-instance clustering, you cannot share a Cluster-type interface across devices. You can add VLAN subinterfaces to the Cluster EtherChannel to provide separate cluster control links per cluster. If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster. The device manager and CDO does not support clustering.

Note This chapter discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the threat defense application. See [FXOS Interfaces vs. Application Interfaces](#), on page 258 for more information.

See the following table for interface type support for the threat defense and ASA applications in standalone and cluster deployments.

Table 17: Interface Type Support

Application		Data	Data: Subinterface	Data-Sharing	Data-Sharing: Subinterface	Mgmt	Eventing	Cluster (EtherChannel only)	Cluster: Subinterface
Threat Defense	Standalone Native Instance	Yes	—	—	—	Yes	Yes	—	—
	Standalone Container Instance	Yes	Yes	Yes	Yes	Yes	Yes	—	—
	Cluster Native Instance	Yes (EtherChannel only for inter-chassis cluster)	—	—	—	Yes	Yes	Yes	—
	Cluster Container Instance	Yes (EtherChannel only for inter-chassis cluster)	—	—	—	Yes	Yes	Yes	Yes

Application		Data	Data: Subinterface	Data-Sharing	Data-Sharing: Subinterface	Mgmt	Eventing	Cluster (EtherChannel only)	Cluster: Subinterface
ASA	Standalone Native Instance	Yes	—	—	—	Yes	—	Yes	—
	Cluster Native Instance	Yes (EtherChannel only for inter-chassis cluster)	—	—	—	Yes	—	Yes	—

FXOS Interfaces vs. Application Interfaces

The Firepower 4100/9300 manages the basic Ethernet settings of physical interfaces, VLAN subinterfaces for container instances, and EtherChannel (port-channel) interfaces. Within the application, you configure higher level settings. For example, you can only create EtherChannels in FXOS; but you can assign an IP address to the EtherChannel within the application.

The following sections describe the interaction between FXOS and the application for interfaces.

VLAN Subinterfaces

For all logical devices, you can create VLAN subinterfaces within the application.

For container instances in standalone mode only, you can *also* create VLAN subinterfaces in FXOS. Multi-instance clusters do not support subinterfaces in FXOS except on the Cluster-type interface. Application-defined subinterfaces are not subject to the FXOS limit. Choosing in which operating system to create subinterfaces depends on your network deployment and personal preference. For example, to share a subinterface, you must create the subinterface in FXOS. Another scenario that favors FXOS subinterfaces comprises allocating separate subinterface groups on a single interface to multiple instances. For example, you want to use Port-channel1 with VLAN 2–11 on instance A, VLAN 12–21 on instance B, and VLAN 22–31 on instance C. If you create these subinterfaces within the application, then you would have to share the parent interface in FXOS, which may not be desirable. See the following illustration that shows the three ways you can accomplish this scenario:

Figure 91: VLANs in FXOS vs. the Application for Container Instances

Independent Interface States in the Chassis and in the Application

You can administratively enable and disable interfaces in both the chassis and in the application. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and application.

The default state of an interface within the application depends on the type of interface. For example, the physical interface or EtherChannel is disabled by default within the application, but a subinterface is enabled by default.

Shared Interface Scalability

Instances can share data-sharing type interfaces. This capability lets you conserve physical interface usage as well as support flexible networking deployments. When you share an interface, the chassis uses unique MAC addresses to forward traffic to the correct instance. However, shared interfaces can cause the forwarding table to grow large due to the need for a full mesh topology within the chassis (every instance must be able to communicate with every other instance that is sharing the same interface). Therefore, there are limits to how many interfaces you can share.

In addition to the forwarding table, the chassis maintains a VLAN group table for VLAN subinterface forwarding. You can create up to 500 VLAN subinterfaces.

See the following limits for shared interface allocation:

Shared Interface Best Practices

For optimal scalability of the forwarding table, share as few interfaces as possible. Instead, you can create up to 500 VLAN subinterfaces on one or more physical interfaces and then divide the VLANs among the container instances.

When sharing interfaces, follow these practices in the order of most scalable to least scalable:

1. Best—Share subinterfaces under a single parent, and use the same set of subinterfaces with the same group of instances.

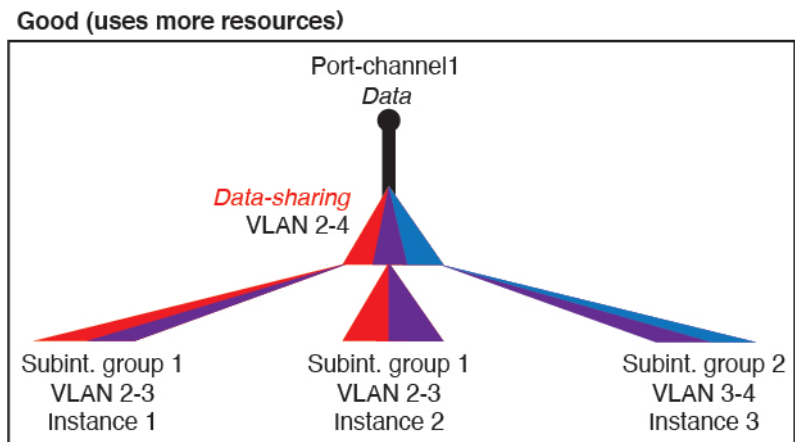

For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel: Port-Channel1.2, 3, and 4 instead of Port-Channel2, Port-Channel3, and Port-Channel4. When you share subinterfaces from a single parent, the VLAN group table provides better scaling of the forwarding table than when sharing physical/EtherChannel interfaces or subinterfaces across parents.

Figure 92: Best: Shared Subinterface Group on One Parent

If you do not share the same set of subinterfaces with a group of instances, your configuration can cause more resource usage (more VLAN groups). For example, share Port-Channel1.2, 3, and 4 with instances 1, 2, and 3 (one VLAN group) instead of sharing Port-Channel1.2 and 3 with instances 1 and 2, while sharing Port-Channel1.3 and 4 with instance 3 (two VLAN groups).

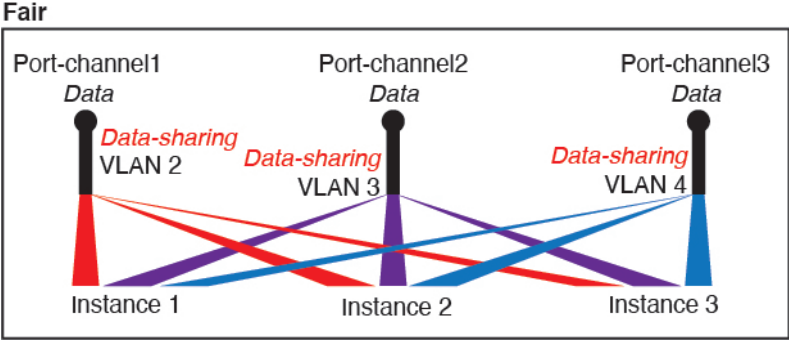

Figure 93: Good: Sharing Multiple Subinterface Groups on One Parent

2. Fair—Share subinterfaces across parents.

For example, share Port-Channel1.2, Port-Channel2.3, and Port-Channel3.4 instead of Port-Channel2, Port-Channel4, and Port-Channel4. Although this usage is not as efficient as only sharing subinterfaces on the same parent, it still takes advantage of VLAN groups.

Figure 94: Fair: Shared Subinterfaces on Separate Parents

- 3. Worst—Share individual parent interfaces (physical or EtherChannel).
This method uses the most forwarding table entries.

Figure 95: Worst: Shared Parent Interfaces

Shared Interface Usage Examples

See the following tables for examples of interface sharing and scalability. The below scenarios assume use of one physical/EtherChannel interface for management shared across all instances, and another physical or EtherChannel interface with dedicated subinterfaces for use with High Availability.

- [Table 18: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with Three SM-44s, on page 263](#)
- [Table 19: Subinterfaces on One Parent and Instances on a Firepower 9300 with Three SM-44s, on page 264](#)
- [Table 20: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with One SM-44, on page 266](#)
- [Table 21: Subinterfaces on One Parent and Instances on a Firepower 9300 with One SM-44, on page 267](#)

Firepower 9300 with Three SM-44s

The following table applies to three SM-44 security modules on a 9300 using only physical interfaces or EtherChannels. Without subinterfaces, the maximum number of interfaces are limited. Moreover, sharing multiple physical interfaces uses more forwarding table resources than sharing multiple subinterfaces.

Each SM-44 module can support up to 14 instances. Instances are split between modules as necessary to stay within limits.

Table 18: Physical/EtherChannel Interfaces and Instances on a Firepower 9300 with Three SM-44s

Dedicated Interfaces	Shared Interfaces	Number of Instances	% Forwarding Table Used
32: <ul style="list-style-type: none"> • 8 • 8 • 8 • 8 	0	4: <ul style="list-style-type: none"> • Instance 1 • Instance 2 • Instance 3 • Instance 4 	16%

Viewing Shared Interface Resources

To view forwarding table and VLAN group usage, see the **Devices & Network > Interface Forwarding Utilization** area. For example:

Inline Set Link State Propagation for the Threat Defense

An inline set acts like a bump on the wire, and binds two interfaces together to slot into an existing network. This function allows the system to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of an inline set unless explicitly dropped.

When you configure an inline set in the threat defense application and enable link state propagation, the threat defense sends inline set membership to the FXOS chassis. Link state propagation means that the chassis automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the chassis senses the change and updates the link state of the other interface to match it. Note that the chassis requires up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

Note Do not enable Hardware Bypass and link state propagation for the same inline set.

About Logical Devices

A logical device lets you run one application instance (either ASA or threat defense) and also one optional decorator application (Radware DefensePro) to form a service chain.

When you add a logical device, you also define the application instance type and version, assign interfaces, and configure bootstrap settings that are pushed to the application configuration.

Note For the Firepower 9300, you can install different application types (ASA and threat defense) on separate modules in the chassis. You can also run different versions of an application instance type on separate modules.

Standalone and Clustered Logical Devices

You can add the following logical device types:

- Standalone—A standalone logical device operates as a standalone unit or as a unit in a High Availability pair.
- Cluster—A clustered logical device lets you group multiple units together, providing all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. Multiple module devices, like the Firepower 9300, support intra-chassis clustering. For the Firepower 9300, all three modules must participate in the cluster, for both native and container instances. The device manager does not support clustering.

Logical Device Application Instances: Container and Native

Application instances run in the following deployment types:

- Native instance—A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance.
- Container instance—A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances. Multi-instance capability is only supported for the threat defense using management center; it is not supported for the ASA or the threat defense using device manager.

Note Multi-instance capability is similar to ASA multiple context mode, although the implementation is different. Multiple context mode partitions a single application instance, while multi-instance capability allows independent container instances. Container instances allow hard resource separation, separate configuration management, separate reloads, separate software updates, and full threat defense feature support. Multiple context mode, due to shared resources, supports more contexts on a given platform. Multiple context mode is not available on the threat defense.

For the Firepower 9300, you can use a native instance on some modules, and container instances on the other module(s).

Container Instance Interfaces

To provide flexible physical interface use for container instances, you can create VLAN subinterfaces in FXOS and also share interfaces (VLAN or physical) between multiple instances. Native instances cannot use VLAN subinterfaces or shared interfaces. A multi-instance cluster cannot use VLAN subinterfaces or shared interfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel. See [Shared Interface Scalability, on page 260](#) and [Add a VLAN Subinterface for Container Instances, on page 293](#).

Note This document discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the threat defense application. See [FXOS Interfaces vs. Application Interfaces, on page 258](#) for more information.

How the Chassis Classifies Packets

Each packet that enters the chassis must be classified, so that the chassis can determine to which instance to send a packet.

- **Unique Interfaces**—If only one instance is associated with the ingress interface, the chassis classifies the packet into that instance. For bridge group member interfaces (in transparent mode or routed mode), inline sets, or passive interfaces, this method is used to classify packets at all times.
- **Unique MAC Addresses**—The chassis automatically generates unique MAC addresses for all interfaces, including shared interfaces. If multiple instances share an interface, then the classifier uses unique MAC addresses assigned to the interface in each instance. An upstream router cannot route directly to an instance without unique MAC addresses. You can also set the MAC addresses manually when you configure each interface within the application.

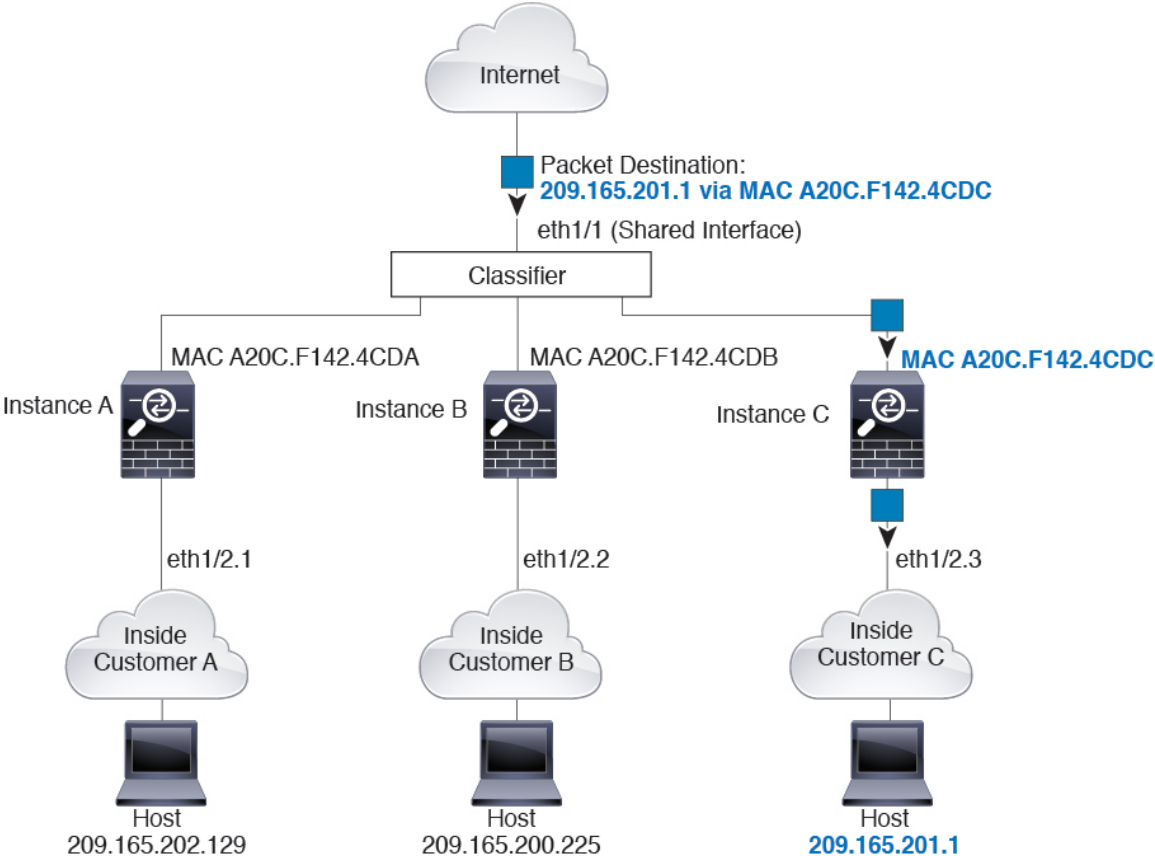

Note If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each instance.

Classification Examples

Packet Classification with a Shared Interface Using MAC Addresses

The following figure shows multiple instances sharing an outside interface. The classifier assigns the packet to Instance C because Instance C includes the MAC address to which the router sends the packet.

Figure 96: Packet Classification with a Shared Interface Using MAC Addresses

Incoming Traffic from Inside Networks

Note that all new incoming traffic must be classified, even from inside networks. The following figure shows a host on the Instance C inside network accessing the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

Figure 97: Incoming Traffic from Inside Networks

Transparent Firewall Instances

For transparent firewalls, you must use unique interfaces. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

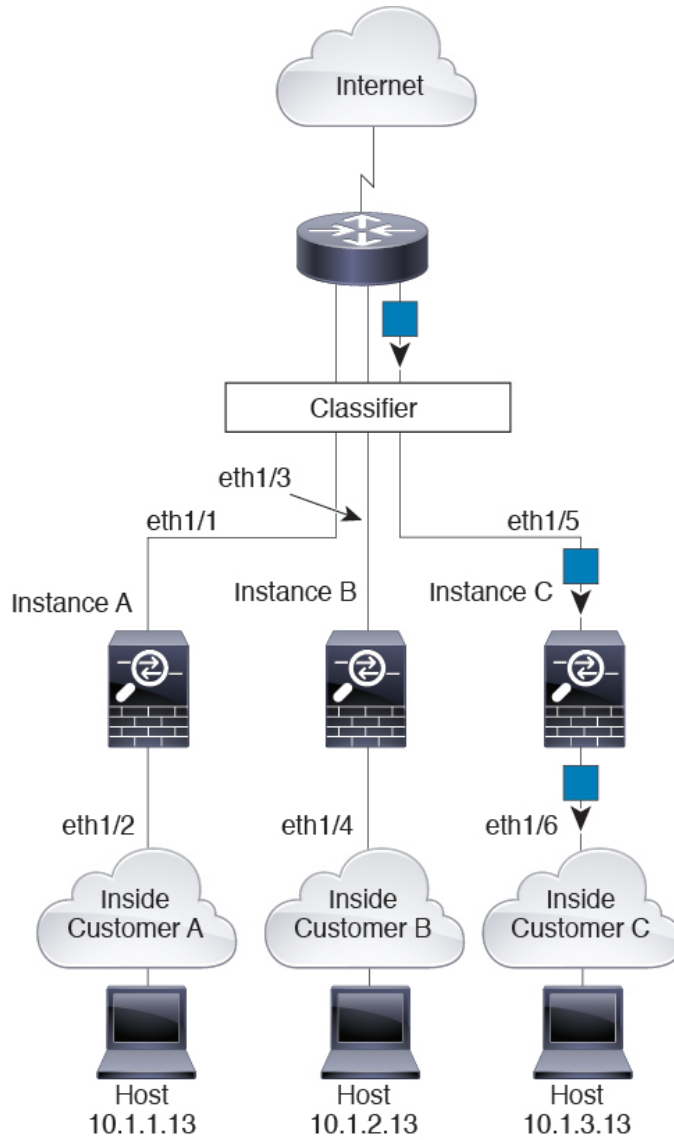

Figure 98: Transparent Firewall Instances

Inline Sets

For inline sets, you must use unique interfaces and they must be physical interfaces or EtherChannels. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/5, which is assigned to Instance C.

Figure 99: Inline Sets

Cascading Container Instances

Placing an instance directly in front of another instance is called *cascading instances*; the outside interface of one instance is the same interface as the inside interface of another instance. You might want to cascade instances if you want to simplify the configuration of some instances by configuring shared parameters in the top instance.

The following figure shows a gateway instance with two instances behind the gateway.

Figure 100: Cascading Instances

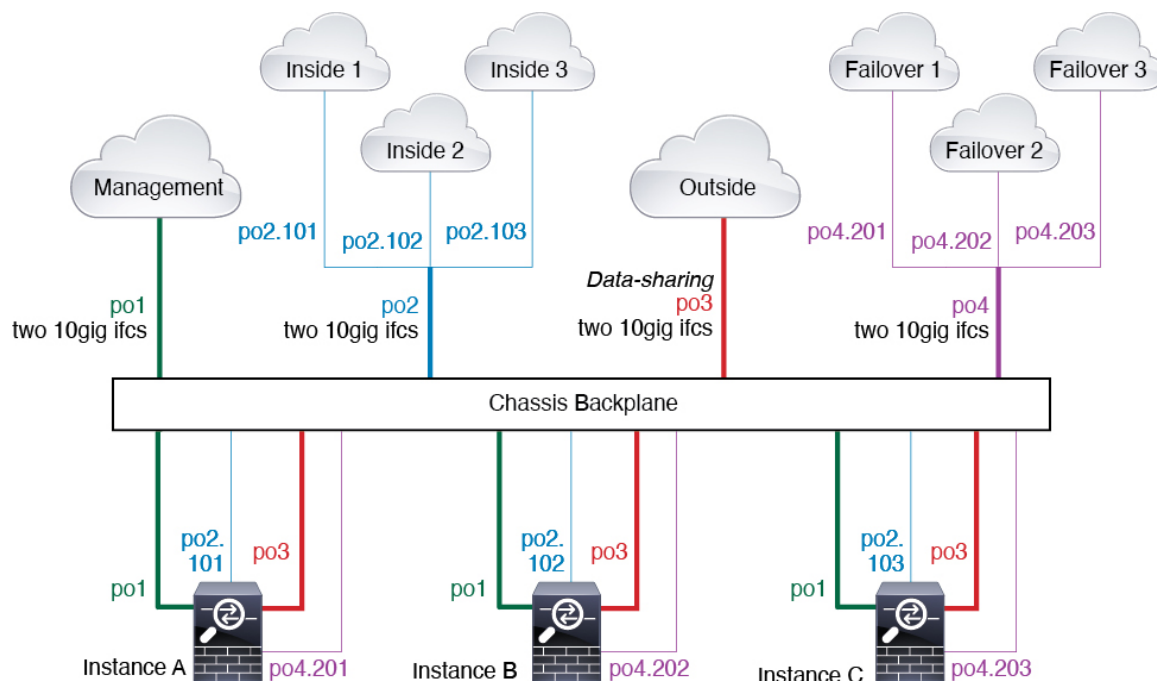

Note Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.

Typical Multi-Instance Deployment

The following example includes three container instances in routed firewall mode. They include the following interfaces:

- **Management**—All instances use the Port-Channel1 interface (management type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same management network.
- **Inside**—Each instance uses a subinterface on Port-Channel2 (data type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Each subinterface is on a separate network.

- Outside—All instances use the Port-Channel3 interface (data-sharing type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same outside network.
- Failover—Each instance uses a subinterface on Port-Channel4 (data type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Each subinterface is on a separate network.

Automatic MAC Addresses for Container Instance Interfaces

The chassis automatically generates MAC addresses for instance interfaces, and guarantees that a shared interface in each instance uses a unique MAC address.

If you manually assign a MAC address to a shared interface within the instance, then the manually-assigned MAC address is used. If you later remove the manual MAC address, the autogenerated address is used. In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, we suggest that you manually set the MAC address for the interface within the instance.

Because autogenerated addresses start with A2, you should not start manual MAC addresses with A2 due to the risk of overlapping addresses.

The chassis generates the MAC address using the following format:

A2xx.yyyz.zzzz

Where xx.yy is a user-defined prefix or a system-defined prefix, and zz.zzzz is an internal counter generated by the chassis. The system-defined prefix matches the lower 2 bytes of the first MAC address in the burned-in MAC address pool that is programmed into the IDPROM. Use **connect fxos**, then **show module** to view the MAC address pool. For example, if the range of MAC addresses shown for module 1 is b0aa.772f.f0b0 to b0aa.772f.f0bf, then the system prefix will be f0b0.

The user-defined prefix is an integer that is converted into hexadecimal. For an example of how the user-defined prefix is used, if you set a prefix of 77, then the chassis converts 77 into the hexadecimal value 004D (yyxx). When used in the MAC address, the prefix is reversed (xyyy) to match the chassis native form:

A24D.00zz.zzzz

For a prefix of 1009 (03F1), the MAC address is:

A2F1.03zz.zzzz

Container Instance Resource Management

To specify resource usage per container instance, create one or more resource profiles in FXOS. When you deploy the logical device/application instance, you specify the resource profile that you want to use. The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance. To view the available resources per model, see [Requirements and Prerequisites for Container Instances, on page 281](#). To add a resource profile, see [Add a Resource Profile for Container Instances, on page 294](#).

Performance Scaling Factor for Multi-Instance Capability

The maximum throughput (connections, VPN sessions, and TLS proxy sessions) for a platform is calculated for a native instance's use of memory and CPU (and this value is shown in **show resource usage**). If you use multiple instances, then you need to calculate the throughput based on the percentage of CPU cores that you assign to the instance. For example, if you use a container instance with 50% of the cores, then you should initially calculate 50% of the throughput. Moreover, the throughput available to a container instance may be less than that available to a native instance.

For detailed instructions on calculating the throughput for instances, see <https://www.cisco.com/c/en/us/products/collateral/security/firewalls/white-paper-c11-744750.html>.

Container Instances and High Availability

You can use High Availability using a container instance on 2 separate chassis; for example, if you have 2 chassis, each with 10 instances, you can create 10 High Availability pairs. Note that High Availability is not configured in FXOS; configure each High Availability pair in the application manager.

For detailed requirements, see [Requirements and Prerequisites for High Availability, on page 282](#) and [Add a High Availability Pair, on page 301](#).

Container Instances and Clustering

You can create a cluster of container instances using one container instance per security module/engine. See [Requirements and Prerequisites for Clustering, on page 282](#) for detailed requirements.

Licenses for Container Instances

All licenses are consumed per security engine/chassis (for the Firepower 4100) or per security module (for the Firepower 9300), and not per container instance. See the following details:

- Essentials licenses are automatically assigned: one per security module/engine.
- Feature licenses are manually assigned to each instance; but you only consume one license per feature per security module/engine. For example, for the Firepower 9300 with 3 security modules, you only need

one URL Filtering license per module for a total of 3 licenses, regardless of the number of instances in use.

For example:

Table 22: Sample License Usage for Container Instances on a Firepower 9300

Firepower 9300	Instance	Licenses
Security Module 1	Instance 1	Essentials, URL Filtering, Malware Defense
	Instance 2	Essentials, URL Filtering
	Instance 3	Essentials, URL Filtering
Security Module 2	Instance 4	Essentials, IPS
	Instance 5	Essentials, URL Filtering, Malware Defense, IPS
Security Module 3	Instance 6	Essentials, Malware Defense, IPS
	Instance 7	Essentials, IPS

Table 23: Total Number of Licenses

Essentials	URL Filtering	Malware Defense	IPS
3	2	3	2

Requirements and Prerequisites for Logical Devices

See the following sections for requirements and prerequisites.

Requirements and Prerequisites for Hardware and Software Combinations

The Firepower 4100/9300 supports multiple models, security modules, application types, and high availability and scalability features. See the following requirements for allowed combinations.

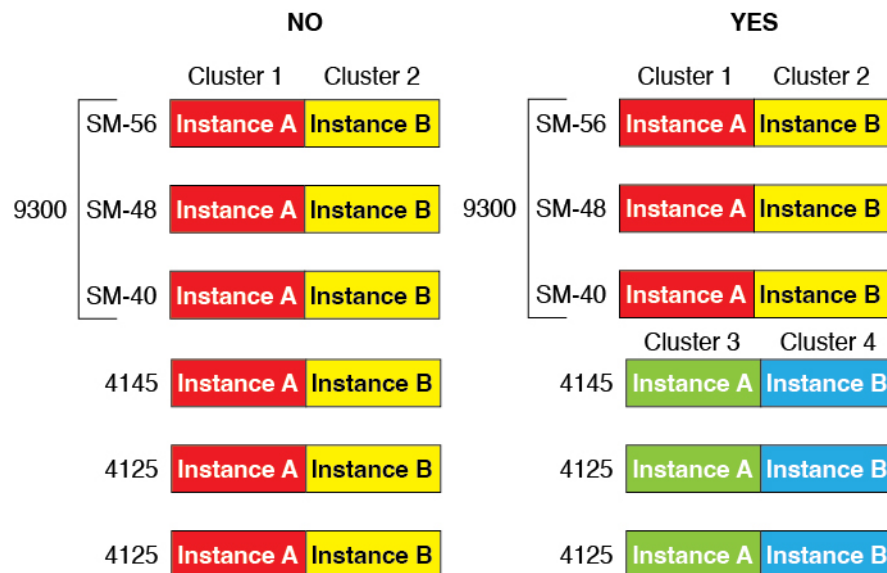

Firepower 9300 Requirements

The Firepower 9300 includes 3 security module slots and multiple types of security modules. See the following requirements:

- **Security Module Types**—You can install modules of different types in the Firepower 9300. For example, you can install the SM-48 as module 1, SM-40 as module 2, and SM-56 as module 3.
- **Native instance Clustering**—All security modules in the cluster, whether it is intra-chassis or inter-chassis, must be the same type. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots. For

example, you can install 2 SM-40s in chassis 1, and 3 SM-40s in chassis 2. You cannot use clustering if you install 1 SM-48 and 2 SM-40s in the same chassis.

- Container instance Clustering—You can create a cluster using instances on different model types. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. You *cannot* mix the Firepower 9300 and the Firepower 4100 in the same cluster, however.

- High Availability—High Availability is only supported between same-type modules on the Firepower 9300. However, the two chassis can include mixed modules. For example, each chassis has an SM-40, SM-48, and SM-56. You can create High Availability pairs between the SM-40 modules, between the SM-48 modules, and between the SM-56 modules.
- ASA and threat defense application types—You can install different application types on separate modules in the chassis. For example, you can install ASA on module 1 and module 2, and threat defense on module 3.
- ASA or threat defense versions—You can run different versions of an application instance type on separate modules, or as separate container instances on the same module. For example, you can install the threat defense 6.3 on module 1, threat defense 6.4 on module 2, and threat defense 6.5 on module 3.

Firepower 4100 Requirements

The Firepower 4100 comes in multiple models. See the following requirements:

- Native and Container instances—When you install a container instance on a Firepower 4100, that device can only support other container instances. A native instance uses all of the resources for a device, so you can only install a single native instance on the device.
- Native instance Clustering—All chassis in the cluster must be the same model.
- Container instance Clustering—You can create a cluster using instances on different model types. For example, you can create a cluster using an instance on a Firepower 4145 and a 4125. You *cannot* mix the Firepower 9300 and the Firepower 4100 in the same cluster, however.

- High Availability—High Availability is only supported between same-type models.
- ASA and threat defense application types—The Firepower 4100 can only run a single application type.
- The threat defense container instance versions—You can run different versions of threat defense as separate container instances on the same module.

Requirements and Prerequisites for Container Instances

For information about high-availability or clustering requirements with multi-instance, see [Requirements and Prerequisites for High Availability, on page 282](#) and see [Requirements and Prerequisites for Clustering, on page 282](#).

Supported Application Types

- The threat defense using management center

Maximum Container Instances and Resources per Model

For each container instance, you can specify the number of CPU cores to assign to the instance. RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

Table 24: Maximum Container Instances and Resources per Model

Model	Max. Container Instances	Available CPU Cores	Available RAM	Available Disk Space
Firepower 4112	3	22	78 GB	308 GB
Firepower 4115	7	46	162 GB	308 GB
Firepower 4125	10	62	162 GB	644 GB
Firepower 4140	7	70	222 GB	311.8 GB

Model	Max. Container Instances	Available CPU Cores	Available RAM	Available Disk Space
Firepower 4145	14	86	344 GB	608 GB
Firepower 9300 SM-40 security module	13	78	334 GB	1359 GB
Firepower 9300 SM-48 security module	15	94	334 GB	1341 GB
Firepower 9300 SM-56 security module	18	110	334 GB	1314 GB

Management Center Requirements

For all instances on a Firepower 4100 chassis or Firepower 9300 module, you must use the same management center due to the licensing implementation.

Requirements and Prerequisites for High Availability

- The two units in a High Availability Failover configuration must:
 - Be on a separate chassis; intra-chassis High Availability for the Firepower 9300 is not supported.
 - Be the same model.
 - Have the same interfaces assigned to the High Availability logical devices.
 - Have the same number and types of interfaces. All interfaces must be preconfigured in FXOS identically before you enable High Availability.
- High Availability is only supported between same-type modules on the Firepower 9300; but the two chassis can include mixed modules. For example, each chassis has an SM-56, SM-48, and SM-40. You can create High Availability pairs between the SM-56 modules, between the SM-48 modules, and between the SM-40 modules.
- For container instances, each unit must use the same resource profile attributes.
- For container instances: Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.
- For other High Availability system requirements, see [High Availability System Requirements, on page 377](#).

Requirements and Prerequisites for Clustering

Cluster Model Support

The Threat Defense supports clustering on the following models:

- Firepower 9300— You can include up to 16 nodes in the cluster. For example, you can use 1 module in 16 chassis, or 2 modules in 8 chassis, or any combination that provides a maximum of 16 modules. Supports clustering with multiple chassis and clustering isolated to security modules within one chassis.
- Firepower 4100—Supported for up to 16 nodes using clustering with multiple chassis.

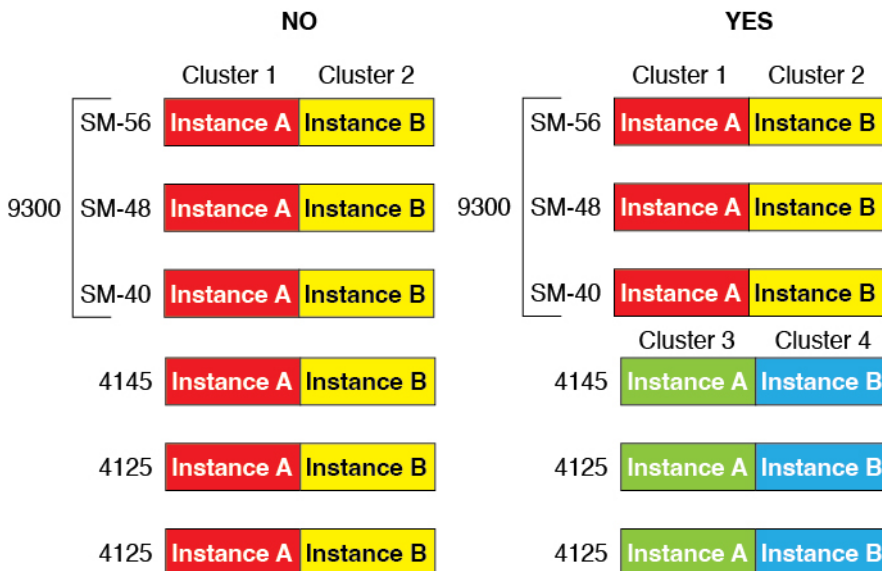

User Roles

- Admin
- Access Admin
- Network Admin

Clustering Hardware and Software Requirements

All chassis in a cluster:

- Native instance clustering—For the Firepower 4100: All chassis must be the same model. For the Firepower 9300: All security modules must be the same type. For example, if you use clustering, all modules in the Firepower 9300 must be SM-40s. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots.
- Container instance clustering—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Must run the identical FXOS and application software except at the time of an image upgrade. Mismatched software versions can lead to poor performance, so be sure to upgrade all nodes in the same maintenance window.

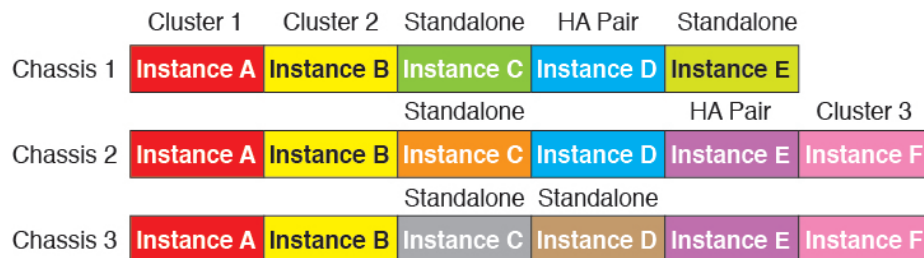

- Must include the same interface configuration for interfaces you assign to the cluster, such as the same Management interface, EtherChannels, active interfaces, speed and duplex, and so on. You can use different network module types on the chassis as long as the capacity matches for the same interface IDs and interfaces can successfully bundle in the same spanned EtherChannel. Note that all data interfaces must be EtherChannels in clusters with multiple chassis. If you change the interfaces in FXOS after you enable clustering (by adding or removing interface modules, or configuring EtherChannels, for example), then perform the same changes on each chassis, starting with the data nodes, and ending with the control node.
- Must use the same NTP server. For threat defense, the management center must also use the same NTP server. Do not set the time manually.

Multi-Instance Clustering Requirements

- No intra-security-module/engine clustering—For a given cluster, you can only use a single container instance per security module/engine. You cannot add 2 container instances to the same cluster if they are running on the same module.

- Mix and match clusters and standalone instances—Not all container instances on a security module/engine need to belong to a cluster. You can use some instances as standalone or High Availability nodes. You can also create multiple clusters using separate instances on the same security module/engine.

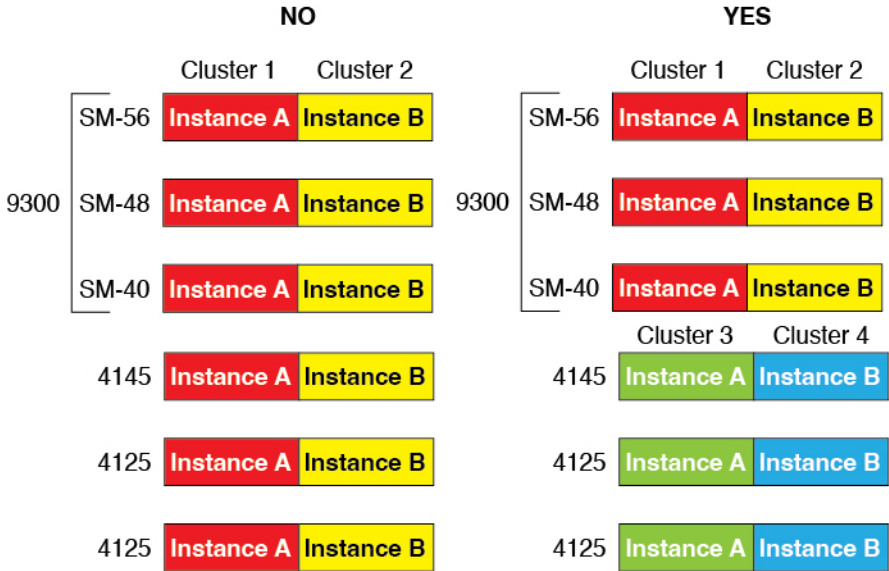

- All 3 modules in a Firepower 9300 must belong to the cluster—For the Firepower 9300, a cluster requires a single container instance on all 3 modules. You cannot create a cluster using instances on module 1 and 2, and then use a native instance on module 3, or example.

- Match resource profiles—We recommend that each node in the cluster use the same resource profile attributes; however, mismatched resources are allowed when changing cluster nodes to a different resource profile, or when using different models.
- Dedicated cluster control link—For clusters with multiple chassis, each cluster needs a dedicated cluster control link. For example, each cluster can use a separate subinterface on the same cluster-type EtherChannel, or use separate EtherChannels.

- No shared interfaces—Shared-type interfaces are not supported with clustering. However, the same Management and Eventing interfaces can be used by multiple clusters.
- No subinterfaces—A multi-instance cluster cannot use FXOS-defined VLAN subinterfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel.
- Mix chassis models—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Maximum 6 nodes—You can use up to six container instances in a cluster.

Switch Requirements

- Be sure to complete the switch configuration and successfully connect all the EtherChannels from the chassis to the switch(es) before you configure clustering on the Firepower 4100/9300 chassis.
- For supported switch characteristics, see [Cisco FXOS Compatibility](#).

Guidelines and Limitations for Logical Devices

See the following sections for guidelines and limitations.

Guidelines and Limitations for Interfaces

VLAN Subinterfaces

- This document discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the threat defense application. See [FXOS Interfaces vs. Application Interfaces, on page 258](#) for more information.
- Subinterfaces (and the parent interfaces) can only be assigned to container instances.

Note If you assign a parent interface to a container instance, it only passes untagged (non-VLAN) traffic. Do not assign the parent interface unless you intend to pass untagged traffic. For Cluster type interfaces, the parent interface cannot be used.

- Subinterfaces are supported on Data or Data-sharing type interfaces, as well as Cluster type interfaces. If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

- For multi-instance clustering, FXOS subinterfaces are not supported on Data interfaces. However, subinterfaces are supported for the cluster control link, so you can use either a dedicated EtherChannel or a subinterface of an EtherChannel for the cluster control link. Note that *application*-defined subinterfaces are supported for Data interfaces.
- You can create up to 500 VLAN IDs.
- See the following limitations within the logical device application; keep these limitations in mind when planning your interface allocation.
 - You cannot use subinterfaces for an threat defense inline set or as a passive interface.
 - If you use a subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links. You cannot use some subinterfaces as failover links, and some as regular data interfaces.

Data-sharing Interfaces

- You cannot use a data-sharing interface with a native instance.
- Maximum 14 instances per shared interface. For example, you can allocate Ethernet1/1 to Instance1 through Instance14.

Maximum 10 shared interfaces per instance. For example, you can allocate Ethernet1/1.1 through Ethernet1/1.10 to Instance1.

- You cannot use a data-sharing interface in a cluster.

- See the following limitations within the logical device application; keep these limitations in mind when planning your interface allocation.
 - You cannot use a data-sharing interface with a transparent firewall mode device.
 - You cannot use a data-sharing interface with threat defense inline sets or passive interfaces.
 - You cannot use a data-sharing interface for the failover link.

Inline Sets for Threat Defense

- Supported for physical interfaces (both regular and breakout ports) and EtherChannels. Subinterfaces are not supported.
- Link state propagation is supported.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

Hardware Bypass

- Supported for the threat defense; you can use them as regular interfaces for the ASA.
- The threat defense only supports Hardware Bypass with inline sets.
- Hardware Bypass-capable interfaces cannot be configured for breakout ports.
- You cannot include Hardware Bypass interfaces in an EtherChannel and use them for Hardware Bypass; you can use them as regular interfaces in an EtherChannel.
- Hardware Bypass is not supported with High Availability.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

Default MAC Addresses

For native instances:

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- EtherChannels—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.

For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See [Automatic MAC Addresses for Container Instance Interfaces, on page 277](#).

General Guidelines and Limitations

Firewall Mode

You can set the firewall mode to routed or transparent in the bootstrap configuration for the threat defense.

High Availability

- Configure high availability within the application configuration.
- You can use any data interfaces as the failover and state links. Data-sharing interfaces are not supported.

Multi-Instance

- Multi-instance capability with container instances is only available for the threat defense using management center.
- For threat defense container instances, a single management center must manage all instances on a security module/engine.
- For threat defense container instances, the following features are not supported:
 - Radware DefensePro link decorator
 - Management Center UCAPL/CC mode
 - Flow offload to hardware

Configure Interfaces

By default, physical interfaces are disabled. You can enable interfaces, add EtherChannels, add VLAN subinterfaces, and edit interface properties.

Enable or Disable an Interface

You can change the **Admin State** of each interface to be enabled or disabled. By default, physical interfaces are disabled. For VLAN subinterfaces, the admin state is inherited from the parent interface.

Procedure

-
- Step 1** Choose **Interfaces** to open the Interfaces page.
- The Interfaces page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.
- Step 2** To enable the interface, click the disabled **Slider disabled** () so that it changes to the enabled **Slider enabled** ()

Click **Yes** to confirm the change. The corresponding interface in the visual representation changes from gray to green.

Step 3 To disable the interface, click the enabled **Slider enabled** () so that it changes to the disabled **Slider disabled** ()

Click **Yes** to confirm the change. The corresponding interface in the visual representation changes from green to gray.

Configure a Physical Interface

You can physically enable and disable interfaces, as well as set the interface speed and duplex. To use an interface, it must be physically enabled in FXOS and logically enabled in the application.

Note For QSFP40G-CUxM, auto-negotiation is always enabled by default and you cannot disable it.

Before you begin

- Interfaces that are already a member of an EtherChannel cannot be modified individually. Be sure to configure settings before you add it to the EtherChannel.

Procedure

Step 1 Choose **Interfaces** to open the Interfaces page.

The **All Interfaces** page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Edit** in the row for the interface you want to edit to open the **Edit Interface** dialog box.

Step 3 To enable the interface, check the **Enable** check box. To disable the interface, uncheck the **Enable** check box.

Step 4 Choose the interface **Type**:

See [Interface Types, on page 256](#) for details about interface type usage.

- **Data**
- **Data-sharing**—For container instances only.
- **Mgmt**
- **Firepower-eventing**—For threat defense only.
- **Cluster**—Do not choose the **Cluster** type; by default, the cluster control link is automatically created on Port-channel 48.

Step 5 (Optional) Choose the speed of the interface from the **Speed** drop-down list.

- Step 6** (Optional) If your interface supports **Auto Negotiation**, click the **Yes** or **No** radio button.
- Step 7** (Optional) Choose the duplex of the interface from the **Duplex** drop-down list.
- Step 8** (Optional) Explicitly configure **Debounce Time (ms)**. Enter a value between 0-15000 milli-seconds.
- Note** Configuring Debounce Time is not supported on 1G interfaces.
- Step 9** Click **OK**.

Add an EtherChannel (Port Channel)

An EtherChannel (also known as a port channel) can include up to 16 member interfaces of the same media type and capacity, and must be set to the same speed and duplex. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface. The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices.

You can configure each physical Data or Data-sharing interface in an EtherChannel to be:

- **Active**—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- **On**—The EtherChannel is always on, and LACP is not used. An “on” EtherChannel can only establish a connection with another “on” EtherChannel.

Note It may take up to three minutes for an EtherChannel to come up to an operational state if you change its mode from On to Active or from Active to On.

Non-data interfaces only support active mode.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. “On” mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

When the Firepower 4100/9300 chassis creates an EtherChannel, the EtherChannel stays in a **Suspended** state for Active LACP mode or a **Down** state for On LACP mode until you assign it to a logical device, even if the physical link is up. The EtherChannel will be brought out of this **Suspended** state in the following situations:

- The EtherChannel is added as a data or management interface for a standalone logical device
- The EtherChannel is added as a management interface or cluster control link for a logical device that is part of a cluster
- The EtherChannel is added as a data interface for a logical device that is part of a cluster and at least one unit has joined the cluster

Note that the EtherChannel does not come up until you assign it to a logical device. If the EtherChannel is removed from the logical device or the logical device is deleted, the EtherChannel will revert to a **Suspended** or **Down** state.

Procedure

-
- Step 1** Choose **Interfaces** to open the Interfaces page.
- The **All Interfaces** page shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.
- Step 2** Click **Add Port Channel** above the interfaces table to open the **Add Port Channel** dialog box.
- Step 3** Enter an ID for the port channel in the **Port Channel ID** field. Valid values are between 1 and 47.
- Port-channel 48 is reserved for the cluster control link when you deploy a clustered logical device. If you do not want to use Port-channel 48 for the cluster control link, you can delete it and configure a Cluster type EtherChannel with a different ID. You can add multiple Cluster type EtherChannels and add VLAN subinterfaces for use with multi-instance clustering. For intra-chassis clustering, do not assign any interfaces to the Cluster EtherChannel.
- Step 4** To enable the port channel, check the **Enable** check box. To disable the port channel, uncheck the **Enable** check box.
- Step 5** Choose the interface **Type**:
- See [Interface Types, on page 256](#) for details about interface type usage.
- **Data**
 - **Data-sharing**—For container instances only.
 - **Mgmt**
 - **Firepower-eventing**—For threat defense only.
 - **Cluster**
- Step 6** Set the required **Admin Speed** for the member interfaces from the drop-down list.
- If you add a member interface that is not at the specified speed, it will not successfully join the port channel.
- Step 7** For Data or Data-sharing interfaces, choose the LACP port-channel **Mode**, **Active** or **On**.
- For non-Data or non-Data-sharing interfaces, the mode is always active.
- Step 8** Set the required **Admin Duplex** for the member interfaces, **Full Duplex** or **Half Duplex**.
- If you add a member interface that is configured with the specified duplex, it will not successfully join the port channel.
- Step 9** To add an interface to the port channel, select the interface in the **Available Interface** list and click **Add Interface** to move the interface to the Member ID list.
- You can add up to 16 member interfaces of the same media type and capacity. The member interfaces must be set to the same speed and duplex, and must match the speed and duplex that you configured for this port channel. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed.

You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface.

Tip You can add multiple interfaces at one time. To select multiple individual interfaces, click on the desired interfaces while holding down the **Ctrl** key. To select a range of interfaces, select the first interface in the range, and then, while holding down the **Shift** key, click to select the last interface in the range.

Step 10 To remove an interface from the port channel, click the **Delete** button to the right of the interface in the Member ID list.

Step 11 Click **OK**.

Add a VLAN Subinterface for Container Instances

You can add between 250 and 500 VLAN subinterfaces to the chassis, depending on your network deployment. You can add up to 500 subinterfaces to your chassis.

For multi-instance clustering, you can only add subinterfaces to the Cluster-type interface; subinterfaces on data interfaces are not supported.

VLAN IDs per interface must be unique, and within a container instance, VLAN IDs must be unique across all assigned interfaces. You can reuse VLAN IDs on *separate* interfaces as long as they are assigned to different container instances. However, each subinterface still counts towards the limit even though it uses the same ID.

This document discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the threat defense application. For more information on when to use *FXOS* subinterfaces vs. application subinterfaces, see [FXOS Interfaces vs. Application Interfaces, on page 258](#).

Procedure

Step 1 Choose **Interfaces** to open the **All Interfaces** tab.

The **All Interfaces** tab shows a visual representation of the currently installed interfaces at the top of the page and provides a listing of the installed interfaces in the table below.

Step 2 Click **Add New > Subinterface** to open the **Add Subinterface** dialog box.

Step 3 Choose the interface **Type**:

See [Interface Types, on page 256](#) for details about interface type usage.

- **Data**
- **Data-sharing**
- **Cluster**—If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

For Data and Data-sharing interfaces: The type is independent of the parent interface type; you can have a Data-sharing parent and a Data subinterface, for example.

Step 4 Choose the parent **Interface** from the drop-down list.

You cannot add a subinterface to a physical interface that is currently allocated to a logical device. If other subinterfaces of the parent are allocated, you can add a new subinterface as long as the parent interface itself is not allocated.

Step 5 Enter a **Subinterface ID**, between 1 and 4294967295.

This ID will be appended to the parent interface ID as *interface_id.subinterface_id*. For example, if you add a subinterface to Ethernet1/1 with the ID of 100, then the subinterface ID will be: Ethernet1/1.100. This ID is not the same as the VLAN ID, although you can set them to match for convenience.

Step 6 Set the **VLAN ID** between 1 and 4095.

Step 7 Click **OK**.

Expand the parent interface to view all subinterfaces under it.

Configure Logical Devices

Add a standalone logical device or a High Availability pair on the Firepower 4100/9300.

For clustering, see [Clustering for the Firepower 4100/9300, on page 623](#).

Add a Resource Profile for Container Instances

To specify resource usage per container instance, create one or more resource profiles. When you deploy the logical device/application instance, you specify the resource profile that you want to use. The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

- The minimum number of cores is 6.

Note Instances with a smaller number of cores might experience relatively higher CPU utilization than those with larger numbers of cores. Instances with a smaller number of cores are more sensitive to traffic load changes. If you experience traffic drops, try assigning more cores.

- You can assign cores as an even number (6, 8, 10, 12, 14 etc.) up to the maximum.
- The maximum number of cores available depends on the security module/chassis model; see [Requirements and Prerequisites for Container Instances, on page 281](#).

The chassis includes a default resource profile called "Default-Small," which includes the minimum number of cores. You can change the definition of this profile, and even delete it if it is not in use. Note that this profile is created when the chassis reloads and no other profile exists on the system.

Changing the resource profile after you assign it is disruptive. See the following guidelines:

- You cannot change the resource profile settings if it is currently in use. You must disable any instances that use it, then change the resource profile, and finally reenable the instance.

- If you change the resource profile settings after you add the threat defense instance to the management center, then update the inventory for each unit on the management center **Devices > Device Management > Device > System > Inventory** dialog box.
- If you assign a different profile to an instance, it reboots.
- If you assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:
 1. Break high availability.
 2. Assign the new profile to both units.
 3. Re-establish high availability.
- If you assign a different profile to instances in an established cluster, which allows mismatched profiles, then apply the new profile on the data nodes first; after they all come back up, you can apply the new profile to the control node.

Procedure

Step 1 Choose **Platform Settings > Resource Profiles** , and click **Add**.

The **Add Resource Profile** dialog box appears.

Step 2 Set the following parameters.

- **Name**—Sets the name of the profile between 1 and 64 characters. Note that you cannot change the name of this profile after you add it.
- **Description**—Sets the description of the profile up to 510 characters.
- **Number of Cores**—Sets the number of cores for the profile, between 6 and the maximum, depending on your chassis, as an even number.

Step 3 Click **OK**.

Add a Standalone Threat Defense

Standalone logical devices work either alone or in a High Availability pair. On the Firepower 9300 with multiple security modules, you can deploy either a cluster or standalone devices. The cluster must use all modules, so you cannot mix and match a 2-module cluster plus a single standalone device, for example.

You can use native instances on some modules, and container instances on the other module(s).

Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300 chassis.

Note For the Firepower 9300, you can install different application types (ASA and threat defense) on separate modules in the chassis. You can also run different versions of an application instance type on separate modules.

- Configure a management interface to use with the logical device. The management interface is required. Note that this management interface is not the same as the chassis management port that is used only for chassis management (and that appears at the top of the **Interfaces** tab as **MGMT**).
- You can later enable management from a data interface; but you must assign a Management interface to the logical device even if you don't intend to use it after you enable data management. See the **configure network management-data-interface** command in the [FTD command reference](#) for more information.
- You must also configure at least one Data type interface. Optionally, you can also create a firepower-eventing interface to carry all event traffic (such as web events). See [Interface Types, on page 256](#) for more information.
- For container instances, if you do not want to use the default profile, add a resource profile according to [Add a Resource Profile for Container Instances, on page 294](#).
- For container instances, before you can install a container instance for the first time, you must reinitialize the security module/engine so that the disk has the correct formatting. Choose **Security Modules** or **Security Engine**, and click the **Reinitialize icon**. An existing logical device will be deleted and then reinstalled as a new device, losing any local application configuration. If you are replacing a native instance with container instances, you will need to delete the native instance in any case. You cannot automatically migrate a native instance to a container instance.
- Gather the following information:
 - Interface IDs for this device
 - Management interface IP address and network mask
 - Gateway IP address
 - management center IP address and/or NAT ID of your choosing
 - DNS server IP address
 - threat defense hostname and domain name

Procedure

Step 1

Choose **Logical Devices**.

Step 2

Click **Add > Standalone**, and set the following parameters:

Add Standalone [?] [X]

Device Name:

Template:

Image Version:

Instance Type:

i Before you add the first container instance, you must reinitialize the security module/engine so that the disk has the correct formatting. You only need to perform this action once.

a) Provide a **Device Name**.

This name is used by the chassis supervisor to configure management settings and to assign interfaces; it is not the device name used in the application configuration.

Note You cannot change this name after you add the logical device.

b) For the **Template**, choose **Cisco Firepower Threat Defense**.

c) Choose the **Image Version**.

d) Choose the **Instance Type**: **Container** or **Native**.

A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance. A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances.

e) Click **OK**.

You see the Provisioning - *device name* window.

Step 3

Expand the **Data Ports** area, and click each interface that you want to assign to the device.

Overview Interfaces **Logical Devices** Security Modules Platform Settings System Tools Help

Provisioning - FTD_Instance2 [>>]

Standalone | Cisco Firepower Threat Defense | 6.4.0.42 [>>]

- Ethernet2/7
- Ethernet2/8

Ethernet1/3.2 Ethernet1/2 Ethernet1/3 Ethernet2/3

FTD - 6.4.0.42
Click to configure

You can only assign data and data-sharing interfaces that you previously enabled on the **Interfaces** page. You will later enable and configure these interfaces in management center, including setting the IP addresses.

You can only assign up to 10 data-sharing interfaces to a container instance. Also, each data-sharing interface can be assigned to at most 14 container instances. A data-sharing interface is indicated by the sharing icon ()

Hardware Bypass-capable ports are shown with the following icon: . For certain interface modules, you can enable the Hardware Bypass feature for Inline Set interfaces only (see the management center configuration guide). Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures. If you do not assign both interfaces in a Hardware Bypass pair, you see a warning message to make sure your assignment is intentional. You do not need to use the Hardware Bypass feature, so you can assign single interfaces if you prefer.

Step 4 Click the device icon in the center of the screen.

A dialog box appears where you can configure initial bootstrap settings. These settings are meant for initial deployment only, or for disaster recovery. For normal operation, you can later change most values in the application CLI configuration.

Step 5 On the **General Information** page, complete the following:

The screenshot shows the 'Cisco Secure Firewall Threat Defense - Bootstrap Configuration' dialog box with the 'General Information' tab selected. The 'Security Module(SM) and Resource Profile Selection' section has three buttons: 'SM 1 - Ok' (highlighted in blue), 'SM 2 - Empty', and 'SM 3 - Empty'. Below this, it shows 'SM 1 - 78 Cores Available' and a 'Resource Profile' dropdown set to 'Default-Small'. The 'Interface Information' section includes a 'Management Interface' dropdown set to 'Ethernet1/4', an 'Address Type' dropdown set to 'IPv4 only', and text input fields for 'Management IP' (10.89.5.22), 'Network Mask' (255.255.255.192), and 'Network Gateway' (10.89.5.1). 'OK' and 'Cancel' buttons are at the bottom.

- a) (For the Firepower 9300) Under **Security Module Selection** click the security module that you want to use for this logical device.
- b) For a container instance, specify the **Resource Profile**.

If you later assign a different resource profile, then the instance will reload, which can take approximately 5 minutes.

Note If you later assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

1. Break high availability.
2. Assign the new profile to both units.
3. Re-establish high availability.

c) Choose the **Management Interface**.

This interface is used to manage the logical device. This interface is separate from the chassis management port.

d) Choose the management interface **Address Type: IPv4 only, IPv6 only, or IPv4 and IPv6**.

e) Configure the **Management IP** address.

Set a unique IP address for this interface.

f) Enter a **Network Mask or Prefix Length**.

g) Enter a **Network Gateway** address.

Step 6

On the **Settings** tab, complete the following:

The screenshot shows the 'Settings' tab of the 'Cisco Secure Firewall Threat Defense - Bootstrap Configuration' dialog. The fields are as follows:

Field	Value
Management type of application instance:	FMC
Permit Expert mode for FTD SSH sessions:	yes
Search domains:	cisco.com
Firewall Mode:	Routed
DNS Servers:	10.89.5.67
Fully Qualified Hostname:	td2.cisco.com
Password:	*****
Confirm Password:	*****
Registration Key:	****
Confirm Registration Key:	****
CDO Onboard:	
Confirm CDO Onboard:	
Firepower Management Center IP:	10.89.5.35
Firepower Management Center NAT ID:	test
Eventing Interface:	

a) For a native instance, in the **Management type of application instance** drop-down list, choose **FMC**.

Native instances also support device manager as a manager. After you deploy the logical device, you cannot change the manager type.

b) Enter the **Firepower Management Center IP** of the managing management center. If you do not know the management center IP address, leave this field blank and enter a passphrase in the **Firepower Management Center NAT ID** field.

c) For a container instance, **Permit Expert mode from FTD SSH sessions: Yes or No**. Expert Mode provides threat defense shell access for advanced troubleshooting.

If you choose **Yes** for this option, then users who access the container instance directly from an SSH session can enter Expert Mode. If you choose **No**, then only users who access the container instance from the FXOS CLI can enter Expert Mode. We recommend choosing **No** to increase isolation between instances.

Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the threat defense CLI.

- d) Enter the **Search Domains** as a comma-separated list.
- e) Choose the **Firewall Mode: Transparent** or **Routed**.

In routed mode, the threat defense is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices.

The firewall mode is only set at initial deployment. If you re-apply the bootstrap settings, this setting is not used.

- f) Enter the **DNS Servers** as a comma-separated list.

The threat defense uses DNS if you specify a hostname for the management center, for example.

- g) Enter the **Fully Qualified Hostname** for the threat defense.
- h) Enter a **Registration Key** to be shared between the management center and the device during registration.

You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the management center when you add the threat defense.

- i) Enter a **Password** for the threat defense admin user for CLI access.
- j) Choose the **Eventing Interface** on which events should be sent. If not specified, the management interface will be used.

This interface must be defined as a Firepower-eventing interface.

- k) For a container instance, set the **Hardware Crypto** as **Enabled** or **Disabled**.

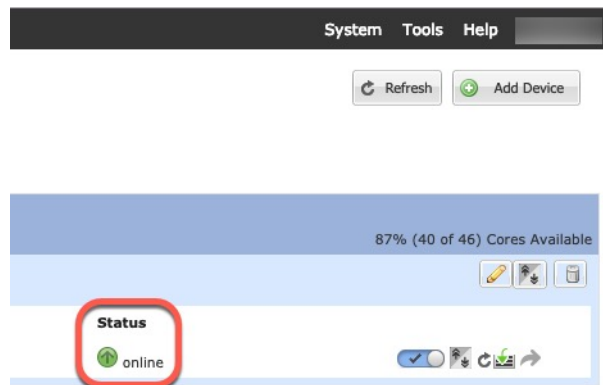

This setting enables TLS crypto acceleration in hardware, and improves performance for certain types of traffic. This feature is enabled by default. You can enable TLS crypto acceleration for up to 16 instances per security module. This feature is always enabled for native instances. To view the percentage of hardware crypto resources allocated to this instance, enter the **show hw-crypto** command.

Step 7 On the **Agreement** tab, read and accept the end user license agreement (EULA).

Step 8 Click **OK** to close the configuration dialog box.

Step 9 Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for the status of the new logical device. When the logical device shows its **Status** as **online**, you can start configuring the security policy in the application.

- Step 10** See the management center configuration guide to add the threat defense as a managed device and start configuring your security policy.

Add a High Availability Pair

Threat Defense High Availability (also known as failover) is configured within the application, not in FXOS. However, to prepare your chassis for high availability, see the following steps.

Before you begin

See [Requirements and Prerequisites for High Availability, on page 282](#).

Procedure

- Step 1** Allocate the same interfaces to each logical device.
- Step 2** Allocate 1 or 2 data interfaces for the failover and state link(s).
- These interfaces exchange high availability traffic between the 2 chassis. We recommend that you use a 10 GB data interface for a combined failover and state link. If you have available interfaces, you can use separate failover and state links; the state link requires the most bandwidth. You cannot use the management-type interface for the failover or state link. We recommend that you use a switch between the chassis, with no other device on the same network segment as the failover interfaces.
- For container instances, data-sharing interfaces are not supported for the failover link. We recommend that you create subinterfaces on a parent interface or EtherChannel, and assign a subinterface for each instance to use as a failover link. Note that you must use all subinterfaces on the same parent as failover links. You cannot use one subinterface as a failover link and then use other subinterfaces (or the parent interface) as regular data interfaces.
- Step 3** Enable High Availability on the logical devices. See [High Availability, on page 377](#).
- Step 4** If you need to make interface changes after you enable High Availability, perform the changes on the standby unit first, and then perform the changes on the active unit.

Change an Interface on a Threat Defense Logical Device

You can allocate or unallocate an interface, or replace a management interface on the threat defense logical device. You can then sync the interface configuration in the management center.

Adding a new interface, or deleting an unused interface has minimal impact on the threat defense configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the threat defense configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the management center.

Deleting an interface will delete any configuration associated with that interface.

Before you begin

- Configure your interfaces, and add any EtherChannels according to [Configure a Physical Interface, on page 290](#) and [Add an EtherChannel \(Port Channel\), on page 291](#).
- If you want to add an already-allocated interface to an EtherChannel (for example, all interfaces are allocated by default to a cluster), you need to unallocate the interface from the logical device first, then add the interface to the EtherChannel. For a new EtherChannel, you can then allocate the EtherChannel to the device.
- If you want to replace the management or eventing interface with a management EtherChannel, then you need to create the EtherChannel with at least 1 unallocated data member interface, and then replace the current management interface with the EtherChannel. After the threat defense device reboots (management interface changes cause a reboot), and you sync the configuration in the management center, you can add the (now unallocated) management interface to the EtherChannel as well.
- For clustering or High Availability, make sure you add or remove the interface on all units before you sync the configuration in the management center. We recommend that you make the interface changes on the data/standby unit(s) first, and then on the control/active unit. Note that new interfaces are added in an administratively down state, so they do not affect interface monitoring.
- In mult-instance mode, for changing a sub-interface with another sub-interface with the same vlan tag, you must first remove all the configuration (including nameif config) of the interface and then unallocate the interface from chassis manager. Once unallocated, add the new interface and then use sync interfaces from the management center.

Procedure

- Step 1** In the chassis manager, choose **Logical Devices**.
- Step 2** Click the **Edit** icon at the top right to edit the logical device.
- Step 3** Allocate a new data interface by selecting the interface in the **Data Ports** area.
- Do not delete any interfaces yet.

Step 4 Replace the management or eventing interface:

For these types of interfaces, the device reboots after you save your changes.

- a) Click the device icon in the center of the page.
- b) On the **General** or **Cluster Information** tab, choose the new **Management Interface** from the drop-down list.
- c) On the **Settings** tab, choose the new **Eventing Interface** from the drop-down list.
- d) Click **OK**.

If you change the IP address of the Management interface, then you must also change the IP address for the device in the management center: go to **Devices > Device Management > Device/Cluster**. In the **Management** area, set the IP address to match the bootstrap configuration address.

Step 5 Click **Save**.

Step 6 Sync the interfaces in the management center.

- a) Log into the management center.
- b) Select **Devices > Device Management** and click **Edit** (🔗) for your threat defense device. The **Interfaces** page is selected by default.
- c) Click the **Sync Device** button on the top left of the **Interfaces** page.
- d) After the changes are detected, you will see a red banner on the **Interfaces** page indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.
- e) If you plan to delete an interface, manually transfer any interface configuration from the old interface to the new interface.

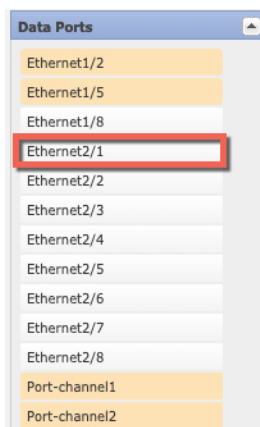

Because you have not yet deleted any interfaces, you can refer to the existing configuration. You will have additional opportunity to fix the configuration after you delete the old interface and re-run the validation. The validation will show you all locations in which the old interface is still used.

- f) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

- g) Click **Save**.
- h) Click **Deploy > Deployment**.
- i) Select the devices and click **Deploy** to deploy the policy to the assigned devices. The changes are not active until you deploy them.

Step 7 In the chassis manager, unallocate a data interface by de-selecting the interface in the **Data Ports** area.

Step 8 Click **Save**.

Step 9 Sync the interfaces again in the management center.

Connect to the Console of the Application

Use the following procedure to connect to the console of the application.

Procedure

Step 1 Connect to the module CLI using a console connection or a Telnet connection.

connect module *slot_number* { **console** | **telnet** }

To connect to the security engine of a device that does not support multiple security modules, always use **1** as the *slot_number*.

The benefits of using a Telnet connection is that you can have multiple sessions to the module at the same time, and the connection speed is faster.

Example:

```
Firepower# connect module 1 console
Telnet escape character is '~'.
Trying 127.5.1.1...
Connected to 127.5.1.1.
Escape character is '~'.
```

```
CISCO Serial Over LAN:
Close Network Connection to Exit
```

```
Firepower-module1>
```

Step 2 Connect to the application console.

connect ftd *name*

To view the instance names, enter the command without a name.

Example:

```
Firepower-module1> connect ftd ftd1
Connecting to ftd(ftd-native) console... enter exit to return to bootCLI
[...]
>
```

Step 3 Exit the application console to the FXOS module CLI.

- Threat Defense—Enter **exit**

Step 4 Return to the supervisor level of the FXOS CLI.

Exit the console:

- Enter ~
You exit to the Telnet application.
- To exit the Telnet application, enter:
telnet>**quit**

Exit the Telnet session:

- Enter **Ctrl-], .**
-

History for Logical Devices

Feature	Minimum Management Center	Minimum Threat Defense	Details
Synchronization between the threat defense operational link state and the physical link state	6.7	Any	<p>The chassis can now synchronize the threat defense operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The threat defense application interface admin state is not considered. Without synchronization from threat defense, data interfaces can be in an Up state physically before the threat defense application has completely come online, for example, or can stay Up for a period of time after you initiate threat defense shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the threat defense before the threat defense can handle it. This feature is disabled by default, and can be enabled per logical device in FXOS.</p> <p>Note This feature is not supported for clustering, container instances, or threat defense with a Radware vDP decorator. It is also not supported for the ASA.</p> <p>New/Modified Firepower Chassis Manager screens: Logical Devices > Enable Link State</p> <p>New/Modified FXOS commands: set link-state-sync enabled, show interface expand detail</p>
Threat Defense configuration backup and restore using management center for container instances	6.7	Any	<p>You can now use the management center backup/restore tool on threat defense container instances.</p> <p>New/Modified management center screens: System > Tools > Backup/Restore > Managed Device Backup</p> <p>New/Modified threat defense CLI commands: restore</p> <p>Supported platforms: Firepower 4100/9300</p> <p>Note Requires FXOS 2.9.</p>
Support for VLAN subinterfaces on a Cluster type interface (multi-instance use only)	6.6	Any	<p>For use with multi-instance clusters, you can now create VLAN subinterfaces on cluster type interfaces. Because each cluster requires a unique cluster control link, VLAN subinterfaces provide a simple method to fulfill this requirement. You can alternatively assign a dedicated EtherChannel per cluster. Multiple cluster interfaces are now allowed.</p> <p>New/Modified Firepower Chassis Manager screens:</p> <p>Interfaces > All Interfaces > Add New drop-down menu > Subinterface > Type field</p> <p>New/Modified FXOS commands: set port-type cluster</p> <p>Note Requires FXOS 2.8.1.</p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Threat Defense on the Firepower 4112	6.6	Any	We introduced the Firepower 4112. Note Requires FXOS 2.8.1.
TLS crypto acceleration for multiple container instances	6.5	Any	TLS crypto acceleration is now supported on multiple container instances (up to 16) on a Firepower 4100/9300 chassis. Previously, you could enable TLS crypto acceleration for only <i>one</i> container instance per module/security engine. New instances have this feature enabled by default. However, the upgrade does <i>not</i> enable acceleration on existing instances. Instead, use the enter hw-crypto and then the set admin-state enabled FXOS commands. New/Modified Firepower Chassis Manager screens: Logical Devices > Add Device > Settings > Hardware Crypto drop-down menu Note Requires FXOS 2.7.1.
Threat Defense on the Firepower 4115, 4125, and 4145	6.4	Any	We introduced the Firepower 4115, 4125, and 4145. Note Requires FXOS 2.6.1.157.
Firepower 9300 SM-40, SM-48, and SM-56 support	6.4	Any	We introduced the following three security modules: SM-40, SM-48, and SM-56. Note Requires FXOS 2.6.1.157.
Support for ASA and threat defense on separate modules of the same Firepower 9300	6.4	Any	You can now deploy ASA and threat defense logical devices on the same Firepower 9300. Note Requires FXOS 2.6.1.157.
Support for SSL hardware acceleration on one threat defense container instance on a module/security engine	6.4	Any	You can now enable SSL hardware acceleration for one container instance on a module/security engine. SSL hardware acceleration is disabled for other container instances, but enabled for native instances. New/Modified FXOS commands: config hwCrypto enable No modified screens. Note Requires FXOS 2.6.1.157.

Feature	Minimum Management Center	Minimum Threat Defense	Details
Multi-instance capability for threat defense on the Firepower 4100/9300	6.3	Any	<p>You can now deploy multiple logical devices, each with a threat defense container instance, on a single security engine/module. Formerly, you could only deploy a single native application instance.</p> <p>To provide flexible physical interface use, you can create VLAN subinterfaces in FXOS and also share interfaces between multiple instances. Resource management lets you customize performance capabilities for each instance.</p> <p>You can use High Availability using a container instance on 2 separate chassis. Clustering is not supported.</p> <p>Note Multi-instance capability is similar to ASA multiple context mode, although the implementation is different. Multiple context mode is not available on the threat defense.</p> <p>New/Modified management center screens:</p> <ul style="list-style-type: none"> • Devices > Device Management > Edit icon > Interfaces tab <p>New/Modified Firepower Chassis Manager screens:</p> <ul style="list-style-type: none"> • Overview > Devices • Interfaces > All Interfaces > Add New drop-down menu > Subinterface • Interfaces > All Interfaces > Type • Logical Devices > Add Device • Platform Settings > Mac Pool • Platform Settings > Resource Profiles <p>New/Modified FXOS commands: connect ftd <i>name</i>, connect module telnet, create bootstrap-key PERMIT_EXPERT_MODE, create resource-profile, create subinterface, scope auto-macpool, set cpu-core-count, set deploy-type, set port-type data-sharing, set prefix, set resource-profile-name, set vlan, scope app-instance ftd <i>name</i>, show cgroups container, show interface, show mac-address, show subinterface, show tech-support module app-instance, show version</p> <p>Supported platforms: Firepower 4100/9300</p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Cluster control link customizable IP Address for the Firepower 4100/9300	6.3	Any	<p>By default, the cluster control link uses the 127.2.0.0/16 network. You can now set the network when you deploy the cluster in FXOS. The chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: 127.2.chassis_id.slot_id. However, some networking deployments do not allow 127.2.0.0/16 traffic to pass. Therefore, you can now set a custom /16 subnet for the cluster control link in FXOS except for loopback (127.0.0.0/8) and multicast (224.0.0.0/4) addresses.</p> <p>New/modified Firepower Chassis Manager screens:</p> <ul style="list-style-type: none"> • Logical Devices > Add Device > Cluster Information > CCL Subnet IP field <p>New/Modified FXOS commands: set cluster-control-link network</p> <p>Supported platforms: Firepower 4100/9300</p>
Support for data EtherChannels in On mode	6.3	Any	<p>You can now set data and data-sharing EtherChannels to either Active LACP mode or to On mode. Other types of EtherChannels only support Active mode.</p> <p>New/Modified Firepower Chassis Manager screens:</p> <ul style="list-style-type: none"> • Interfaces > All Interfaces > Edit Port Channel > Mode <p>New/Modified FXOS commands: set port-channel-mode</p> <p>Supported platforms: Firepower 4100/9300</p>
Support for EtherChannels in threat defense inline sets	6.2	Any	<p>You can now use EtherChannels in a threat defense inline set.</p> <p>Supported platforms: Firepower 4100/9300</p>
Inter-chassis clustering for 6 threat defense modules	6.2	Any	<p>You can now enable inter-chassis clustering for the threat defense. You can include up to 6 modules in up to 6 chassis.</p> <p>New/modified Firepower Chassis Manager screens:</p> <ul style="list-style-type: none"> • Logical Devices > Configuration <p>Supported platforms: Firepower 4100/9300</p>
Hardware bypass support on the Firepower 4100/9300 for supported network modules	6.1	Any	<p>Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures.</p> <p>New/Modified screens:</p> <ul style="list-style-type: none"> • Devices > Device Management > Interfaces > Edit Physical Interface <p>Supported platforms: Firepower 4100/9300</p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Inline set link state propagation support for the threat defense	6.1	Any	<p>When you configure an inline set in the threat defense application and enable link state propagation, the threat defense sends inline set membership to the FXOS chassis. Link state propagation means that the chassis automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down.</p> <p>New/Modified FXOS commands: show fault grep link-down, show interface detail</p> <p>Supported platforms: Firepower 4100/9300</p>
Support for intra-chassis clustering on the threat defense on the Firepower 9300	6.0.1	Any	<p>The Firepower 9300 supports intra-chassis clustering with the threat defense application.</p> <p>New/Modified Firepower Chassis Manager screens:</p> <ul style="list-style-type: none"> • Logical Devices > Configuration <p>New/Modified FXOS commands: enter mgmt-bootstrap ftd, enter bootstrap-key FIREPOWER_MANAGER_IP, enter bootstrap-key FIREWALL_MODE, enter bootstrap-key-secret REGISTRATION_KEY, enter bootstrap-key-secret PASSWORD, enter bootstrap-key FQDN, enter bootstrap-key DNS_SERVERS, enter bootstrap-key SEARCH_DOMAINS, enter ipv4 firepower, enter ipv6 firepower, set value, set gateway, set ip, accept-license-agreement</p> <p>Supported platforms: Firepower 4100/9300</p>

CHAPTER 8

Multi-Instance Mode for the Secure Firewall 3100/4200

You can deploy the Secure Firewall 3100/4200 as a single device (*appliance mode*) or as multiple container instances (*multi-instance mode*). This chapter describes how to deploy the device in multi-instance mode.

- [About Multi-Instance Mode, on page 311](#)
- [Licenses for Instances, on page 324](#)
- [Requirements and Prerequisites for Instances, on page 324](#)
- [Guidelines and Limitations for Instances, on page 326](#)
- [Configure Instances, on page 328](#)
- [Monitoring Multi-Instance Mode, on page 373](#)
- [History for Multi-Instance Mode, on page 376](#)

About Multi-Instance Mode

In multi-instance mode, you can deploy multiple container instances on a single chassis that act as completely independent devices.

Multi-Instance Mode vs. Appliance Mode

You can run the device in either multi-instance mode or appliance mode.

Appliance Mode

Appliance mode is the default. The device runs the native threat defense image and acts as a single device. The only chassis-level configuration available (on the **Chassis Manager** page) is for network module management (breakout ports or enabling/disabling a network module).

Multi-Instance Mode

If you change to multi-instance mode, the device runs the Secure Firewall eXtensible Operating System (FXOS) on the chassis, while each instance runs separate threat defense images. You can configure the mode using the FXOS CLI.

Because multiple instances run on the same chassis, you need to perform chassis-level management of:

- CPU and memory resources using resource profiles.

- Interface configuration and assignment.
- Deployment and monitoring of instances.

For a multi-instance device, you add the *chassis* to the management center and configure chassis-level settings on the **Chassis Manager** page.

Chassis Management Interface

Chassis Management

The chassis uses the dedicated Management interface on the device. Multi-instance mode does not support using a data interface for chassis management or DHCP addressing for the Management interface.

You can only configure the chassis Management interface at the threat defense CLI (at initial setup) or FXOS CLI (after you convert to multi-instance mode). See [Change Chassis Management Settings at the FXOS CLI, on page 371](#) to change Management interface settings in multi-instance mode.

Note By default, SSH is not allowed to this interface in multi-instance mode unless you enable the SSH server and an SSH access list. This difference means that you can connect to the application-mode threat defense Management interface using SSH, but after you convert to multi-instance mode, you can no longer connect using SSH by default. See [Configure SSH and SSH Access List, on page 353](#).

Instance Management

All instances share the chassis management interface, and each instance has its own IP address on the Management network. After you add the instance and specify the IP address, you can make changes to the network settings at the threat defense CLI.

The instance Management IP address allows SSH by default.

Instance Eventing Interface

The Secure Firewall 4200 includes a second dedicated interface, Management 1/2, that you can use for events. You can configure this interface at the threat defense CLI in each instance. Assign an IP address on the same network for each instance. See [Configure an Event Interface, on page 25](#).

Instance Interfaces

To provide flexible physical interface use for instances, you can create VLAN subinterfaces on the chassis and also share interfaces (VLAN or physical) between multiple instances. See [Shared Interface Scalability, on page 315](#) and [Configure a Subinterface, on page 339](#).

Note This chapter discusses *chassis* VLAN subinterfaces only. You can separately create subinterfaces within the threat defense instance. See [Chassis Interfaces vs. Instance Interfaces, on page 313](#) for more information.

Interface Types

Physical interfaces, VLAN subinterfaces, and EtherChannel interfaces can be one of the following types:

- **Data**—Use for regular data or the failover link. Data interfaces cannot be shared between instances, and instances cannot communicate over the backplane to other instances. For traffic on Data interfaces, all traffic must exit the chassis on one interface and return on another interface to reach another instance. You can add VLAN subinterfaces to a data interface to provide separate failover links per High Availability pair.
- **Data-sharing**—Use for regular data. These data interfaces can be shared by one or more instances. Each instance can communicate over the backplane with all other instances that share this interface. Shared interfaces can affect the number of instances you can deploy. Shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode), inline sets, passive interfaces, or failover links.

Chassis Interfaces vs. Instance Interfaces

At the chassis level, you manage the basic Ethernet settings of physical interfaces, VLAN subinterfaces for instances, and EtherChannel interfaces. Within the instance, you configure higher level settings. For example, you can only create EtherChannels in the chassis; but you can assign an IP address to the EtherChannel within the instance.

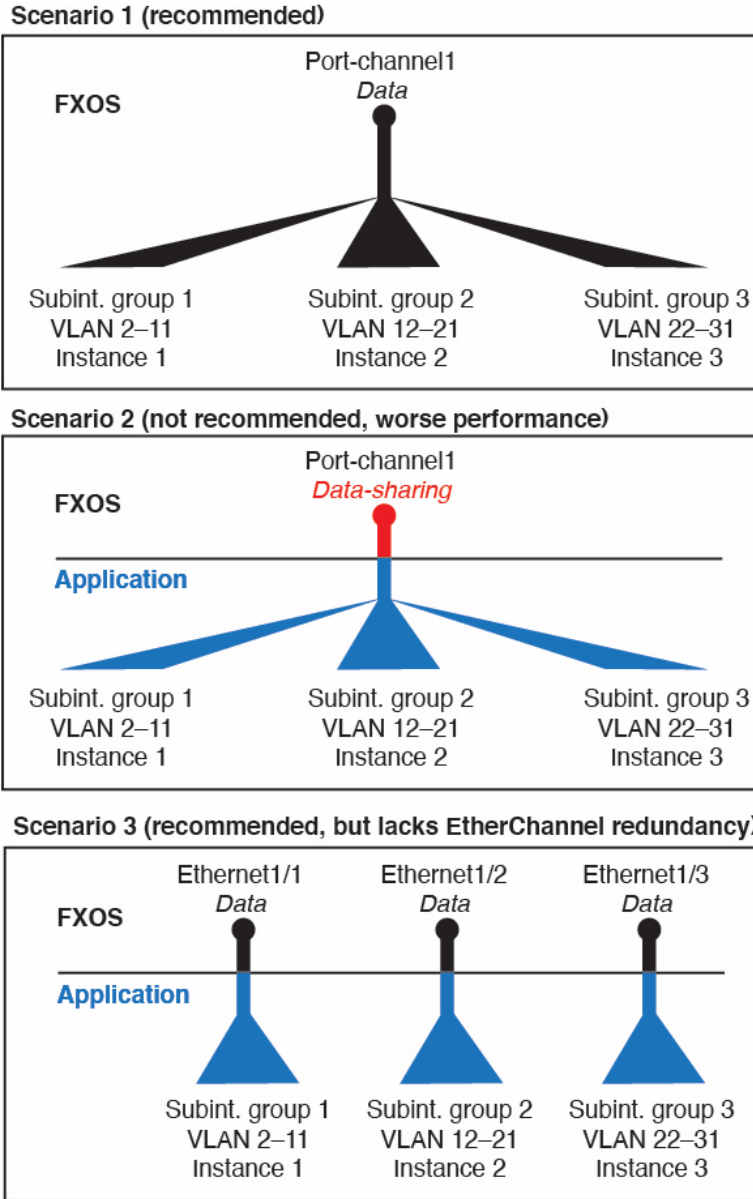

The following sections describe the interaction between the chassis and the instance for interfaces.

VLAN Subinterfaces

You can create VLAN subinterfaces within the instance, just as you would for any device.

You can *also* create VLAN subinterfaces in the chassis. The instance-defined subinterfaces are not subject to the chassis limit. Choosing in which location to create subinterfaces depends on your network deployment and personal preference. For example, to share a subinterface, you must create the subinterface on the chassis. Another scenario that favors chassis subinterfaces comprises allocating separate subinterface groups on a single interface to multiple instances. For example, you want to use Port-channel1 with VLAN 2–11 on instance A, VLAN 12–21 on instance B, and VLAN 22–31 on instance C. If you create these subinterfaces in the instance, then you would have to share the parent interface in the chassis, which may not be desirable. See the following illustration that shows the three ways you can accomplish this scenario:

Figure 101: VLANs in the Chassis vs. the Instance

Independent Interface States in the Chassis and in the Instance

You can administratively enable and disable interfaces in both the chassis and in the instance. For an interface to be operational, the interface must be enabled in both locations. Because the interface state is controlled independently, you may have a mismatch between the chassis and instance.

The default state of an interface within the instance depends on the type of interface. For example, the physical interface or EtherChannel is disabled by default within the instance, but a subinterface is enabled by default.

Shared Interface Scalability

Instances can share data-sharing type interfaces. This capability lets you conserve physical interface usage as well as support flexible networking deployments. When you share an interface, the chassis uses unique MAC addresses to forward traffic to the correct instance. However, shared interfaces can cause the forwarding table to grow large due to the need for a full mesh topology within the chassis (every instance must be able to communicate with every other instance that is sharing the same interface). Therefore, there are limits to how many interfaces you can share.

In addition to the forwarding table, the chassis maintains a VLAN group table for VLAN subinterface forwarding. You can create up to 500 VLAN subinterfaces.

See the following limits for shared interface allocation:

Shared Interface Best Practices

For optimal scalability of the forwarding table, share as few interfaces as possible. Instead, you can create up to 500 VLAN subinterfaces on one or more physical interfaces and then divide the VLANs among the container instances.

When sharing interfaces, follow these practices in the order of most scalable to least scalable:

1. Best—Share subinterfaces under a single parent, and use the same set of subinterfaces with the same group of instances.

For example, create a large EtherChannel to bundle all of your like-kind interfaces together, and then share subinterfaces of that EtherChannel: Port-Channel1.2, 3, and 4 instead of Port-Channel2,

Port-Channel3, and Port-Channel4. When you share subinterfaces from a single parent, the VLAN group table provides better scaling of the forwarding table than when sharing physical/EtherChannel interfaces or subinterfaces across parents.

Figure 102: Best: Shared Subinterface Group on One Parent

If you do not share the same set of subinterfaces with a group of instances, your configuration can cause more resource usage (more VLAN groups). For example, share Port-Channel1.2, 3, and 4 with instances 1, 2, and 3 (one VLAN group) instead of sharing Port-Channel1.2 and 3 with instances 1 and 2, while sharing Port-Channel1.3 and 4 with instance 3 (two VLAN groups).

Figure 103: Good: Sharing Multiple Subinterface Groups on One Parent

2. Fair—Share subinterfaces across parents.

For example, share Port-Channel1.2, Port-Channel2.3, and Port-Channel3.4 instead of Port-Channel2, Port-Channel4, and Port-Channel4. Although this usage is not as efficient as only sharing subinterfaces on the same parent, it still takes advantage of VLAN groups.

Figure 104: Fair: Shared Subinterfaces on Separate Parents

3. Worst—Share individual parent interfaces (physical or EtherChannel). This method uses the most forwarding table entries.

Figure 105: Worst: Shared Parent Interfaces

How the Chassis Classifies Packets

Each packet that enters the chassis must be classified, so that the chassis can determine to which instance to send a packet.

- **Unique Interfaces**—If only one instance is associated with the ingress interface, the chassis classifies the packet into that instance. For bridge group member interfaces (in transparent mode or routed mode), inline sets, or passive interfaces, this method is used to classify packets at all times.
- **Unique MAC Addresses**—The chassis automatically generates unique MAC addresses for all interfaces, including shared interfaces. If multiple instances share an interface, then the classifier uses unique MAC addresses assigned to the interface in each instance. An upstream router cannot route directly to an instance without unique MAC addresses. You can also set the MAC addresses manually when you configure each interface within the application.

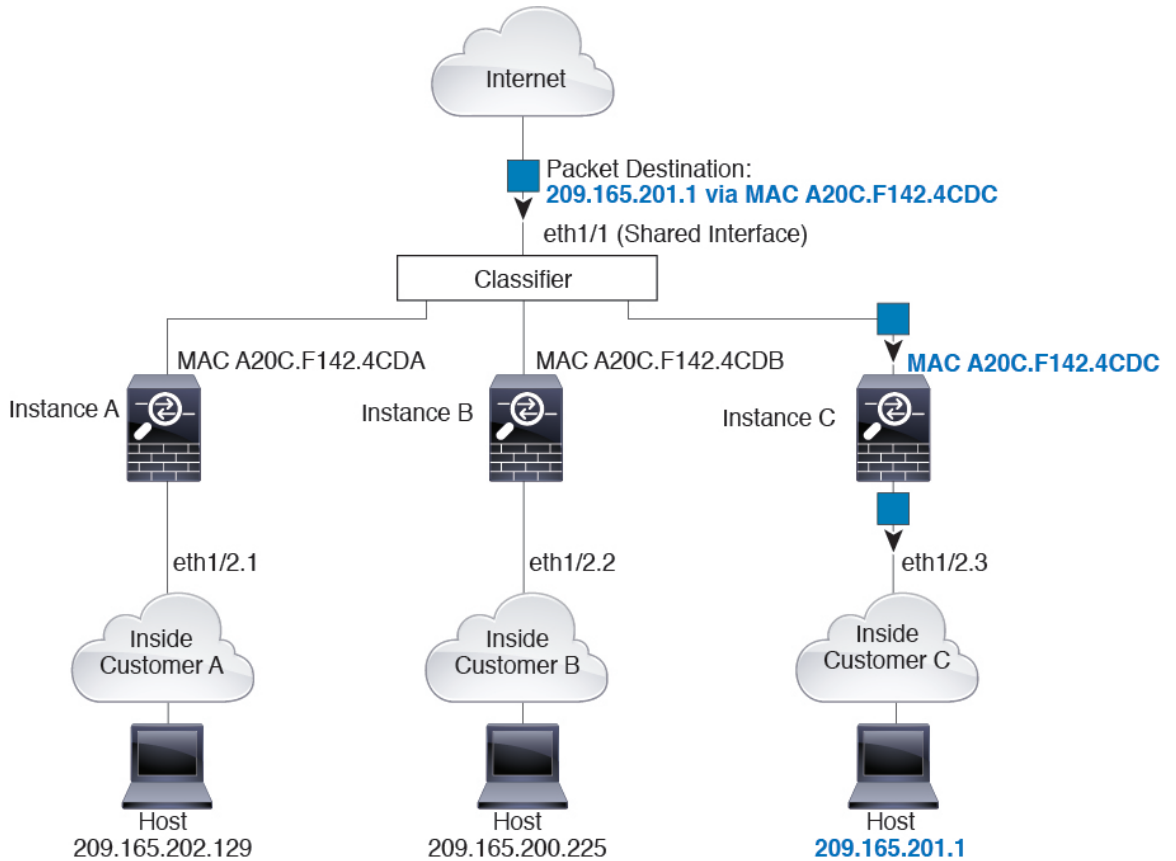

Note If the destination MAC address is a multicast or broadcast MAC address, the packet is duplicated and delivered to each instance.

Classification Examples

Packet Classification with a Shared Interface Using MAC Addresses

The following figure shows multiple instances sharing an outside interface. The classifier assigns the packet to Instance C because Instance C includes the MAC address to which the router sends the packet.

Figure 106: Packet Classification with a Shared Interface Using MAC Addresses

Incoming Traffic from Inside Networks

Note that all new incoming traffic must be classified, even from inside networks. The following figure shows a host on the Instance C inside network accessing the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

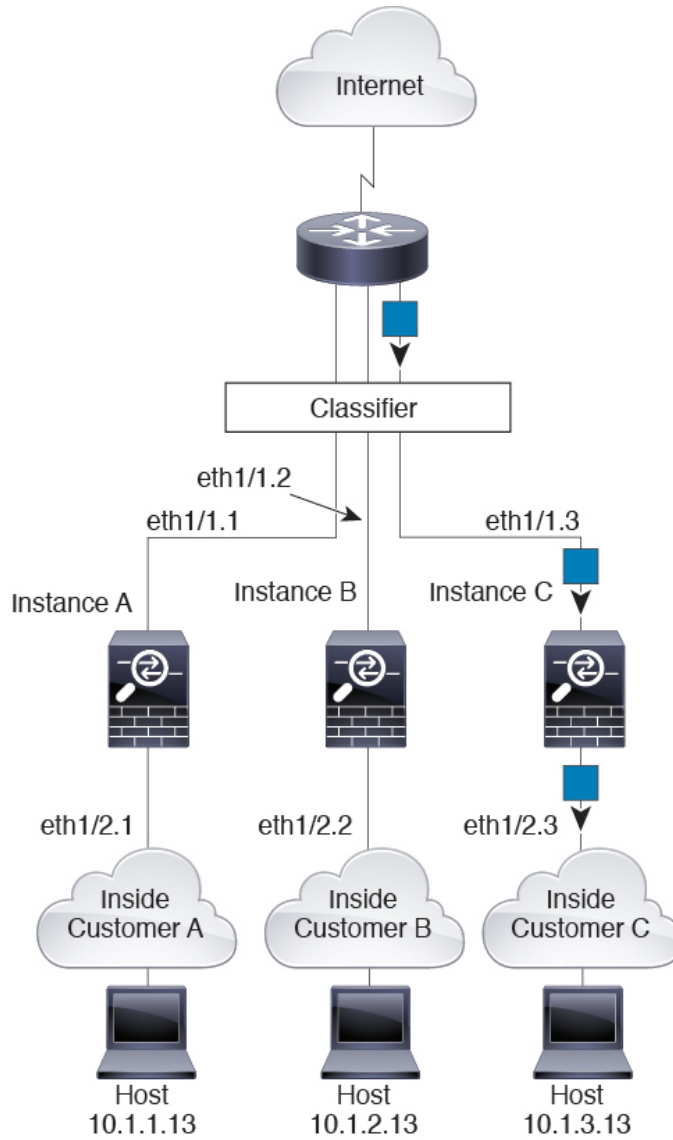

Figure 107: Incoming Traffic from Inside Networks

Transparent Firewall Instances

For transparent firewalls, you must use unique interfaces. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/2.3, which is assigned to Instance C.

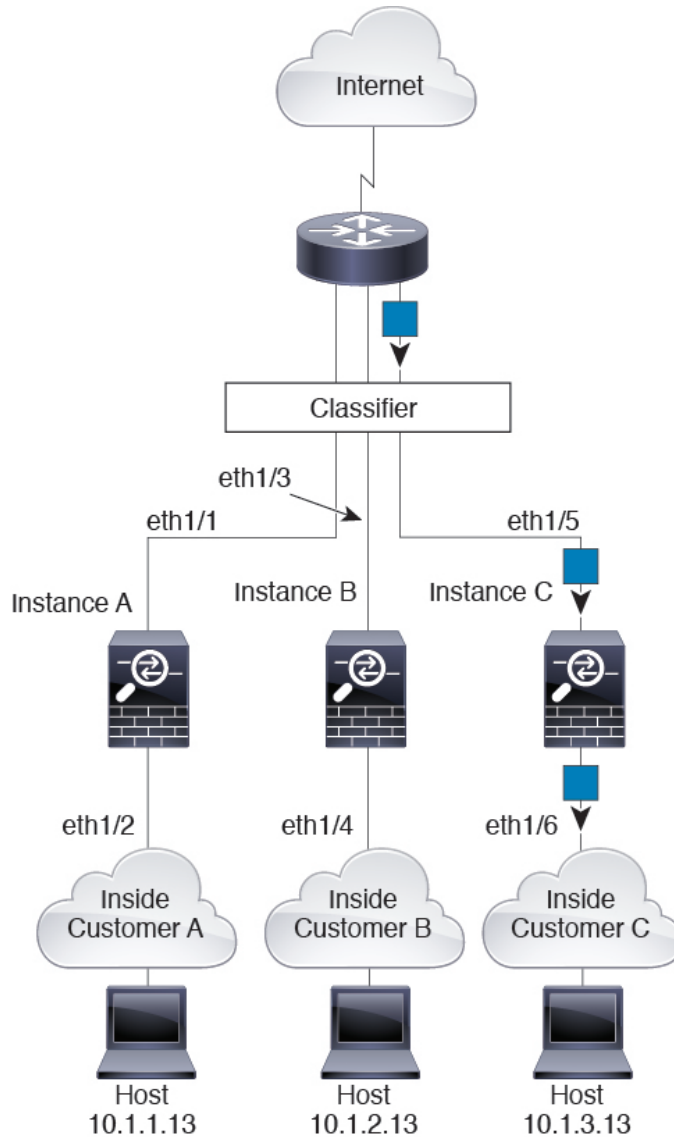

Figure 108: Transparent Firewall Instances

Inline Sets

For inline sets, you must use unique interfaces and they must be physical interfaces or EtherChannels. The following figure shows a packet destined to a host on the Instance C inside network from the internet. The classifier assigns the packet to Instance C because the ingress interface is Ethernet 1/5, which is assigned to Instance C.

Figure 109: Inline Sets

Cascading Instances

Placing an instance directly in front of another instance is called *cascading instances*; the outside interface of one instance is the same interface as the inside interface of another instance. You might want to cascade instances if you want to simplify the configuration of some instances by configuring shared parameters in the top instance.

The following figure shows a gateway instance with two instances behind the gateway.

Figure 110: Cascading Instances

Note Do not use cascading instances (using a shared interface) with High Availability. After a failover occurs and the standby unit rejoins, MAC addresses can overlap temporarily and cause an outage. You should instead use unique interfaces for the gateway instance and inside instance using an external switch to pass traffic between the instances.

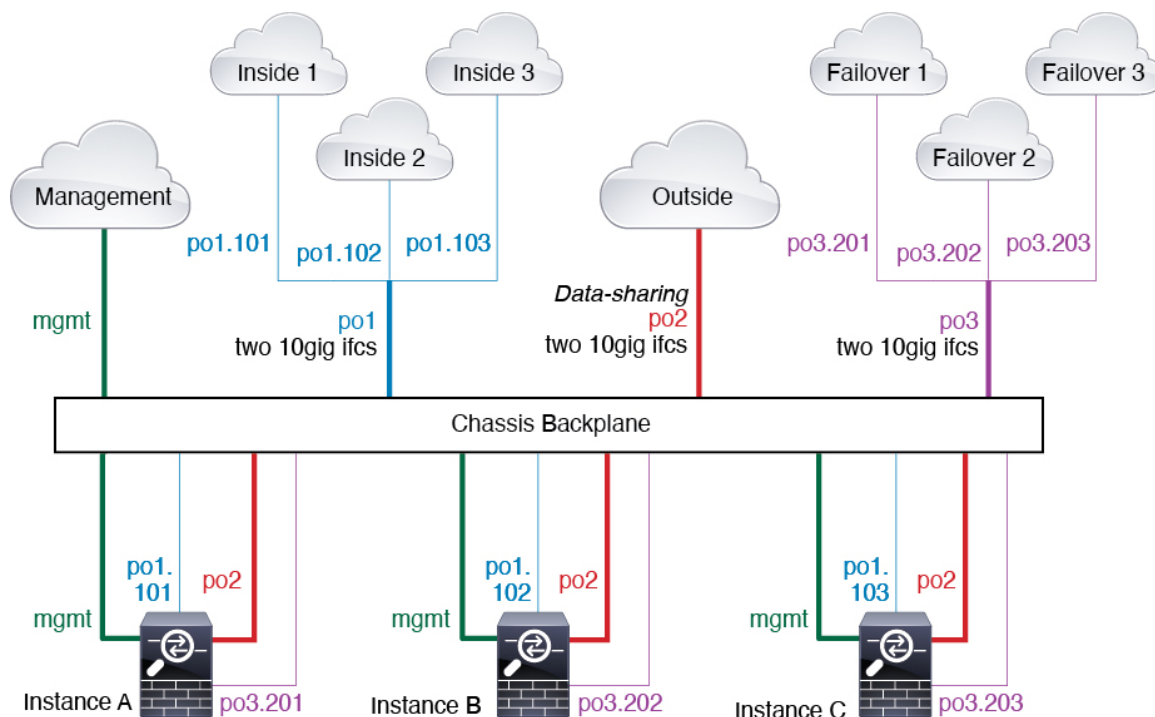

Typical Multi-Instance Deployment

The following example includes three container instances in routed firewall mode. They include the following interfaces:

- Management—All instances and the chassis use the dedicated Management interface. Within each instance (and the chassis), the interface uses a unique IP address on the same management network.
- Inside—Each instance uses a subinterface on Port-Channel1 (data type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Each subinterface is on a separate network.

- Outside—All instances use the Port-Channel2 interface (data-sharing type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Within each application, the interface uses a unique IP address on the same outside network.
- Failover—Each instance uses a subinterface on Port-Channel3 (data type). This EtherChannel includes two 10 Gigabit Ethernet interfaces. Each subinterface is on a separate network.

Figure 111: Typical Multi-Instance Deployment

Automatic MAC Addresses for Instance Interfaces

The chassis automatically generates MAC addresses for instance interfaces, and guarantees that a shared interface in each instance uses a unique MAC address.

If you manually assign a MAC address to a shared interface within the instance, then the manually-assigned MAC address is used. If you later remove the manual MAC address, the autogenerated address is used. In the rare circumstance that the generated MAC address conflicts with another private MAC address in your network, we suggest that you manually set the MAC address for the interface within the instance.

Because autogenerated addresses start with A2, you should not start manual MAC addresses with A2 due to the risk of overlapping addresses.

The chassis generates the MAC address using the following format:

A2xx.yyyz.zzzz

Where xx.yy is a user-defined prefix or a system-defined prefix, and zz.zzzz is an internal counter generated by the chassis. The system-defined prefix matches the lower 2 bytes of the first MAC address in the burned-in MAC address pool that is programmed into the IDPROM. Use **connect fxos**, then **show module** to view the

MAC address pool. For example, if the range of MAC addresses shown for module 1 is b0aa.772f.f0b0 to b0aa.772f.f0bf, then the system prefix will be f0b0.

The user-defined prefix is an integer that is converted into hexadecimal. For an example of how the user-defined prefix is used, if you set a prefix of 77, then the chassis converts 77 into the hexadecimal value 004D (yyxx). When used in the MAC address, the prefix is reversed (xxyy) to match the chassis native form:

A24D.00zz.zzzz

For a prefix of 1009 (03F1), the MAC address is:

A2F1.03zz.zzzz

Performance Scaling Factor for Multi-Instance Mode

The maximum throughput (connections, VPN sessions) for a platform is calculated for an appliance mode device's use of memory and CPU (and this value is shown in **show resource usage**). If you use multiple instances, then you need to calculate the throughput based on the percentage of CPU cores that you assign to the instance. For example, if you use an instance with 50% of the cores, then you should initially calculate 50% of the throughput. Moreover, the throughput available to an instance may be less than that available to an appliance.

For detailed instructions on calculating the throughput for instances, see <https://www.cisco.com/c/en/us/products/collateral/security/firewalls/white-paper-c11-744750.html>.

Instances and High Availability

You can use High Availability using an instance on 2 separate chassis; for example, if you have 2 chassis, each with 10 instances, you can create 10 High Availability pairs. You can also have standalone instances on the same chassis as High Availability instances. For detailed requirements, see [Requirements and Prerequisites for Instances, on page 324](#).

Note Clustering is not supported.

Licenses for Instances

All licenses are consumed per chassis and not per instance. See the following details:

- Essentials licenses are assigned to the chassis as a whole, one per chassis.
- Feature licenses are assigned to each instance, but you only *consume* one license per feature per chassis.

Requirements and Prerequisites for Instances

Model Support

- Secure Firewall 3110

- Secure Firewall 3120
- Secure Firewall 3130
- Secure Firewall 3140
- Secure Firewall 4215
- Secure Firewall 4225
- Secure Firewall 4245

Note The Secure Firewall 3105 is not supported.

Maximum Container Instances and Resources per Model

For each container instance, you can specify the number of CPU cores (or more specifically, threads) to assign to the instance. We use the term "core" generically to account for different hardware architecture. RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance.

Table 25: Maximum Container Instances and Resources per Model

Model	Max. Container Instances	Available CPU Cores (Threads)
Secure Firewall 3110	3	22
Secure Firewall 3120	5	30
Secure Firewall 3130	7	46
Secure Firewall 3140	10	62
Secure Firewall 4215	10	62
Secure Firewall 4225	14	126
Secure Firewall 4245	34	254

Software Requirements

You can run different versions of threat defense software on each instance as long as they are all compatible with the version of FXOS running on the chassis.

High Availability Requirements

- The two instances in a High Availability configuration must:
 - Be on separate chassis.
 - Be on the same model.
 - Have the same interfaces assigned. All interfaces must be preconfigured in the chassis identically before you enable High Availability.

- Use the same resource profile attributes. The profile names can be different, but the definitions need to match.

Management Center Requirements

For chassis management and all instances on the chassis, you must use the same management center due to the licensing implementation.

Guidelines and Limitations for Instances

General Guidelines

- A single management center must manage all instances on a chassis, as well as manage the chassis itself.
- For instances, the following features are not supported:
 - TLS crypto acceleration
 - Clustering
 - Management Center UCAPL/CC mode
 - Flow offload to hardware
- Primary management of the chassis by CDO cloud-delivered management center and separate analytics-only management of the chassis by an on-prem management center is not supported. You can however add CDO-managed instances to an analytics-only on-prem management center.

Management Interface

- No support for a data interface for chassis management; only the dedicated Management interface can be used
- No DHCP addressing for the Management interface

VLAN Subinterfaces

- This document discusses *chassis* VLAN subinterfaces only. You can separately create subinterfaces within the instance.
- If you assign a parent interface to an instance, it only passes untagged (non-VLAN) traffic. Do not assign the parent interface unless you intend to pass untagged traffic.
- Subinterfaces are supported on Data or Data-sharing type interfaces.
- You can create up to 500 VLAN IDs.
- You cannot use subinterfaces for an inline set or as a passive interface.
- If you use a subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links. You cannot use some subinterfaces as failover links, and some as regular data interfaces.

EtherChannels

- You can configure up to 48 EtherChannels, limited by the number of physical interfaces.
- The EtherChannel can have up to 8 active interfaces.
- All interfaces in the EtherChannel must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, unless you set the speed to **Detect SFP**; in this case, you can use different interface capacities, and the lowest common speed is used.
- The chassis does not support LACPDU s that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **vlan dot1Q tag native** command, then the chassis will drop the tagged LACPDU s. Be sure to disable native VLAN tagging on the neighboring switch.
- In Cisco IOS software versions earlier than 15.1(1)S2, the chassis did not support connecting an EtherChannel to a switch stack. With default switch settings, if the chassis EtherChannel is connected cross stack, and if the primary switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.

Data-sharing Interfaces

- Maximum 14 instances per shared interface. For example, you can allocate Ethernet1/1 to Instance1 through Instance14.

Maximum 10 shared interfaces per instance. For example, you can allocate Ethernet1/1.1 through Ethernet1/1.10 to Instance1.

- You cannot use a data-sharing interface with a transparent firewall mode instance.
- You cannot use a data-sharing interface with inline sets or passive interfaces.
- You cannot use a data-sharing interface for the failover link.

Default MAC Addresses

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See [Automatic MAC Addresses for Instance Interfaces, on page 323](#).

Configure Instances

Before you configure instances, you need to enable multi-instance mode, add the chassis to the management center, and configure chassis interfaces. You can also customize the chassis settings.

Convert a Device to Multi-Instance Mode

Use this procedure to convert a device in the management center to multi-instance mode. The conversion takes approximately 15 minutes. The system reboots and, as part of changing the mode, erases the configuration

with the exception of the Management network settings and the admin password. The chassis hostname is set to "firepower-*model*." The Management IP address is assigned to the chassis for the management connection with the management center. When you add instances, they will use separate IP addresses on the Management interface and maintain their own management connections.

After you convert to multi-instance mode, you can use the management center to configure all chassis settings as well as instances. The Secure Firewall chassis manager or configuration at the FXOS CLI is not supported.

Note If you would prefer to use the CLI to convert to multi-instance mode before adding the device to the management center, see [Enable Multi-Instance Mode at the CLI, on page 366](#).

Before you begin

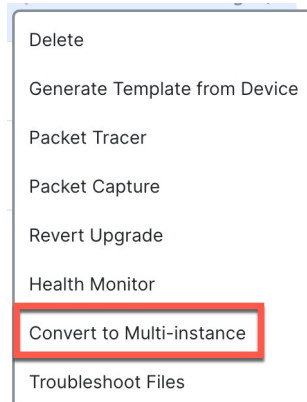

Add the appliance-mode device to the management center as a standalone device. This device cannot use:

- A data interface for manager access
- DHCP for the Management interface
- Zero-Touch Provisioning

Procedure

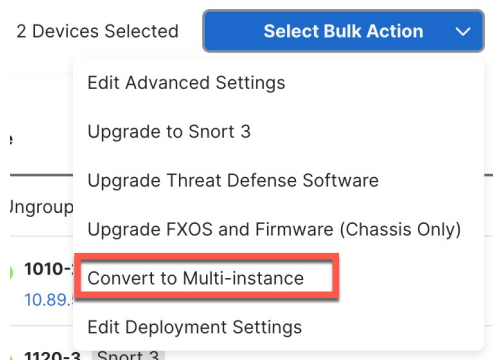

Step 1 On **Devices > Device Management**, next to the device you want to convert to multi-instance mode, choose **More (⋮) > Convert to Multi-Instance**.

Figure 112: Convert to Multi-Instance

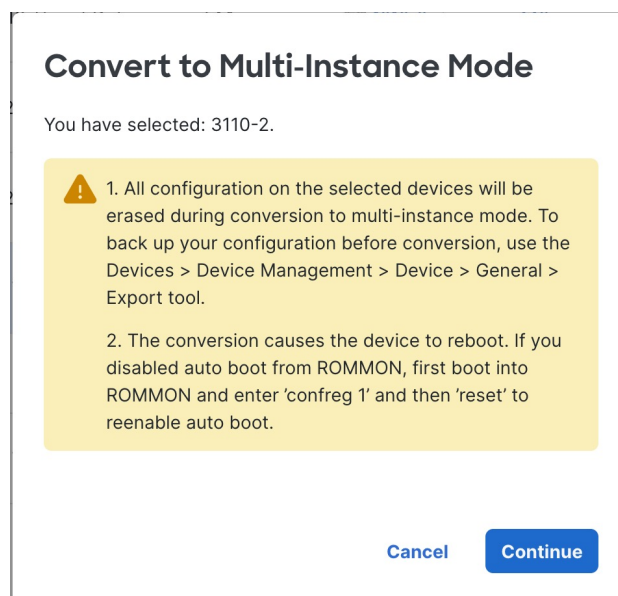

You can alternatively check the check-box next to multiple devices that you want to convert, and choose **Select Bulk Action > Convert to Multi-Instance**.

Figure 113: Bulk Conversion

Step 2 Confirm that you want to perform the conversion and click **Continue**.

Figure 114: Conversion Confirmation

A readiness check is performed. The check might fail if, for example, a deployment is in progress.

Step 3 Optionally change the name of the chassis, and click **Convert to Multi-Instance**. By default, the device name is used, but you may want a different naming convention for multi-instance chassis.

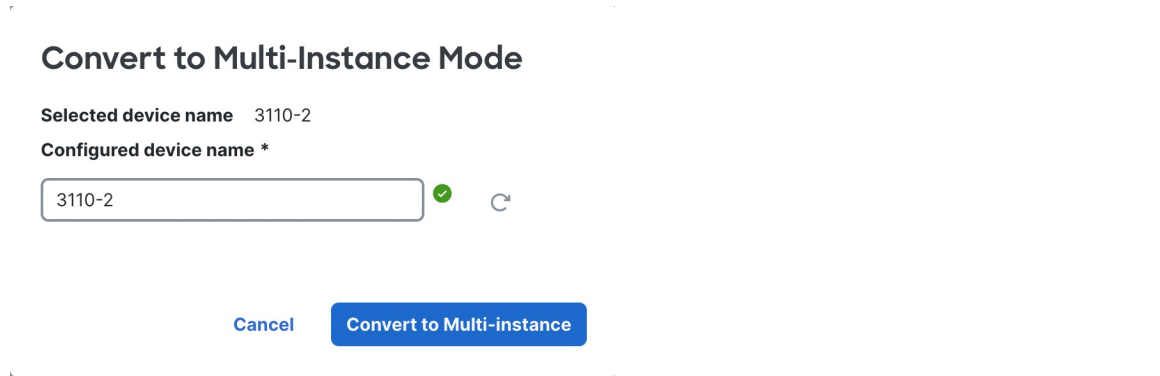

Note If the readiness check failed, for example because of a deployment in progress, you can wait for the process to complete and click  to rerun the readiness check so you can continue.

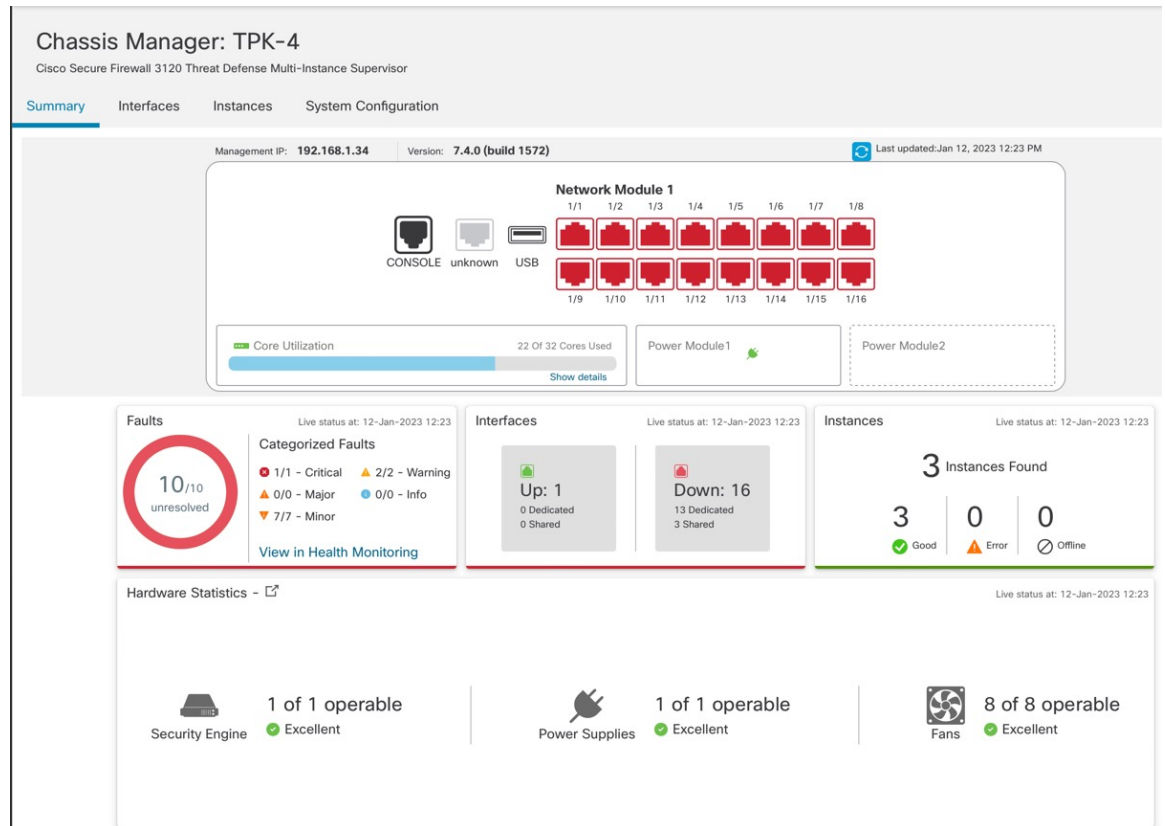

Figure 115: Rename Chassis

Wait for approximately 15 minutes, during which the device is removed from the device list, and then after conversion, it is re-added as a chassis.

- Step 4** To view and configure the chassis, click **Manage** in the **Chassis** column, or click **Edit** (✎). The **Chassis Manager** page opens for the chassis to the **Summary** page.

Figure 116: Chassis Summary

Configure Chassis Interfaces

At the chassis-level, you configure basic Ethernet settings of physical interfaces, VLAN subinterfaces for instances, and EtherChannel interfaces. By default, physical interfaces are disabled.

Note To configure breakout ports and perform other network module operations, see [Manage the Network Module for the Secure Firewall 3100/4200, on page 716](#).

Note For information about the **Sync Device** button, see [Sync Interface Changes with the Management Center, on page 713](#).

Configure a Physical Interface

You can physically enable and disable interfaces, as well as set the interface speed and duplex and other hardware settings. To use an interface, it must be physically enabled for the chassis and logically enabled in the instance. By default, physical interfaces are disabled. For VLAN subinterfaces, the admin state is inherited from the parent interface.

Procedure

Step 1 From **Devices > Device Management**, click **Manage** in the **Chassis** column or click **Edit** (✎).

Figure 117: Manage Chassis

The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **Interfaces**.

Figure 118: Interfaces

Cancel Save

Step 4 Enable the interface by checking the **Enabled** check box.

Step 5 For the **Port Type**, choose **Data** or **Data Sharing**.

Figure 120: Port Type

Port Type

Data

Data

Data Sharing

Step 6 Set the **Admin Duplex**.

Speeds of 1Gbps and higher only support **Full** duplex. SFP interfaces only support **Full** duplex.

Step 7 Set the **Admin Speed**.

For SFPs, Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.

Step 8 (Optional) Check **LLDP Transmit** and/or **LLDP Receive** to enable Link Layer Discovery Protocol (LLDP) packets.

Step 9 (Optional) Check **Flow Control Send** to enable pause (XOFF) frames for flow control.

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If the threat defense port experiences congestion (exhaustion of queuing resources on the internal switch) and cannot receive any more traffic, it notifies the other port by

sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

Note The threat defense supports transmitting pause frames so that the remote peer can rate-control the traffic.

However, receiving of pause frames is not supported.

The internal switch has a global pool of 8000 buffers of 250 bytes each, and the switch allocates buffers dynamically to each port. A pause frame is sent out every interface with flow control enabled when the buffer usage exceeds the global high-water mark (2 MB (8000 buffers)); and a pause frame is sent out of a particular interface when its buffer exceeds the port high-water mark (.3125 MB (1250 buffers)). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark (1.25 MB globally (5000 buffers); .25 MB per port (1000 buffers)). The link partner can resume traffic after receiving an XON frame.

Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

- Step 10** (Optional) Check **Auto Negotiation** to set the interface to negotiate the speed, link status, and flow control. You cannot edit this setting for speeds lower than 1Gbps. For SFP interfaces, you can only disable auto-negotiation when the speed is set to 1Gbps.
- Step 11** Click **Save** and then **Save** in the top right of the **Interfaces** page.
- You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Configure an EtherChannel

An EtherChannel (also known as a port channel) can include up to 8 member interfaces of the same media type and capacity, and must be set to the same speed and duplex. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, unless you set the speed to **Detect SFP**; in this case, you can use different interface capacities, and the lowest common speed is used.

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDUs) between two network devices. LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. “On” mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

When the chassis creates an EtherChannel, the EtherChannel stays in a **Suspended** state for Active LACP mode or a **Down** state for On LACP mode until you assign it to a logical device, even if the physical link is up. The EtherChannel will be brought out of this **Suspended** state when it is added to an instance.

Before you begin

Enable physical interfaces and set hardware parameters. See [Configure a Physical Interface, on page 332](#).

Procedure

Step 1 From **Devices > Device Management**, click **Manage** in the **Chassis** column or click **Edit** (✎).

Figure 121: Manage Chassis

The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **Interfaces**.

- For the **EtherChannel ID**, specify an ID between 1 and 48.
- Check **Enabled**.
- For the **Port Type**, choose **Data** or **Data Shared**.

For information about the port type, see [Interface Types, on page 313](#).

- To add a physical interface to the EtherChannel, select click **Add (+)** in the **Available Interfaces** list to move it to the **Selected Interfaces** list.

To add or remove all interfaces, click the double arrow button.

Note You cannot add an interface that is already assigned to an instance.

Step 5 (Optional) Set the following **Configuration** parameters.

Many of these settings (excluding the LACP settings) set the requirements for interfaces to be included in the EtherChannel; they do not override the settings of member interfaces. So if you check **LLDP Transmit**, for example, you should only add interfaces that have that setting. If you set the **Admin Speed** to 1Gbps, then only 1Gbps interfaces can be included.

Figure 125: Configuration Settings

The screenshot shows the 'Add EtherChannel Interface' configuration window. It has two tabs: 'Interfaces' and 'Configuration'. The 'Configuration' tab is selected. The settings are as follows:

- Admin Duplex:** Full (dropdown menu)
- Admin Speed:** 1Gbps (dropdown menu)
- LACP Mode:** Active (dropdown menu)
- LACP Rate:** Default (dropdown menu)
- Auto Negotiation:**
- LLDP Transmit:**
- LLDP Receive:**
- Flow Control Send:**

At the bottom right, there are two buttons: 'Cancel' and 'Save'.

- Choose the required **Admin Duplex** for the member interfaces, **Full Duplex** or **Half Duplex**.
If you add a member interface that is configured with the specified duplex, it will not successfully join the port channel.
- Choose the required **Admin Speed** for the member interfaces from the drop-down list.
If you add a member interface that is not at the specified speed, it will not successfully join the port channel.
- Choose the **LACP Mode**, **Active** or **On**.
 - Active**—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
 - On**—The EtherChannel is always on, and LACP is not used. An “on” EtherChannel can only establish a connection with another “on” EtherChannel.

Note It may take up to three minutes for an EtherChannel to come up to an operational state if you change its mode from On to Active or from Active to On.
- Choose the **LACP Rate**, **Default**, **Fast**, or **Normal**.

The default is **Fast**.

- e) Choose the required Link Layer Discovery Protocol (LLDP) settings for member interfaces by checking **LLDP Transmit** and/or **LLDP Receive**.
- f) Check the required **Flow Control Send** setting for member interfaces.

Step 6 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Configure a Subinterface

You can add up to 500 subinterfaces to your chassis.

VLAN IDs per interface must be unique, and within an instance, VLAN IDs must be unique across all assigned interfaces. You can reuse VLAN IDs on *separate* interfaces as long as they are assigned to different instances. However, each subinterface still counts towards the limit even though it uses the same ID.

This section discusses *FXOS* VLAN subinterfaces only. You can separately create subinterfaces within the instance. See [Chassis Interfaces vs. Instance Interfaces, on page 313](#).

Procedure

Step 1 From **Devices > Device Management**, click **Manage** in the **Chassis** column or click **Edit** (🔗).

a)

Step 5 Click **Save** and then **Save** in the top right of the **Interfaces** page.

You can now **Deploy** the policy to the chassis. The changes are not active until you deploy them.

Add an Instance

You can add one or more instances to a chassis in multi-instance mode. The number of supported instances depends on your model; see [Requirements and Prerequisites for Instances, on page 324](#).

Before you begin

[Convert a Device to Multi-Instance Mode, on page 328](#).

Procedure

Step 1 From **Devices > Device Management**, click **Manage** in the **Chassis** column or click **Edit** (✎).

Figure 130: Manage Chassis

<input type="checkbox"/>	TPK-4 192.168.1.34	Firewall 3120 Threat Defense Multi- Instance Supervisor	7.4.0	Manage	N/A
--------------------------	-----------------------	---	-------	---------------	-----

The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **Instances**, and click **Add Instance**.

End User License Agreement
 Effective: May 10, 2022
 Secure Firewall Terms and Conditions

By clicking 'Accept' below or using this Cisco Technology, you agree that such use is governed by the Cisco End User License Agreement and applicable Product Specific Terms available at:

<https://www.cisco.com/c/en/us/about/legal/cloud-and-software/software-terms.html>

You also acknowledge that you have read the Cisco Privacy Statement at:

<https://www.cisco.com/c/en/us/about/legal/privacy-full.html>

If you are a Cisco partner accepting on behalf of an end customer, you must inform the end customer that the EULA applies to such end customer's use of the Cisco Technology and provide the end customer with access to all relevant terms. If you do not have authority to bind your company and its affiliates, or if you do not agree with the terms of the EULA, do not click 'Accept' and do not use the Cisco Technology.

I understand and accept the agreement.

Cancel Next

Step 4 On **Instance Configuration**, set the instance parameters, then click **Next**.

Figure 133: Instance Configuration

- **Display Name**

- **Device Version**—Versions listed are packages currently downloaded to the chassis. To upgrade to a new package, see **Devices > Chassis Upgrade**. When you upgrade, both the old threat defense version and the new threat defense version will be listed in the menu. To download an older package, you need to use the FXOS CLI. Note: Both FXOS and threat defense images are included in the same package. See the [troubleshooting guide](#) for more information.

For example:

```
firepower-3110# scope firmware
firepower-3110# download image
https://10.10.7.89/Cisco_FTD_SSP_FP3K_Upgrade-7.4.1-1.sh.DEV.tar
Please use the command 'show download-task' or 'show download-task detail' to check
download progress.
% Download-task Cisco_FTD_SSP_FP3K_Upgrade-7.4.1-1.sh.DEV.tar : completed successfully.
```

- **IPv4, IPv6, or Both**—Set a **Management IP** address on the same network as the chassis Management interface. Set the **Network Mask** and gateway (likely the same gateway as the chassis). The chassis Management interface is shared with each instance, and each instance has its own IP address on the network. You can SSH to this IP address by default to reach the threat defense CLI.
- (Optional) **FQDN**
- **Firewall Mode**—**Routed** or **Transparent**. For more information about the firewall mode, see [Transparent or Routed Firewall Mode, on page 243](#).
- **DNS Servers**—Enter a comma-separated list of DNS servers for management traffic only.
- (Optional) **Permit Expert Mode for CLI**—Expert Mode provides threat defense shell access for advanced troubleshooting.

If you enable this option, then users who access the instance directly from an SSH session can enter Expert Mode. If you disable this option, then only users who access the instance from the FXOS CLI can enter Expert Mode. We recommend disabling this option to increase isolation between instances.

Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the threat defense CLI.

- **Resource Profile**—The resource profile sets the number of CPU cores; RAM is dynamically allocated according to the number of cores, and disk space is set to 40 GB per instance. The chassis includes the following default resource profiles: Default-Small, Default-Medium, and Default-Large. You can add additional profiles for this chassis by clicking **Add (+)**. You cannot later edit the resource profile.

Figure 134: Add Resource Profile

Add resource profile ×

Name*
silver

(Set the name of the profile between 1 and 64 characters.)

Description

Number of Cores*
24

Assign an even number of cores, 6 to 100.

Cancel Add

- The minimum number of cores is 6.

Note Instances with a smaller number of cores might experience relatively higher CPU utilization than those with larger numbers of cores. Instances with a smaller number of cores are more sensitive to traffic load changes. If you experience traffic drops, try assigning more cores.

- You can assign cores as an even number (6, 8, 10, 12, 14 etc.) up to the maximum.
- The maximum number of cores available depends on the model; see [Requirements and Prerequisites for Instances, on page 324](#).

If you later assign a different resource profile, then the instance will reload, which can take approximately 5 minutes. Note that for an established High Availability pair, if you assign a different-sized resource profile, be sure to make all members the same size as soon as possible.

- **Device SSH Password**—Set the threat defense admin user password for CLI access, either SSH or console. Repeat the password in the **Confirm Password** field.

Step 5 On **Interface Assignment**, assign the chassis interfaces to the instance, then click **Next**.

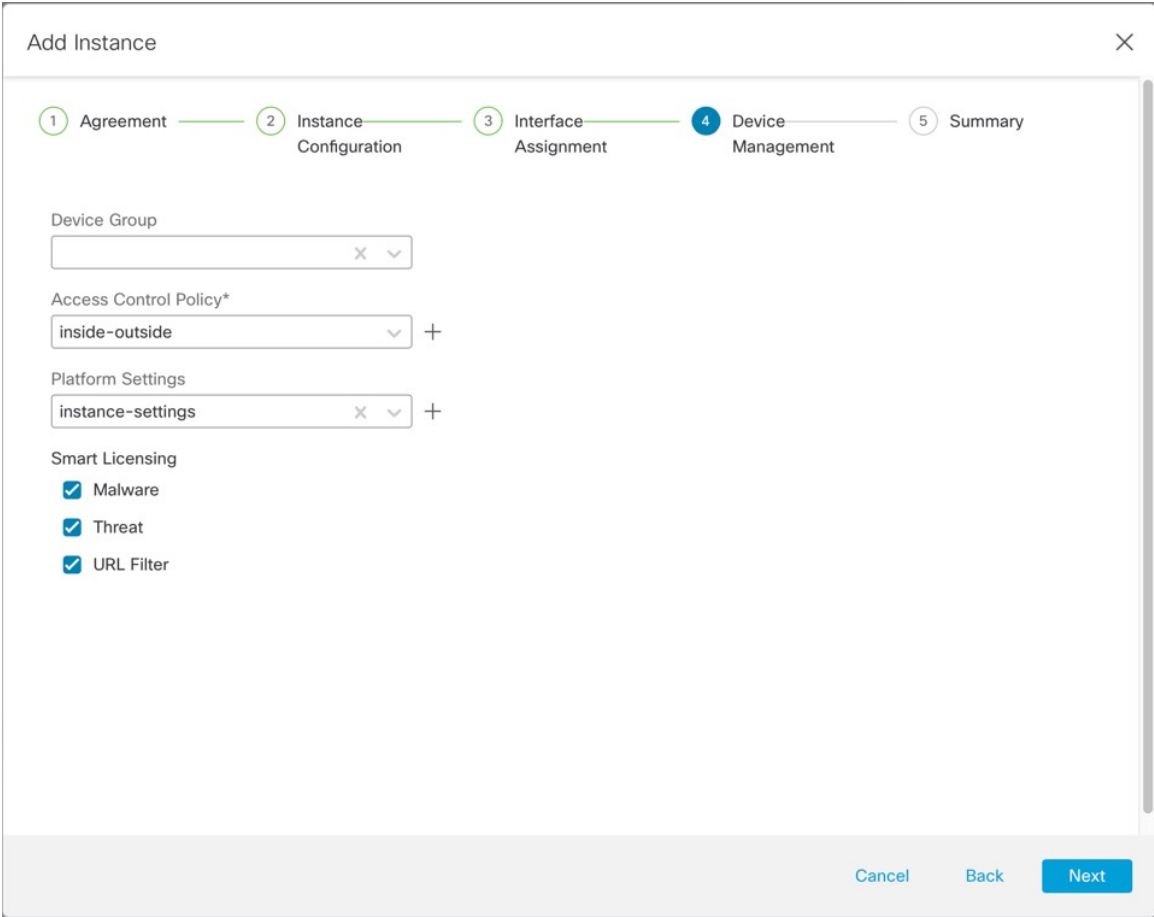

Figure 135: Interface Assignment

The screenshot shows the 'Add Instance' configuration wizard at the 'Interface Assignment' step. The progress bar at the top indicates five steps: 1. Agreement, 2. Instance Configuration, 3. Interface Assignment (current step), 4. Device Management, and 5. Summary. Below the progress bar, there are two columns of interface lists. The 'Available Interfaces (5)' column lists Ethernet1/7, Ethernet1/8, Ethernet1/14 (highlighted), Ethernet1/15, and Ethernet1/16. The 'Selected Interfaces (3)' column lists Ethernet1/4, Ethernet1/6, and Ethernet1/9. Between the columns are '>>' and '<<' buttons. At the bottom right, there are 'Cancel', 'Back', and 'Next' buttons.

Shared interfaces show the sharing icon ()

Step 6 On **Device Management**, set the device-specific settings, then click **Next**.

Figure 136: Device Management

- **Device Group**
- **Access Control Policy**—Choose an existing access control policy, or create a new policy.
- **Platform Settings**—Choose an existing platform setting policy, or create a new policy.
- **Smart Licensing**

Step 7 On **Summary**, confirm your settings, then click **Save**.

Figure 137: Summary

Cancel Back Save

You can edit any settings on this screen before saving the instance. After you save, the instance is added to the **Instances** screen.

Step 8 On the **Instances** screen, click **Save**.

Step 9 Deploy the chassis configuration.

After deployment, the instance will be added as a device on the **Device Management** page.

Customize the System Configuration

You can configure chassis-level settings such as SNMP. You can also import or export the chassis FXOS configuration.

Configure SNMP

You can access chassis-level MIBs through the data interface of one of the instances, which you specify in the chassis system configuration. You can only use this instance for chassis SNMP information. You cannot access SNMP through the chassis Management interface.

Before you begin

Configure SNMP for one of the instances. See [SNMP, on page 884](#).

Procedure

Step 1 From **Devices > Device Management**, click **Manage** in the **Chassis** column or click **Edit** (✎).

Figure 138: Manage Chassis

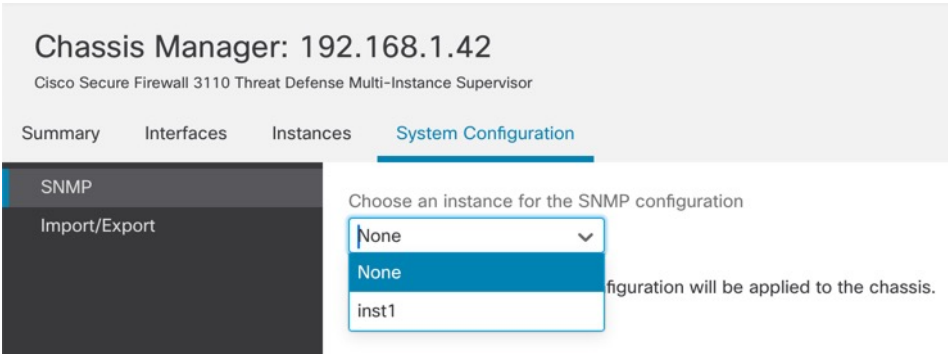

The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **System Configuration**.

Step 3 Click **SNMP**, and choose the instance from the drop-down list.

Figure 139: SNMP

SNMP on the chassis will be accessible from the selected instance.

Step 4 Click **Save**.

Step 5 Deploy the chassis configuration.

Import or Export the Chassis Configuration

You can use the configuration export feature to export an XML file containing chassis configuration settings to your local computer. You can later import that configuration file to quickly apply the configuration settings to your chassis to return to a known good configuration or to recover from a system failure. You can also import the chassis configuration to a new chassis, for example for an RMA, as long as the prerequisites are met.

When exporting, only chassis configurations are exported; instance configuration settings are not exported. Instances need to be backed up separately using the device backup/restore feature.

When importing, all existing configurations on the chassis will be replaced by the configuration in the import file.

Before you begin

For the chassis where you want to import a configuration, the following characteristics must match:

- Same chassis software version
- Same threat defense instance images
- Same network modules

Procedure

Step 1 From **Devices > Device Management**, click **Manage** in the **Chassis** column or click **Edit** (✎).

Figure 140: Manage Chassis

<input type="checkbox"/>	✔ TPK-4 192.168.1.34	Firewall 3120 Threat Defense Multi- Instance Supervisor	7.4.0	Manage	N/A
--------------------------	---	---	-------	------------------------	-----

The **Chassis Manager** page opens for the chassis to the **Summary** page.

Step 2 Click **System Configuration**.

Step 3 Click **Import/Export**.

Step 4 To export the configuration, follow these steps.

a) In the **Export** area, click **Click here to export**.

Figure 144: Import

Configure Chassis Platform Settings

Chassis platform settings configure a range of features for managing the chassis. You can share the policy among multiple chassis. If you want different settings per chassis, you must create multiple policies.

Create a Chassis Platform Settings Policy

Use the **Platform Settings** page (**Devices > Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

Procedure

Step 1 Choose **Devices > Platform Settings**.

Step 2 For an existing policy, you can **Copy** (📄), **Edit** (✎), or **Delete** (🗑) the policy.

Caution You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is good practice to deploy a different policy to those targets.

Step 3 To create a new policy, click **New Policy**.

- Choose **Chassis Platform Settings** from the drop-down list.
- Enter a **Name** for the new policy and optionally, a **Description**.
- Optionally, choose the **Available Chassis** where you want to apply the policy and click **Add** (or drag and drop) to add the selected chassis. You can enter a search string in the **Search** field to narrow the list of chassis.
- Click **Save**.

The system creates the policy and opens it for editing.

- Step 4** To change the target chassis for a policy, click **Edit** (✎) next to the platform settings policy that you want to edit.
- Click **Policy Assignment**.
 - To assign a chassis to the policy, select it in the **Available Chassis** list and click **Add**. You can also drag and drop.
 - To remove a chassis assignment, click **Delete** (🗑) next to a chassis in the **Selected Chassis** list.
 - Click **OK**.

Configure DNS

You need to specify a DNS server if the chassis requires resolution of hostnames to IP addresses. These chassis DNS settings are separate from the DNS settings per instance, which are configured in the device platform settings.

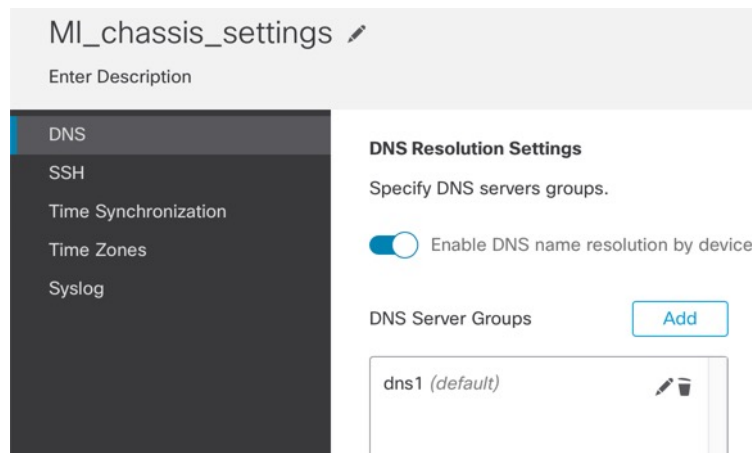

When you configure multiple DNS servers, the chassis uses servers in a random order. You can configure up to four servers across four DNS server groups. For example, you can configure a single server group with four servers, or you can configure four server groups with one server each.

Procedure

Step 1 Choose **Devices > Platform Settings** and create or edit the chassis policy.

Step 2 Choose **DNS**.

Figure 145: DNS

Step 3 Enable the **Enable DNS name resolution by device** slider.

Step 4 Click **Add** to add a DNS server group.

Figure 146: Add DNS Server Group

- Step 5** Either select an existing DNS server group (see [Creating DNS Server Group Objects, on page 1282](#)), or click **+ New Group**.

If you add a new group, you see the following dialog box. Provide a name and up to four DNS server IP addresses as comma-separated values, and click **Add**.

Figure 147: New DNS Server Group Object

- Step 6** Click **Save** to add the DNS server to the list.
- Step 7** Repeat these steps to add additional server groups.
Make sure you only identify a maximum of four DNS servers in all groups combined.
- Step 8** Click **Save** to save all policy changes.

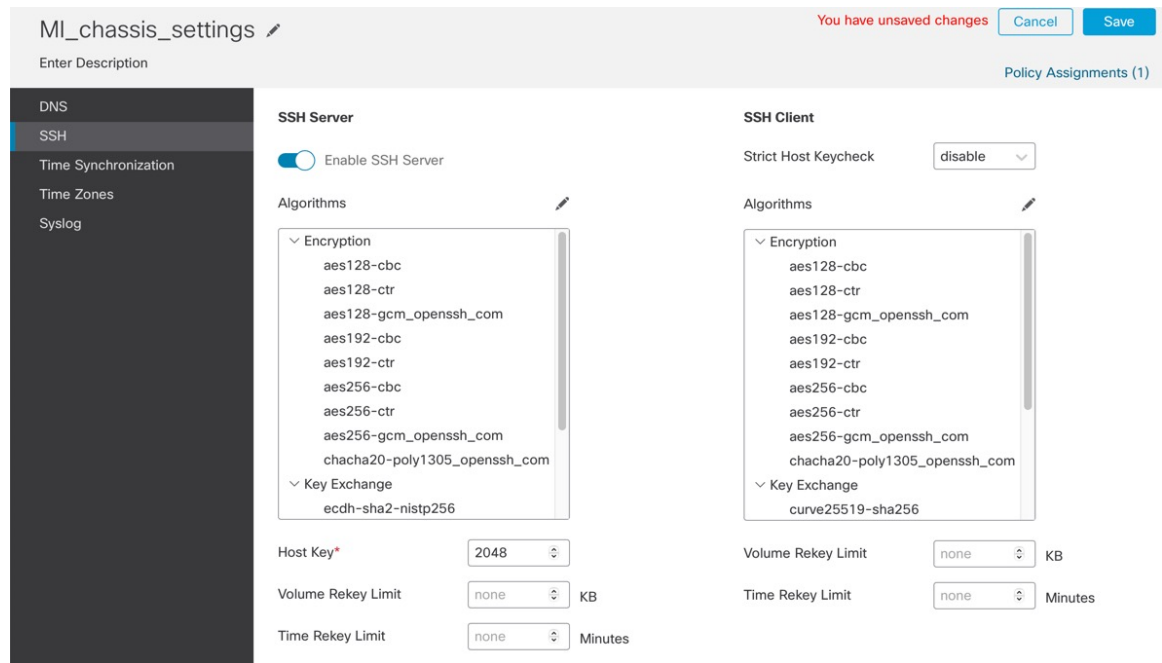

Configure SSH and SSH Access List

To allow SSH sessions from the admin user to the chassis on the Management interface, enable the SSH server and configure the allowed networks.

Procedure

- Step 1** Choose **Devices > Platform Settings** and create or edit the chassis policy.
- Step 2** Choose **SSH**.
- Step 3** To enable SSH access to the chassis, enable the **Enable SSH Server** slider.

Figure 148: SSH

- Step 4** To set the allowed **Algorithms**, click **Edit** (✎).

Figure 149: Add Algorithms

- a) Select the **Encryption** algorithms.
- b) Select the **Key Exchange** algorithms.

The key exchange provides a shared secret that cannot be determined by either party alone. The key exchange is combined with a signature and the host key to provide host authentication. This key-exchange method provides explicit server authentication.

- c) Select the **Mac** integrity algorithms.

Step 5 For **Host Key**, enter the modulus size for the RSA key pairs.

The modulus value (in bits) is in multiples of 8 from 1024 to 2048. The larger the key modulus size you specify, the longer it takes to generate an RSA key pair. We recommend a value of 2048.

Step 6 For the server **Volume Rekey Limit**, set the amount of traffic in KB allowed over the connection before FXOS disconnects from the session.

Step 7 For the server **Time Rekey Limit**, set the minutes for how long an SSH session can be idle before FXOS disconnects the session.

Step 8 For the **SSH Client**, configure the following settings.

Figure 150: SSH

By sending syslog messages to a remote destination, you can archive messages according to the available disk space on the external syslog server, and manipulate logging data after it is saved. For example, you could specify actions to be executed when certain types of syslog messages are logged, extract data from the log and save the records to another file for reporting, or track statistics using a site-specific script.

Name	Description
Admin State field	Check the Enable check box if you want to have syslog messages stored in a remote log file.

Name	Description
Faults > Enable Admin State	Enable system fault logging.
Audits > Enable Admin State	Enable audit logging.
Events > Enable Admin State	Enable system event logging.

Step 6 Click **Save** to save all policy changes.

Configure Time Synchronization

NTP is used to implement a hierarchical system of servers that provide a precisely synchronized time among network systems. This kind of accuracy is required for time-sensitive operations, such as validating CRLs, which include a precise time stamp. You can configure up to four NTP servers.

- Note**
- FXOS uses NTP version 3.
 - If the stratum value of an external NTP server is 13 or greater, the application instance cannot sync to the NTP server on the FXOS chassis. Each time a NTP client syncs to a NTP server, the stratum value increases by one.
- If you have set up your own NTP server, you can find its stratum value in the /etc/ntp.conf file on the server. If the NTP server has stratum value of 13 or greater you can either change the stratum value in the ntp.conf file and restart the server, or use a different NTP server (for example: pool.ntp.org).

Before you begin

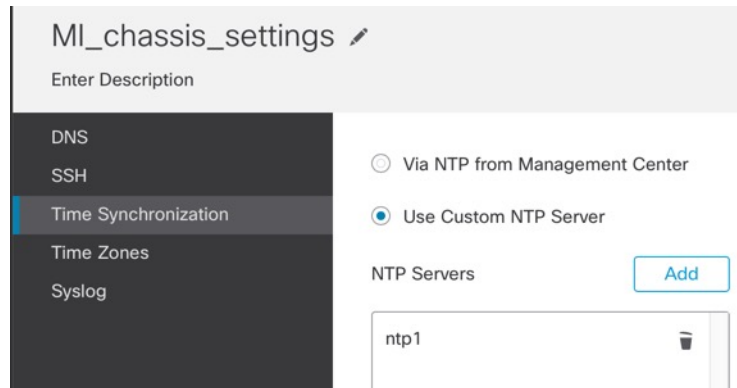

If you use a hostname for the NTP server, you must configure a DNS server. See [Configure DNS, on page 352](#).

Procedure

Step 1 Choose **Devices > Platform Settings** and create or edit the chassis policy.

Step 2 Choose **Time Synchronization**.

Figure 156: Time Synchronization

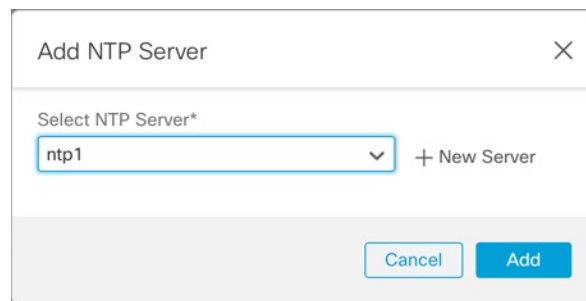

Step 3 If you want to obtain the time from the management center, click **Via NTP from Management Center**. This option ensures both the chassis and the management center have the same time.

Step 4 To use an external NTP server, click **Use Custom NTP Server**.

a) Click **Add** to add a server.

Figure 157: Add NTP Server

b) Choose any already-defined servers from the drop-down menu and click **Add**, or click **+ New Server** to add a new server.

Figure 158: Add New NTP Server

c) For a new server, enter the following fields, and click **Add**.

- **NTP Server Name**—A name to identify this server.
- **IP/FQDN**—The IP address or hostname of the server.
- **Authentication Key** and **Authentication Value**—Obtain the key ID and value from the NTP server. For example, to generate the SHA1 key on NTP server Version 4.2.8p8 or later with OpenSSL installed, enter the **ntp-keygen -M** command, and then view the key ID and value in the ntp.keys file. The key is used to tell both the client and server which value to use when computing the message digest.

Only SHA1 is supported for NTP server authentication.

Step 5 Click **Save** to save all policy changes.

Configure Time Zones

Set the time zone for the chassis.

Procedure

- Step 1** Choose **Devices > Platform Settings** and create or edit the chassis policy.
- Step 2** Choose **Time Zones**.

Figure 159: Time Zones

Step 3 Choose your **Time Zone** from the drop-down menu.

Step 4 Click **Save** to save all policy changes.

Manage Multi-Instance Mode

This section describes less common tasks, including changing settings at the FXOS CLI or changing interfaces assigned to the chassis.

Enable Multi-Instance Mode at the CLI

If you want to pre-configure your devices for multi-instance mode before you add them to the management center, you can perform this procedure. To use the management center to convert to multi-instance mode, see [Convert a Device to Multi-Instance Mode, on page 328](#).

You need to connect to the threat defense CLI at the console port to enable multi-instance mode. After you configure the mode, you can add it to the management center.

Note Although you can connect to SSH on the management port, we recommend using the console port to avoid multiple disconnections. This procedure covers the console port.

Procedure

Step 1 Connect to the chassis console port.

The console port connects to the FXOS CLI.

Step 2 Log in with the username **admin** and the password **Admin123**.

The first time you log in to FXOS, you are prompted to change the password.

Note If the password was already changed, and you do not know it, you must reimage the device to reset the password to the default. See the [FXOS troubleshooting guide](#) for the [reimage procedure](#).

Example:

```
firepower login: admin
Password: Admin123
Successful login attempts for user 'admin' : 1

[...]

Hello admin. You must change your password.
Enter new password: *****
Confirm new password: *****
Your password was updated successfully.

[...]

firepower#
```

Step 3 Check your current mode, Native or Container. If the mode is Native, you can continue with this procedure to convert to multi-instance (Container) mode.

show system detail

Example:

```
firepower # show system detail

Systems:
  Name: firepower
  Mode: Stand Alone
  System IP Address: 172.16.0.50
  System IPv6 Address: ::
  System Owner:
  System Site:
  Deploy Mode: Native
  Description for System:
firepower #
```

Step 4 Connect to the threat defense CLI.

connect ftd

Example:

```
firepower# connect ftd
>
```

Step 5 The first time you log in to the threat defense, you are prompted to accept the General Terms. You are then presented with the CLI setup script.

The setup script lets you set the Management interface IP address and other settings. However, when you convert to multi-instance mode, the only settings that are retained are the following.

- Admin password (that you set at initial login)
- DNS servers
- Search domains

You will reset the Management IP address and gateway as part of the multi-instance mode command. After you convert to multi-instance mode, you can change Management settings at the FXOS CLI. See [Change Chassis Management Settings at the FXOS CLI, on page 371](#).

Step 6

Enable multi-instance mode, set the chassis management interface settings, and identify the management center. You can use IPv4 and/or IPv6 static addressing; DHCP is not supported. After you enter the command, you will be prompted to erase the configuration and reboot. Enter **ERASE** (all caps). The system reboots and, as part of changing the mode, erases the configuration with the exception of the Management network settings you set in the command and the admin password. The chassis hostname is set to "firepower-model."

IPv4:

```
configure multi-instance network ipv4 ip_address network_mask gateway_ip_address manager  
manager_name {hostname | ipv4_address | DONTRESOLVE} registration_key nat_id
```

IPv6:

```
configure multi-instance network ipv6 ipv6_address prefix_length gateway_ip_address manager  
manager_name {hostname | ipv6_address | DONTRESOLVE} registration_key nat_id
```

See the following **manager** components:

- *{hostname | ipv4_address | DONTRESOLVE}*—Specifies either the FQDN or IP address of the management center. At least one of the devices, either the management center or the chassis, must have a reachable IP address to establish the two-way, SSL-encrypted communication channel between the two devices. If you don't specify a manager hostname or IP address in this command, then enter **DONTRESOLVE**; in this case, the chassis must have a reachable IP address or hostname, and you must specify the *nat_id*.
- *registration_key*—Enter a one-time registration key of your choice that you will also specify on the management center when you register the chassis. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).
- *nat_id*—Specifies a unique, one-time string of your choice that you will also specify on the management center when you register the chassis when one side does not specify a reachable IP address or hostname. It is required if you do not specify a manager address or hostname, however, we recommend that you always set the NAT ID even when you specify a hostname or IP address. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the management center.

To change the mode back to appliance mode, you must use the FXOS CLI and enter **scope system** and then **set deploymode native**. See [Change Chassis Management Settings at the FXOS CLI, on page 371](#).

Example:

```
> configure multi-instance network ipv4 172.16.0.104 255.255.255.0 172.16.0.1 manager  
fmcl 172.16.0.103 impala67 winchester1  
WARNING: This command will discard any FTD configuration (except admin's credentials).  
Make sure you backup your content. All previous content will be lost. System is going to
```

```

be re-initialized.
Type ERASE to confirm:ERASE
Exit...
>

```

Step 7 Add the chassis to the management center. See [Add a Chassis to the Management Center, on page 35](#).

Change Interfaces Assigned to an Instance

You can allocate or unallocate an interface on the instance. Adding a new interface, or deleting an unused interface, has minimal impact on the instance configuration. You can also edit the membership of an allocated EtherChannel without affecting the instance. However, deleting an interface that is used in your security policy will impact the configuration.

Interfaces can be referenced directly in many places in the instance configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface.

Policies that refer to security zones are not affected.

Note For high availability, you need to make the same interface changes for the other unit. Otherwise, high availability might not operate correctly.

Before you begin

- Configure your interfaces according to [Configure Instances, on page 328](#).
- If you want to add an already-allocated interface to an EtherChannel, you need to unallocate the interface from the instance first, then add the interface to the EtherChannel. For a new EtherChannel, you can then allocate the EtherChannel to the instance.

Procedure

Step 1 From **Devices > Device Management**, click **Manage** in the **Chassis** column or click **Edit** (✎).

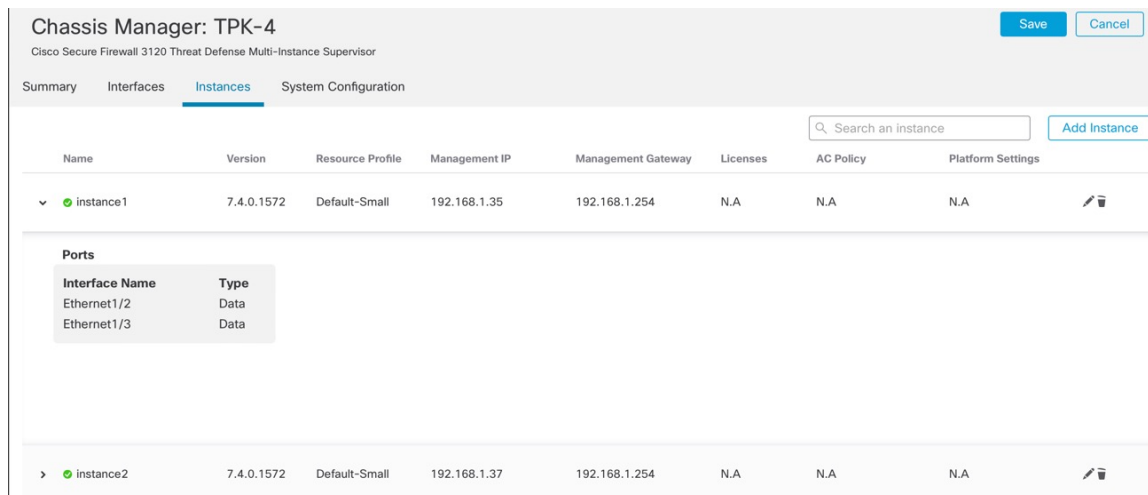

Figure 160: Manage Chassis

<input type="checkbox"/>	<input checked="" type="checkbox"/> TPK-4 192.168.1.34	Firewall 3120 Threat Defense Multi- Instance Supervisor	7.4.0	Manage	N/A
--------------------------	---	---	-------	---------------	-----

The **Chassis Manager** page opens for the chassis to the **Summary** page.

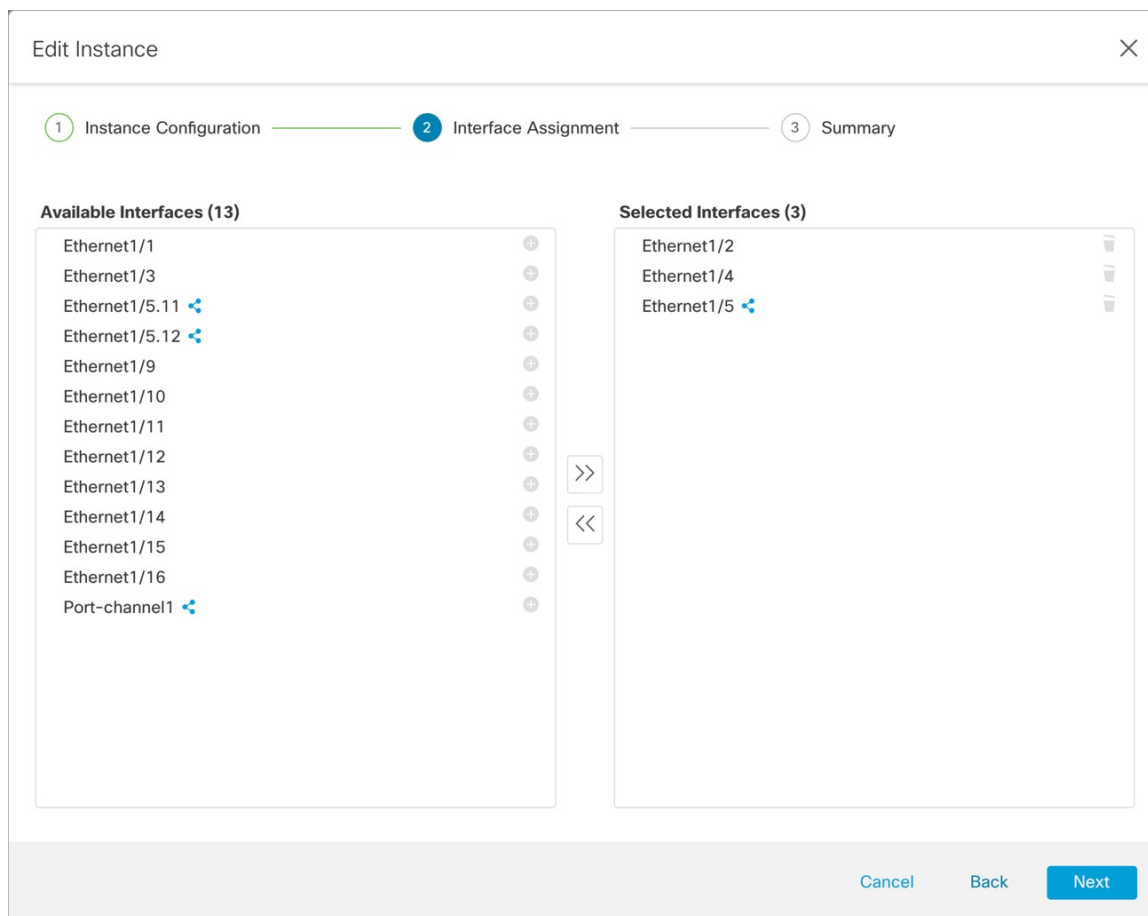

Step 2 Click **Instances**, and click **Edit** (✎) next to the instance for which you want to change interfaces.

Figure 161: Instances

Step 3 Click **Next** until you get to the **Interface Assignment** screen.

Figure 162: Interface Assignment

Shared interfaces show the sharing icon ()

- Step 4** Make your interface changes, and then click **Next**.
- Step 5** Click **Save** on the **Summary** screen.
- Step 6** For high availability, you need to make the same interface changes for the other unit. Otherwise, high availability might not operate correctly.

Change Chassis Management Settings at the FXOS CLI

If you want to change the chassis management interface IP address and gateway, change the management center to a new manager, change the admin password, or disable multi-instance mode, you can do so from the FXOS CLI.

Procedure

- Step 1** Connect to the chassis console port.

The console port connects to the FXOS CLI.

Note We recommend using the console port. You can also connect using SSH to the management interface, if configured in the chassis platform settings in the management center; however, if you change the management IP address, you will be disconnected.

- Step 2** Log in with the username **admin** and the password you set during initial setup.
- Step 3** Change the Management IP address. You can use a static IPv4 and/or IPv6 address.

IPv4:

scope fabric-interconnect

set out-of-band static ip *ip_address* **netmask** *network_mask* **gw** *gateway_ip_address*

IPv6:

scope fabric-interconnect

scope ipv6-config

set out-of-band static ipv6 *ipv6_address* **ipv6-prefix** *prefix_length* **ipv6-gw** *gateway_address*

Example:

IPv4:

```
firepower-3110# scope fabric-interconnect
firepower-3110 /fabric-interconnect # set out-of-band static ip 10.5.23.8 netmask
255.255.255.0
gw 10.5.23.1
```

IPv6:

```
firepower-3110# scope fabric-interconnect
firepower-3110 / fabric-interconnect # scope ipv6-config
```

```
firepower-3110 / fabric-interconnect / ipv6-config # set out-of-band static ipv6 2001:DB8::34
ipv6-prefix 64 ipv6-gw 2001:DB8::1
```

Step 4 Change the management center.

You should first unregister the chassis from the current management center.

enter device-manager *manager_name* [**hostname** {*hostname* | *ipv4_address* | *ipv6_address*}] [**nat-id** *nat_id*]

You are prompted for the registration key.

You can enter this command from any scope.

- **hostname** {*hostname* | *ipv4_address* | *ipv6_address*}—Specifies either the FQDN or IP address of the management center. At least one of the devices, either the management center or the chassis, must have a reachable IP address to establish the two-way, TLS-1.3-encrypted communication channel between the two devices. If you do not specify a **hostname**, then the chassis must have a reachable IP address or hostname and you must specify the **nat-id**.
- **nat-id** *nat_id*—Specifies a unique, one-time string of your choice that you will also specify on the management center when you register the chassis when one side does not specify a reachable IP address or hostname. It is required if you do not specify a **hostname**, however we recommend that you always set the NAT ID even when you specify a hostname or IP address. The NAT ID must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-). This ID cannot be used for any other devices registering to the management center.
- **Registration Key:** *reg_key*—You will be prompted for a one-time registration key of your choice that you will also specify on the management center when you register the chassis. The registration key must not exceed 37 characters. Valid characters include alphanumerical characters (A–Z, a–z, 0–9) and the hyphen (-).

Example:

```
firepower-3110# enter device-manager boulder_fmc hostname 10.89.5.35 nat-id 93002
(Valid registration key characters: [a-z],[A-Z],[0-9],[ -]. Length: [2-36])
Registration Key: Impala67
```

Step 5 Change the admin password.

scope security

set password

Enter a password: *password*

Confirm the password: *password*

Example:

```
firepower-3110# scope security
firepower-3110 /security # set password
Enter new password: Sw@nsong67
Confirm new password: Sw@nsong67
firepower-3110 /security #
```

Step 6 Disable multi-instance mode and set the system back to appliance mode.

scope system

set deploymode native

You are prompted to reboot.

Example:

```
firepower-3110# scope system
firepower-3110 /system # set deploymode native
All configuration and bootable images will be lost and system will reboot.
If there was out of band upgrade, it might reboot with the base version and
need to re-image to get the expected running version.
Do you still want to change deploy mode? (yes/no):yes
firepower-3110 /system #
```

To change the mode back to multi-instance mode, enter **set deploymode container**. You can check the current mode using the **show system detail** command.

Monitoring Multi-Instance Mode

This section helps you troubleshoot and diagnose your multi-instance mode chassis and instances.

Monitoring Multi-Instance Setup

show system detail

This FXOS command shows the current mode, Native or Container. If the mode is Native (also known as appliance mode), you can convert to multi-instance (Container) mode. Note that the prompt/name in multi-instance mode is generic "firepower-<model>" while the prompt in appliance mode is the hostname you set for the threat defense (by default "firepower")

```
firepower # show system detail

Systems:
  Name: firepower
  Mode: Stand Alone
  System IP Address: 172.16.0.50
  System IPv6 Address: ::
  System Owner:
  System Site:
  Deploy Mode: Native
  Description for System:
firepower #
```

scope system > show

This FXOS command shows the current mode in a table format. Note that the prompt/name in multi-instance mode is generic "firepower-<model>" while the prompt in appliance mode is the hostname you set for the threat defense.

```
firepower-3110# scope system
```

```
firepower-3110 /system # show

Systems:
  Name           Mode           Deploy Mode System IP Address System IPv6 Address
  -----
  firepower-3110
                Stand Alone Container  10.89.5.42          ::

3110-1# scope system
3110-1 /system # show

Systems:
  Name           Mode           Deploy Mode System IP Address System IPv6 Address
  -----
  3110-1         Stand Alone Native   10.89.5.41          ::
3110-1 /system #
```

Monitoring Instance Interfaces

show portmanager switch forward-rules hardware mac-filter

This command shows the internal switch-forwarding rule for two instances with a dedicated physical interface assigned to each instance. Ethernet 1/2 is assigned to ftd1 and Ethernet 1/1 is assigned to ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

```
secfw-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN  SRC_PORT  PC_ID  SRC_ID  DST_PORT  PKT_CNT  DMAC
1         0         17      0      17       19      29164  0:0:0:0:0:0
2         0         19      0      19       17      67588  0:0:0:0:0:0
3         0          1      0     101     1541         0  a2:5b:83:0:0:15
4         0          1      0     101     1541     8181  ff:ff:ff:ff:ff:ff
5         0          2      0     102     1540         0  a2:5b:83:0:0:18
6         0          2      0     102     1540        431  ff:ff:ff:ff:ff:ff
7         0         17      0         0         0     11133  0:0:0:0:0:0
8         0         17      0         0         0         0  0:0:0:0:0:0
```

This command shows the internal switch-forwarding rule for two instances with shared physical interfaces assigned to two instances. Ethernet 1/1 is shared between ftd1 and ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

MCAST group 4096 is used for replicating broadcast traffic between ftd1 and ftd2.

```
firepower-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN  SRC_PORT  PC_ID  SRC_ID  DST_PORT  PKT_CNT  DMAC
1         0         17      0         0         0     2268  0:0:0:0:0:0
2         0         19      0         0         0     4844  0:0:0:0:0:0
3         0          1      0     101     1541         0  a2:5b:83:0:0:9
4         0          1      0     101     4096         0  ff:ff:ff:ff:ff:ff
5         0          1      0     101     1540         0  a2:5b:83:0:0:c
6         0         17      0         0         0     1263  0:0:0:0:0:0
7         0         17      0         0         0         0  0:0:0:0:0:0
```

This command shows the internal switch-forwarding rule for two instances with shared subinterfaces assigned to both instances. Ethernet 1/1.2452 is shared between ftd1 and ftd2.

ECMP group 1540 is assigned to ftd1 and ECMP group 1541 is assigned to ftd2.

MCAST group 4097 is used for replicating broadcast traffic between ftd1 and ftd2.

```
firepower-3140(local-mgmt)# show portmanager switch forward-rules hardware mac-filter
      VLAN   SRC_PORT   PC_ID   SRC_ID   DST_PORT   PKT_CNT   DMAC
1         0         17       0        17        19      21305  0:0:0:0:0:0
2         0         19       0        19        17      50976  0:0:0:0:0:0
3       2452         1       0        101       1541        430  a2:5b:83:0:0:f
4       2452         1       0        101       4097         0  ff:ff:ff:ff:ff:ff
5       2452         1       0        101       1540         0  a2:5b:83:0:0:12
6         0         17       0         0         0      11038  0:0:0:0:0:0
7         0         17       0         0         0         0  0:0:0:0:0:0
```

show portmanager switch ecmp-groups detail

Use this command to list each Instance Ecmp-Vport-Physical port mapping detail.

Note Physical-Port 18 is the backplane uplink interface between the internal switch and the instance.

```
firepower-3140(local-mgmt)# show portmanager switch ecmp-groups detail
      ECMP-GROUP  VPORT   PHYSICAL-PORT
1         1536     256       18
2         1537     257       18
3         1538     258       18
4         1539     259       18
5         1540     260       18
6         1541     261       18
7         1542     262       18
8         1543     263       18
9         1544     264       18
10        1545     265       18
```

show portmanager switch mcast-groups detail

Use this command to list MCAST group membership details.

```
firepower-3140(local-mgmt)# show portmanager switch mcast-groups detail
      MCAST-GROUP
1         4096
      Member-ports
      Ethernet 1/1
      ECMP-ID 1541
      ECMP-ID 1540
```

show portmanager counters mcast-group

Use this command to check the MCAST group packet counter.

```
firepower-3140(local-mgmt)# show portmanager counters mcast-group 4096
PKT_CNT: 8106
```

show portmanager counters ecmp

Use this command to check the ECMP group packet counter.

```
firepower-3140(local-mgmt)# show portmanager counters ecmp 1541
PKT_CNT: 430
```

History for Multi-Instance Mode

Table 26:

Feature	Minimum Management Center	Minimum Threat Defense	Details
Multi-instance mode conversion in the management center	7.6.0	7.6.0	<p>You can now register an application-mode device to the management center and then convert it to multi-instance mode without having to use the CLI.</p> <p>New/modified screens:</p> <ul style="list-style-type: none"> • Devices > Device Management > More (⋮) > Convert to Multi-Instance • Devices > Device Management > Select Bulk Action > Convert to Multi-Instance
Multi-instance mode for the Secure Firewall 4200	7.6.0	7.6.0	Multi-instance mode is now supported for the Secure Firewall 4200.
Multi-instance mode for the Secure Firewall 3100.	7.4.1	7.4.1	<p>You can deploy the Secure Firewall 3100 as a single device (<i>appliance mode</i>) or as multiple container instances (<i>multi-instance mode</i>). In multi-instance mode, you can deploy multiple container instances on a single chassis that act as completely independent devices. CHAPTER 9

High Availability

The following topics describe how to configure Active/Standby failover to accomplish high availability of the threat defense.

- [About Secure Firewall Threat Defense High Availability, on page 377](#)
- [Config-Sync Optimization, on page 391](#)
- [Requirements and Prerequisites for High Availability, on page 392](#)
- [Guidelines for High Availability, on page 392](#)
- [Add a High Availability Pair, on page 395](#)
- [Configure Optional High Availability Parameters, on page 397](#)
- [Manage High Availability, on page 399](#)
- [Monitoring High Availability, on page 406](#)
- [Troubleshoot Configuration Sync Failure, on page 406](#)
- [History for High Availability, on page 407](#)

About Secure Firewall Threat Defense High Availability

Configuring high availability, also called failover, requires two identical threat defense devices connected to each other through a dedicated failover link and, optionally, a state link. threat defense supports Active/Standby failover, where one unit is the active unit and passes traffic. The standby unit does not actively pass traffic, but synchronizes configuration and other state information from the active unit. When a failover occurs, the active unit fails over to the standby unit, which then becomes active.

The health of the active unit (hardware, interfaces, software, and environmental status) is monitored to determine if specific failover conditions are met. If those conditions are met, failover occurs.

Note High availability is not supported on threat defense virtual running in the public cloud. See the [Cisco Secure Firewall Threat Defense Virtual Getting Started Guide](#) for more information about configuring the threat defense virtual device for high availability.

High Availability System Requirements

This section describes the hardware, software, and license requirements for threat defense devices in a High Availability configuration.

Hardware Requirements

The two units in a High Availability configuration must:

- Be the same model. In addition, for container instances, they must use the same resource profile attributes.

For the Firepower 9300, High Availability is only supported between same-type modules; but the two chassis can include mixed modules. For example, each chassis has an SM-56, SM-48, and SM-40. You can create High Availability pairs between the SM-56 modules, between the SM-48 modules, and between the SM-40 modules.

If you change the resource profile after you add the High Availability pair to the management center, update the inventory for each unit on the **Devices > Device Management > Device > System > Inventory** dialog box.

If you assign a different profile to instances in an established high-availability pair, which requires the profile to be the same on both units, you must:

1. Break high availability.
2. Assign the new profile to both units.
3. Re-establish high availability.

- Have the same number and types of interfaces.

For the Firepower 4100/9300 chassis, all interfaces must be preconfigured in FXOS identically before you enable High Availability. If you change the interfaces after you enable High Availability, make the interface changes in FXOS on the Standby unit, and then make the same changes on the Active unit.

If you are using units with different flash memory sizes in your High Availability configuration, make sure the unit with the smaller flash memory has enough space to accommodate the software image files and the configuration files. If it does not, configuration synchronization from the unit with the larger flash memory to the unit with the smaller flash memory will fail.

Software Requirements

The two units in a High Availability configuration must:

- Be in the same firewall mode (routed or transparent).
- Have the same software version.
- Be in the same domain or group on the management center.
- Have the same NTP configuration. See [Configure NTP Time Synchronization for Threat Defense](#).
- Be fully deployed on the management center with no uncommitted changes.
- Not have DHCP or PPPoE configured in any of their interfaces.
- (Firepower 4100/9300) Have the same flow offload mode, either both enabled or both disabled.

License Requirements for Threat Defense Devices in a High Availability Pair

Both threat defense units in a high availability configuration must have the same licenses.

High availability configurations require two license entitlements: one for each device in the pair.

Before high availability is established, it does not matter which licenses are assigned to the secondary/standby device. During high availability configuration, the management center releases any unnecessary licenses assigned to the standby unit and replaces them with identical licenses assigned to the primary/active unit. For example, if the active unit has a Essentials license and a IPS license, and the standby unit has only a Essentials license, the management center communicates with the Smart Software Manager to obtain an available IPS license from your account for the standby unit. If your license account does not include enough purchased entitlements, your account becomes Out-of-Compliance until you purchase the correct number of licenses.

Failover and Stateful Failover Links

The failover link and the optional stateful failover link are dedicated connections between the two units. Cisco recommends to use the same interface between two devices in a failover link or a stateful failover link. For example, in a failover link, if you have used eth0 in device 1, use the same interface (eth0) in device 2 as well.

Failover Link

The two units in a failover pair constantly communicate over a failover link to determine the operating status of each unit.

Failover Link Data

The following information is communicated over the failover link:

- The unit state (active or standby)
- Hello messages (keep-alives)
- Network link status
- MAC address exchange
- Configuration replication and synchronization

Interface for the Failover Link

You can use an unused data interface (physical, or EtherChannel) as the failover link; however, you cannot specify an interface that is currently configured with a name. You also cannot use a subinterface with the exception of a subinterface defined on the chassis for multi-instance mode. The failover link interface is not configured as a normal networking interface; it exists for failover communication only. This interface can only be used for the failover link (and also for the state link).

The threat defense does not support sharing interfaces between user data and the failover link. You also cannot use separate subinterfaces on the same parent for the failover link and for data (multi-instance chassis subinterfaces only). If you use a chassis subinterface for the failover link, then all subinterfaces on that parent, and the parent itself, are restricted for use as failover links.

Note When using an EtherChannel as the failover or state link, you must confirm that the same EtherChannel with the same member interfaces exists on both devices before establishing high availability.

See the following guidelines for the failover link:

- Firepower 4100/9300—We recommend that you use a 10 GB data interface for the combined failover and state link.
- All other models—1 GB interface is large enough for a combined failover and state link.

The alternation frequency is equal to the unit hold time.

Note If you have a large configuration and a low unit hold time, alternating between the member interfaces can prevent the secondary unit from joining/re-joining. In this case, disable one of the member interfaces until after the secondary unit joins.

For an EtherChannel used as the failover link, to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a failover link.

Connecting the Failover Link

Connect the failover link in one of the following two ways:

- Using a switch, with no other device on the same network segment (broadcast domain or VLAN) as the failover interfaces of the threat defense device.
- Using an Ethernet cable to connect the units directly, without the need for an external switch.

If you do not use a switch between the units, if the interface fails, the link is brought down on both peers. This condition may hamper troubleshooting efforts because you cannot easily determine which unit has the failed interface and caused the link to come down.

Stateful Failover Link

To use Stateful Failover, you must configure a Stateful Failover link (also known as the state link) to pass connection state information.

Shared with the Failover Link

Sharing a failover link is the best way to conserve interfaces. However, you must consider a dedicated interface for the state link and failover link, if you have a large configuration and a high traffic network.

Dedicated Interface for the Stateful Failover Link

You can use a dedicated data interface (physical or EtherChannel) for the state link. See [Interface for the Failover Link, on page 379](#) for requirements for a dedicated state link, and [Connecting the Failover Link, on page 380](#) for information about connecting the state link as well.

For optimum performance when using long distance failover, the latency for the state link should be less than 10 milliseconds and no more than 250 milliseconds. If latency is more than 10 milliseconds, some performance degradation occurs due to retransmission of failover messages.

Avoiding Interrupted Failover and Data Links

We recommend that failover links and data interfaces travel through different paths to decrease the chance that all interfaces fail at the same time. If the failover link is down, the threat defense device can use the data

interfaces to determine if a failover is required. Subsequently, the failover operation is suspended until the health of the failover link is restored.

See the following connection scenarios to design a resilient failover network.

Scenario 1—Not Recommended

If a single switch or a set of switches are used to connect both failover and data interfaces between two threat defense devices, then when a switch or inter-switch-link is down, both threat defense devices become active. Therefore, the two connection methods shown in the following figures are **not** recommended.

Figure 163: Connecting with a Single Switch ❖❖❖ **Not Recommended**

Figure 164: Connecting with a Double-Switch—Not Recommended

Scenario 2—Recommended

We recommend that failover links not use the same switch as the data interfaces. Instead, use a different switch or use a direct cable to connect the failover link, as shown in the following figures.

Figure 165: Connecting with a Different Switch

Figure 166: Connecting with a Cable

Scenario 3—Recommended

If the threat defense data interfaces are connected to more than one set of switches, then a failover link can be connected to one of the switches, preferably the switch on the secure (inside) side of network, as shown in the following figure.

Figure 167: Connecting with a Secure Switch

Scenario 4—Recommended

The most reliable failover configurations use a redundant interface on the failover link, as shown in the following figures.

Figure 168: Connecting with Redundant Interfaces

Figure 169: Connecting with Inter-switch Links

MAC Addresses and IP Addresses in High Availability

When you configure your interfaces, you can specify an active IP address and a standby IP address on the same network. Generally, when a failover occurs, the new active unit takes over the active IP addresses and

MAC addresses. Because network devices see no change in the MAC to IP address pairing, no ARP entries change or time out anywhere on the network.

Note Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state. You also cannot connect to the standby unit on that interface for management purposes.

The IP address and MAC address for the state link do not change at failover.

Active/Standby IP Addresses and MAC Addresses

For Active/Standby High Availability, see the following for IP address and MAC address usage during a failover event:

1. The active unit always uses the primary unit's IP addresses and MAC addresses.
2. When the active unit fails over, the standby unit assumes the IP addresses and MAC addresses of the failed unit and begins passing traffic.
3. When the failed unit comes back online, it is now in a standby state and takes over the standby IP addresses and MAC addresses.

However, if the secondary unit boots without detecting the primary unit, then the secondary unit becomes the active unit and uses its own MAC addresses, because it does not know the primary unit MAC addresses. When the primary unit becomes available, the secondary (active) unit changes the MAC addresses to those of the primary unit, which can cause an interruption in your network traffic. Similarly, if you swap out the primary unit with new hardware, a new MAC address is used.

If you reload the standby unit with the failover configuration disabled, the standby unit boots up as the active unit and uses the primary unit's IP addresses and MAC addresses. This leads to duplicate IP addresses and causes network traffic disruptions. Use the command **configure high-availability resume** to enable failover and restore the traffic flow.

Virtual MAC addresses guard against this disruption, because the active MAC addresses are known to the secondary unit at startup, and remain the same in the case of new primary unit hardware. We recommend that you configure the virtual MAC address on both the primary and secondary units to ensure that the secondary unit uses the correct MAC addresses when it is the active unit, even if it comes online before the primary unit. If you do not configure virtual MAC addresses, you might need to clear the ARP tables on connected routers to restore traffic flow. The threat defense device does not send gratuitous ARPs for static NAT addresses when the MAC address changes, so connected routers do not learn of the MAC address change for these addresses.

Virtual MAC Addresses

The threat defense device has multiple methods to configure virtual MAC addresses. We recommend using only one method. If you set the MAC address using multiple methods, the MAC address used depends on many variables, and might not be predictable.

For multi-instance capability, the FXOS chassis autogenerates only primary MAC addresses for all interfaces. You can overwrite the generated MAC address with a virtual MAC address with both the primary and secondary MAC addresses, but predefining the secondary MAC address is not essential; setting the secondary MAC address does ensure that to-the-box management traffic is not interrupted in the case of new secondary unit hardware.

MAC Address Table Update in Failover

During failover, the device designated as the new active device generates multicast packets for each MAC address entry in the MAC table and sends them to all bridge group interfaces. This action prompts the upstream switches in the bridge group to update their routing tables with the new active device's interface to ensure accurate traffic forwarding.

The time taken to generate multicast packets and update the routing tables of the upstream switches depends on the number of entries in the MAC address table and the number of bridge group interfaces. Use the command **show failover statistics state-switch-delay** to display statistics related to the delays encountered during failover events.

Stateful Failover

During Stateful Failover, the active unit continually passes per-connection state information to the standby unit. After a failover occurs, the same connection information is available at the new active unit. Supported end-user applications are not required to reconnect to keep the same communication session.

Supported Features

For Stateful Failover, the following state information is passed to the standby threat defense device:

- NAT translation table.
- TCP and UDP connections and states, including HTTP connection states. Other types of IP protocols, and ICMP, are not parsed by the active unit, because they get established on the new active unit when a new packet arrives.
- Snort connection states, inspection results, and pin hole information, including strict TCP enforcement.
- The ARP table
- The Layer 2 bridge table (for bridge groups)
- The ISAKMP and IPsec SA table
- GTP PDP connection database
- SIP signaling sessions and pin holes.
- Static and dynamic routing tables—Stateful Failover participates in dynamic routing protocols, like OSPF and EIGRP, so routes that are learned through dynamic routing protocols on the active unit are maintained in a Routing Information Base (RIB) table on the standby unit. Upon a failover event, packets travel normally with minimal disruption to traffic because the active secondary unit initially has rules that mirror the primary unit. Immediately after failover, the re-convergence timer starts on the newly active unit. Then the epoch number for the RIB table increments. During re-convergence, OSPF and EIGRP routes become updated with a new epoch number. Once the timer is expired, stale route entries (determined by the epoch number) are removed from the table. The RIB then contains the newest routing protocol forwarding information on the newly active unit.

Note Routes are synchronized only for link-up or link-down events on an active unit. If the link goes up or down on the standby unit, dynamic routes sent from the active unit may be lost. This is normal, expected behavior.

- DHCP Server—DHCP address leases are not replicated. However, a DHCP server configured on an interface will send a ping to make sure an address is not being used before granting the address to a DHCP client, so there is no impact to the service. State information is not relevant for DHCP relay or DDNS.
- Access control policy decisions—Decisions related to traffic matching (including URL, URL category, geolocation, and so forth), intrusion detection, malware, and file type are preserved during failover. However, for connections being evaluated at the moment of failover, there are the following caveats:
 - AVC—App-ID verdicts are replicated, but not detection states. Proper synchronization occurs as long as the App-ID verdicts are complete and synchronized before failover occurs.
 - Intrusion detection state—Upon failover, once mid-flow pickup occurs, new inspections are completed, but old states are lost.
 - File malware blocking—The file disposition must become available before failover.
 - File type detection and blocking—The file type must be identified before failover. If failover occurs while the original active device is identifying the file, the file type is not synchronized. Even if your file policy blocks that file type, the new active device downloads the file.
- User identity decisions from the identity policy, including the user-to-IP address mappings gathered passively through ISE Session Directory, and active authentication through captive portal. Users who are actively authenticating at the moment of failover might be prompted to authenticate again.
- Network AMP—Cloud lookups are independent from each device, so failover does not affect this feature in general. Specifically:
 - Signature Lookup—If failover occurs in the middle of a file transmission, no file event is generated and no detection occurs.
 - File Storage—If failover occurs when the file is being stored, it is stored on the original active device. If the original active device went down while the file was being stored, the file does not get stored.
 - File Pre-classification (Local Analysis)—If failover occurs in the middle of pre-classification, detection fails.
 - File Dynamic Analysis (Connectivity to the cloud)—If failover occurs, the system might submit the file to the cloud.
 - Archive File Support—If failover occurs in the middle of an analysis, the system loses visibility into the file/archive.
 - Custom Blocking—If failover occurs, no events are generated.
- Security Intelligence decisions. However, DNS-based decisions that are in process at the moment of failover are not completed.
- RA VPN—Remote access VPN end users do not have to reauthenticate or reconnect the VPN session after a failover. However, applications operating over the VPN connection could lose packets during the failover process and not recover from the packet loss.
- From all the connections, only established ones will be replicated on the Standby ASA.

Unsupported Features

For Stateful Failover, the following state information is not passed to the standby threat defense device:

- Sessions in plaintext tunnels other than GREv0 and IPv4-in-IP. Sessions inside tunnels are not replicated and the new active node will not be able to reuse existing inspection verdicts to match the correct policy rules.
- Decrypted TLS/SSL connections—The decryption states are not synchronized, and if the active unit fails, then decrypted connections will be reset. New connections will need to be established to the new active unit. Connections that are not decrypted (in other words, those that match a TLS/SSL Do Not Decrypt rule action) are not affected and are replicated correctly.
- TCP state bypass connections
- Multicast routing.

Bridge Group Requirements for High Availability

There are special considerations for high availability when using bridge groups.

When the active unit fails over to the standby unit, the switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss on the bridge group member interfaces while the port is in a blocking state, you can configure one of the following workarounds:

- Switch port is in Access mode—Enable the STP PortFast feature on the switch:

```
interface interface_id
  spanning-tree portfast
```

The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, the port eventually transitions into STP blocking mode.

- If the switch port is in Trunk mode, or you cannot enable STP PortFast, then you can use one of the following less desirable workarounds that impacts failover functionality or STP stability:
 - Disable interface monitoring on the bridge group and member interfaces.
 - Increase the interface hold time in the failover criteria to a high value that will allow STP to converge before the unit fails over.
 - Decrease the STP timers on the switch to allow STP to converge faster than the interface hold time.

Failover Health Monitoring

The threat defense device monitors each unit for overall health and for interface health. This section includes information about how the threat defense device performs tests to determine the state of each unit.

Unit Health Monitoring

The threat defense device determines the health of the other unit by monitoring the failover link with hello messages. When a unit does not receive three consecutive hello messages on the failover link, the unit sends LANTEST messages on each data interface, including the failover link, to validate whether or not the peer is responsive. The action that the threat defense device takes depends on the response from the other unit. See the following possible actions:

- If the threat defense device receives a response on the failover link, then it does not fail over.
- If the threat defense device does not receive a response on the failover link, but it does receive a response on a data interface, then the unit does not failover. The failover link is marked as failed. You should restore the failover link as soon as possible because the unit cannot fail over to the standby while the failover link is down.
- If the threat defense device does not receive a response on any interface, then the standby unit switches to active mode and classifies the other unit as failed.

Heartbeat Module Redundancy

Each unit in the HA periodically sends a broadcast keepalive heartbeat packet over the cluster control link. If the control plane is too busy handling traffic, sometimes the heartbeat packets do not reach the peers, or the peers do not process the heartbeat packets due to CPU overloading. When peers cannot communicate the keepalive status within the configurable timeout period, a false failover or split-brain scenario occurs.

The heartbeat module in the data plane helps to avoid the occurrence of false failover or split-brain due to traffic congestion in the control plane.

- The additional heartbeat module works similarly to the control plane module but sends and receives heartbeat messages using the data plane transport infrastructure.
- When the peer receives heartbeat packets in the data plane, a counter gets incremented.
- If the heartbeat transfer in the control plane fails, the node checks the heartbeat counter in the data plane. If the counter is incrementing, then the peer is alive, and the cluster does not perform a failover in this situation.

Note

- The additional heartbeat module is enabled by default whenever HA is enabled. You do not have to set a poll interval for the additional heartbeat module in the data plane. This module uses the same heartbeat interval that you set for the control plane.
-

Interface Monitoring

When a unit does not receive hello messages on a monitored interface for 15 seconds, it runs interface tests. If one of the interface tests fails for an interface, but this same interface on the other unit continues to successfully pass traffic, then the interface is considered to be failed, and the device stops running tests.

If the threshold you define for the number of failed interfaces is met (see **Devices > Device Management > High Availability > Failover Trigger Criteria**), and the active unit has more failed interfaces than the standby unit, then a failover occurs. If an interface fails on both units, then both interfaces go into the “Unknown” state and do not count towards the failover limit defined by failover interface policy.

An interface becomes operational again if it receives any traffic. A failed device returns to standby mode if the interface failure threshold is no longer met.

If an interface has IPv4 and IPv6 addresses configured on it, the device uses the IPv4 addresses to perform the health monitoring. If an interface has only IPv6 addresses configured on it, then the device uses IPv6 neighbor discovery instead of ARP to perform the health monitoring tests. For the broadcast ping test, the device uses the IPv6 all nodes address (FE02::1).

Interface Tests

The threat defense device uses the following interface tests. The duration of each test is approximately 1.5 seconds.

1. **Link Up/Down test**—A test of the interface status. If the Link Up/Down test indicates that the interface is down, then the device considers it failed, and testing stops. If the status is Up, then the device performs the Network Activity test.
2. **Network Activity test**—A received network activity test. At the start of the test, each unit clears its received packet count for its interfaces. As soon as a unit receives any eligible packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the ARP test.
3. **ARP test**—A test for successful ARP replies. Each unit sends a single ARP request for the IP address in the most recent entry in its ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If the unit does not receive an ARP reply, then the device sends a single ARP request for the IP address in the *next* entry in the ARP table. If the unit receives an ARP reply or other network traffic during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then the device starts the Broadcast Ping test.
4. **Broadcast Ping test**—A test for successful ping replies. Each unit sends a broadcast ping, and then counts all received packets. If the unit receives any packets during the test, then the interface is considered operational. If both units receive traffic, then testing stops. If one unit receives traffic, and the other unit does not, then the interface on the unit that does not receive traffic is considered failed, and testing stops. If neither unit receives traffic, then testing starts over again with the ARP test. If both units continue to receive no traffic from the ARP and Broadcast Ping tests, then these tests will continue running in perpetuity.

Interface Status

Monitored interfaces can have the following status:

- **Unknown**—Initial status. This status can also mean the status cannot be determined.
- **Normal**—The interface is receiving traffic.
- **Normal (Waiting)**—The interface is up, but has not yet received a hello packet from the corresponding interface on the peer unit.
- **Normal (Not-Monitored)**—The interface is up, but is not monitored by the failover process.
- **Testing**—Hello messages are not heard on the interface for five poll times.
- **Link Down**—The interface or VLAN is administratively down.

- Link Down (Waiting)—The interface or VLAN is administratively down and has not yet received a hello packet from the corresponding interface on the peer unit.
- Link Down (Not-Monitored)—The interface or VLAN is administratively down, but is not monitored by the failover process.
- No Link—The physical link for the interface is down.
- No Link (Waiting)—The physical link for the interface is down and has not yet received a hello packet from the corresponding interface on the peer unit.
- No Link (Not-Monitored)—The physical link for the interface is down, but is not monitored by the failover process.
- Failed—No traffic is received on the interface, yet traffic is heard on the peer interface.

Failover Triggers and Detection Timing

The following events trigger failover in a Firepower high availability pair:

- More than 50% of the Snort instances on the active unit are down.
- Disk space on the active unit is more than 90% full.
- The **no failover active** command is run on the active unit or the **failover active** command is run on the standby unit.
- The active unit has more failed interfaces than the standby unit.
- Interface failure on the active device exceeds the threshold configured.

By default, failure of a single interface causes failover. You can change the default value by configuring a threshold for the number of interfaces or a percentage of monitored interfaces that must fail for the failover to occur. If the threshold breaches on the active device, failover occurs. If the threshold breaches on the standby device, the unit moves to **Fail** state.

To change the default failover criteria, enter the following command in global configuration mode:

Table 27:

Command	Purpose
failover interface-policy num [%] hostname (config)# failover interface-policy 20%	Changes the default failover criteria. When specifying a specific number of interfaces, the <i>num</i> argument can be from 1 to 250. When specifying a percentage of interfaces, the <i>num</i> argument can be from 1 to 100.

The following table shows the failover triggering events and associated failure detection timing. If failover occurs, you can view the reason for the failover in the Message Center, along with various operations pertaining to the high availability pair. You can configure these thresholds to a value within the specified minimum-maximum range.

Table 28: Threat Defense Failover Times

Failover Triggering Event	Minimum	Default	Maximum
Active unit loses power, hardware goes down, or the software reloads or crashes. When any of these occur, the monitored interfaces or failover link do not receive any hello message.	800 milliseconds	15 seconds	45 seconds
Active unit interface physical link down.	500 milliseconds	5 seconds	15 seconds
Active unit interface up, but connection problem causes interface testing.	5 seconds	25 seconds	75 seconds

About Active/Standby Failover

Active/Standby failover lets you use a standby threat defense device to take over the functionality of a failed unit. When the active unit fails, the standby unit becomes the active unit.

Primary/Secondary Roles and Active/Standby Status

When setting up Active/Standby failover, you configure one unit to be primary and the other to be secondary. During configuration, the primary unit's policies are synchronized to the secondary unit. At this point, the two units act as a single device for device and policy configuration. However, for events, dashboards, reports and health monitoring, they continue to display as separate devices.

The main differences between the two units in a failover pair are related to which unit is active and which unit is standby, namely which IP addresses to use and which unit actively passes traffic.

However, a few differences exist between the units based on which unit is primary (as specified in the configuration) and which unit is secondary:

- The primary unit always becomes the active unit if both units start up at the same time (and are of equal operational health).
- The primary unit MAC addresses are always coupled with the active IP addresses. The exception to this rule occurs when the secondary unit becomes active and cannot obtain the primary unit MAC addresses over the failover link. In this case, the secondary unit MAC addresses are used.

Active Unit Determination at Startup

The active unit is determined by the following:

- If a unit boots and detects a peer already running as active, it becomes the standby unit.
- If a unit boots and does not detect a peer, it becomes the active unit.
- If both units boot simultaneously, then the primary unit becomes the active unit, and the secondary unit becomes the standby unit.

Failover Events

In Active/Standby failover, failover occurs on a unit basis.

The following table shows the failover action for each failure event. For each failure event, the table shows the failover policy (failover or no failover), the action taken by the active unit, the action taken by the standby unit, and any special notes about the failover condition and actions.

Table 29: Failover Events

Failure Event	Policy	Active Unit Action	Standby Unit Action	Notes
Active unit failed (power or hardware)	Failover	n/a	Become active Mark active as failed	No hello messages are received on any monitored interface or the failover link.
Formerly active unit recovers	No failover	Become standby	No action	None.
Standby unit failed (power or hardware)	No failover	Mark standby as failed	n/a	When the standby unit is marked as failed, then the active unit does not attempt to fail over, even if the interface failure threshold is surpassed.
Failover link failed during operation	No failover	Mark failover link as failed	Mark failover link as failed	You should restore the failover link as soon as possible because the unit cannot fail over to the standby unit while the failover link is down.
Failover link failed at startup	No failover	Become active Mark failover link as failed	Become active Mark failover link as failed	If the failover link is down at startup, both units become active.
State link failed	No failover	No action	No action	State information becomes out of date, and sessions are terminated if a failover occurs.
Interface failure on active unit above threshold	Failover	Mark active as failed	Become active	None.
Interface failure on standby unit above threshold	No failover	No action	Mark standby as failed	When the standby unit is marked as failed, then the active unit does not attempt to fail over even if the interface failure threshold is surpassed.

Config-Sync Optimization

When there is node reboot or node rejoin following suspend or resume failover, the joining unit clears its running configuration. The active unit sends its entire configuration to the joining unit for a full config-sync. If the active unit has large configuration, the joining unit takes several minutes to synchronize the configuration.

The Config-Sync Optimization feature enables comparing the configuration of the joining unit and the active unit by exchanging config-hash values. If the hash computed on both active and joining units match, the

joining unit skips full configuration synchronization and rejoin the HA. This feature enables faster HA peering and reduces maintenance window and upgrade time.

Guidelines and Limitations of Config-Sync Optimization

- The Config-Sync Optimization feature is enabled by default on threat defense version 7.2 and later.
- threat defense multiple context mode supports the Config-Sync Optimization feature by sharing the context order during full configuration synchronization, allowing comparison of context order during subsequent node-rejoin.
- If you configure passphrase and failover IPsec key, then Config-Sync Optimization is not effective as the hash value computed in the active and standby unit differs.
- If you configure the device with dynamic ACL or SNMPv3, the Config-Sync Optimization feature is not effective.
- Active unit syncs full configuration with flapping LAN links as default behavior. During failover flaps between active and standby units, the Config-Sync Optimization feature is not triggered and performs a full configuration synchronization.

Monitoring Config-Sync Optimization

When Config-Sync Optimization feature is enabled, syslog messages are generated displaying whether the hash values computed on the active and joining unit match, does not match, or if the operation timeout expires. The syslog message also displays the time elapsed, from the time of sending the hash request to the time of getting and comparing the hash response.

Guidelines for High Availability

Model Support

- Firepower 1010:

- You should not use the switch port functionality when using High Availability. Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High Availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High Availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Theoretically, you can put a single switch port on a VLAN and successfully use High Availability, but a simpler setup is to use physical firewall interfaces instead.
- You can only use a firewall interface as the failover link.
- Firepower 9300—Intra-chassis High Availability is not supported.
- The threat defense virtual on public cloud networks such as Microsoft Azure and Amazon Web Services are not supported with High Availability because Layer 2 connectivity is required.

Additional Guidelines

- When the active unit fails over to the standby unit, the connected switch port running Spanning Tree Protocol (STP) can go into a blocking state for 30 to 50 seconds when it senses the topology change. To avoid traffic loss while the port is in a blocking state, you can enable the STP PortFast feature on the switch:

interface *interface_id* spanning-tree portfast

This workaround applies to switches connected to both routed mode and bridge group interfaces. The PortFast feature immediately transitions the port into STP forwarding mode upon linkup. The port still participates in STP. So if the port is to be a part of the loop, the port eventually transitions into STP blocking mode.

- Configuring port security on the switches connected to the threat defense device failover pair can cause communication problems when a failover event occurs. This problem occurs when a secure MAC address configured or learned on one secure port moves to another secure port, a violation is flagged by the switch port security feature.
- For Active/Standby High Availability and a VPN IPsec tunnel, you cannot monitor both the active and standby units using SNMP over the VPN tunnel. The standby unit does not have an active VPN tunnel, and will drop traffic destined for the NMS. You can instead use SNMPv3 with encryption so the IPsec tunnel is not required.
- Both the peer devices go into unknown state and high-availability configuration fails if you run clish in any of the peer devices while creating a High Availability pair.
- Immediately after failover, the source address of syslog messages will be the failover interface address for a few seconds.
- For better convergence (during a failover), you must shut down the interfaces on a HA pair that are not associated with any configuration or instance.
- If you configure failover encryption in evaluation mode, the systems use DES for the encryption. If you then register the devices using an export-compliant account, the devices will use AES after a reboot. Thus, if a system reboots for any reason, including after installing an upgrade, the peers will be unable to communicate and both units will become the active unit. We recommend that you do not configure encryption until after you register the devices. If you do configure this in evaluation mode, we recommend you remove the encryption before registering the devices.

- When using SNMPv3 with failover, if you replace a failover unit, then SNMPv3 users are not replicated to the new unit. You must remove the users, re-add them, and then redeploy your configuration to force the users to replicate to the new unit.
- The device does not share SNMP client engine data with its peer.
- If you have a very large number of access control and NAT rules, the size of the configuration can prevent efficient configuration replication, resulting in the standby unit taking an excessively long time to reach standby ready state. This can also impact your ability to connect to the standby unit during replication through the console or SSH session. To enhance configuration replication performance, enable transactional commit for both access rules and NAT, using the **asp rule-engine transactional-commit access-group** and **asp rule-engine transactional-commit nat** commands.
- A unit in a High Availability pair transitioning to the standby role synchronizes its clock with the active unit.

Example:

```
firepower#show clock
01:00:52 UTC Mar 1 2022

...
01:01:18 UTC Mar 1 2022 <===== Incorrect (previous) clock
Cold Standby                Sync Config                Detected an Active mate

19:38:21 UTC Apr 9 2022 <===== Updated clock
Sync Config                  Sync File System          Detected an Active mate
...
firepower/sec/stby#show clock
19:38:40 UTC Apr 9 2022
```

- The units in High Availability do not dynamically synchronize the clock. Here are some examples of events when synchronization takes place:
 - A new High Availability pair is created.
 - High Availability is broken and re-created.
 - Communication over the failover link was disrupted and reestablished.
 - Failover status was manually changed at the CLI using the **no failover/failover** or **configure high-availability suspend/resume** (threat defense) commands.
- Enabling High Availability forces all routes to be deleted and are re-added after the High Availability progression changes to the Active state. You could experience connection loss during this phase.
- If you replace the primary unit, then when you re-create high-availability, you should set the replacement unit as the *secondary* unit so that the configurations are replicated from the former secondary unit to the replacement unit. If you set the replacement unit as primary, you will accidentally overwrite the configuration that is present on the operational unit.
- Deploying Firepower 1100 devices in high availability with hundreds of interfaces configured on them can result in increased delay in the failover time (seconds).
- In the High Availability configuration, short-lived connections, usually using port 53, are closed quickly and never transferred or synchronized from Active to Standby, so there might be a difference in the number of connections on both High Availability devices. This is expected behavior for short-lived connections. You can try to compare the connections that are long-lived (for example, more than 30-60 seconds).

- In the High Availability configuration, embryonic connections—connection requests that have not yet completed the three-way handshake process—are closed quickly and not synchronized between the active and standby devices. This design ensures HA system efficiency and security. For this reason, there might be a difference in the number of connections on both High Availability devices, which is to be expected.
- If the failover LAN link is not connected back-to-back and instead connected through one or more switches, a failure within the intermediate path can cause the active unit to lose connectivity with the standby unit, resulting in inconsistent active/standby states. Although this does not impact High Availability functionality, it is recommended to check and recover the failover-link path between the active and standby units.

When the failover LAN link is down, it is not recommended to deploy any configuration, as it may not be replicated to the peer unit.

- See the [Cisco Secure Firewall Threat Defense Virtual Getting Started Guide](#) and review your threat defense virtual device configurations for high availability.

Add a High Availability Pair

When establishing an Active/Standby high-availability pair, you designate one of the devices as primary and the other as secondary. The management center deploys a merged configuration to the paired devices. If there is a conflict, the primary device setting is used.

In a multidomain deployment, devices in a high-availability pair must belong to the same domain.

Note The failover link and the stateful failover link are in a private IP space and are only used for communication between peers in a high-availability pair. After high availability is established, selected interface links and encryption settings cannot be modified without breaking the high-availability pair and reconfiguring it.

Caution Creating or breaking a high-availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) for more information. The system warns you that continuing to create a high-availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Before you begin

Confirm that both devices:

- Are the same model.
- Have the same number and type of interfaces.
- Are in the same domain and group.
- Have normal health status and are running the same software.
- Are either in routed or transparent mode.

Note Only routed mode is supported for manager access on a data interface.

- Have the same NTP configuration. See [Time Synchronization, on page 918](#).
- Are fully deployed with no uncommitted changes.
- Do not have DHCP or PPPoE configured on any interfaces.
- For manager access on a data interface:
 - Use the same data interface on both devices for manager access.
 - Redundant manager access data interface is not supported.
 - You cannot use DHCP; only a static IP address is supported. Features that rely on DHCP cannot be used, including DDNS and zero-touch provisioning.
 - Have different static IP addresses in the same subnet.
 - Use either IPv4 or IPv6; you cannot set both.
 - Use the same manager configuration (**configure manager add** command) to ensure that the connectivity is the same.
 - You cannot use the data interface as the failover or state link.

Note The high availability formation is possible between the two threat defense devices when the certificate available on the primary device is not present on the secondary device. When high availability is formed, the certificate will be synched on the secondary device.

Procedure

- Step 1** Add both devices to the management center according to [Add a Device to the Management Center Using a Registration Key, on page 27](#).
- Step 2** Choose **Devices > Device Management**.
- Step 3** From the **Add** drop-down menu, choose **High Availability**.
- Step 4** Enter a display **Name** for the high-availability pair.
- Step 5** Choose the **Primary Peer** device for the high-availability pair.
- Step 6** Choose the **Secondary Peer** device for the high-availability pair.
- Step 7** Click **Continue**.
- Step 8** Under **LAN Failover Link**, choose an **Interface** with enough bandwidth to reserve for failover communications.
- Note** Only interfaces that do not have a logical name and do not belong to a security zone, will be listed in the **Interface** drop-down in the **Add High Availability Pair** dialog.
- Step 9** Type any identifying **Logical Name**.

- Step 10** Type a **Primary IP** address for the failover link on the active unit.
This address should be on an unused subnet. This subnet can be 31-bits (255.255.255.254 or /31) with only two IP addresses.
Note 169.254.1.0/24 and fd00:0:0::*:/64 are internally used subnets and cannot be used for the failover or state links.
- Step 11** Optionally, choose **Use IPv6 Address**.
- Step 12** Type a **Secondary IP** address for the failover link on the standby unit. This IP address must be in the same subnet as the primary IP address.
- Step 13** If IPv4 addresses are used, type a **Subnet Mask** that applies to both the primary and secondary IP addresses.
- Step 14** Optionally, under **Stateful Failover Link**, choose the same **Interface**, or choose a different interface and enter the high availability configuration information.
This subnet can be 31-bits (255.255.255.254 or /31) with only two IP addresses.
Note 169.254.1.0/24 and fd00:0:0::*:/64 are internally used subnets and cannot be used for the failover or state links.
- Step 15** Optionally, choose **Enabled** and choose the **Key Generation** method for IPsec Encryption between the failover links.
- Step 16** Click **OK**. This process takes a few minutes as the process synchronizes system data.

What to do next

Back up the devices. You can use the backup to quickly replace the devices when they fail and to restore the high availability service without being delinked from the management center. For more information, see [Cisco Secure Firewall Management Center Administration Guide](#).

Configure Optional High Availability Parameters

You can view the initial High Availability Configuration on the management center. You cannot edit these settings without breaking the high availability pair and then re-establishing it.

You can edit the Failover Trigger Criteria to improve failover results. Interface Monitoring allows you to determine which interfaces are better suited for failover.

Configure Standby IP Addresses and Interface Monitoring

For each interface, set a standby IP address. Although recommended, the standby address is not required. Without a standby IP address, the active unit cannot perform network tests to check the standby interface health; it can only track the link state.

By default, monitoring is enabled on all physical interfaces, for the Firepower 1010 all VLAN interfaces, with logical names configured. You might want to exclude interfaces attached to less critical networks from affecting your failover policy. Firepower 1010 switch ports are not eligible for interface monitoring.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device high-availability pair you want to edit, click the **Edit** (✎).
- Step 3** Click the **High Availability** tab.
- Step 4** In the **Monitored Interfaces** area, click the **Edit** (✎) next to the interface you want to edit.
- Step 5** Check the **Monitor this interface for failures** check box.
- Step 6** On the **IPv4** tab, enter the **Standby IP Address**.
This address must be a free address on the same network as the active IP address.
- Step 7** If you configured the IPv6 address manually, on the **IPv6** tab, click the **Edit** (✎) next to the active IP address, enter the **Standby IP Address**, and click **OK**.
This address must be a free address on the same network as the active IP address. For autogenerated and **Enforce EUI 64** addresses, the standby address is automatically generated.
- Step 8** Click **OK**.
-

Edit High Availability Failover Criteria

You can customize failover criteria based on your network deployment.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device high-availability pair you want to edit, click the **Edit** (✎).
- Step 3** Choose **High Availability**.
- Step 4** Next to **Failover Trigger Criteria**, click the **Edit** (✎).
- Step 5** Under **Interface Failure Threshold**, choose the number or percentage of interfaces that must fail before the device fails over.
- Step 6** Under **Hello packet Intervals**, choose how often hello packets are sent over the failover link.
- Step 7** Click **OK**.
-

Configure Virtual MAC Addresses

You can configure active and standby MAC addresses for failover using the following methods in the Secure Firewall Management Center:

- From the **Advanced tab** on the **Edit Interface** page during interface configuration; see [Configure the MAC Address, on page 804](#).
- From the **Add Interface MAC Address** dialog-box which is accessed from the **High Availability** page; see this procedure.

Note To configure the MAC address in both primary and secondary units (so that the MAC address is transferred to all sub-interfaces to both the high-availability units), the recommended approach is to use the **Interfaces** tab to replicate the MAC addresses on sub-interfaces over both active and standby high-availability units.

If you configure active and standby MAC addresses in both locations, the addresses defined during interface configuration take precedence for failover.

You can minimize loss of traffic during failover by designating active and standby MAC addresses to the physical interface. This feature offers redundancy against IP address mapping for failover.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the device high-availability pair you want to edit, click **Edit** (✎).
- Step 3** Click **High Availability**.
- Step 4** Click the **Add** (+) icon next to Interface MAC Addresses.
- Step 5** Choose a **Physical Interface**.
- Step 6** Enter the **Active Interface Mac Address**.
- Step 7** Enter the **Standby Interface Mac Address**.
- Step 8** Click **OK**.

Note For detailed information, see [Task 2](#), steps from 10 to 14 in [Configure FTD High Availability on Firepower Appliances](#).

Manage High Availability

This section describes how to manage High Availability units after you enable High Availability, including how to change the High Availability setup and how to force failover from one unit to another.

Switch the Active Peer in the Threat Defense High Availability Pair

After you establish the threat defense high availability pair, you can manually switch the active and standby units, effectively forcing failover for reasons such as persistent fault or health events on the current active unit. Both units should be fully deployed before you complete this procedure.

Before you begin

[Refresh Node Status for a Single Threat Defense High Availability Pair, on page 400](#). This ensures that the status on the threat defense high availability device pair is in sync with the status on the management center.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the high availability pair where you want to change the active peer, click the **Switch Active Peer**.
- Step 3** You can:
- Click **Yes** to immediately make the standby device the active device in the high availability pair.
 - Click **No** to cancel and return to the Device Management page.
-

Refresh Node Status for a Single Threat Defense High Availability Pair

Whenever active or standby devices in the threat defense high availability pair are rebooted, the management center may not display accurate high availability status for either device. This is because when the device reboots, the high availability status is immediately updated on the device and its corresponding event is sent to the management center. However, the status may not be updated on the management center because the communication between the device and the management center is yet to be established.

Communication failures or weak communication channels between the management center and devices may result in out of sync data. When you switch the active and standby devices in a high availability pair, the change may not be reflected in the management center even after a significant time duration.

In these scenarios, you can refresh the high availability node status to obtain accurate information about the active and standby device in a high availability pair.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the high availability pair where you want to refresh the node status, click the **Refresh HA Node Status**.
- Step 3** Click **Yes** to refresh the node status.
-

Suspend and Resume High Availability

You can suspend a unit in a high-availability pair, which is useful when:

- Both units are in an active-active situation, and fixing the communication on the failover link does not correct the problem.
- You want to troubleshoot an active or standby unit and do not want the units to fail over during that time.

When you suspend high availability, the currently active device remains active, handling all user connections. However, failover criteria are no longer monitored, and the system will never fail over to the now pseudo-standby device.

When using a data interface for manager access, the management connection will be broken until after you resume.

The key difference between suspending high availability and breaking high availability is that on a suspended high-availability device, the high-availability configuration is retained. When you break high availability, the configuration is erased. Thus, you have the option to resume high availability on a suspended system, which enables the existing configuration and makes the two devices function as a failover pair again.

To suspend high availability, use the **configure high-availability suspend** command.

```
> configure high-availability suspend
Please ensure that no deployment operation is in progress before suspending
high-availability.
Please enter 'YES' to continue if there is no deployment operation in
progress and 'NO' if you wish to abort: YES
Successfully suspended high-availability.
```

If you suspend high availability from the active unit, the configuration is suspended on both the active and standby units. The standby unit interface configuration is also erased. If you suspend it from the standby unit, it is suspended on the standby unit only, but the active unit will not attempt to fail over to a suspended unit.

To resume failover, use the **configure high-availability resume** command.

```
> configure high-availability resume
Successfully resumed high-availability.
```

You can resume a unit only if it is in Suspended state. The unit will negotiate active/standby status with the peer unit.

Note Suspending high availability is a temporary state. If you reload a unit, it resumes the high-availability configuration automatically and negotiates the active/standby state with the peer.

Replace a Unit in Threat Defense High Availability Pair

To replace a failed unit in the threat defense high availability pair using a backup file, see *Restoring Management Centers and Managed Devices* in the [Cisco Secure Firewall Management Center Administration Guide](#).

If you do not have a backup of the failed device, you must break high availability. Then, register the replacement device to the Secure Firewall Management Center and reestablish high availability. The process varies depending on whether the device is primary or secondary:

- [Replace a Primary Threat Defense HA Unit with no Backup, on page 401](#)
- [Replace a Secondary Threat Defense HA Unit with no Backup, on page 402](#)

Replace a Primary Threat Defense HA Unit with no Backup

Follow the steps below to replace a failed primary unit in the threat defense high availability pair. Failing to follow these steps can overwrite the existing high availability configuration.

Caution Creating or breaking the threat defense high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) for more information. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Caution Never move a disk from sensor or management center to another device without reimaging the disk. This is an unsupported configuration and can cause breakage in functionality.

Procedure

- Step 1** Choose **Force Break** to separate the high availability pair; see [Break a High Availability Pair, on page 403](#).
- Note** The break operation removes all the configuration related to HA from threat defense and management center, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.
- Step 2** Unregister the failed primary threat defense device from the management center; see [Unregister a Device from the Management Center, on page 37](#).
- Step 3** Register the replacement threat defense to the management center; see [Add a Device to the Management Center Using a Registration Key, on page 27](#).
- Step 4** Configure high availability, using the existing secondary/active unit as the primary device and the replacement device as the secondary/standby device during registration; see [Add a High Availability Pair, on page 395](#).
-

Replace a Secondary Threat Defense HA Unit with no Backup

Follow the steps below to replace a failed secondary unit in the threat defense high availability pair.

Caution Creating or breaking the threat defense high availability pair immediately restarts the Snort process on the primary and secondary devices, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) for more information. The system warns you that continuing to create a high availability pair restarts the Snort process on the primary and secondary devices and allows you to cancel.

Procedure

- Step 1** Choose **Force Break** to separate the high availability pair; see [Break a High Availability Pair, on page 403](#).

Note The break operation removes all the configuration related to HA from threat defense and management center, and you need to recreate it manually later. To successfully configure the same HA pair, ensure that you save the IPs, MAC addresses, and monitoring configuration of all the interfaces/subinterfaces prior to executing the HA break operation.

- Step 2** Unregister the secondary threat defense device from the management center; see [Unregister a Device from the Management Center, on page 37](#).
- Step 3** Register the replacement threat defense to the management center; see [Add a Device to the Management Center Using a Registration Key, on page 27](#).
- Step 4** Configure high availability, using the existing primary/active unit as the primary device and the replacement device as the secondary/standby device during registration; see [Add a High Availability Pair, on page 395](#).
-

Break a High Availability Pair

When you break a high-availability pair, the high-availability configuration is removed from both units.

When using the Management interface for manager access: The active unit remains up and passing traffic. The standby unit interface configuration is erased.

When using a data interface for manager access: See the following details.

- The active unit remains up and passing traffic.
- The standby unit data interfaces are shut down except for the manager access interface, which remains up using the standby IP address so it can maintain the management connection.
- If the primary unit is in the standby state:
 - The IP addresses for manager access are swapped permanently in the management center configuration: the primary unit uses the standby IP address, and the secondary unit uses the active IP address.
 - If the management center initiated the management connection, and you specified a hostname for the device, then you need to update the DNS server so the swapped IP addresses are associated with the correct hostnames.
 - Breaking high availability causes a deployment to the standby unit. If the management connection is not yet reestablished because of the swapped IP addresses, the deployment may fail. In this case, you will need to manually trigger the deployment later (after the management connection is established). Be sure to complete the standby deployment before deploying changes to the active unit.

Policies that were not deployed to the active unit prior to the break operation continue to remain un-deployed after the break operation is complete. Deploy the policies on the standalone device after the break operation is complete.

**Note**

- When IPsec is enabled on high availability interfaces on the threat defense device, the device cannot prioritize the encrypted packets into the high-priority receive queue. As a result, during high-volume data traffic scenarios, attempts to break high availability may fail as the device cannot efficiently manage and prioritize the large number of encrypted connections. To view the device's resource usage and the maximum throughput, use the `show resource usage` command.
- If you cannot reach the high-availability pair using the management center, connect to the CLI on each device and enter **configure high-availability disable** to manually break high availability. See also [Unregister a High Availability Pair and Register to a New Management Center, on page 405](#).

**Caution**

Breaking the threat defense high-availability pair immediately restarts the Snort process on the primary and secondary units, temporarily interrupting traffic inspection on both devices. Whether traffic drops during this interruption or passes without further inspection depends on how the target device handles traffic. See [Snort Restart Traffic Behavior, on page 212](#) for more information.

Before you begin

- [Refresh Node Status for a Single Threat Defense High Availability Pair, on page 400](#). This ensures that the status on the high-availability pair is in sync with the status on the management center.

Procedure

Step 1 Choose **Devices > Device Management**.

Step 2 Next to the high-availability pair you want to break, click the more actions icon () and choose **Break**.

Step 3 If the standby peer does not respond, check **Force Break**.

Step 4 Click **Yes**.

The Break operation removes the high-availability configuration from the active and standby units.

A FlexConfig policy deployed on the active unit may show a deployment failure after the break high-availability operation. You must alter and re-deploy the FlexConfig policy on the active unit.

What to do next

If you are using a FlexConfig policy on the active unit, alter and re-deploy the FlexConfig policy to eliminate deployment errors.

**Note**

After you break high availability, the threat defense device that was operating as the active unit will still have the standby unit's IP address listed in its configuration. To resolve this, do an additional deployment on the formerly active threat defense device to remove the standby unit's IP address from its configuration.

Unregister a High Availability Pair and Register to a New Management Center

You can unregister the pair from the management center, which keeps the High Availability pair intact. You might want to unregister the pair if you want to register it to a new management center or if the management center can no longer reach the pair.

Unregistering a High Availability pair:

- Severs all communication between the management center and the pair.
- Removes the pair from the **Device Management** page.
- Returns the pair to local time management if the pair's platform settings policy is configured to receive time from the management center using NTP.
- Leaves the configuration intact, so the pair continues to process traffic.

Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the pair again to the same or a different management center causes the configuration to be removed, so the pair will stop processing traffic at that point; the High Availability configuration remains intact so you can add the pair as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

Before you begin

- This procedure requires CLI access to the primary unit.

Procedure

-
- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the High Availability pair you want to unregister, click **More** (⋮) and choose **Unregister**.
- Step 3** Click **Yes**. The device High Availability pair is unregistered.
- Step 4** You can register the pair to a new (or the same) management center by adding the primary unit as a new device.
- Determine the primary unit by connecting to the CLI on one unit, and entering the **show failover** command. The first line of the output shows whether this unit is Primary or Secondary.

```
> show failover
Failover unit Primary
Failover LAN Interface: failover GigabitEthernet0/2 (up)
Reconnect timeout 0:00:00
Unit Poll frequency 1 seconds, holdtime 15 seconds
Failover On

[...]
```
 - At the primary unit's CLI, identify the new management center using the **configure manager add** command. See [Modify Threat Defense Management Interfaces at the CLI, on page 75](#).
 - Choose **Devices > Device Management**, and then click **Add > Device**.

You only need to add the primary unit as a device, and the management center will discover the secondary unit.

Monitoring High Availability

This section lets you monitor the High Availability status.

View Failover History

You can view the failover history of both high availability devices in a single view. The history displays in chronological order and includes the reason for any failover.

Procedure

- Step 1** Choose **Devices > Device Management**.
 - Step 2** Next to the device high-availability pair you want to edit, click **Edit** (✎).
 - Step 3** Choose **Summary**.
 - Step 4** Under General, click **View** (👁).
-

View Stateful Failover Statistics

You can view the stateful failover link statistics of both the primary and secondary devices in the high availability pair.

Procedure

- Step 1** Choose **Devices > Device Management**.
 - Step 2** Next to the device high-availability pair you want to edit, click **Edit** (✎).
 - Step 3** Choose **High Availability**.
 - Step 4** Under Stateful Failover Link, click **View** (👁).
 - Step 5** Choose a device to view statistics.
-

Troubleshoot Configuration Sync Failure

When forming a failover pair, the joining unit clears its running configuration and replicates the entire configuration from the active unit. Upon completing full configuration sync, the joining unit assumes the

standby ready role and establishes the failover pair. After the unit joins the failover pair, any configuration change on the active unit are also replicated on the standby unit to keep both the units synchronized.

If the standby unit fails to replicate any configuration change commands, it reports configuration sync failure and exit the high availability by disabling failover. This section describes steps for identifying and troubleshooting configuration sync failure error reported by the standby unit.

To view the configuration sync errors or stats, you can use the following CLI commands through an SSH session or the Threat Defense CLI:

- **show failover config-sync errors all** to display all configuration synchronization errors related to failover.
- **show failover config-sync stats all** to view statistics regarding failover configuration synchronization.

To re-enable high availability:

- Re-enable failover by executing the **failover reset** command on the active unit.
- If re-enabling the failover is not successful, delete or update the configuration change that the standby unit failed to replicate, and then re-enable the failover.

History for High Availability

Feature	Minimum Management Center	Minimum Threat Defense	Details
High availability support for the manager access data interface	7.4	7.4	You can now use a data interface for manager access with threat defense high availability.
Unregistering a high-availability pair now allows you to re-register without breaking the pair	7.3	Any	When you delete (unregister) a high-availability pair, you no longer have to manually break the pair at the CLI and re-register standalone devices. You can now add the primary unit to a new management center, and the standby unit will be discovered automatically. Re-registering the pair will still erase the configuration, and your policies will need to be re-applied.
Policy rollback support for high availability	7.2	Any	The configure policy rollback command is supported for high availability.
Config-Sync Optimization feature for faster HA peering	7.2	Any	The Config-Sync Optimization feature enables comparing the configuration of the joining unit and the active unit by exchanging config-hash values. If the hash computed on both active and joining units match, the joining unit skips full config-sync and rejoin the HA. This feature enables faster HA peering and reduces maintenance window and upgrade time.

Feature	Minimum Management Center	Minimum Threat Defense	Details
Improvements to the upgrade workflow for clustered and high-availability devices	7.1	Any	<p>We made the following improvements to the upgrade workflow for clustered and high-availability devices:</p> <ul style="list-style-type: none"> • The upgrade wizard now correctly displays clustered and high-availability units as groups, rather than as individual devices. The system can identify, report, and preemptively require fixes for group-related issues you might have. For example, you cannot upgrade a cluster on the Firepower 4100/9300 if you have made unsynced changes on Firepower Chassis Manager. • We improved the speed and efficiency of copying upgrade packages to clusters and high-availability pairs. Previously, the FMC copied the package to each group member sequentially. Now, group members can get the package from each other as part of their normal sync process. • You can now specify the upgrade order of data units in a cluster. The control unit always upgrades last.
Clearing routes in a high-availability group or cluster.	7.1	Any	<p>In previous releases, the clear route command cleared the routing table on the unit only. Now, when operating in a high-availability group or cluster, the command is available on the active or control unit only, and clears the routing table on all units in the group or cluster.</p>
FTD High Availability Hardening	6.2.3	Any	<p>Version 6.2.3 introduces the following features for FTD devices in high availability:</p> <ul style="list-style-type: none"> • Whenever active or standby FTD devices in a high-availability pair restart, the FMC may not display accurate high-availability status for either managed device. However, the status may not upgrade on the FMC because the communication between the device and the FMC is not established yet. The Refresh Node Status option on the Devices > Device Management page allows you to refresh the high-availability unit status to obtain accurate information about the active and standby device in a high-availability pair. • The Devices > Device Management page of the FMC UI has a new Switch Active Peer icon. • Version 6.2.3 includes a new REST API object, Device High Availability Pair Services, that contains four functions: <ul style="list-style-type: none"> • DELETE <code>ftddevicehapairs</code> • PUT <code>ftddevicehapairs</code> • POST <code>ftddevicehapairs</code> • GET <code>ftddevicehapairs</code>

CHAPTER 10

Clustering for the Secure Firewall 3100/4200

Clustering lets you group multiple threat defense units together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

Note Some features are not supported when using clustering. See [Unsupported Features with Clustering](#), on page 459.

- [About Clustering for the Secure Firewall 3100/4200](#), on page 409
- [Licenses for Clustering](#), on page 411
- [Requirements and Prerequisites for Clustering](#), on page 411
- [Guidelines for Clustering](#), on page 412
- [Configure Clustering](#), on page 416

- [Examples for Clustering](#), on page 457
- [Reference for Clustering](#), on page 459
- [History for Clustering](#), on page 472

About Clustering for the Secure Firewall 3100/4200

This section describes the clustering architecture and how it works.

How the Cluster Fits into Your Network

The cluster consists of multiple firewalls acting as a single unit. To act as a cluster, the firewalls need the following infrastructure:

- Isolated, high-speed backplane network for intra-cluster communication, known as the *cluster control link*.
- Management access to each firewall for configuration and monitoring.

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using one of the following methods:

- **Spanned EtherChannel (Recommended)**—Interfaces on multiple members of the cluster are grouped into a single EtherChannel; the EtherChannel performs load balancing between units.
- **Policy-Based Routing (Routed firewall mode only)**—The upstream and downstream routers perform load balancing between units using route maps and ACLs.
- **Equal-Cost Multi-Path Routing (Routed firewall mode only)**—The upstream and downstream routers perform load balancing between units using equal cost static or dynamic routes.

Control and Data Node Roles

One member of the cluster is the control node. If multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority. All other members are data nodes. When you first create the cluster, you specify which node you want to be the control node, and it will become the control node simply because it is the first node added to the cluster.

All nodes in the cluster share the same configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Cluster Interfaces

You can configure data interfaces as either Spanned EtherChannels or as Individual interfaces. All data interfaces in the cluster must be one type only. See [About Cluster Interfaces, on page 416](#) for more information.

For Spanned EtherChannels: You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces). For Individual interfaces: IPS-only interfaces are not supported.

Cluster Control Link

Each unit must dedicate at least one hardware interface as the cluster control link. See [Cluster Control Link, on page 416](#) for more information.

Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management Network

You must manage each node using the Management interface; management from a data interface is not supported with clustering.

Licenses for Clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the management center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster in the **System** (⚙️) > **Licenses** > **Smart Licenses** > **Edit Licenses** or **Devices** > **Device Management** > **Cluster** > **License** area.

Note If you add the cluster before the management center is licensed (and running in Evaluation mode), then when you license the management center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and Prerequisites for Clustering

Model Requirements

- Secure Firewall 3100—Maximum 16 units
- Secure Firewall 4200—Maximum 16 units

User Roles

- Admin
- Access Admin
- Network Admin

Hardware and Software Requirements

All units in a cluster:

- Must be the same model.
- Must include the same interfaces.
- The management center access must be from the Management interface; data interface management is not supported.
- Must run the identical software except at the time of an image upgrade. Hitless upgrade is supported.
- Must be in the same firewall mode, routed or transparent.
- Must be in the same domain.
- Must be in the same group.

- Must not have any deployment pending or in progress.
- The control node must not have any unsupported features configured (see [Unsupported Features with Clustering, on page 459](#)).
- Data nodes must not have any VPN configured. The control node can have site-to-site VPN configured.

Switch Requirements

- Be sure to complete the switch configuration before you configure clustering. Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. By default, the cluster control link MTU is set to 100 bytes higher than the data interfaces. If the switches have an MTU mismatch, the cluster formation will fail.

Guidelines for Clustering

Firewall Mode

The firewall mode must match on all units.

High Availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Switches

- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR *IPv4* MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.
- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- On the switch, we recommend that you use one of the following EtherChannel load-balancing algorithms: **source-dest-ip** or **source-dest-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.

- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.
- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:

```
router(config)# port-channel id hash-distribution fixed
```

Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.

- You should disable the LACP Graceful Convergence feature on all cluster-facing EtherChannel interfaces for Cisco Nexus switches.

EtherChannels

- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
 - Spanned EtherChannels—For cluster unit *Spanned* EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.

- Device-local EtherChannels—For cluster unit *Device-local* EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.

Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the threat defense or the switch, adding an additional switch to form a VSS or vPC) you should disable the health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel, when the syslog server port is down and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the ASA cluster. These messages can result in some units of the ASA cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a

new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

Defaults for Clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Configure Clustering

To add a cluster to the management center, add each node to the management center as a standalone unit, configure interfaces on the unit you want to make the control node, and then form the cluster.

About Cluster Interfaces

You can configure data interfaces as either Spanned EtherChannels or as Individual interfaces. All data interfaces in the cluster must be one type only. You cannot configure Ethernet 1/1 as a Spanned EtherChannel and configure Ethernet 1/2 as an Individual interface within the same cluster, for example.

For Spanned EtherChannels: You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces). For Individual interfaces: IPS-only interfaces are not supported.

Each unit must also dedicate at least one hardware interface as the cluster control link.

Cluster Control Link

Each unit must dedicate at least one hardware interface as the cluster control link. We recommend using an EtherChannel for the cluster control link if available.

Cluster Control Link Traffic Overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.

- Connection ownership queries and data packet forwarding.

Cluster Control Link Interfaces and Network

You can use any physical interface or EtherChannel for the cluster control link. You cannot use a VLAN subinterface as the cluster control link. You also cannot use the Management interface.

Each cluster control link has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

Note For a 2-member cluster, do not directly-connect the cluster control link from one node to the other node. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit. If you need to directly-connect the units (for testing purposes, for example), then you should configure and enable the cluster control link interface on both nodes before you form the cluster.

Size the Cluster Control Link

If possible, you should size the cluster control link to match the expected throughput of each chassis so the cluster control link can handle the worst-case scenarios.

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features. For example:

- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

Note If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

Cluster Control Link Redundancy

The following diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.

Cluster Control Link Reliability

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.

The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

Spanned EtherChannels (Recommended)

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces: A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.

Spanned EtherChannel Benefits

The EtherChannel method of load-balancing is recommended over other methods for the following benefits:

- Faster failure discovery.
- Faster convergence time. Individual interfaces rely on routing protocols to load-balance traffic, and routing protocols often have slow convergence during a link failure.
- Ease of configuration.

Guidelines for Maximum Throughput

To achieve maximum throughput, we recommend the following:

- Use a load-balancing hash algorithm that is “symmetric,” meaning that packets from both directions will have the same hash and will be sent to the same threat defense in the Spanned EtherChannel. We recommend using the source and destination IP address (the default) or the source and destination port as the hashing algorithm.
- Use the same type of line cards when connecting the threat defenses to the switch so that hashing algorithms applied to all packets are the same.

Load Balancing

The EtherChannel link is selected using a proprietary hash algorithm, based on source or destination IP addresses and TCP and UDP port numbers.

Note On the switch, we recommend that you use one of the following algorithms: **source-dest-ip** or **source-dest-ip-port** (see the Cisco Nexus OS or Cisco IOS **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the ASAs in a cluster.

The number of links in the EtherChannel affects load balancing.

Symmetric load balancing is not always possible. If you configure NAT, then forward and return packets will have different IP addresses and/or ports. Return traffic will be sent to a different unit based on the hash, and the cluster will have to redirect most returning traffic to the correct unit.

EtherChannel Redundancy

The EtherChannel has built-in redundancy. It monitors the line protocol status of all links. If one link fails, traffic is re-balanced between remaining links. If all links in the EtherChannel fail on a particular unit, but other units are still active, then the unit is removed from the cluster.

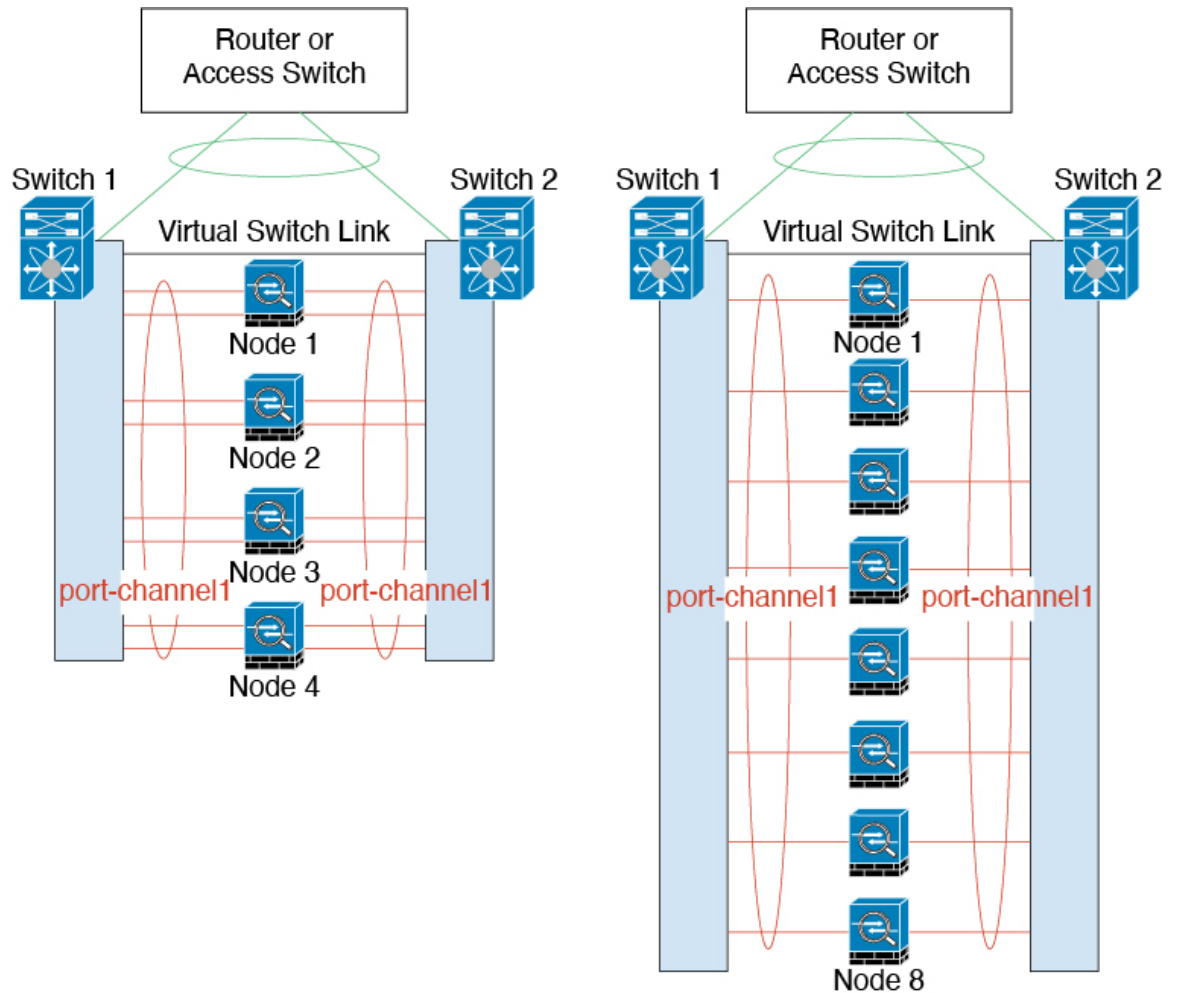

Connecting to a Redundant Switch System

You can include multiple interfaces per threat defense in the Spanned EtherChannel. Multiple interfaces per threat defense are especially useful for connecting to both switches in a VSS, vPC, StackWise, or StackWise Virtual system.

Depending on your switches, you can configure up to 32 active links in the spanned EtherChannel. This feature requires both switches in the vPC to support EtherChannels with 16 active links each (for example the Cisco Nexus 7000 with F2-Series 10 Gigabit Ethernet Module).

For switches that support 8 active links in the EtherChannel, you can configure up to 16 active links in the spanned EtherChannel when connecting to two switches in a redundant system.

The following figure shows a 16-active-link spanned EtherChannel in a 4-node cluster and an 8-node cluster.

Individual Interfaces (Routed Firewall Mode Only)

Individual interfaces are normal routed interfaces, each with their own *Local IP address* used for routing. The *Main cluster IP address* for each interface is a fixed address that always belongs to the control node. When the control node changes, the Main cluster IP address moves to the new control node, so management of the cluster continues seamlessly.

IPS-only interfaces (inline sets and passive interfaces) are not supported as Individual interfaces.

Because interface configuration must be configured only on the control node, you configure a pool of IP addresses to be used for a given interface on the cluster nodes, including one for the control node.

Load balancing must be configured separately on the upstream switch.

Policy-Based Routing

When using Individual interfaces, each threat defense interface maintains its own IP address and MAC address. One method of load balancing is Policy-Based Routing (PBR).

We recommend this method if you are already using PBR, and want to take advantage of your existing infrastructure.

PBR makes routing decisions based on a route map and ACL. You must manually divide traffic between all threat defenses in a cluster. Because PBR is static, it may not achieve the optimum load balancing result at all times. To achieve the best performance, we recommend that you configure the PBR policy so that forward and return packets of a connection are directed to the same threat defense. For example, if you have a Cisco router, redundancy can be achieved by using Cisco IOS PBR with Object Tracking. Cisco IOS Object Tracking monitors each threat defense using ICMP ping. PBR can then enable or disable route maps based on reachability of a particular threat defense. See the following URLs for more details:

<http://www.cisco.com/c/en/us/solutions/data-center-virtualization/intelligent-traffic-director/index.html>

http://www.cisco.com/en/US/products/ps6599/products_white_paper09186a00800a4409.shtml

Equal-Cost Multi-Path Routing

When using Individual interfaces, each threat defense interface maintains its own IP address and MAC address. One method of load balancing is Equal-Cost Multi-Path (ECMP) routing.

We recommend this method if you are already using ECMP, and want to take advantage of your existing infrastructure.

ECMP routing can forward packets over multiple “best paths” that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses and/or source and destination ports can be used to send a packet to one of the next hops. If you use static routes for ECMP routing, then the threat defense failure can cause problems; the route continues to be used, and traffic to the failed threat defense will be lost.

If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each threat defense to participate in dynamic routing.

Cisco Intelligent Traffic Director (Routed Firewall Mode Only)

When using Individual interfaces, each threat defense interface maintains its own IP address and MAC address. Intelligent Traffic Director (ITD) is a high-speed hardware load-balancing solution for Nexus 5000, 6000, 7000, and 9000 switch series. In addition to fully covering the functional capabilities of traditional PBR, it offers a simplified configuration workflow and multiple additional features for a more granular load distribution.

ITD supports IP stickiness, consistent hashing for bi-directional flow symmetry, virtual IP addressing, health monitoring, sophisticated failure handling policies with N+M redundancy, weighted load-balancing, and application IP SLA probes including DNS. Due to the dynamic nature of load-balancing, it achieves a more even traffic distribution across all cluster nodes as compared to PBR. In order to achieve bi-directional flow symmetry, we recommend configuring ITD such that forward and return packets of a connection are directed to the same threat defense. See the following URL for more details:

https://www.cisco.com/c/dam/en/us/td/docs/switches/datacenter/sw/design/itd_deployment/ITD_ASA_Deployment_Guide.pdf

Cable and Add Devices to the Management Center

Before configuring clustering, you need to prepare your devices. In particular, the cluster will not come up unless all nodes can communicate over the cluster control link. Therefore, before you form the cluster, the cluster control link must be ready to go.

Procedure

-
- Step 1** Cable the cluster control link network, management network, and data networks.
- Step 2** Configure the upstream and downstream equipment.
- For the cluster control link network, set the MTU to be at least 100 bytes higher than the data interface MTU.

By default, the data interface MTU is 1500 bytes, so the cluster control link MTU on the cluster node will be set to 1600 bytes. If you use higher MTUs on your data interfaces, increase the cluster control link MTU on connecting switches accordingly.
 - Configure cluster control link interfaces on upstream and downstream equipment, including for an optional EtherChannel.

See [Cluster Control Link Interfaces and Network, on page 417](#) for cluster control link requirements.
 - Configure data interfaces on upstream and downstream equipment, including Spanned EtherChannels, if you choose that cluster interface mode.

See [About Cluster Interfaces, on page 416](#) for information about how to cable Spanned EtherChannels.
- Step 3** Add each node to the management center as a standalone device in the same domain and group.

See [Add a Device to the Management Center Using a Registration Key, on page 27](#). You can create a cluster with a single device, and then add more nodes later. The initial settings (licensing, access control policy) that

you set when you add a device will be inherited by all cluster nodes from the control node. You will choose the control node when forming the cluster.

Step 4 Enable the cluster control link on the device you want to be the control node.

When you add the other nodes, they will inherit the cluster control link configuration.

Note Do *not* configure the name or IP addressing for the cluster control link. The MTU of the cluster control link interface is automatically set to 100 bytes more than the highest data interface MTU when you form the cluster, so you do not need to set it now. However, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation. If the MTU is set in this range when you add the cluster, we recommend returning to the **Interfaces** page and manually increasing it above 8362.

- On the device you want to be the control node, choose **Devices > Device Management**, and click **Edit** (✎).
- Click **Interfaces**.
- Enable the interface. If you are going to use an EtherChannel for the cluster control link, enable all members. See [Enable the Physical Interface and Configure Ethernet Settings, on page 703](#).

Figure 170: Enable the Cluster Control Link Interface

- (Optional) Add an EtherChannel. See [Configure an EtherChannel, on page 710](#).

We recommend using the On mode for cluster control link member interfaces to reduce unnecessary traffic on the cluster control link (Active mode is the default). The cluster control link does not need the overhead of LACP traffic because it is an isolated, stable network. **Note:** We recommend setting *data* EtherChannels to Active mode.

- Click **Save** and then **Deploy** to deploy the interface changes to the control node.

Create a Cluster

Form a cluster from one or more devices in the management center.

Procedure

Step 1 Choose **Devices > Device Management**, and then choose **Add > Cluster**.

The **Add Cluster Wizard** appears.

Figure 171: Add Cluster Wizard

Add Cluster Wizard

1 Configuration — 2 Summary

! Create a cluster for supported models. Note: For the Firepower 4100/9300 and threat defense virtual (AWS/GCP/Azure), use the Add Device option. Make sure connected switches match the MTUs for data interfaces and the cluster control link interface.

Continue

Step 2 Specify a **Cluster Name** and an authentication **Cluster Key** for control traffic.

- **Cluster Name**—An ASCII string from 1 to 38 characters.
- **Cluster Key**—An ASCII string from 1 to 63 characters. The **Cluster Key** value is used to generate the encryption key. This encryption does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.

Step 3 For the **Control Node**, set the following:

- **Node**—Choose the device that you want to be the control node initially. When the management center forms the cluster, it will add this node to the cluster first so it will be the control node.

Note If you see an **Error** (❗) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation. For example:

Figure 172: Configuration Issues

To resolve the above issues, remove the unsupported VPN license and deploy pending configuration changes to the device.

- **Cluster Control Link Network**—Specify an IPv4 subnet; IPv6 is not supported for this interface. Specify a **24, 25, 26, or 27** subnet.
- **Cluster Control Link**—Choose the physical interface or EtherChannel you want to use for the cluster control link.

Note The MTU of the cluster control link interface is automatically set to 100 bytes more than the highest data interface MTU; by default, the MTU is 1600 bytes. We do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation. If the MTU is set in this range when you add the cluster, we recommend increasing the MTU above 8362 on the **Devices > Device Management > Interfaces** page.

Make sure you configure switches connected to the cluster control link to the correct (higher) MTU; otherwise, cluster formation will fail.

- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the first address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority. Even if you set the priority to be lower than other nodes, this node will still be the control node when the cluster is first formed.
- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

Step 4 For the **Cluster Mode**, choose **Spanned EtherChannel Mode** or **Individual Interface Mode**.

Step 5 For **Data Nodes (Optional)**, click **Add a data node** to add a node to the cluster.

You can form the cluster with only the control node for faster cluster formation, or you can add all nodes now. Set the following for each data node:

- **Node**—Choose the device that you want to add.

Note If you see an **Error** (❗) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation.

- **Cluster Control Link IPv4 Address**—This field will be auto-populated with the next address on the cluster control link network. You can edit the host address if desired.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority.
- **Site ID**—(FlexConfig feature) Enter the site ID for this node between 1 and 8. A value of 0 disables inter-site clustering. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the FlexConfig feature.

Step 6 Click **Continue**. Review the **Summary**, and then click **Save**.

The cluster name shows on the **Devices > Device Management** page; expand the cluster to see the cluster nodes.

Figure 173: Cluster Management

Node Name	IP Address	Role	Version	Actions	Policy
172.16.0.50 (Control)	172.16.0.50 - Transparent	Firewall 3120 Threat Defense	7.1.0	Manage	Base, Threat (2 more...)
172.16.0.51	172.16.0.51 - Transparent	Firewall 3120 Threat Defense	7.1.0	N/A	Base, Threat (2 more...)

A node that is currently registering shows the loading icon.

Figure 174: Node Registration

Node Name	IP Address	Role
172.16.0.50 (Control)	172.16.0.50 - Transparent	
172.16.0.51	172.16.0.51 - Transparent	

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**. The management center updates the Cluster Registration task as each node registers.

Deploy					
Deployments	Upgrades	Health	Tasks	Show Notifications	
3 total	0 running	3 success	0 warnings	0 failures	Filter
✓ 10.10.1.12	Deployment to device successful.			1m 54s	
✓ 10.10.1.13	Deployment to device successful.			1m 3s	
✓ TD_Cluster	Deployment to device successful.			35s	

Step 7 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.

Step 8 On the **Devices > Device Management > Cluster** screen, you see **General** and other settings for the cluster.

Figure 175: Cluster Settings

Force Deploy: →

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the management center so that it can reach the device on the network. First disable the connection, edit the **Host** address in the **Management** area, then re-enable the connection.

Management	
Host:	10.89.5.20
Status:	✓

Configure Interfaces

You can configure data interfaces as either Spanned EtherChannels or as Individual interfaces. Each method uses a different load-balancing mechanism. You cannot configure both types in the same configuration.

Configure Spanned EtherChannels

Configure data interfaces as Spanned EtherChannels.

Procedure

- Step 1** Choose **Devices > Device Management**, and click **Edit** (✎) next to the cluster.
- Step 2** Click **Interfaces**.
- Step 3** Configure Spanned EtherChannel data interfaces.
 - a) Configure one or more EtherChannels. See [Configure an EtherChannel, on page 710](#).

You can include one or more member interfaces in the EtherChannel. Because this EtherChannel is spanned across all of the nodes, you only need one member interface per node; however, for greater throughput and redundancy, multiple members are recommended.

- b) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the EtherChannel. The rest of this procedure applies to the subinterfaces. See [Add a Subinterface, on page 759](#).
- c) Click **Edit** (✎) for the EtherChannel interface.
- d) Configure the name and other parameters. For regular firewall interfaces, see [Configure Routed Mode Interfaces, on page 778](#) or, for transparent mode, [Configure Bridge Group Interfaces, on page 783](#). For IPS-only interfaces, see [Inline Sets and Passive Interfaces, on page 815](#).
 - If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. By default, the cluster control link MTU is 1600 bytes. If you want to increase the MTU of data interfaces, first increase the cluster control link MTU. Note that we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
 - For routed mode, DHCP, PPPoE, IPv6 autoconfig and manual link-local addresses are not supported. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254). In this case, no IP addresses are reserved for the network or broadcast addresses.
- e) Set a manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active Mac Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.
 For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.
 Do not set the **Standby Mac Address**; it is ignored.
 You must configure a MAC address for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.
- f) Click **OK**. Repeat the above steps for other data interfaces.

Step 4 Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Individual Interfaces

Individual interfaces are normal routed interfaces, each with their own IP address taken from a pool of IP addresses. The Main cluster IP address is a fixed address for the cluster that always belongs to the control node.

Individual management interfaces let you SSH directly to each unit if necessary, while a Spanned EtherChannel interface only allows connection to the control node.

IPS-only interfaces (inline sets or passive interfaces) are not supported for Individual interfaces.

Before you begin

- You must be in Individual interface mode.
- Individual interfaces require you to configure load balancing on neighbor devices. External load balancing is not required for the management interface.
- (Optional) Configure the interface as a device-local EtherChannel interface, and/or configure subinterfaces.
For an EtherChannel, this EtherChannel is local to the unit, and is not a Spanned EtherChannel.

Procedure

Step 1 Choose **Objects > Object Management > Address Pools** to add an IPv4 and/or IPv6 address pool. See [Address Pools, on page 1272](#).

Include at least as many addresses as there are units in the cluster. The main IP address is not a part of this pool, but needs to be on the same network. You cannot determine the exact Local address assigned to each unit in advance.

Figure 179: Add Address Pool

Add IPv4 Pool ⓘ

Name*
cluster1-outside-pool

Description
[Empty text box]

IPv4 Address Range*
10.89.5.55-10.89.5.61

Format: ipaddr-ipaddr e.g., 10.72.1.1-10.72.1.150

Mask*
255.255.255.192

Allow Overrides

ⓘ Configure device overrides in the address pool object to avoid IP address conflicts in case of object is shared across multiple devices

> Override (0)

Cancel Save

Note Although not common, if you want to set the MAC addresses manually, you can also add a MAC address pool object.

Step 2 On **Devices > Device Management > Interfaces**, click **Edit** (✎) for the interface you want to configure.

Step 3 On the **IPv4** page, enter the **Virtual IP Address** and mask. This main ("virtual") IP address is a fixed address for the cluster, and always belongs to the control node.

DHCP and PPPoE are not supported. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254). In this case, no IP addresses are reserved for the network or broadcast addresses.

Figure 180: IPv4 Page

General **IPv4** IPv6 Hardware C

IP Type:
Use Static IP

Virtual IP Address:
10.89.5.43/255.255.255.192
eg. 192.0.2.1/255.255.255.128 or 192.0.2.1/25

IPv4 Address Pool:
cluster1-outside-pool

Step 4 From the **IPv4 Address Pool** drop-down list, choose the address pool you created.

Step 5 On **IPv6 > Basic**, from the **IPv6 Address Pool** drop-down list, choose the address pool you created.

IPv6 autoconfig and manual link-local addresses are not supported.

Step 6 Configure other interface settings as normal.

To set the MAC addresses manually, you can select the MAC address pool from the interface's **Advanced** page.

Note If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. By default, the cluster control link MTU is 1600 bytes. If you want to increase the MTU of data interfaces, first increase the cluster control link MTU. Note that we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.

Configure Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 181: Cluster Health Monitor Settings

Cluster Health Monitor Settings			
Timeouts			
Hold Time			3 s
Interface Debounce Time			9000 ms
Monitored Interfaces			
Service Application			Enabled
Unmonitored Interfaces			None
Auto-Rejoin Settings			
	Attempts	Interval Between Attempts	Interval Variation
Cluster Interface	-1	5	1
Data Interface	3	5	2
System	3	5	2

Table 30: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.

Field	Description
<i>Attempts</i>	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
<i>Interval Between Attempts</i>	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
<i>Interval Variation</i>	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
<i>Attempts</i>	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
<i>Interval Between Attempts</i>	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
<i>Interval Variation</i>	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
<i>Attempts</i>	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
<i>Interval Between Attempts</i>	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
<i>Interval Variation</i>	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the cluster you want to modify, click **Edit** (✎).
- Step 3** Click **Cluster**.
- Step 4** In the **Cluster Health Monitor Settings** section, click **Edit** (✎).
- Step 5** Disable the system health check by clicking the **Health Check** slider.

Figure 182: Disable the System Health Check

Edit Cluster Health Monitor Settings

Health Check ⓘ

▼ Timeouts

Hold Time Range: 0.3 to 45 seconds

Interface Debounce Time Range: 300 to 9000 milliseconds

> Auto-Rejoin Settings

> Monitored Interfaces

Reset to Defaults Cancel Save

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6 Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7 Customize the auto-rejoin cluster settings after a health check failure.

Figure 183: Configure Auto-Rejoin Settings

▼ Auto-Rejoin Settings

Cluster Interface

Attempts Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts Range: 2-60 minutes between rejoin attempts

Interval Variation Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

Data Interface

Attempts Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts Range: 2-60 minutes between rejoin attempts

Interval Variation Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

System

Attempts Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts Range: 2-60 minutes between rejoin attempts

Interval Variation Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8

Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 184: Configure Monitored Interfaces

▼ Monitored Interfaces

Monitored Interfaces

- GigabitEthernet0/0
- GigabitEthernet0/1
- GigabitEthernet0/2
- GigabitEthernet0/3
- GigabitEthernet0/4
- GigabitEthernet0/5
- GigabitEthernet0/6
- GigabitEthernet0/7
- Diagnostic0/0

Unmonitored Interfaces ⓘ

[Add](#)

Enable Service Application Monitoring

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Step 10 Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

Manage Cluster Nodes

After you deploy the cluster, you can change the configuration and manage cluster nodes.

Add a New Cluster Node

You can add one or more new cluster nodes to an existing cluster.

Procedure

Step 1 Choose **Devices > Device Management**, click **More** (⋮) for the cluster, and choose **Add Nodes**.

Figure 185: Add Nodes

The **Manage Cluster Wizard** appears.

Step 2 From the **Node** menu, choose a device, adjust the IP address, priority, and Site ID if desired.

Figure 186: Manage Cluster Wizard

The screenshot shows the 'Manage Cluster Wizard' interface. It has two steps: 'Configuration' (active) and 'Summary'. The configuration fields are as follows:

- Cluster Name***: ftdcluster
- Cluster Key**: Two fields with masked content (*****).
- Control Node**:
 - Node***: 172.16.0.50
 - Cluster Control Link Network***: 10.10.10.0 / 24 (254 addresses)
 - Cluster Control Link***: Ethernet1/7
 - Cluster Control Link IPv4 Address***: 10.10.10.1
 - Priority***: 1
 - Site ID**: 0
- Data Nodes (Optional)**:
 - Node***: 172.16.0.51
 - Cluster Control Link IPv4 Address***: 10.10.10.2
 - Priority***: 2
 - Site ID**: 0
- Node*** (highlighted with a red box):
 - Cluster Control Link IPv4 Address***: 10.10.10.3
 - Priority***: 3
 - Site ID**: 0
 - Remove** button

At the bottom, there is a link: [Add a data node](#).

Step 3 To add additional nodes, click **Add a data node**.

Step 4 Click **Continue**. Review the **Summary**, and then click **Save**

The node that is currently registering shows the loading icon.

Figure 187: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**.

Break a Node

You can remove a node from the cluster so that it becomes a standalone device. You cannot break the control node unless you break the entire cluster. The data node has its configuration erased.

Procedure

Step 1 Choose **Devices > Device Management**, click **More** (⋮) for the node you want to break, and choose **Break Node**.

Figure 188: Break a Node

You can optionally break one or more nodes from the cluster More menu by choosing **Break Nodes**.

Step 2 You are prompted to confirm the break; click **Yes**.

Figure 189: Confirm Break

You can monitor the cluster node break by clicking the **Notifications** icon and choosing **Tasks**.

Break the Cluster

You can break the cluster and convert all nodes to standalone devices. The control node retains the interface and security policy configuration, while data nodes have their configuration erased.

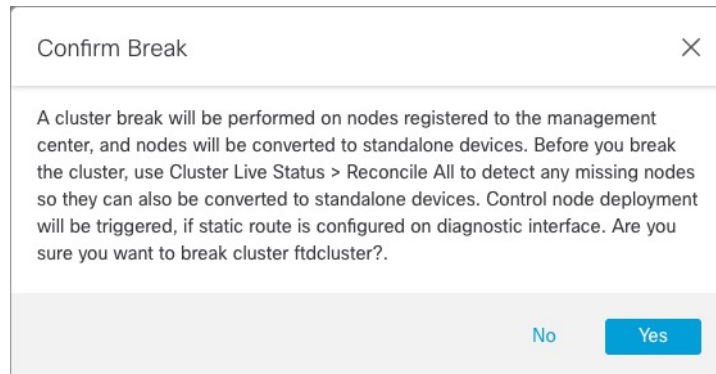

Procedure

- Step 1** Make sure all cluster nodes are being managed by the management center by reconciling nodes. See [Reconcile Cluster Nodes, on page 447](#).
- Step 2** Choose **Devices > Device Management**, click **More** (⋮) for the cluster, and choose **Break Cluster**.

Figure 190: Break Cluster

- Step 3** You are prompted to break the cluster; click **Yes**.

Figure 191: Confirm Break

You can monitor the cluster break by clicking the **Notifications** icon and choosing **Tasks**.

Disable Clustering

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the management center device list. When a node becomes inactive, all data interfaces are shut down.

Procedure

- Step 1** For the unit you want to disable, choose **Devices > Device Management**, click **More** (⋮), and choose **Disable Node Clustering**.

Figure 192: Disable Clustering

If you disable clustering on the control node, one of the data nodes will become the new control node. Note that for centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node. You cannot disable clustering on the control node if it is the only node in the cluster.

- Step 2** Confirm that you want to disable clustering on the node.
The node will show **(Disabled)** next to its name in the **Devices > Device Management** list.
- Step 3** To reenable clustering, see [Rejoin the Cluster, on page 445](#).

Rejoin the Cluster

If a node was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. See [Rejoining the Cluster, on page 467](#) for more information about why a node can be removed from a cluster.

Procedure

- Step 1** For the unit you want to reactivate, choose **Devices > Device Management**, click **More** (⋮), and choose **Enable Node Clustering**.
- Step 2** Confirm that you want to enable clustering on the unit.
-

Change the Control Node

Caution The best method to change the control node is to disable clustering on the control node, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control node, use the procedure in this section. Note that for centralized features, if you force a control node change using either method, then all connections are dropped, and you have to re-establish the connections on the new control node.

To change the control node, perform the following steps.

Procedure

- Step 1** Open the **Cluster Status** dialog box by choosing **Devices > Device Management > More** (⋮) **> Cluster Live Status**.

Figure 193: Cluster Status

Cluster Status ?

Overall Status:  Cluster has all nodes in sync

Nodes details (2)

	Status	Device Name	Unit Name	Chassis URL	
>	In Sync.	172.16.0.50 Control	172.16.0.50	N/A	⋮
>	In Sync.	172.16.0.51	172.16.0.51	N/A	⋮

Dated: 11:52:26 | 20 Dec 2021

- Step 2** For the unit you want to become the control unit, choose **More (⋮) > Change Role to Control**.
- Step 3** You are prompted to confirm the role change. Check the checkbox, and click **OK**.

Edit the Cluster Configuration

You can edit the cluster configuration. If you change the cluster key, cluster control link interface, or cluster control link network, the cluster will be broken and reformed automatically. Until the cluster is reformed, you may experience traffic disruption. If you change the cluster control link IP address for a node, node priority, or site ID, only the affected nodes are broken and readded to the cluster.

Procedure

- Step 1** Choose **Devices > Device Management**, click **More (⋮)** for the cluster, and choose **Edit Configuration**.

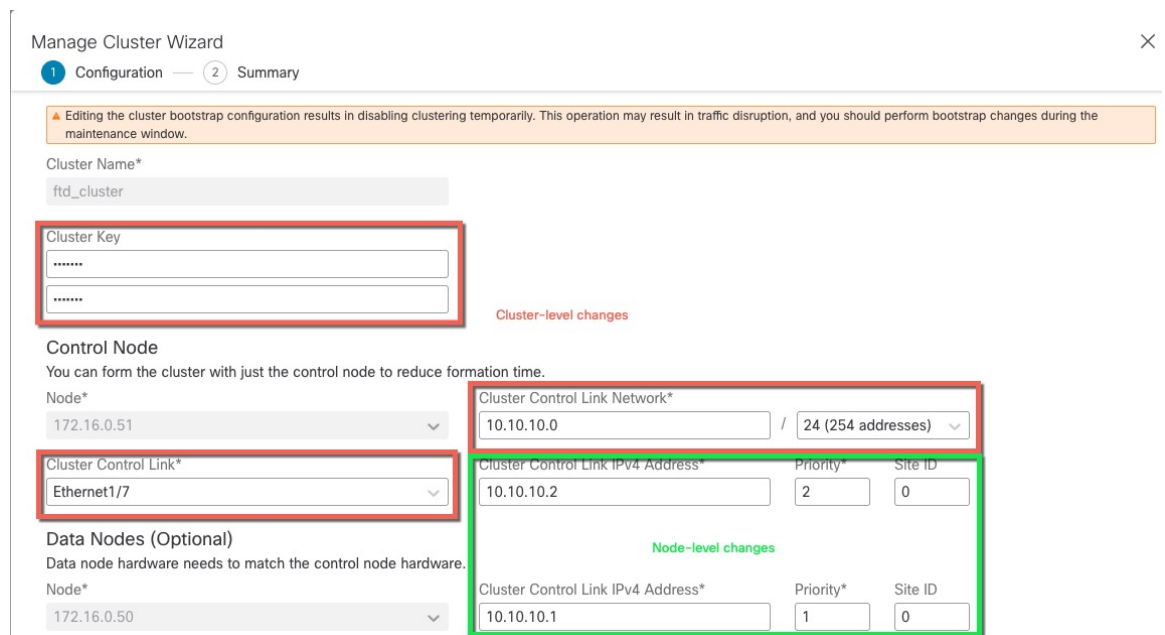

Figure 194: Edit Configuration

The **Manage Cluster Wizard** appears.

Step 2 Update the cluster configuration.

Figure 195: Manage Cluster Wizard

If the cluster control link is an EtherChannel, you can edit the interface membership and LACP configuration by clicking **Edit** (🔗) next to the interface drop-down menu.

Step 3 Click **Continue**. Review the **Summary**, and then click **Save**

Reconcile Cluster Nodes

If a cluster node fails to register, you can reconcile the cluster membership from the device to the management center. For example, a data node might fail to register if the management center is occupied with certain processes, or if there is a network issue.

Procedure

Step 1 Choose **Devices > Device Management > More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Figure 196: Cluster Live Status

Step 2 Click **Reconcile All**.

Figure 197: Reconcile All

Cluster Status ?

Overall Status: ✔ Cluster has all nodes in sync

Nodes details (2) Refresh Reconcile All

	Status	Device Name	Unit Name	Chassis URL	
>	In Sync.	172.16.0.50 Control	172.16.0.50	N/A	⋮
>	In Sync.	172.16.0.51	172.16.0.51	N/A	⋮

Dated: 11:52:26 | 20 Dec 2021 Close

For more information about the cluster status, see [Monitoring the Cluster](#), on page 450.

Unregister the Cluster or Nodes and Register to a New Management Center

You can unregister the cluster from the management center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new management center.

You can also unregister a node from the management center without breaking the node from the cluster. Although the node is not visible in the management center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the management center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the management center and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the management center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different management center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

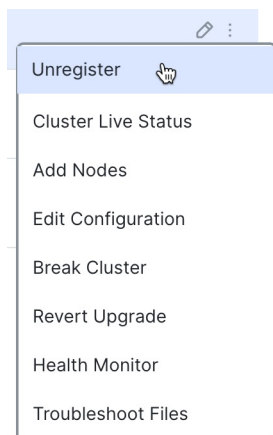

Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

Step 1 Choose **Devices > Device Management**, click **More** (☰) for the cluster or node, and choose **Unregister**.

Figure 198: Unregister Cluster or Node

- Step 2** You are prompted to unregister the cluster or node; click **Yes**.
- Step 3** You can register the cluster to a new (or the same) management center by adding one of the cluster members as a new device.
 You only need to add one of the cluster nodes as a device, and the rest of the cluster nodes will be discovered.
 - a) Connect to one cluster node's CLI, and identify the new management center using the **configure manager add** command. See [Modify Threat Defense Management Interfaces at the CLI, on page 75](#).
 - b) Choose **Devices > Device Management**, and then click **Add > Device**.
- Step 4** To re-add an unregistered node, see [Reconcile Cluster Nodes, on page 447](#).

Monitoring the Cluster

You can monitor the cluster in the management center and at the threat defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices > Device Management > More** icon or from the **Devices > Device Management > Cluster** page > **General** area > **Cluster Live Status** link.

Figure 199: Cluster Status

The screenshot shows the 'Cluster Status' dialog box. At the top, it says 'Cluster Status' with a help icon. Below that, the overall status is 'Cluster has all nodes in sync'. There are buttons for 'Refresh' and 'Reconcile All', and a search box for 'Enter node name'. A table lists two nodes, both 'In Sync'. The first node has a 'Control' role. At the bottom, there is a 'Dated: 11:52:26 | 20 Dec 2021' timestamp and a 'Close' button.

	Status	Device Name	Unit Name	Chassis URL	
>	In Sync.	172.16.0.50 Control	172.16.0.50	N/A	⋮
>	In Sync.	172.16.0.51	172.16.0.51	N/A	⋮

The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The node is registered with the management center.
- Pending Registration—The node is part of the cluster, but has not yet registered with the management center. If a node fails to register, you can retry registration by clicking **Reconcile All**.

- Clustering is disabled—The node is registered with the management center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the management center.

For each node, you can view the **Summary** or the **History**.

Figure 200: Node Summary

Status	Device Name	Unit Name	Chassis URL

- **System** (⚙️) > **Tasks** page.

The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management** > *cluster_name*.

When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl_name*] | **conn** [*count*] | **cpu** [*usage*] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

To view cluster information, use the **show cluster info** command.

Cluster Health Monitor Dashboard

Cluster Health Monitor

When a threat defense is the control node of a cluster, the management center collects various metrics periodically from the device metric data collector. The cluster health monitor is comprised of the following components:

- Overview dashboard—Displays information about the cluster topology, cluster statistics, and metric charts:
 - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the management center), or *Normal* (ideal state of the node).
 - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

- The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.
- Load Distribution dashboard—Displays load distribution across the cluster nodes in two widgets:
 - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
 - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.
- Member Performance dashboard—Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard—Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range—An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.

- Custom Dashboard—Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

Viewing Cluster Health

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

- Ensure you have created a cluster from one or more devices in the management center.

Procedure

-
- Step 1** Choose **System** (⚙) > **Health** > **Monitor**.
Use the Monitoring navigation pane to access node-specific health monitors.
- Step 2** In the device list, click **Expand** (➤) and **Collapse** (▼) to expand and collapse the list of managed cluster devices.
- Step 3** To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:
- Overview — Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
 - Load Distribution — Traffic and packet distribution across the cluster nodes.
 - Member Performance — Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
 - CCL — Interface status and aggregate traffic statistics.
- You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, see [Cisco Secure Firewall Threat Defense Health Metrics](#).
- Step 4** You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.
Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.
- Step 5** Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.
The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.
- Step 6** (For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

- Step 7** (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:
- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
 - CPU — CPU utilization, including the CPU usage by process and by physical cores.
 - Memory — Device memory utilization, including data plane and Snort memory usage.
 - Interfaces — Interface status and aggregate traffic statistics.
 - Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
 - Snort — Statistics that are related to the Snort process.
 - ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See [Cisco Secure Firewall Threat Defense Health Metrics](#) for a comprehensive list of the supported device metrics.

- Step 8** Click the plus sign (+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.
- For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster Metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 31: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number

Metric	Description	Format
Distribution	Connection distribution count in the cluster for every second.	number
Packets	Packet distribution count in the cluster for every second.	number

Troubleshooting the Cluster

You can use the **CCL Ping** tool to make sure the cluster control link is operating correctly. You can also use the following tools that are available for devices and clusters:

- Troubleshooting files—If a node fails to join the cluster, a troubleshooting file is automatically generated. You can also generate and download troubleshooting files from the **Devices > Device Management > Cluster > General** area. See [Generate Troubleshooting Files, on page 42](#).

You can also generate files from the **Device Management** page by clicking **More** (ⓘ) and choosing **Troubleshoot Files**.

- CLI output—From the **Devices > Device Management > Cluster > General** area, you can view a set of pre-defined CLI outputs that can help you troubleshoot the cluster. The following commands are automatically run for the cluster:
 - **show running-config cluster**
 - **show cluster info**
 - **show cluster info health**
 - **show cluster info transport cp**
 - **show version**
 - **show asp drop**
 - **show counters**
 - **show arp**
 - **show int ip brief**
 - **show blocks**
 - **show cpu detailed**
 - **show interface *ccl_interface***
 - **ping *ccl_ip size ccl_mtu repeat 2***

You can also enter any **show** command in the Command field. See [View CLI Output, on page 45](#) for more information.

Perform a Ping on the Cluster Control Link

You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.

Procedure

- Step 1** Choose **Devices > Device Management**, click the **More** (⋮) icon next to the cluster, and choose **> Cluster Live Status**.

Figure 202: Cluster Status

Summary History **CCL Ping**

```
ping 10.10.3.2 size 1654
Sending 5, 1654-byte ICMP Echos to 10.10.3.2, timeout is 2 seconds:
?????
Success rate is 0 percent (0/5)
```

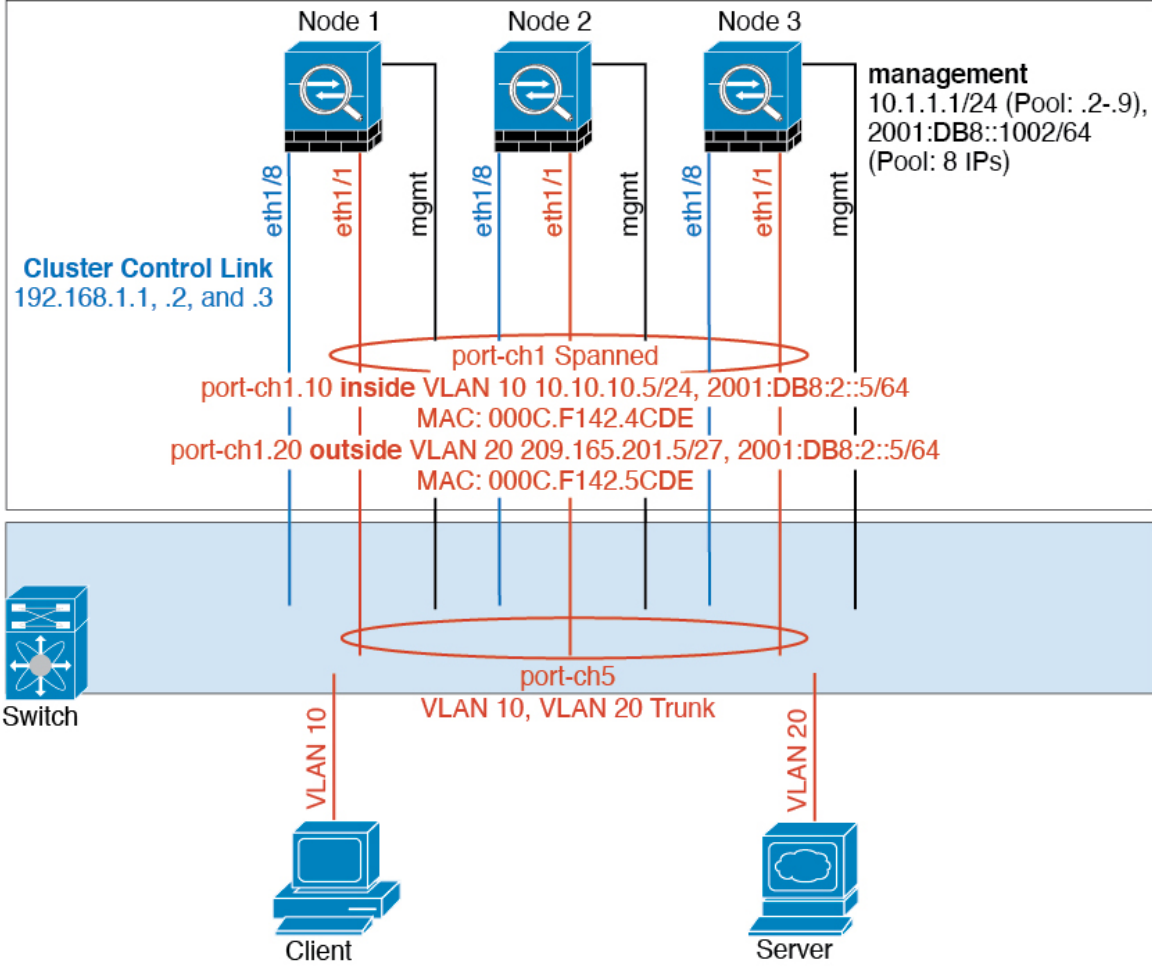

Dated: 18:38:41 | 01 Mar 2023 Close

The node sends a ping on the cluster control link to every other node using a packet size that matches the maximum MTU.

Examples for Clustering

These examples include examples for typical deployments.

Firewall on a Stick

Data traffic from different security domains are associated with different VLANs, for example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. This is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the becomes unavailable, the switch will rebalance traffic between the remaining units.

Traffic Segregation

You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

Reference for Clustering

This section includes more information about how clustering operates.

Threat Defense Features and Clustering

Some threat defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported Features with Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2553](#).

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Management Center UCAPL/CC mode

Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2553](#).

- The following application inspections:
 - DCERPC
 - ESMTTP
 - NetBIOS
 - PPTP
 - RSH
 - SQLNET
 - SUNRPC

- TFTP
- XDMCP
- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing (Spanned EtherChannel mode only)

Connection Settings and Clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

Multicast Routing in Individual Interface Mode

In Individual interface mode, units do not act independently with multicast. All data and routing packets are processed and forwarded by the control unit, thus avoiding packet replication.

Multicast Routing in Individual Interface Mode

In Individual interface mode, units do not act independently with multicast. All data and routing packets are processed and forwarded by the control unit, thus avoiding packet replication.

NAT and Clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different threat defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the threat defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- No Proxy ARP—For Individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router needs a static route or PBR with Object Tracking for the mapped addresses that points to the Main cluster IP address. This is not an issue for a Spanned EtherChannel, because there is only one IP address associated with the cluster interface.
- No interface PAT on an Individual interface—Interface PAT is not supported for Individual interfaces.
- PAT with Port Block Allocation—See the following guidelines for this feature:
 - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
 - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
 - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
 - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—

- FTP
 - RSH
 - SQLNET
 - TFTP
 - XDMCP
 - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the `asp rule-engine transactional-commit nat` command in the device CLI. Otherwise, the node might not be able to join the cluster.

Dynamic Routing

The routing process only runs on the control node, and routes are learned through the control node and replicated to data nodes. If a routing packet arrives at a data node, it is redirected to the control node.

Figure 204: Dynamic Routing in Spanned EtherChannel Mode

After the data node learn the routes from the control node, each node makes forwarding decisions independently.

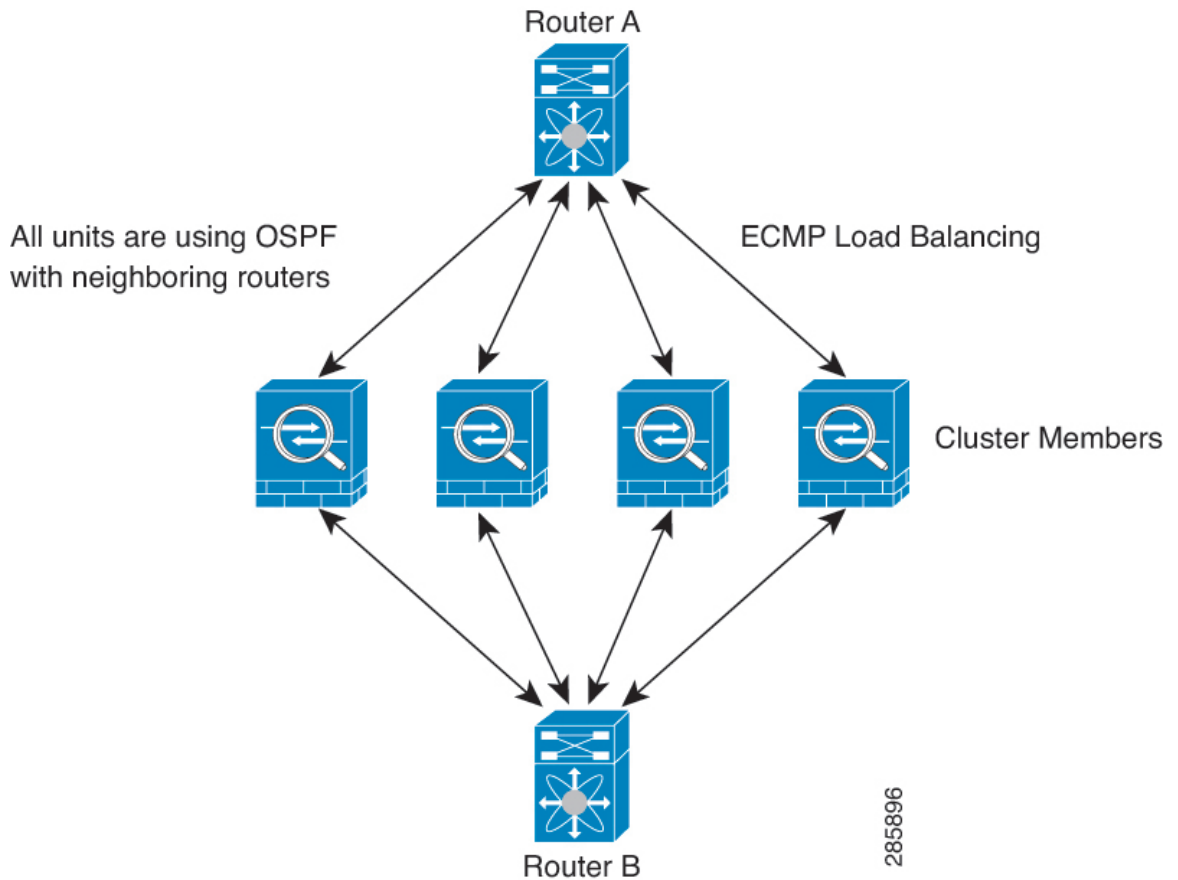

The OSPF LSA database is not synchronized from the control node to data nodes. If there is a control node switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process

picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

Dynamic Routing in Individual Interface Mode

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

Figure 205: Dynamic Routing in Individual Interface Mode

In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

EIGRP does not form neighbor relationships with cluster peers in individual interface mode.

Note If the cluster has multiple adjacencies to the same router for redundancy purposes, asymmetric routing can lead to unacceptable traffic loss. To avoid asymmetric routing, group all of these node interfaces into the same traffic zone. See [Create an ECMP Zone, on page 1135](#).

SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and Clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

Cisco TrustSec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and Clustering

Site-to-site VPN is a centralized feature; only the control node supports VPN connections.

Note Remote access VPN is not supported with clustering.

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned EtherChannel address, connections are automatically forwarded to the control node. For connections to an Individual interface when using PBR or ECMP, you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control Node Election

Nodes of the cluster communicate over the cluster control link to elect a control node as follows:

1. When you enable clustering for a node (or when it first starts up with clustering already enabled), it broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request; the priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node; the existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, then the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High Availability Within the Cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node Health Monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail

in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

See [Control Node Election, on page 466](#) for more information.

Interface Monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

- **Spanned EtherChannel**—Uses cluster Link Aggregation Control Protocol (cLACP). Each node monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel. The status is reported to the control node.
- **Individual interfaces (Routed mode only)**—Each node self-monitors its interfaces and reports interface status to the control node.

When you enable health monitoring, all physical interfaces (including the main EtherChannel) are monitored by default; you can optionally disable monitoring per interface. Only named interfaces can be monitored. For example, the named EtherChannel must fail to be considered failed, which means all member ports of an EtherChannel must fail to trigger cluster removal.

A node is removed from the cluster if its monitored interfaces fail. The amount of time before the threat defense removes a member from the cluster depends on the type of interface and whether the node is an established member or is joining the cluster. For EtherChannels (spanned or not): If the interface is down on an established member, then the threat defense removes the member after 9 seconds. The threat defense does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the threat defense to be removed from the cluster. For non-EtherChannels, the node is removed after 500 ms, regardless of the member state.

Status After Failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The threat defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the threat defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- **Failed cluster control link when initially joining**—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- **Failed cluster control link after joining the cluster**—The threat defense automatically tries to rejoin every 5 minutes, indefinitely.

- Failed data interface—The threat defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the threat defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The threat defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from management center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 32: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—
SNMP Engine ID	No	—

How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection Roles

See the following roles defined for each connection:

- **Owner**—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- **Backup owner**—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- **Director**—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

ICMP/ICMPv6 hash details:

- For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
 - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
 - For other packets, both source and destination ports are 0.
- **Forwarder**—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

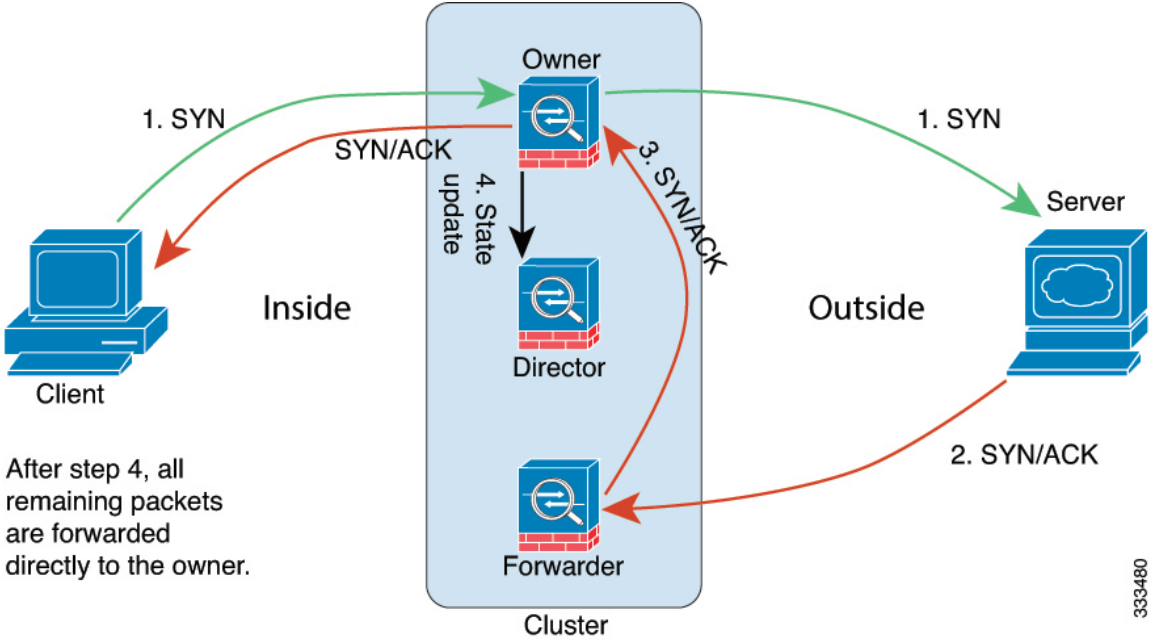

- **Fragment Owner**—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

New Connection Ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Sample Data Flow for TCP

The following example shows the establishment of a new connection.

1. The SYN packet originates from the client and is delivered to one threat defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different threat defense (based on the load balancing method). This threat defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.

4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 206: ICMP and UDP Data Flow*

The first UDP packet originates from the client and is delivered to one threat defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.

6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for Clustering

CHAPTER 11

Clustering for Threat Defense Virtual in a Private Cloud

Clustering lets you group multiple threat defense virtuals together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. You can deploy threat defense virtual clusters in a private cloud using VMware and KVM. Only routed firewall mode is supported.

Note Some features are not supported when using clustering. See [Unsupported Features and Clustering](#), on page 514.

About Threat Defense Virtual Clustering in the Private Cloud

This section describes the clustering architecture and how it works.

How the Cluster Fits into Your Network

The cluster consists of multiple firewalls acting as a single device. To act as a cluster, the firewalls need the following infrastructure:

- Isolated network for intra-cluster communication, known as the *cluster control link*, using VXLAN interfaces. VXLANs, which act as Layer 2 virtual networks over Layer 3 physical networks, let the threat defense virtual send broadcast/multicast messages over the cluster control link.

- Management access to each firewall for configuration and monitoring. The threat defense virtual deployment includes a Management 0/0 interface that you will use to manage the cluster nodes.

When you place the cluster in your network, the upstream and downstream routers need to be able to load-balance the data coming to and from the cluster using Layer 3 Individual interfaces and one of the following methods:

- Policy-Based Routing—The upstream and downstream routers perform load balancing between nodes using route maps and ACLs.
- Equal-Cost Multi-Path Routing—The upstream and downstream routers perform load balancing between nodes using equal cost static or dynamic routes.

Note Layer 2 Spanned EtherChannels are not supported.

Control and Data Node Roles

One member of the cluster is the control node. If multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority. All other members are data nodes. When you first create the cluster, you specify which node you want to be the control node, and it will become the control node simply because it is the first node added to the cluster.

All nodes in the cluster share the same configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Individual Interfaces

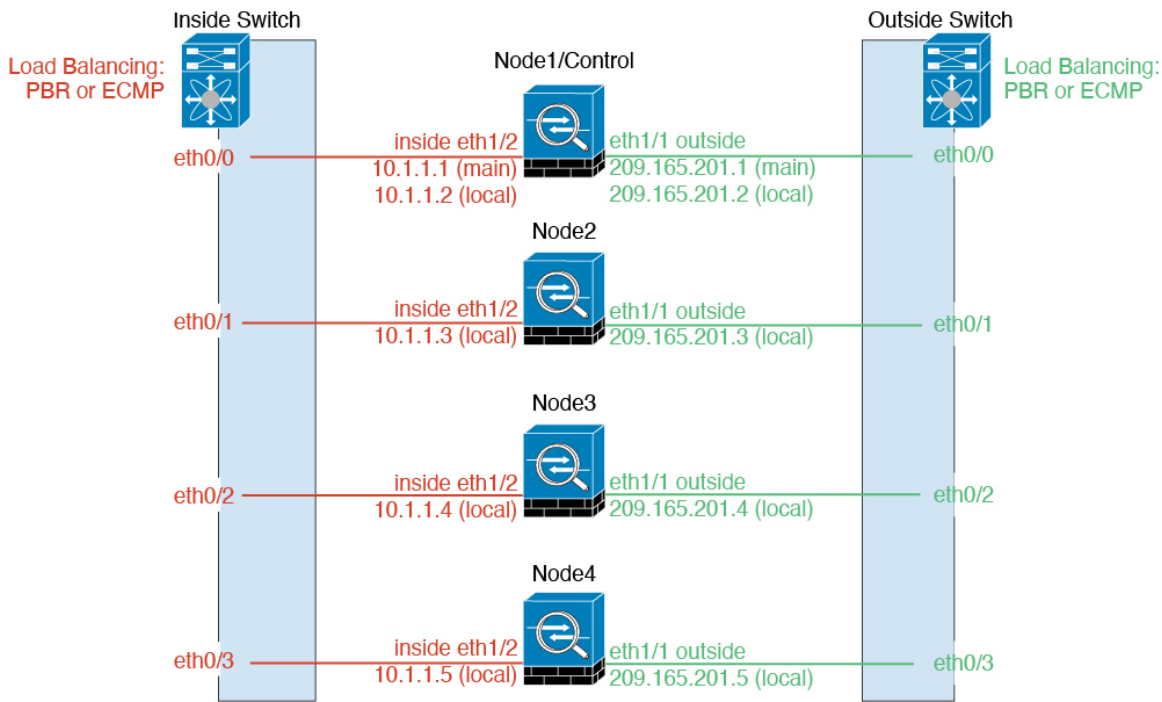

You can configure cluster interfaces as *Individual interfaces*.

Individual interfaces are normal routed interfaces, each with their own *Local IP address* used for routing. The *Main cluster IP address* for each interface is a fixed address that always belongs to the control node. When the control node changes, the Main cluster IP address moves to the new control node, so management of the cluster continues seamlessly.

IPS-only interfaces (inline sets and passive interfaces) are not supported as Individual interfaces.

Because interface configuration must be configured only on the control node, you configure a pool of IP addresses to be used for a given interface on the cluster nodes, including one for the control node.

Load balancing must be configured separately on the upstream switch.

Note Layer 2 Spanned EtherChannels are not supported.

Policy-Based Routing

When using Individual interfaces, each threat defense interface maintains its own IP address and MAC address. One method of load balancing is Policy-Based Routing (PBR).

We recommend this method if you are already using PBR, and want to take advantage of your existing infrastructure.

PBR makes routing decisions based on a route map and ACL. You must manually divide traffic between all threat defenses in a cluster. Because PBR is static, it may not achieve the optimum load balancing result at all times. To achieve the best performance, we recommend that you configure the PBR policy so that forward and return packets of a connection are directed to the same threat defense. For example, if you have a Cisco router, redundancy can be achieved by using Cisco IOS PBR with Object Tracking. Cisco IOS Object Tracking monitors each threat defense using ICMP ping. PBR can then enable or disable route maps based on reachability of a particular threat defense. See the following URLs for more details:

<http://www.cisco.com/c/en/us/solutions/data-center-virtualization/intelligent-traffic-director/index.html>

http://www.cisco.com/en/US/products/ps6599/products_white_paper09186a00800a4409.shtml

Equal-Cost Multi-Path Routing

When using Individual interfaces, each threat defense interface maintains its own IP address and MAC address. One method of load balancing is Equal-Cost Multi-Path (ECMP) routing.

We recommend this method if you are already using ECMP, and want to take advantage of your existing infrastructure.

ECMP routing can forward packets over multiple “best paths” that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses and/or source and destination ports can be used to send a packet to one of the next hops. If you use static routes for ECMP routing, then the threat defense failure can cause problems; the route continues to be used, and traffic to the failed threat defense will be lost. If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each threat defense to participate in dynamic routing.

Cluster Control Link

Each node must dedicate one interface as a VXLAN (VTEP) interface for the cluster control link. For more information about VXLAN, see [Configure VXLAN Interfaces, on page 770](#).

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP Source Interface

The VTEP source interface is a regular threat defense virtual interface with which you plan to associate the VNI interface. You can configure one VTEP source interface to act as the cluster control link. The source interface is reserved for cluster control link use only. Each VTEP source interface has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

VNI Interface

A VNI interface is similar to a VLAN interface: it is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. You can only configure one VNI interface. Each VNI interface has an IP address on the same subnet.

Peer VTEPs

Unlike regular VXLAN for data interfaces, which allows a single VTEP peer, The threat defense virtual clustering allows you to configure multiple peers.

Cluster Control Link Traffic Overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.

- Connection ownership queries and data packet forwarding.

Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management Network

You must manage each node using the Management interface; management from a data interface is not supported with clustering.

Licenses for Threat Defense Virtual Clustering

Each threat defense virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the management center, you can specify the feature licenses you want to use for the cluster. Before you create the cluster, it doesn't matter which licenses are assigned to the data nodes; the license settings for the control node are replicated to each of the data nodes. You can modify licenses for the cluster in the **System** (⚙️) > **Licenses** > **Smart Licenses** > **Edit Licenses** or **Devices** > **Device Management** > **Cluster** > **License** area.

Note If you add the cluster before the management center is licensed (and running in Evaluation mode), then when you license the management center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and Prerequisites for Threat Defense Virtual Clustering

Model Requirements

- FTDv5, FTDv10, FTDv20, FTDv30, FTDv50, FTDv100
- VMware or KVM

- In threat defense virtual 7.4.1+, a maximum of 16 nodes in a cluster in a 4x4 configuration is supported. You can set up a maximum of four hosts with a maximum of four threat defense virtual instances in each host.
- In threat defense virtual 7.3 and earlier, a maximum of 4 nodes in a cluster in a 2x2 configuration is supported. You can set up a maximum of two hosts with a maximum of two threat defense virtual instances in each host.

User Roles

- Admin
- Access Admin
- Network Admin

Hardware and Software Requirements

All units in a cluster:

- Must have jumbo frame reservation enabled for the cluster control link. Do this in the Day 0 configuration when you deploy the threat defense virtual by setting "DeploymentType": "Cluster". Otherwise, you must restart each node to enable jumbo frames after the cluster has formed and is healthy.
- (KVM only) Must use CPU hard partitioning (CPU pinning) for all VMs on the KVM host.
- Must be the same performance tier. We recommend using the same number of CPUs and memory for all nodes, or performance will be limited on all nodes to match the least capable node.
- Must use the management interface for management center communications. Data interface management is not supported.
- Must run the same version, except during upgrade. Hitless upgrade is supported.
- Must be in the same domain.
- Must be in the same group.
- Must not have any deployment pending or in progress.
- Must not have any unsupported features configured on the control node: [Unsupported Features and Clustering, on page 514](#).
- Must not have VPN configured on the data nodes. The control node can have site-to-site VPN configured.

Management Center Requirements

Make sure the management center NTP server is set to a reliable server that is reachable by all cluster nodes to ensure proper clock sync. By default, the device uses the same NTP server as the management center. If the time is not set to be the same on all cluster nodes, they can be removed automatically from the cluster.

Switch Requirements

Be sure to complete the switch configuration before you configure clustering. Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. By default, the cluster control link MTU

is set to 154 bytes higher than the data interfaces. If the switches have an MTU mismatch, the cluster formation will fail.

Guidelines for Threat Defense Virtual Clustering

High Availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the threat defense virtual, adding an additional switch to form a VSS or vPC, configuring IP addresses or interface flap on the cluster) you should disable the health check feature and also disable interface monitoring for the interfaces that are affected by the topology changes. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.
- We do not support VXLANs for data interfaces; only the cluster control link supports VXLAN.

Defaults for Clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Configure Threat Defense Virtual Clustering

To configure clustering after you deploy your threat defense virtuals, perform the following tasks.

Add Devices to the Management Center

Before configuring clustering, deploy each cluster node, then add the devices as standalone units on the management center.

Procedure

Step 1 Deploy each cluster node according the [Cisco Secure Firewall Threat Defense Virtual Getting Started Guide](#).

All units in a cluster:

- Must have jumbo frame reservation enabled for the cluster control link. Do this in the Day 0 configuration when you deploy the threat defense virtual by setting `"DeploymentType": "Cluster"`. Otherwise, you must restart each node to enable jumbo frames after the cluster has formed and is healthy.
- (KVM only) Must use CPU hard partitioning (CPU pinning) for all VMs on the KVM host.

Step 2 Add each node to the management center as a standalone device in the same domain and group.

See [Add a Device to the Management Center Using a Registration Key, on page 27](#). You can create a cluster with a single device, and then add more nodes later. The initial settings (licensing, access control policy) that you set when you add a device will be inherited by all cluster nodes from the control node. You will choose the control node when forming the cluster.

Create a Cluster

Form a cluster from one or more devices in the management center.

Before you begin

Some features are not compatible with clustering, so you should wait to perform configuration until after you enable clustering. Some features will block cluster creation if they are already configured. For example, do not configure any IP addresses on interfaces, or unsupported interface types such as BVIs.

Procedure

Step 1 Choose **Devices > Device Management**, and then choose **Add > Cluster**.

The **Add Cluster Wizard** appears.

Figure 207: Add Cluster Wizard

Add Cluster Wizard

1 Configuration — 2 Summary

▲ Create a cluster for supported models. Note: For the Firepower 4100/9300/AWS/Azure/GCP, use the Add Device option.

Cluster Name*

cluster1

Cluster Key

....

....

Control Node

You can form the cluster with just the control node to reduce formation time.

Node*

node1

VXLAN Network Identifier (VNI) Network*

10.10.1.0 / 27 (30 addresses)

Virtual Tunnel Endpoint (VTEP) Network*

209.165.200.224 / 27 (30 addresses)

Cluster Control Link*

GigabitEthernet0/7

VTEP IPv4 Address*

209.165.200.225

Priority*

1

Data Nodes (Optional)

Data node hardware needs to match the control node hardware.

[Add a data node](#)

Step 2 Specify a **Cluster Name** and an authentication **Cluster Key** for control traffic.

- **Cluster Name**—An ASCII string from 1 to 38 characters.
- **Cluster Key**—An ASCII string from 1 to 63 characters. The **Cluster Key** value is used to generate the encryption key. This encryption does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.

Step 3 For the **Control Node**, set the following:

- **Node**—Choose the device that you want to be the control node initially. When the management center forms the cluster, it will add this node to the cluster first so it will be the control node.

Note If you see an **Error** (❗) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation. For example:

Figure 208: Configuration Issues

To resolve the above issues, remove the unsupported VPN license and deploy pending configuration changes to the device.

- **VXLAN Network Identifier (VNI) Network**—Specify an IPv4 subnet for the VNI network; IPv6 is not supported for this network. Specify a **24**, **25**, **26**, or **27** subnet. An IP address will be auto-assigned to each node on this network. The VNI network is the encrypted virtual network that runs on top of the physical VTEP network.
- **Cluster Control Link**—Choose the physical interface you want to use for the cluster control link.
- **Virtual Tunnel Endpoint (VTEP) Network**—Specify an IPv4 subnet for the physical interface network; IPv6 is not supported for this network. The VTEP network is a different network than the VNI network, and it is used for the physical cluster control link.
- **VTEP IPv4 Address**—This field will be auto-populated with the first address on the VTEP network.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority. Even if you set the priority to be lower than other nodes, this node will still be the control node when the cluster is first formed.

Step 4 For **Data Nodes (Optional)**, click **Add a data node** to add a node to the cluster.

You can form the cluster with only the control node for faster cluster formation, or you can add all nodes now. Set the following for each data node:

- **Node**—Choose the device that you want to add.

Note If you see an **Error** (❗) icon next to the node name, click the icon to view configuration issues. You must cancel cluster formation, resolve the issues, and then return to cluster formation.

- **VTEP IPv4 Address**—This field will be auto-populated with the next address on the VTEP network.
- **Priority**—Set the priority of this node for control node elections. The priority is between 1 and 100, where 1 is the highest priority.

Step 5 Click **Continue**. Review the **Summary**, and then click **Save**.

The cluster bootstrap configuration is saved to the cluster nodes. The bootstrap configuration includes the VXLAN interface used for the cluster control link.

The cluster name shows on the **Devices > Device Management** page; expand the cluster to see the cluster nodes.

Figure 209: Cluster Management

Node ID	Role	Version	Management	Base, Threat (2 more...)	Default AC Policy
172.16.0.50 (Control) 172.16.0.50 - Routed	FTDv for VMware	7.2.0	Manage	Base, Threat (2 more...)	Default AC Policy
172.16.0.51 172.16.0.51 - Routed	FTDv for VMware	7.2.0	N/A	Base, Threat (2 more...)	Default AC Policy

A node that is currently registering shows the loading icon.

Figure 210: Node Registration

Node ID	Role	Management
172.16.0.50 (Control) 172.16.0.50 - Routed	FTDv for VMware	Manage
172.16.0.51 172.16.0.51 - Routed	FTDv for VMware	N/A

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**. The management center updates the Cluster Registration task as each node registers.

Task ID	Task Description	Duration
10.10.1.12	Deployment to device successful.	1m 54s
10.10.1.13	Deployment to device successful.	1m 3s
TD_Cluster	Deployment to device successful.	35s

Step 6 Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.

Step 7 On the **Devices > Device Management > Cluster** screen, you see **General** and other settings for the cluster.

Cluster Live Status: View

Troubleshoot:

Step 8 On the **Devices > Device Management > Devices**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.

Figure 213: Device Settings

The screenshot displays the 'Device Settings' page for a cluster named 'ftdcluster'. The page is organized into several sections:

- General:** Name: 172.16.0.50, Mode: Transparent, Compliance Mode: None, TLS Crypto Acceleration: Enabled. Includes 'Import', 'Export', and 'Download' buttons for Device Configuration.
- System:** Model: Cisco Secure Firewall 3120 Threat Defense, Serial: FJZ2512139M, Time: 2021-12-22 19:39:13, Time Zone: UTC (UTC+0:00), Version: 7.1.0, Time Zone setting for Time based Rules: UTC (UTC+0:00), Inventory: View.
- Health:** Status: (Green dot), Policy: Initial_Health_Policy 2021-10-30 01:21:29, Excluded: None.
- Management:** Host: 172.16.0.50, Status: (Green dot).
- Inventory Details:** CPU Type: CPU Ryzen Zen 2 2800 MHz, CPU Cores: 1 CPU (32 cores), Memory: 34335 MB RAM, Storage: N/A, Chassis URL: N/A, Chassis Serial Number: N/A, Chassis Module Number: N/A, Chassis Module Serial Number: N/A.

Figure 214: Choose Node

The screenshot shows a dropdown menu with the following options:

- 172.16.0.50
- 172.16.0.50 (highlighted)
- 172.16.0.51

- **General > Name**—Change the cluster member display name by clicking the **Edit** (✎).

The screenshot shows the 'General' configuration tab with the following details:

- Name:** 10.89.5.21 (highlighted with a red circle and pencil icon)
- Transfer Packets:** Yes
- Mode:** routed
- Compliance Mode:** None
- TLS Crypto Acceleration:** Enabled

Then set the **Name** field.

General ?

Name:

Transfer Packets:

Mode: routed

Compliance Mode: None

Performance Profile: Default

TLS Crypto Acceleration: Disabled

Force Deploy: →

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the management center so that it can reach the device on the network. First disable the connection, edit the **Host** address in the **Management** area, then re-enable the connection.

Management	
Host:	10.89.5.20
Status:	✓

- Step 9** If you deployed your cluster nodes without enabling jumbo-frame reservation, then restart all cluster nodes to enable jumbo frames, which are required for the cluster control link. See [Shut Down or Restart the Device, on page 39](#).

If you previously enabled jumbo-frame reservation, you can skip this step.

Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead (100 bytes) and VXLAN overhead (54 bytes). When you create the cluster, the MTU is set to 154 bytes higher than the highest data interface MTU (1654 by default). If you later increase the data interface MTU, be sure to also increase the cluster control link MTU. For example, because the maximum MTU is 9198 bytes, then the highest data interface MTU can be 9044, while the cluster control link can be set to 9198. See [Configure the MTU, on page 803](#).

Note Make sure you configure switches connected to the cluster control link to the correct (higher) MTU; otherwise, cluster formation will fail.

Configure Interfaces

This section describes how to configure interfaces to be Individual interfaces compatible with clustering. Individual interfaces are normal routed interfaces, each with their own IP address taken from a pool of IP

addresses. The Main cluster IP address is a fixed address for the cluster that always belongs to the current control node. All data interfaces must be Individual interfaces.

Note You cannot use subinterfaces.

Procedure

- Step 1** Choose **Objects > Object Management > Address Pools** to add an IPv4 and/or IPv6 address pool. See [Address Pools, on page 1272](#).
- Include at least as many addresses as there are units in the cluster. The Virtual IP address is not a part of this pool, but needs to be on the same network. You cannot determine the exact Local address assigned to each unit in advance.
- Step 2** Choose **Devices > Device Management**, and click **Edit** (✎) next to the cluster.
- Step 3** Click **Interfaces**, and then click **Edit** (✎) for a data interface.
- Step 4** On the **IPv4**, enter the **IP Address** and mask. This IP address is a fixed address for the cluster, and always belongs to the current control unit.
- Step 5** From the **IPv4 Address Pool** drop-down list, choose the address pool you created.
- Note** If you want to manually assign a MAC address to this interface, you need to create a **mac-address pool** using FlexConfig.
- Step 6** On **IPv6 > Basic**, from the **IPv6 Address Pool** drop-down list, choose the address pool you created.
- Step 7** Configure other interface settings as normal.
- Step 8** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

Configure Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

Figure 215: Cluster Health Monitor Settings

Cluster Health Monitor Settings			
Timeouts			
Hold Time			3 s
Interface Debounce Time			9000 ms
Monitored Interfaces			
Service Application			Enabled
Unmonitored Interfaces			None
Auto-Rejoin Settings			
	Attempts	Interval Between Attempts	Interval Variation
Cluster Interface	-1	5	1
Data Interface	3	5	2
System	3	5	2

Table 33: Cluster Health Monitor Settings Section Table Fields

Field	Description
Timeouts	
Hold Time	Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.
Interface Debounce Time	Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.
Monitored Interfaces	The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster.
Service Application	Shows whether the Snort and disk-full processes are monitored.
Unmonitored Interfaces	Shows unmonitored interfaces.
Auto-Rejoin Settings	
Cluster Interface	Shows the auto-rejoin settings after a cluster control link failure.

Field	Description
<i>Attempts</i>	Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.
<i>Interval Between Attempts</i>	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
<i>Interval Variation</i>	Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.
Data Interfaces	Shows the auto-rejoin settings after a data interface failure.
<i>Attempts</i>	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
<i>Interval Between Attempts</i>	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
<i>Interval Variation</i>	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.
System	Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.
<i>Attempts</i>	Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.
<i>Interval Between Attempts</i>	Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.
<i>Interval Variation</i>	Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.

Note If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the cluster you want to modify, click **Edit** (✎).
- Step 3** Click **Cluster**.
- Step 4** In the **Cluster Health Monitor Settings** section, click **Edit** (✎).
- Step 5** Disable the system health check by clicking the **Health Check** slider.

Figure 216: Disable the System Health Check

Edit Cluster Health Monitor Settings

Health Check ⓘ

▼ Timeouts

Hold Time Range: 0.3 to 45 seconds

Interface Debounce Time Range: 300 to 9000 milliseconds

> Auto-Rejoin Settings

> Monitored Interfaces

Reset to Defaults Cancel Save

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 6

Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

Step 7

Customize the auto-rejoin cluster settings after a health check failure.

Figure 217: Configure Auto-Rejoin Settings

▼ Auto-Rejoin Settings

Cluster Interface

Attempts Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts Range: 2-60 minutes between rejoin attempts

Interval Variation Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

Data Interface

Attempts Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts Range: 2-60 minutes between rejoin attempts

Interval Variation Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

System

Attempts Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts Range: 2-60 minutes between rejoin attempts

Interval Variation Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

Step 8

Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

Figure 218: Configure Monitored Interfaces

▼ Monitored Interfaces

Monitored Interfaces

- GigabitEthernet0/0
- GigabitEthernet0/1
- GigabitEthernet0/2
- GigabitEthernet0/3
- GigabitEthernet0/4
- GigabitEthernet0/5
- GigabitEthernet0/6
- GigabitEthernet0/7
- Diagnostic0/0

Unmonitored Interfaces 1

Add

Enable Service Application Monitoring

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

Step 9 Click **Save**.

Step 10 Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

Manage Cluster Nodes

Add a New Cluster Node

You can add one or more new cluster nodes to an existing cluster.

Procedure

Step 1 Choose **Devices > Device Management**, click the **More** (⋮) for the cluster, and choose **Add Nodes**.

Figure 219: Add Nodes

The **Manage Cluster Wizard** appears.

Step 2 From the **Node** menu, choose a device, and adjust the IP address and priority if desired.

Figure 220: Manage Cluster Wizard

 A screenshot of the 'Manage Cluster Wizard' configuration page. The page has two steps: '1 Configuration' and '2 Summary'. The configuration fields are:

- Cluster Name*: cluster1
- Cluster Key: [Redacted]
- Control Node: You can form the cluster with just the control node to reduce formation time. Node*: node1
- VXLAN Network Identifier (VNI) Network*: 10.10.1.0 / 27 (30 addresses)
- Virtual Tunnel Endpoint (VTEP) Network*: 209.165.200.224 / 27 (30 addresses)
- Cluster Control Link*: GigabitEthernet0/7
- VTEP IPv4 Address*: 209.165.200.225
- Priority*: 1
- Data Nodes (Optional): Data node hardware needs to match the control node hardware. Node*: [Redacted] VTEP IPv4 Address*: 209.165.200.226 Priority*: 2 [Remove]

 The 'Node*' field in the 'Data Nodes' section is highlighted with a red box.

Step 3 To add additional nodes, click **Add a data node**.

Step 4 Click **Continue**. Review the **Summary**, and then click **Save**. The node that is currently registering shows the loading icon.

Figure 221: Node Registration

You can monitor cluster node registration by clicking the **Notifications** icon and choosing **Tasks**.

Break a Node

You can remove a node from the cluster so that it becomes a standalone device. You cannot break the control node unless you break the entire cluster. The data node has its configuration erased.

Procedure

Step 1 Choose **Devices > Device Management**, click the **More** (⋮) for the node you want to break, and choose **Break Node**.

Figure 222: Break a Node

You can optionally break one or more nodes from the cluster More menu by choosing **Break Nodes**.

Step 2 You are prompted to confirm the break; click **Yes**.

Figure 223: Confirm Break

You can monitor the cluster node break by clicking the **Notifications** icon and choosing **Tasks**.

Break the Cluster

You can break the cluster and convert all nodes to standalone devices. The control node retains the interface and security policy configuration, while data nodes have their configuration erased.

Procedure

- Step 1** Make sure all cluster nodes are being managed by the management center by reconciling nodes. See [Reconcile Cluster Nodes, on page 503](#).
- Step 2** Choose **Devices > Device Management**, click the **More** (⋮) for the cluster, and choose **Break Cluster**.

Figure 224: Break Cluster

- Step 3** You are prompted to break the cluster; click **Yes**.

Figure 225: Confirm Break

You can monitor the cluster break by clicking the **Notifications** icon and choosing **Tasks**.

Disable Clustering

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the management center device list. When a node becomes inactive, all data interfaces are shut down.

Procedure

- Step 1** For the unit you want to disable, choose **Devices > Device Management**, click the **More** (⋮), and choose **Disable Node Clustering**.

Figure 226: Disable Clustering

If you disable clustering on the control node, one of the data nodes will become the new control node. Note that for centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node. You cannot disable clustering on the control node if it is the only node in the cluster.

- Step 2** Confirm that you want to disable clustering on the node.
The node will show **(Disabled)** next to its name in the **Devices > Device Management** list.
- Step 3** To reenable clustering, see [Rejoin the Cluster, on page 501](#).

Rejoin the Cluster

If a node was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. See [Rejoining the Cluster, on page 521](#) for more information about why a node can be removed from a cluster.

Procedure

- Step 1** For the unit you want to reactivate, choose **Devices > Device Management**, click the **More** (⋮), and choose **Enable Node Clustering**.
- Step 2** Confirm that you want to enable clustering on the node.
-

Change the Control Node

Caution The best method to change the control node is to disable clustering on the control node, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control node, use the procedure in this section. Note that for centralized features, if you force a control node change using either method, then all connections are dropped, and you have to re-establish the connections on the new control node.

To change the control node, perform the following steps.

Procedure

- Step 1** Open the **Cluster Status** dialog box by choosing **Devices > Device Management > More** (⋮) **> Cluster Live Status**.

Figure 227: Cluster Status

Cluster Status ?

Overall Status:  Cluster has all nodes in sync

Nodes details (2) [Refresh](#) [Reconcile All](#)

	Status	Device Name	Unit Name	Chassis URL	
>	In Sync.	172.16.0.50 Control	172.16.0.50	N/A	⋮
>	In Sync.	172.16.0.51	172.16.0.51	N/A	⋮

Dated: 11:52:26 | 20 Dec 2021 [Close](#)

- Step 2** For the unit you want to become the control unit, choose **More** (⋮) > **Change Role to Control**.
- Step 3** You are prompted to confirm the role change. Check the checkbox, and click **OK**.

Edit the Cluster Configuration

You can edit the cluster configuration. If you change any values other than the VTEP IP address for a node or node priority, the cluster will be broken and reformed automatically. Until the cluster is reformed, you may experience traffic disruption. If you change the VTEP IP address for a node or node priority, only the affected nodes are broken and readded to the cluster.

Procedure

- Step 1** Choose **Devices** > **Device Management**, click the **More** (⋮) for the cluster, and choose **Edit Configuration**.

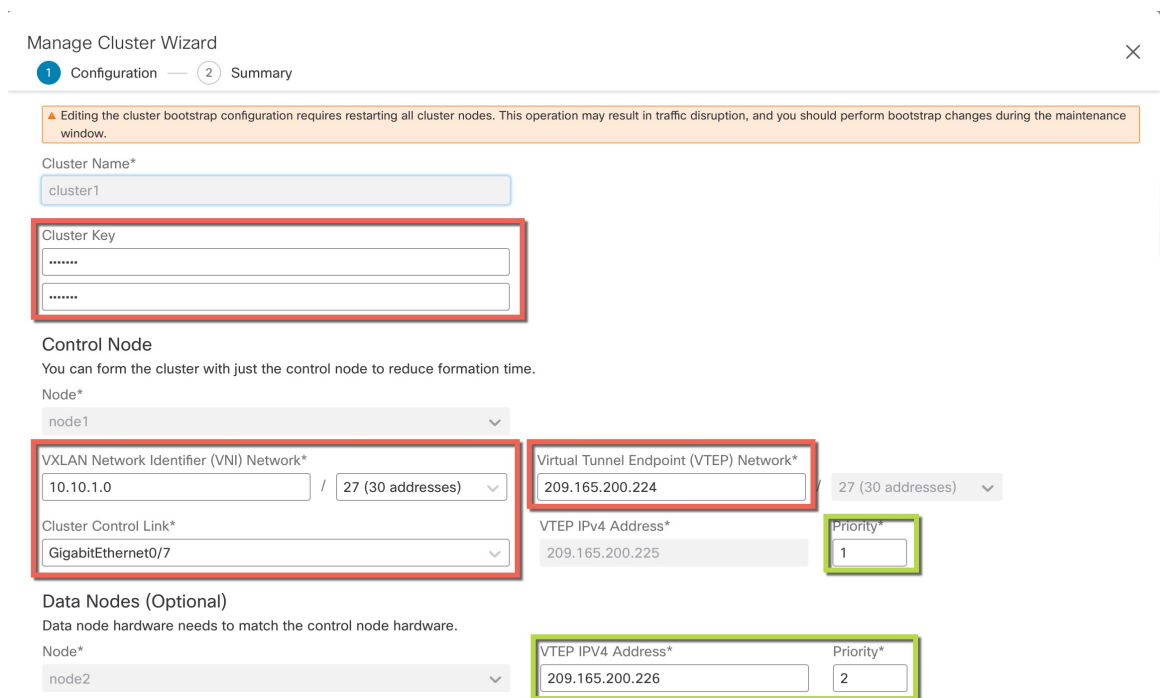

Figure 228: Edit Configuration

The **Manage Cluster Wizard** appears.

Step 2 Update the cluster configuration.

Figure 229: Manage Cluster Wizard

Step 3 Click **Continue**. Review the **Summary**, and then click **Save**

Reconcile Cluster Nodes

If a cluster node fails to register, you can reconcile the cluster membership from the device to the management center. For example, a data node might fail to register if the management center is occupied with certain processes, or if there is a network issue.

Procedure

Step 1 Choose **Devices > Device Management > More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

Figure 230: Cluster Live Status

Step 2 Click **Reconcile All**.

Figure 231: Reconcile All

Cluster Status ?

Overall Status: ✔ Cluster has all nodes in sync

Nodes details (2) Refresh Reconcile All

	Status	Device Name	Unit Name	Chassis URL	
>	In Sync.	172.16.0.50 Control	172.16.0.50	N/A	⋮
>	In Sync.	172.16.0.51	172.16.0.51	N/A	⋮

Dated: 11:52:26 | 20 Dec 2021 Close

For more information about the cluster status, see [Monitoring the Cluster](#), on page 506.

Delete (Unregister) the Cluster or Nodes and Register to a New Management Center

You can unregister the cluster from the management center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new management center.

You can also unregister a node from the management center without breaking the node from the cluster. Although the node is not visible in the management center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the management center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the management center and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the management center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different management center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

Before you begin

This procedure requires CLI access to one of the nodes.

Procedure

-
- Step 1** Choose **Devices > Device Management**, click **More** (⋮) for the cluster or node, and choose **Unregister**.

Figure 232: Unregister Cluster or Node

Step 2 You are prompted to unregister the cluster or node; click **Yes**.

Step 3 You can register the cluster to a new (or the same) management center by adding one of the cluster members as a new device.

- a) Connect to one cluster node's CLI, and identify the new management center using the **configure manager add** command. See [Modify Threat Defense Management Interfaces at the CLI](#).
- b) Choose **Devices > Device Management**, and then click **Add Device**.

You only need to add one of the cluster nodes as a device, and the rest of the cluster nodes will be discovered.

Step 4 To re-add a deleted node, see [Reconcile Cluster Nodes, on page 503](#).

Monitoring the Cluster

You can monitor the cluster in the management center and at the threat defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices > Device Management > More** (⋮) icon or from the **Devices > Device Management > Cluster** page > **General** area > **Cluster Live Status** link.

Figure 233: Cluster Status

Cluster Status ?

Overall Status:  Cluster has all nodes in sync

Nodes details (2)

	Status	Device Name	Unit Name	Chassis URL	
>	In Sync.	172.16.0.50 Control	172.16.0.50	N/A	⋮
>	In Sync.	172.16.0.51	172.16.0.51	N/A	⋮

Dated: 11:52:26 | 20 Dec 2021

The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The node is registered with the management center.
- Pending Registration—The node is part of the cluster, but has not yet registered with the management center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the management center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the management center.

For each node, you can view the **Summary** or the **History**.

Cluster Health Monitor Dashboard

Cluster Health Monitor

When a threat defense is the control node of a cluster, the management center collects various metrics periodically from the device metric data collector. The cluster health monitor is comprised of the following components:

- Overview dashboard—Displays information about the cluster topology, cluster statistics, and metric charts:
 - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the management center), or *Normal* (ideal state of the node).
 - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

Note The CPU and memory metrics display the individual average of the data plane and snort usage.

- The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.
- Load Distribution dashboard—Displays load distribution across the cluster nodes in two widgets:
 - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
 - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.
- Member Performance dashboard—Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard—Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range—An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard—Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

Viewing Cluster Health

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

Before you begin

- Ensure you have created a cluster from one or more devices in the management center.

Procedure

Step 1 Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

Step 2 In the device list, click **Expand** (➤) and **Collapse** (▼) to expand and collapse the list of managed cluster devices.

Step 3 To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution — Traffic and packet distribution across the cluster nodes.
- Member Performance — Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL — Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, see [Cisco Secure Firewall Threat Defense Health Metrics](#).

Step 4 You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

Step 5 Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

Step 6 (For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

- Step 7** (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:
- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
 - CPU — CPU utilization, including the CPU usage by process and by physical cores.
 - Memory — Device memory utilization, including data plane and Snort memory usage.
 - Interfaces — Interface status and aggregate traffic statistics.
 - Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
 - Snort — Statistics that are related to the Snort process.
 - ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See [Cisco Secure Firewall Threat Defense Health Metrics](#) for a comprehensive list of the supported device metrics.

- Step 8** Click the plus sign (+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

Cluster Metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

Table 34: Cluster Metrics

Metric	Description	Format
CPU	Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Memory	Average of memory metrics on the nodes of a cluster (individually for data plane and snort).	percentage
Data Throughput	Incoming and outgoing data traffic statistics for a cluster.	bytes
CCL Throughput	Incoming and outgoing CCL traffic statistics for a cluster.	bytes
Connections	Count of active connections in a cluster.	number
NAT Translations	Count of NAT translations for a cluster.	number
Distribution	Connection distribution count in the cluster for every second.	number

Metric	Description	Format
Packets	Packet distribution count in the cluster for every second.	number

Troubleshooting the Cluster

You can use the **CCL Ping** tool to make sure the cluster control link is operating correctly. You can also use the following tools that are available for devices and clusters:

- Troubleshooting files—If a node fails to join the cluster, a troubleshooting file is automatically generated. You can also generate and download troubleshooting files from the **Devices > Device Management > Cluster > General** area. See [Generate Troubleshooting Files, on page 42](#).

You can also generate files from the **Device Management** page by clicking **More** (☰) and choosing **Troubleshoot Files**.

- CLI output—From the **Devices > Device Management > Cluster > General** area, you can view a set of pre-defined CLI outputs that can help you troubleshoot the cluster. The following commands are automatically run for the cluster:

- **show running-config cluster**
- **show cluster info**
- **show cluster info health**
- **show cluster info transport cp**
- **show version**
- **show asp drop**
- **show counters**
- **show arp**
- **show int ip brief**
- **show blocks**
- **show cpu detailed**
- **show interface *ccl_interface***
- **ping *ccl_ip* size *ccl_mtu* repeat 2**

You can also enter any **show** command in the Command field. See [View CLI Output, on page 45](#) for more information.

Perform a Ping on the Cluster Control Link

You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.

Procedure

Step 1 Choose **Devices > Device Management**, click the **More** (⋮) icon next to the cluster, and choose **> Cluster Live Status**.

Figure 236: Cluster Status

Cluster Status ?

Overall Status: Cluster has all nodes in sync

Nodes details (2) Refresh Reconcile All

	Status	Device Name	Unit Name	Chassis URL	
>	In Sync.	172.16.0.50 Control	172.16.0.50	N/A	⋮
>	In Sync.	172.16.0.51	172.16.0.51	N/A	⋮

Dated: 11:52:26 | 20 Dec 2021 Close

Step 2 Expand one of the nodes, and click **CCL Ping**.

Figure 237: CCL Ping

Cluster Status ?

Overall Status: ■ Clustering is disabled for 1 node(s)

Nodes details (3) Refresh Reconcile All

Status	Device Name	Unit Name	Chassis URL
In Sync.	10.10.43.21 Control	10.10.43.21	N/A
> Clustering is disabled	10.10.43.22	10.10.43.22	N/A

Summary History CCL Ping

```
ping 10.10.3.2 size 1654
Sending 5, 1654-byte ICMP Echos to 10.10.3.2, timeout is 2 seconds:
?????
Success rate is 0 percent (0/5)
-----
ping 10.10.3.1 size 1654
```

Dated: 18:38:41 | 01 Mar 2023 Close

The node sends a ping on the cluster control link to every other node using a packet size that matches the maximum MTU.

Reference for Clustering

This section includes more information about how clustering operates.

Threat Defense Features and Clustering

Some threat defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

Unsupported Features and Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

Note To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2553](#).

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.

- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Management Center UCAPL/CC mode

Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

Note Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

Note To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2553](#).

- The following application inspections:
 - DCERPC
 - ESMTTP
 - NetBIOS
 - PPTP
 - RSH
 - SQLNET
 - SUNRPC
 - TFTP
 - XDMCP
- Static route monitoring

Connection Settings and Clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the

cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

Dynamic Routing and Clustering

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

Figure 238: Dynamic Routing in Individual Interface Mode

In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

NAT and Clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different threat defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the threat defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- No Proxy ARP—For Individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router needs a static route or PBR with Object Tracking for the mapped addresses that points to the Main cluster IP address.
- No interface PAT on an Individual interface—Interface PAT is not supported for Individual interfaces.
- PAT with Port Block Allocation—See the following guidelines for this feature:
 - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
 - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
 - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
 - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.

- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
 - FTP
 - RSH
 - SQLNET
 - TFTP
 - XDMCP
 - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

SNMP and Clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

Cisco Trustsec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

VPN and Clustering

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

For connections to an Individual interface when using PBR or ECMP, you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

Note Remote access VPN is not supported with clustering.

Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

Control Node Election

Nodes of the cluster communicate over the cluster control link to elect a control node as follows:

1. When you enable clustering for a node (or when it first starts up with clustering already enabled), it broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request; the priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

Note If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node; the existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, then the node with highest priority retains the role while the other nodes return to data node roles.

Note You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

High Availability within the Cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

Node Health Monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

Interface Monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

All physical interfaces are monitored; only named interfaces can be monitored. You can optionally disable monitoring per interface.

A node is removed from the cluster if its monitored interfaces fail. The node is removed after 500 ms.

Status After Failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The threat defense automatically tries to rejoin the cluster, depending on the failure event.

Note When the threat defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The threat defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The threat defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the threat defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The threat defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from management center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

Table 35: Features Replicated Across the Cluster

Traffic	State Support	Notes
Up time	Yes	Keeps track of the system up time.
ARP Table	Yes	—
MAC address table	Yes	—
User Identity	Yes	—
IPv6 Neighbor database	Yes	—
Dynamic routing	Yes	—

Traffic	State Support	Notes
SNMP Engine ID	No	—

How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

Connection Roles

See the following roles defined for each connection:

- **Owner**—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- **Backup owner**—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- **Director**—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

ICMP/ICMPv6 hash details:

- For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
- For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
- For other packets, both source and destination ports are 0.
- **Forwarder**—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner.

A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

Note We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- **Fragment Owner**—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

New Connection Ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

Sample Data Flow for TCP

The following example shows the establishment of a new connection.

1. The SYN packet originates from the client and is delivered to one threat defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different threat defense (based on the load balancing method). This threat defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 239: ICMP and UDP Data Flow*

The first UDP packet originates from the client and is delivered to one threat defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

History for Threat Defense Virtual Clustering in a Private Cloud

Feature	Minimum Management Center	Minimum Threat Defense	Details
Clustering for the Threat Defense Virtual on VMware and KVM	7.4.1	7.4.1	The Threat Defense Virtual now supports individual interface clustering for up to 16 nodes on VMware and KVM.
Cluster control link ping tool.	7.2.6/7.4.1	Any	<p>You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.</p> <p>New/modified screens: Devices > Device Management > More (⋮) > Cluster Live Status</p> <p>Other version restrictions: Not supported with management center Version 7.3.x or 7.4.0.</p>
Troubleshooting file generation and download available from Device and Cluster pages.	7.4.1	7.4.1	<p>You can generate and download troubleshooting files for each device on the Device page and also for all cluster nodes on the Cluster page. For a cluster, you can download all files as a single compressed file. You can also include cluster logs for the cluster for cluster nodes. You can alternatively trigger file generation from the Devices > Device Management > More (⋮) > Troubleshoot Files menu.</p> <p>New/modified screens:</p> <ul style="list-style-type: none"> • Devices > Device Management > Device > General • Devices > Device Management > Cluster > General
Automatic generation of a troubleshooting file on a node when it fails to join the cluster.	7.4.1	7.4.1	If a node fails to join the cluster, a troubleshooting file is automatically generated for the node. You can download the file from Tasks or from the Cluster page.
View CLI output for a device or device cluster.	7.4.1	Any	<p>You can view a set of pre-defined CLI outputs that can help you troubleshoot the device or cluster. You can also enter any show command and see the output.</p> <p>New/modified screens: Devices > Device Management > Cluster > General</p>
Cluster health monitor settings	7.3.0	Any	<p>You can now edit cluster health monitor settings.</p> <p>New/Modified screens: Devices > Device Management > Cluster > Cluster Health Monitor Settings</p> <p>Note If you previously configured these settings using FlexConfig, be sure to remove the FlexConfig configuration before you deploy. Otherwise the FlexConfig configuration will overwrite the management center configuration.</p>

Feature	Minimum Management Center	Minimum Threat Defense	Details
Cluster health monitor dashboard	7.3.0	Any	You can now view cluster health on the cluster health monitor dashboard. New/Modified screens: System (⚙️) > Health > Monitor
Clustering for the Threat Defense Virtual on VMware and KVM	7.2.0	7.2.0	The threat defense virtual supports Individual interface clustering for up to 4 nodes on VMware and KVM. CHAPTER 12

Clustering for Threat Defense Virtual in a Public Cloud

Clustering lets you group multiple Threat Defense Virtuals together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices. You can deploy Threat Defense Virtual clusters in a public cloud using the following public cloud platforms:

- Amazon Web Services (AWS)
- Microsoft Azure
- Google Cloud Platform (GCP)

Currently, only routed firewall mode is supported.

Note Some features are not supported when using clustering. See [Unsupported Features and Clustering](#), on page 609.

- [About Threat Defense Virtual Clustering in the Public Cloud](#), on page 530
- [Licenses for Threat Defense Virtual Clustering](#), on page 532
- [Requirements and Prerequisites for Threat Defense Virtual Clustering](#), on page 533
- [Guidelines for Threat Defense Virtual Clustering](#), on page 534
- [Deploy the Cluster in AWS](#), on page 536

About Threat Defense Virtual Clustering in the Public Cloud

This section describes the clustering architecture and how it works.

How the Cluster Fits into Your Network

The cluster consists of multiple firewalls acting as a single device. To act as a cluster, the firewalls need the following infrastructure:

- Isolated network for intra-cluster communication, known as the *cluster control link*, using VXLAN interfaces. VXLANs, which act as Layer 2 virtual networks over Layer 3 physical networks, let the Threat Defense Virtual send broadcast/multicast messages over the cluster control link.
- Load Balancer(s)—For external load balancing, you have the following options depending on your public cloud:

- AWS Gateway Load Balancer

The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint) using a Geneve interface single-arm proxy.

- Azure Gateway Load Balancer

In an Azure service chain, Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

- Native GCP load balancers, internal and external

- Equal-Cost Multi-Path Routing (ECMP) using inside and outside routers such as Cisco Cloud Services Router

ECMP routing can forward packets over multiple “best paths” that tie for top place in the routing metric. Like EtherChannel, a hash of source and destination IP addresses and/or source and destination ports can be used to send a packet to one of the next hops. If you use static routes for ECMP routing, then the Threat Defense failure can cause problems; the route continues to be used, and traffic to the failed Threat Defense will be lost. If you use static routes, be sure to use a static route monitoring feature such as Object Tracking. We recommend using dynamic routing protocols to add and remove routes, in which case, you must configure each Threat Defense to participate in dynamic routing.

Note Layer 2 Spanned EtherChannels are not supported for load balancing.

Individual Interfaces

You can configure cluster interfaces as *Individual interfaces*.

Individual interfaces are normal routed interfaces, each with their own local IP address. Interface configuration must be configured only on the control node, and each interface uses DHCP.

Note Layer 2 Spanned EtherChannels are not supported.

Control and Data Node Roles

One member of the cluster is the control node. If multiple cluster nodes come online at the same time, the control node is determined by the priority setting; the priority is set between 1 and 100, where 1 is the highest priority. All other members are data nodes. When you first create the cluster, you specify which node you want to be the control node, and it will become the control node simply because it is the first node added to the cluster.

All nodes in the cluster share the same configuration. The node that you initially specify as the control node will overwrite the configuration on the data nodes when they join the cluster, so you only need to perform initial configuration on the control node before you form the cluster.

Some features do not scale in a cluster, and the control node handles all traffic for those features.

Cluster Control Link

Each node must dedicate one interface as a VXLAN (VTEP) interface for the cluster control link. For more information about VXLAN, see [Configure VXLAN Interfaces, on page 770](#).

VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

VTEP Source Interface

The VTEP source interface is a regular threat defense virtual interface with which you plan to associate the VNI interface. You can configure one VTEP source interface to act as the cluster control link. The source interface is reserved for cluster control link use only. Each VTEP source interface has an IP address on the same subnet. This subnet should be isolated from all other traffic, and should include only the cluster control link interfaces.

VNI Interface

A VNI interface is similar to a VLAN interface: it is a virtual interface that keeps network traffic separated on a given physical interface by using tagging. You can only configure one VNI interface. Each VNI interface has an IP address on the same subnet.

Peer VTEPs

Unlike regular VXLAN for data interfaces, which allows a single VTEP peer, The threat defense virtual clustering allows you to configure multiple peers.

Cluster Control Link Traffic Overview

Cluster control link traffic includes both control and data traffic.

Control traffic includes:

- Control node election.
- Configuration replication.
- Health monitoring.

Data traffic includes:

- State replication.
- Connection ownership queries and data packet forwarding.

Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

Management Network

You must manage each node using the Management interface; management from a data interface is not supported with clustering.

Licenses for Threat Defense Virtual Clustering

Each threat defense virtual cluster node requires the same performance tier license. We recommend using the same number of CPUs and memory for all members, or else performance will be limited on all nodes to match the least capable member. The throughput level will be replicated from the control node to each data node so they match.

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add the control node to the Management Center, you can specify the feature licenses you want to use for the cluster. You can modify licenses for the cluster in the **Devices > Device Management > Cluster > License** area.

Note If you add the cluster before the Management Center is licensed (and running in Evaluation mode), then when you license the Management Center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

Requirements and Prerequisites for Threat Defense Virtual Clustering

Model Requirements

- FTDv5, FTDv10, FTDv20, FTDv30, FTDv50, FTDv100

Note FTDv5 and FTDv10 do not support Amazon Web Services (AWS) Gateway Load Balancer (GWLB) and Azure GWLB.

- The following public cloud services:
 - Amazon Web Services (AWS)
 - Microsoft Azure
 - Google Cloud Platform (GCP)
- Maximum 16 nodes

See also the general requirements for the Threat Defense Virtual in the [Cisco Secure Firewall Threat Defense Virtual Getting Started Guide](#).

User Roles

- Admin
- Access Admin
- Network Admin

Hardware and Software Requirements

All units in a cluster:

- Must be in the same performance tier. We recommend using the same number of CPUs and memory for all nodes, or else performance will be limited on all nodes to match the least capable node.
- The Management Center access must be from the Management interface; data interface management is not supported.
- Must run the identical software except at the time of an image upgrade. Hitless upgrade is supported.
- All units in a cluster must be deployed in the same availability zone.
- Cluster control link interfaces of all units must be in the same subnet.

MTU

Make sure the ports connected to the cluster control link have the correct (higher) MTU configured. If there is an MTU mismatch, the cluster formation will fail. The cluster control link MTU should be 154 bytes higher than the data interfaces. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead (100 bytes) plus VXLAN overhead (54 bytes).

For AWS with GWLB, the data interface uses Geneve encapsulation. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. You should set the source interface MTU to be the network MTU + 306 bytes. So for the standard 1500 MTU network path, the source interface MTU should be 1806, and the cluster control link MTU should be +154, 1960.

For Azure with GWLB, the data interface uses VXLAN encapsulation. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. You should set the cluster control link MTU to be the source interface MTU + 80 bytes.

The following table shows the default values for the cluster control link MTU and the data interface MTU.

Note We do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.

Table 36: Default MTU

Public Cloud	Cluster Control Link MTU	Data Interface MTU
AWS with GWLB	1980	1826
AWS	1654	1500
Azure with GWLB	1454	1374
Azure	1454	1300
GCP	1554	1400

Guidelines for Threat Defense Virtual Clustering

High Availability

High Availability is not supported with clustering.

IPv6

The cluster control link is only supported using IPv4.

Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Threat Defense or the switch, adding an additional switch to form a VSS or vPC) you should disable the health check feature and also disable interface monitoring for the disabled

- interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the interface health check feature.
- When adding a node to an existing cluster, or when reloading a node, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang your connection; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
 - Do not power off a node without first disabling clustering on the node.
 - For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new node. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.
 - Dynamic scaling is not supported.
 - If you are using Secure Firewall versions 7.2 or 7.3, Stateful Target Failover is not supported when you deploy the cluster on AWS.
 - Perform a global deployment after the completion of each maintenance window.
 - Ensure that you do not remove more than one device at a time from the auto scale group (AWS) / instance group (GCP) / scale set (Azure). We also recommend that you run the **cluster disable** command on the device before removing the device from the auto scale group (AWS) / instance group (GCP) / scale set (Azure).
 - If you want to disable data nodes and the control node in a cluster, we recommend that you disable the data nodes before disabling the control node. If a control node is disabled while there are other data nodes in the cluster, one of the data nodes has to be promoted to be the control node. Note that the role change could disturb the cluster.
 - In the customized day 0 configuration scripts given in this guide, you can change the IP addresses as per your requirement, provide custom interface names, and change the sequence of the CCL-Link interface.
 - If you experience CCL instability issues, such as intermittent ping failures, after deploying a Threat Defense Virtual cluster on a cloud platform, we recommend that you address the reasons that are causing CCL instability. Also, you can increase the hold time as a temporary workaround to mitigate CCL instability issues to a certain extent. For more information on how to change the hold time, see [Edit Cluster Health Monitor Settings](#).
 - When you are configuring your security firewall rule or security group for the Management Center virtual, you must include both Private and Public IP addresses of the Threat Defense Virtual in the Source IP address range. Also, ensure to specify the Private and Public IP addresses of the Management Center Virtual in the security firewall rule or security group of the Threat Defense Virtual. This is important to ensure proper registration of nodes during clustering deployment.

Defaults for Clustering

- The cLACP system ID is auto-generated, and the system priority is 1 by default.
- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is unlimited attempts every 5 minutes.

- The cluster auto-rejoin feature for a failed data interface is 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

Deploy the Cluster in AWS

To deploy a cluster in AWS, you can either manually deploy or use CloudFormation templates to deploy a stack. You can use the cluster with AWS Gateway Load Balancer, or with a non-native load-balancer such as the Cisco Cloud Services Router.

AWS Gateway Load Balancer and Geneve Single-Arm Proxy

Note This use case is the only currently supported use case for Geneve interfaces.

The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The Threat Defense Virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

Note Transport Layer Security (TLS) Server Identity Discovery is not supported with Geneve single-arm setup on AWS.

Figure 240: Geneve Single-Arm Proxy

Sample Topologies

Threat Defense Virtual Clustering with Autoscale in Single and Multiple Availability Zones of an AWS Region

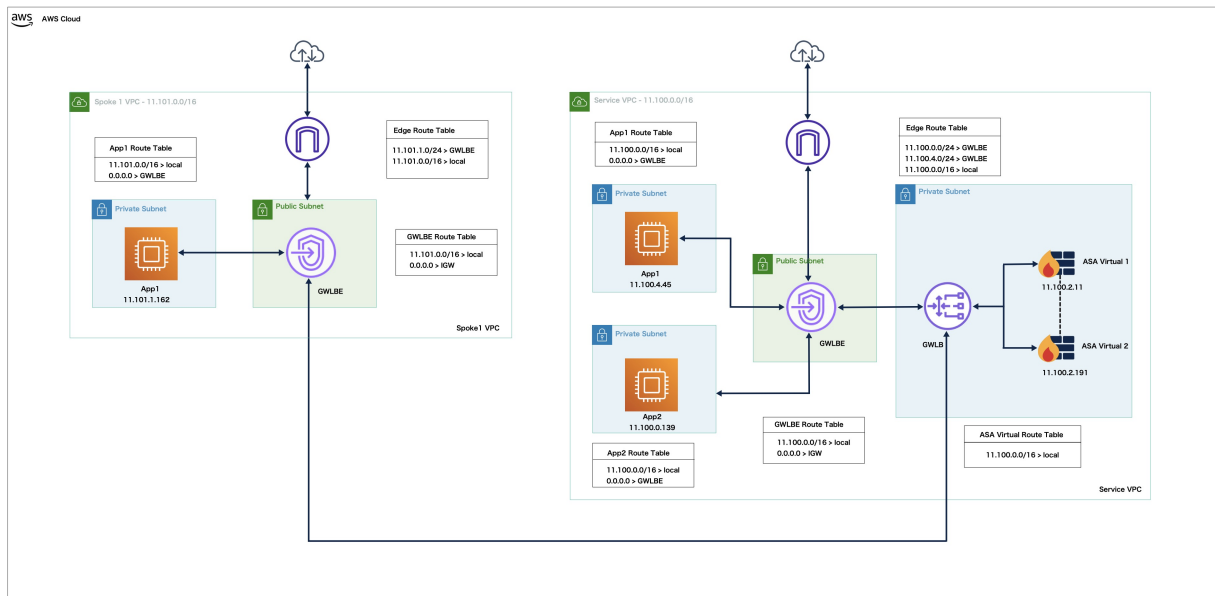

An availability zone is a standalone data center or a set of independent data centers within an AWS region that operate independently. Each zone has its own networking infrastructure, connectivity, and power source ensuring a failure in one zone does not affect others. To improve redundancy and reliability, companies use multiple availability zones in their disaster recovery plans.

Deploying Threat Defense Virtual across multiple availability zones and configuring clustering with dynamic scaling can significantly enhance the availability and scalability of your infrastructure. In addition, utilizing multiple availability zones in the same region can offer extra redundancy and guarantee high availability in the event of a failure.

You can modify the IP allocation mechanism of Cluster Control Link (CCL) to support both single and multiavailability zone deployments of Threat Defense Virtual clusters on AWS. The topologies given below depict both inbound and outbound traffic flow in a single and multiple availability zones with autoscaling ability.

Threat Defense Virtual Clustering with Autoscale in Single Availability Zone

There are two Threat Defense Virtual instances in the cluster that are connected to a GWLB.

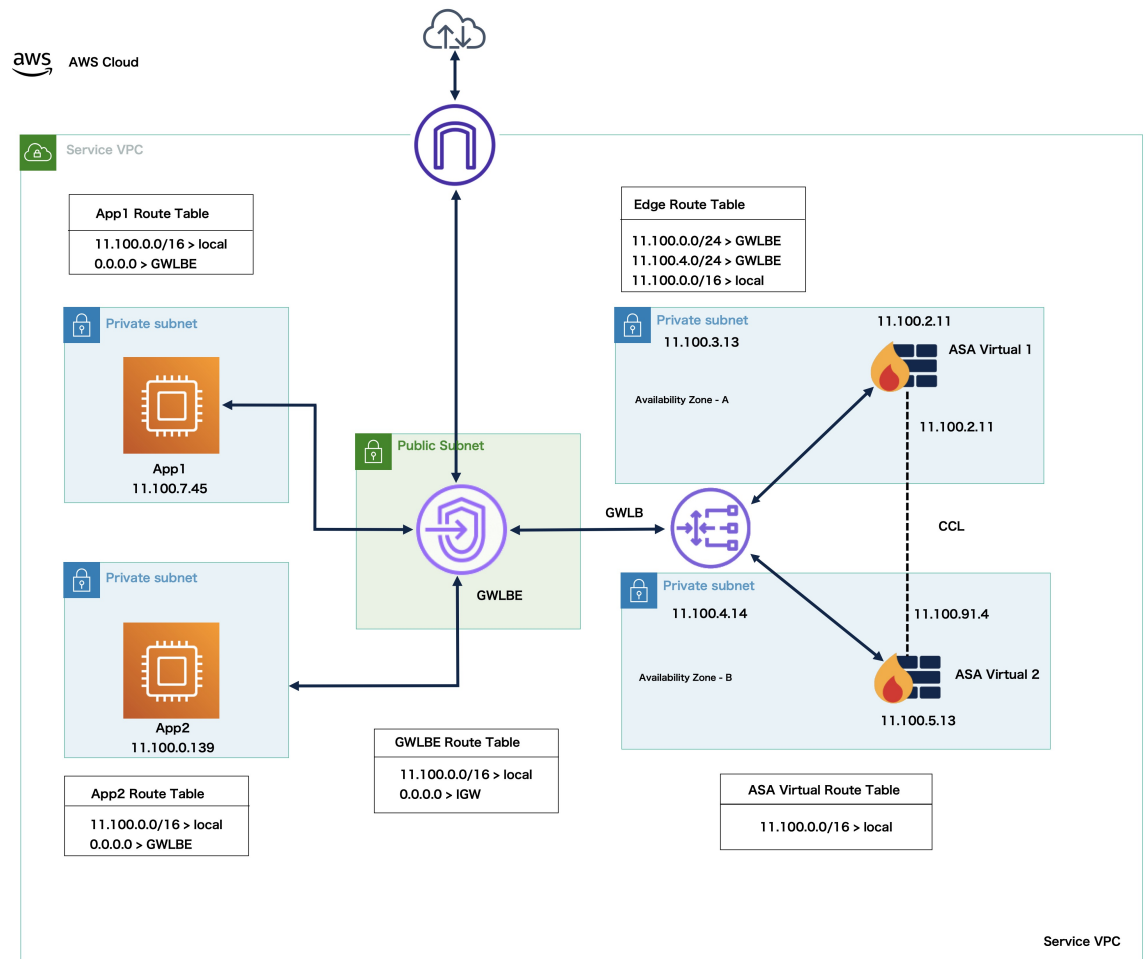

Inbound traffic from the internet goes to the GWLB endpoint, which is then transmits the traffic to the GWLB. Traffic is then forwarded to the Threat Defense Virtual cluster. After the traffic is inspected by an Threat Defense Virtual instance in the cluster, it is forwarded to the application VM, App1.

Outbound traffic from App1 is transmitted to the GWLB endpoint > GWLB > ASA v > GWLB > GWLB Endpoint, which then sends it out to the internet.

Threat Defense Virtual Clustering with Autoscale in Multiple Availability Zones with Autoscale Solution

There are two Threat Defense Virtual instances in the cluster in different availability zones that are connected to a GWLB.

Inbound traffic from the internet goes to the GWLB endpoint, which then transmits the traffic to the GWLB. Based on the availability zone, the traffic is then routed to the Threat Defense Virtual cluster. After the traffic is inspected by an Threat Defense Virtual instance in the cluster, it is forwarded to the application VM, App1.

End-to-End Process for Deploying Threat Defense Virtual Cluster on AWS

Template-based Deployment

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster on AWS.

	Workspace	Steps
①	Local Host	Download templates and files from GitHub.
②	Local Host	Modify <i>infrastructure.yaml</i> and <i>deploy_ngfw_cluster.yaml</i> templates.
③	Local Host	Update the <i>Configuration.json</i> file with initial settings.
④	Linux Host	Create <i>cluster_layer.zip</i> file.
⑤	Local Host	Copy <i>cluster_layer.zip</i> file to the Lambda python files folder.
⑥	Local Host	Create <i>cluster_manager.zip</i> and <i>cluster_lifecycle.zip</i> files.
⑦	Local Host	Build zip files from Python files for Lambda functions and copy to target folder.
⑧	AWS Console	Deploy <i>infrastructure.yaml</i> template.
⑨	AWS Console	Upload <i>cluster_layer.zip</i> , <i>cluster_lifecycle.zip</i> , and <i>cluster_manager.zip</i> , to the S3 bucket.
⑩	AWS Console	Deploy <i>deploy_ngfw_cluster.yaml</i> template.
⑪	AWS Console	Log in and verify cluster deployment.

Manual Deployment

The following flowchart illustrates the workflow for manual deployment of the Threat Defense Virtual cluster on AWS.

	Workspace	Steps
1	Local Host	Create the Day0 Configuration for AWS
2	AWS Console	Deploy Threat Defense Virtual instance.
3	AWS Console	Attach interfaces to instance.
4	AWS Console	Verify if nodes have joined cluster.
5	AWS Console	Create target group and GWLB; attach target group to the GWLB.
6	AWS Console	Register instances with the target group using data interface IP.
7	Management Center	Register control node.

Templates

The templates given below are available in GitHub. The parameter values are self-explanatory with the parameter names, default values, allowed values, and description, given in the template.

- [infrastructure.yaml](#) – Template for infrastructure deployment.
- [deploy_ngfw_cluster.yaml](#) – Template for cluster deployment.

Note Ensure that you check the list of supported AWS instance types before deploying cluster nodes. This list is found in the *deploy_ngfw_cluster.yaml* template, under allowed values for the parameter InstanceType.

Deploy the Stack in AWS Using a CloudFormation Template

Deploy the stack in AWS using the customized CloudFormation template.

Before you begin

- You need a Linux computer with Python 3.
- To allow the cluster to auto-register with the management center, you need to create *two* users with administrative privileges on the management center that can use the REST API. See the [Cisco Secure Firewall Management Center Administration Guide](#).
- Add an access policy in the management center that matches the name of the policy that you specified in `configuration.json`.

Procedure

Step 1

Prepare the template.

- a) Clone the GitHub repository to your local folder. See <https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/aws>.
- b) Modify `infrastructure.yaml` and `deploy_ngfw_cluster.yaml` with the required parameters.
- c) Modify `cloud-clustering/ftdv-cluster/lambda-python-files/Configuration.json` with initial settings.

For example:

```
{
  "licenseCaps": ["BASE", "MALWARE", "THREAT"],
  "performanceTier": "FTDv50",
  "fmcIpforDeviceReg": "DONTRESOLVE",
  "RegistrationId": "cisco",
  "NatId": "cisco",
  "fmcAccessPolicyName": "AWS-ACL"
}
```

- Keep the `fmcIpforDeviceReg` setting as DONTRESOLVE.
- The `fmcAccessPolicyName` needs to match an access policy on the management center.

Note FTDv5 and FTDv10 tiers are not supported.

- d) Create a file named `cluster_layer.zip` to provide essential Python libraries to Lambda functions.

We recommend to use the Amazon Linux with Python 3.9 installed to create the `cluster_layer.zip` file.

Note If you need an Amazon Linux environment, you can create an EC2 instance using Amazon Linux 2023 AMI or use AWS Cloudshell, which runs the latest version of Amazon Linux.

For creating the `cluster-layer.zip` file, you need to first create `requirements.txt` file that consists of the python library package details and then run the shell script.

1. Create the `requirements.txt` file by specifying the python package details.

The following is the sample package details that you provide in the `requirements.txt` file:

```
$ cat requirements.txt
pycryptodome
paramiko
requests
scp
jsonschema
cffi
zip
importlib-metadata
```

2. Run the following shell script to create **cluster_layer.zip** file.

```
$ pip3 install --platform manylinux2014_x86_64
--target=./python/lib/python3.9/site-packages
--implementation cp --python-version 3.9 --only-binary=:all:
--upgrade -r requirements.txt
$ zip -r cluster_layer.zip ./python
```

Note If you encounter a dependency conflict error during installation, such as urllib3 or cryptography, it is recommended that you include the conflicting packages along with their recommended versions in the **requirements.txt** file. After that, you can run the installation again to resolve the conflict.

- e) Copy the resulting **cluster_layer.zip** file to the lambda python files folder.
- f) Create the **cluster_layer.zip**, **custom_metrics_publisher.zip**, **cluster_manger.zip** and **lifecycle_ftdv.zip** files.

A **make.py** file can be found in the cloned repository. This will zip the python files into a Zip file and copy to a target folder.

python3 make.py build

Note Before cluster deployment, ensure that you have customized the AWS CFT template files - **infrastructure.yaml** and **deploy_ngfw_cluster.yaml** for your infrastructure requirement like VPC, Subnets, S3 buckets required for the Threat Defense Virtual clustering autoscale deployment.

Step 2

Deploy **infrastructure.yaml** and note the output values for cluster deployment. Before deploying the infrastructure stack, it is important to identify the AWS region and the availability zones that will be used. Each AWS region has a different set of availability zones and VPC infrastructure, therefore it is essential to select the correct region and availability zones for your deployment.

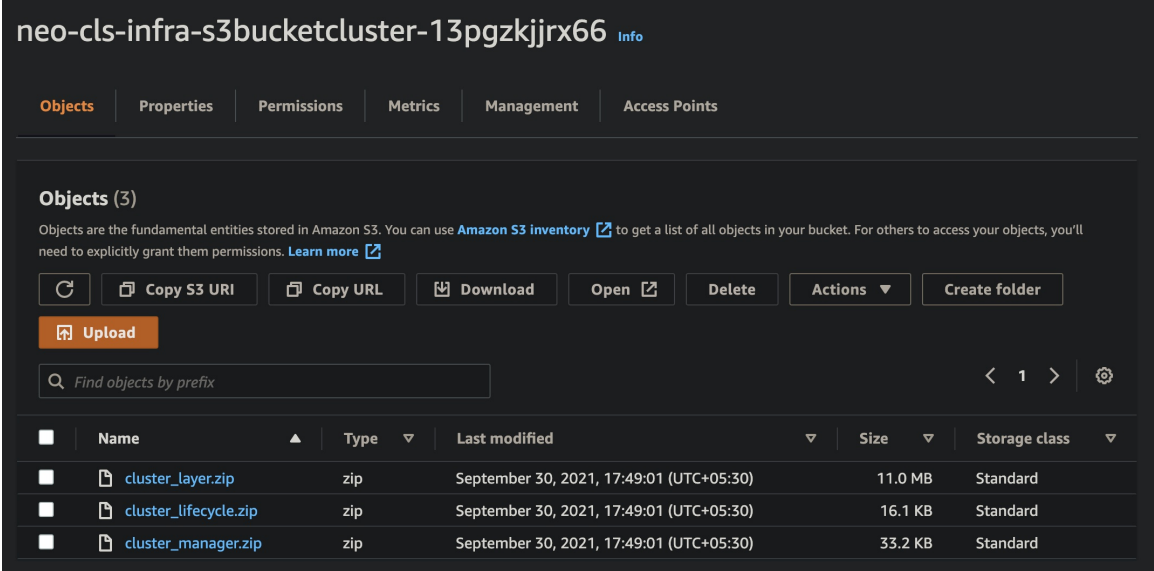

- a) On the AWS Console, go to **CloudFormation** and click **Create stack**; select **With new resources(standard)**.
- b) Select **Upload a template file**, click **Choose file**, and select **infrastructure.yaml** from the target folder.
- c) Click **Next** and provide the required information.
- d) Enter a unique **Cluster Name** and **Cluster Number** for the cluster.
- e) Select the availability zone from the **Availability Zone** list. This field lists only availability zones based on the AWS region that you select for deploying the infrastructure stack using the ClusterFormation template.
- f) Enter the predefined subnet CIDR values separated by a comma in the **Inside subnet CIDR** field.
- g) Choose the availability zones required for Lambda to communicate across availability zones from the **List of Lambda AZs**.
- h) Click **Next**, then **Create stack**.
- i) After the deployment is complete, go to **Outputs** and note the S3 **BucketName**.

Figure 241: Output of infrastructure.yaml

Outputs (16)				
<input type="text" value="Search outputs"/>				
Key ▲	Value ▼	Description ▼	Export name	
AZ	me-south-1a	Availability zone	-	
AppInstanceSGId	sg-02b07af19c3e746d9	Security Group ID for Application Instances	-	
ApplicationSubnetIds	subnet-03217efc6049e5fee	Application subnet ID	-	
BucketName	neo-cls-infra-s3bucketcluster-13pgzkjrx66	Name of the sample Amazon S3 bucket with Private Static Web hosting Configuration	-	
BucketUrl	http://neo-cls-infra-s3bucketcluster-13pgzkjrx66.s3-website.me-south-1.amazonaws.com	URL of S3 Bucket Static Website	-	
CCLSubnetId	subnet-0caf6c4801922d8b1	CCL subnet ID	-	
EIPforNATgw	15.184.208.231	EIP reserved for NAT GW	-	
FmcInstanceSGID	sg-0a0d3797b04370aa3	Security Group ID for FMC if user would like to launch in this VPC itself	-	
InInterfaceSGId	sg-0522ebe5acb8a2827	Security Group ID for Instances Inside Interface	-	
InsideSubnetIds	subnet-056fdc9fe5389bf88	Inside subnet ID	-	
InstanceSGId	sg-0be5b62647eb53dec	Security Group ID for Instances Management Interface	-	
LambdaSecurityGroupID	sg-0347d191d724b2574	Security Group ID for Lambda Functions	-	
LambdaSubnetIds	subnet-0989fbaeb522a906c,subnet-0c7a9b649d506f930	List of lambda subnet IDs (comma seperated)	-	
MgmtSubnetIds	subnet-08c386d4b06890532	Mangement subnet ID	-	
UseGWLB	Yes	Use Gateway Load Balancer	-	
VpcName	vpc-0d94d3eaaa1f1354d	Name of the VPC created	-	

Step 3 Upload `cluster_layer.zip`, `cluster_manager.zip`, and `cluster_lifecycle.zip` to the S3 bucket created by `infrastructure.yaml`.

Figure 242: S3 Bucket

Step 4 Deploy `deploy_ngfw_cluster.yaml`.

- a) Go to **CloudFormation** and click on **Create stack**; select **With new resources(standard)**.
- b) Select **Upload a template file**, click **Choose file**, and select `deploy_ngfw_cluster.yaml` from the target folder.
- c) Click **Next** and provide the required information.
- d) Provide the following cluster and infrastructure configuration information.

Parameter	Allowed Values/Type	Description
Cluster Configuration		
ClusterGrpNamePrefix	String	This is the cluster name Prefix. The cluster number will be added as a suffix.
Cluster Number	String	This is the cluster number. This will be suffixed to the cluster name (msa-ftdv-infra). For example, if this value is 1 , the group name will be <i>msa-ftdv-infra-1</i> . It should be at least 1 digit, but not more than 3 digits. Default: 1.
Cluster Size	Numbers	This is the total number of Threat Defense Virtual nodes in a cluster. Minimum: 1 Maximum:16
Infrastructure Details		
Number of Availability Zones	String	This is the total number of availability zones into which Threat Defense Virtual is deployed. (The number of

Parameter	Allowed Values/Type	Description
		<p>availability zones varies from a Minimum 1 to Maximum 3 depending on a region).</p> <p>The subnet will be created in these availability zones.</p> <p>The availability zones available in this list is based on the region selected for deploying the cluster.</p> <p>Note Lambda is created across two availability zones. Management and Inside subnet are created across three availability zones based on this parameters.</p>
Enter Valid Availability Zones for launching NGFWs	String	<p>The availability zone list is based on the region you plan to deploy.</p> <p>In Availability Zone list, select the valid availability zone (1 availability zone or 2 availability zones or 3 availability zones).</p> <p>Count should match with the value of Number of Availability Zones parameter.</p>
Cluster Email Notification	String	<p>Email address to which cluster events email will be sent. You must accept a subscription email request to receive this email notification.</p> <p>Example: admin@company.com</p>
S3 Bucket Name	String	The S3 Bucket that contains the uploaded Lambda zip files. You must specify correct bucket name.
GWLB Configuration		
Deploy Gateway Load Balancer Endpoint	String	<p>Click Yes to deploy the GWLB endpoint.</p> <p>By default, the value is set to No.</p>
VPC ID for Gateway Load Balancer Endpoint	String	<p>Enter VPC to deploy Gateway Load Balancer Endpoint.</p> <p>Note Do not enter any value in this field if you are not deploying the GWLB endpoint.</p>
Subnet ID for Gateway Load Balancer Endpoint	String	<p>Enter only one subnet ID.</p> <p>Note Do not enter any value in this field if you are not deploying the GWLB endpoint.</p> <p>Ensure that the subnet belongs to the correct VPC, and the availability zones that you have specified.</p>
Target Failover	String	Enable Target Failover support when a target fails or deregisters. (By default, the value of this parameter is set to rebalance).

Parameter	Allowed Values/Type	Description
		<ul style="list-style-type: none"> • no_rebalance: Directs existing flows to failed targets and new flows to healthy targets, ensuring backward compatibility. • rebalance: Redistributes existing flows while ensuring that new flows go to healthy targets.
Enter Health Check Port for Gateway Load Balancer Endpoint	String	Enter Health Check Port for GWLB. Note By default, this port must not be used for traffic. Ensure the value you provide is a valid TCP port. Default: 80
Cisco NGFWv Instance Configuration		
NGFWv Instance Type	String	Cisco NGFWv EC2 instance type. Ensure that the AWS Region supports Instance Type you select. By default, c5.xlarge is selected.
NGFWv Instance License Type	String	Choose Cisco NGFWv EC2 instance license type. Ensure that the AMI ID that you enter in AMI-ID parameter is of the same licensing type. By default, BYOL is selected.
Assign Public IP for NGFWv from AWS IP Pool	String	Set the value as true to assign a public IP address for NGFWv from the AWS IP address pool.
NGFWv AMI-ID	String	Choose the correct AMI ID as per the region, version, and license type (BYOL or PAYG). Threat Defense Virtual 7.2 and later support clustering, and Threat Defense Virtual Version 7.6 and later support the autoscaling and multiple availability zone enhancements. Type: AWS::EC2::Image::Id By default: ami-09963e452646cef87
NGFWv Password	String	Threat Defense Virtual instance password. All NGFWv instances come up with a default password, which is in the Userdata field of the Launch Template (Cluster Group). The password is activated after Threat Defense Virtual is accessible.

Parameter	Allowed Values/Type	Description
		Minimum length must be 8 characters. The password can either be a plain text password or a KMS encrypted password.
FMC Automation Configuration		
FMC host IP address	String	The IP address can be an external IP address or the IP address reachable in NGFWv management subnet in the VPC. Minimum length: 7 Maximum length:15
FMC Username for Cluster Automation	String	Provide a unique internal user name for Management Center Virtual for CloudWatch. The user must have Administrator privileges.
FMC Password for Publishing Metrics to CloudWatch	String	Enter the password. If you have mentioned KMS Master Key ARN parameter, ensure to provide an encrypted password.
Scaling Configuration		
Lower, Upper CPU Thresholds	CommaDelimitedList	(Optional) Specifying non-zero lower and upper thresholds will create scale policies. If (0,0) is selected, no CPU scaling alarm or policies will be created. Evaluation points and data points are at default or recommended values. By default, Autoscale is enabled in this template. Autoscale can be disabled after deployment.
Lower, Upper Memory Thresholds	CommaDelimitedList	Specifying non-zero lower and upper threshold will create scale policies. If (0,0) is selected, no CPU scaling alarm or policies will be created. Evaluation points and data points are at default or recommended values.

- e) Click **Next**.
- f) Click to acknowledge all the AWS CloudFormation options.
- g) Click **Submit** to deploy the cluster.
- h) Click **Next**, then **Create stack**.

The Lambda functions manage the rest of the process, and the threat defense virtuals will automatically register with the management center.

Figure 243: Deployed Resources

Logical ID	Physical ID	Type	Status
ASmanagerTopic	arn:aws:sns:me-south-1:797661843114:neo-cls-1-1-autoscale-manager-topic	AWS::SNS::Topic	CREATE_COMPLETE

What to do next

[Autoscale Parameter Configuration, on page 549.](#)

Autoscale Parameter Configuration

After the deployment is completed, you must specify **Minimum**, **Maximum**, and **Desired** capacity of the Threat Defense Virtual Autoscale group. You must verify the Autoscale functionality.

Procedure

- Step 1** From the AWS console, choose **Services > EC2 > Auto Scaling groups > Created ClusterAutoscale group**.

The screenshot displays the AWS Management Console interface for an Auto Scaling group. At the top, there's a navigation bar with 'EC2 > Auto Scaling groups'. Below that, a search bar and several action buttons are visible: 'Launch configurations', 'Launch templates', 'Actions', and a prominent orange 'Create Auto Scaling group' button. A table lists the Auto Scaling groups, with 'mAZ-cl5-ngfwv-26' selected. Below the table, the 'Auto Scaling group: mAZ-cl5-ngfwv-26' details are shown, including tabs for 'Details', 'Activity', 'Automatic scaling', 'Instance management', 'Monitoring', and 'Instance refresh'. The 'Details' tab is active, showing a grid of key-value pairs for the group's configuration.

Group details			
Auto Scaling group name	Desired capacity	Desired capacity type	Amazon Resource Name (ARN)
mAZ-cl5-ngfwv-26	3	Units (number of instances)	arn:aws:autoscaling:us-east-1:183117696075:autoScalingGroup:9126b776-5e99-4bff-8c9c-1aba7c84467f:autoScalingGroupName/mAZ-cl5-ngfwv-26
Date created	Minimum capacity	Status	
Tue Apr 30 2024 12:27:26 GMT+0530 (India Standard Time)	3	-	
	Maximum capacity		
	3		

- Step 2** Select the autoscale group check box.
- Step 3** Click **Actions** to edit the autoscaling group capacity.
- Step 4** Configure **Desired capacity**, and then set the **Scaling limits** capacity.
- Step 5** Check if the CPU metric data is available and whether scaling is occurring as expected in AWS Cloudwatch alarms.
- Step 6** To verify the autoscaling functionality, go to the AWS CloudWatch alarms page and verify CPU metric data is available and scaling happening as expected.

Configure IMDSv2 Required Mode in Threat Defense Virtual Clustering by Updating Stack

You can configure the IMDSv2 Required mode for the Threat Defense Virtual autoscale group instances that are already deployed on the AWS.

Before you begin

IMDSv2 Required mode is only supported by Threat Defense Virtual version 7.6 and later. You must ensure that your existing instances version is compatible (upgraded to version 7.6) with IMDSv2 mode before configuring the IMDSv2 mode for your deployment.

Procedure

- Step 1** On the AWS Console, go to **CloudFormation** and click **Stacks**.
- Step 2** Select the stack of the initially deployed clustering instances.
- Step 3** Click **Update**.
- Step 4** On the **Update stack** page, click **Replace existing template**.
- Step 5** Under **Specify template** section, click **Upload a template file**.
- Step 6** Choose and upload the template which support IMDSv2.
- Step 7** Provide values for the input parameters in the template.

Step 8 Update the stack.

Deploy the Cluster in AWS Manually

To deploy the cluster manually, prepare the day 0 configuration, deploy each node, and then add the control node to the management center.

Create the Day0 Configuration for AWS

You can use either a fixed configuration or a customized configuration. We recommend using the fixed configuration.

Create the Day0 Configuration With a Fixed Configuration for AWS

The fixed configuration will auto-generate the cluster bootstrap configuration.

```
{
  "AdminPassword": "password",
  "Hostname": "hostname",
  "FirewallMode": "Routed",
  "ManageLocally": "No",
  "Cluster": {
    "CclSubnetRange": "ip_address_start ip_address_end",
    "ClusterGroupName": "cluster_name",
    [For Gateway Load Balancer] "Geneve": "{Yes | No}",
    [For Gateway Load Balancer] "HealthProbePort": "port"
  }
}
```

For example:

```
{
  "AdminPassword": "Sup3rnatural",
  "Hostname": "ciscoftdv",
  "FirewallMode": "Routed",
  "ManageLocally": "No",
  "Cluster": {
    "CclSubnetRange": [
      "10.5.90.4 10.5.90.30", //mandatory user input
      "10.5.91.4 10.5.91.30",
      "10.5.92.4 10.5.92.30"
    ],
    "ClusterGroupName": "ftdv-cluster", //mandatory user input
    "Geneve": "Yes",
    "HealthProbePort": "7777"
  }
}
```

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration.

For the **CelSubnetRange** variable, specify a range of IP addresses starting from x.x.x.4. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start (*ip_address_start*) and end (*ip_address_end*) IP addresses given below.

Table 37: Examples of Start and End IP addresses

CIDR	Start IP Address	End IP Address
10.1.1.0/27	10.1.1.4	10.1.1.30
10.1.1.32/27	10.1.1.36	10.1.1.62
10.1.1.64/27	10.1.1.68	10.1.1.94
10.1.1.96/27	10.1.1.100	10.1.1.126
10.1.1.128/27	10.1.1.132	10.1.1.158
10.1.1.160/27	10.1.1.164	10.1.1.190
10.1.1.192/27	10.1.1.196	10.1.1.222
10.1.1.224/27	10.1.1.228	10.1.1.254
10.1.1.0/24	10.1.1.4	10.1.1.254

Create the Day0 Configuration With a Customized Configuration for AWS

You can enter the entire cluster bootstrap configuration using commands.

```
{
  "AdminPassword": "password",
  "Hostname": "hostname",
  "FirewallMode": "Routed",
  "ManageLocally": "No",
  "run_config": [comma_separated_threat_defense_configuration]
}
```

Gateway Load Balancer Example

The following example creates a configuration for a Gateway Load Balancer with one Geneve interface for U-turn traffic and one VXLAN interface for the cluster control link. Note the values in bold that need to be unique per node.

A sample day 0 configuration for **version 7.4 and later** is given below.

```
{
  "AdminPassword": "Sam&Dean",
  "Hostname": "ftdvl",
  "FirewallMode": "Routed",
  "ManageLocally": "No",
  "run_config": [
    "cluster interface-mode individual force",
    "interface TenGigabitEthernet0/0",
    "nameif geneve-vtep-ifc",
    "ip address dhcp",
    "no shutdown",
  ]
}
```

```

"interface TenGigabitEthernet0/1",
"nve-only cluster",
"nameif ccl_link",
"ip address dhcp",
"no shutdown",
"interface vni1",
"description Clustering Interface",
"segment-id 1",
"vtep-nve 1",
"interface vni2",
"proxy single-arm",
"nameif uturn-ifc",
"vtep-nve 2",
"object network ccl#link",
"range 10.1.90.4 10.1.90.19",
"object-group network cluster#group",
"network-object object ccl#link",
"nve 2",
"encapsulation geneve",
"source-interface geneve-vtep-ifc",
"nve 1",
"encapsulation vxlan",
"source-interface ccl_link",
"peer-group cluster#group",
"jumbo-frame reservation",
"mtu geneve-vtep-ifc 1826",
"mtu ccl_link 1980",
"cluster group ftdv-cluster",
"local-unit 1",
"cluster-interface vni1 ip 10.1.1.1 255.255.255.0",
"priority 1",
"enable",
"aaa authentication listener http geneve-vtep-ifc port 7777"
]
}

```

A sample day 0 configuration for **version 7.3 and earlier** is given below.

```

{
"AdminPassword": "Sam&Dean",
"Hostname": "ftdv1",
"FirewallMode": "Routed",
"ManageLocally": "No",
"run_config": [
"cluster interface-mode individual force",
"interface TenGigabitEthernet0/0",
"nameif geneve-vtep-ifc",
"ip address dhcp",
"no shutdown",
"interface TenGigabitEthernet0/1",
"nve-only cluster",
"nameif ccl_link",
"ip address dhcp",
"no shutdown",
"interface vni1",
"description Clustering Interface",
"segment-id 1",
"vtep-nve 1",
"interface vni2",
"proxy single-arm",
"nameif uturn-ifc",
"vtep-nve 2",
"object network ccl#link",
"range 10.1.90.4 10.1.90.19",

```

```

"object-group network cluster#group",
"network-object object ccl#link",
"nve 2",
"encapsulation geneve",
"source-interface geneve-vtep-ifc",
"nve 1",
"encapsulation vxlan",
"source-interface ccl_link",
"peer-group cluster#group",
"jumbo-frame reservation",
"mtu geneve-vtep-ifc 1806",
"mtu ccl_link 1960",
"cluster group ftdv-cluster",
"local-unit 1",
"cluster-interface vni1 ip 10.1.1.1 255.255.255.0",
"priority 1",
"enable",
"aaa authentication listener http geneve-vtep-ifc port 7777"
]
}

```

Note For the CCL subnet range, specify IP addresses from the CCL subnet CIDR, excluding reserved IP addresses. Refer the [Table 37: Examples of Start and End IP addresses](#) given above for some examples.

For the AWS health check settings, ensure that you specify the **aaa authentication listener http** port you set here.

Non-Native Load Balancer Example

The following example creates a configuration for use with non-native load balancers with Management, Inside, and Outside interfaces, and a VXLAN interface for the cluster control link. Note the values in bold that need to be unique per node.

```

{
  "AdminPassword": "Wlnch3sterBr0s",
  "Hostname": "ftdv1",
  "FirewallMode": "Routed",
  "ManageLocally": "No",
  "run_config": [
    "cluster interface-mode individual force",
    "interface Management0/0",
    "management-only",
    "nameif management",
    "ip address dhcp",
    "interface GigabitEthernet0/0",
    "no shutdown",
    "nameif outside",
    "ip address dhcp",
    "interface GigabitEthernet0/1",
    "no shutdown",
    "nameif inside",
    "ip address dhcp",
    "interface GigabitEthernet0/2",
    "nve-only cluster",
    "nameif ccl_link",
    "ip address dhcp",
    "no shutdown",
    "interface vni1",
    "description Clustering Interface",

```

```

"segment-id 1",
"vtep-nve 1",
"jumbo-frame reservation",
"mtu ccl_link 1654",
"object network ccl#link",
"range 10.1.90.4 10.1.90.19",           //mandatory user input
"object-group network cluster#group",
"network-object object ccl#link",
"nve 1",
"encapsulation vxlan",
"source-interface ccl_link",
"peer-group cluster#group",
"cluster group ftdv-cluster",         //mandatory user input
"local-unit 1",
"cluster-interface vni1 ip 10.1.1.1 255.255.255.0",
"priority 1",
"enable"
]
}

```

For the cluster control link network object, specify only as many addresses as you need (up to 16). A larger range can affect performance.

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration.

Deploy Cluster Nodes

Deploy the cluster nodes so they form a cluster.

Procedure

Step 1 Deploy the Threat Defense Virtual instance by using the cluster day 0 configuration with the required number of interfaces - four interfaces if you are using Gateway Load Balancer (GWLB), or five interfaces if you are using non-native load balancer. To do this, in the **Configure Instance Details > Advanced Details** section, paste the cluster day 0 configuration.

Note Ensure that you attach interfaces to the instances in the order given below.

- AWS Gateway Load Balancer - four interfaces - management, diagnostic, inside, and cluster control link.
- Non-native load balancers - five interfaces - management, diagnostic, inside, outside, and cluster control link.

For more information on deploying Threat Defense Virtual on AWS, see [Deploy the Threat Defense Virtual on AWS](#).

Step 2 Repeat Step 1 to deploy the required number of additional nodes.

Step 3 Use the **show cluster info** command on the Threat Defense Virtual console to verify if all nodes have successfully joined the cluster.

Step 4 Configure the AWS Gateway Load Balancer.

- a) Create a target group and GWLB.
- b) Attach the target group to the GWLB.

Note Ensure that you configure the GWLB to use the correct security group, listener configuration, and health check settings.

- c) Register the data interface (inside interface) with the Target Group using IP addresses.

For more information, see [Create a Gateway Load Balancer](#).

Step 5 Add the control node to the Management Center. See [Add the Cluster to the Management Center \(Manual Deployment\)](#), on page 586.

Configure Target Failover for Secure Firewall Threat Defense Virtual Clustering with GWLB in AWS

Threat Defense Virtual clustering in AWS utilizes the Gateway Load Balancer (GWLB) to balance and forward network packets for inspection to a designated Threat Defense Virtual node. The GWLB is designed to continue sending network packets to the target node in the event of a failover or deregistration of that node.

The Target Failover feature in AWS enables GWLB to redirect network packets to a healthy target node in the event of node deregistration during planned maintenance or a target node failure. It takes advantage of the cluster's stateful failover.

In AWS, you can configure Target Failover through the AWS Elastic Load Balancing (ELB) API or AWS console.

Note If a target node fails while the GWLB routes traffic using certain protocols such as SSH, SCP, CURL, and so on, then there may be a delay in redirecting traffic to a healthy target. This delay is due to rebalancing and rerouting of traffic flow.

In AWS, you can configure Target Failover through the AWS ELB API or AWS console.

- AWS API - In the AWS ELB API - *modify-target-group-attributes* you can define the flow handling behavior by modifying the following two new parameters.
 - `target_failover.on_unhealthy` - It defines how the GWLB handles the network flow when the target becomes unhealthy.
 - `target_failover.on_deregistration` - It defines how the GWLB handles the network flow when the target is deregistered.

The following command shows the sample API parameter configuration of defining these two parameters.

```
aws elbv2 modify-target-group-attributes \
--target-group-arn arn:aws:elasticloadbalancing:.../my-targets/73e2d6bc24d8a067 \
--attributes \
Key=target_failover.on_unhealthy, Value=rebalance[no_rebalance] \
Key=target_failover.on_deregistration, Value=rebalance[no_rebalance]
```

For more information, refer [TargetGroupAttribute](#) in the AWS documentation.

- AWS Console – In the EC2 console, you can enable the Target Failover option on the Target Group page by configuring the following options.
 - Edit Target Groups Attributes
 - Enable Target Failover
 - Verify Rebalance Flows

For more information about how to enable Target Failover, see [Enable Target Failover for Secure Firewall Threat Defense Virtual Clustering in AWS, on page 557](#).

Enable Target Failover for Secure Firewall Threat Defense Virtual Clustering in AWS

The data interface of threat defense virtual is registered to a target group of GWLB in AWS. In the threat defense virtual clustering, each instance is associated with a Target Group. The GWLB load balances and sends the traffic to this healthy instance identified or registered as a target node in the target group.

Before you begin

You must have deployed the cluster in AWS either by manual method or using CloudFormation templates.

If you are deploying a cluster using a CloudFormation template, you can also enable the **Target Failover** parameter by assigning the **rebalance** attribute that is available under **GWLB Configuration** section of the cluster deployment file, `deploy_ftdv_clustering.yaml`. In the template, by default, the value is set to **rebalance** for this parameter. However, the default value for this parameter is set to **no_rebalance** on the AWS console.

Where,

- **no_rebalance** - GWLB continues to send the network flow to the failed or deregistered target.
- **rebalance** - GWLB sends the network flow to another healthy target when the existing target is failed or deregistered.

For information on deploying stack in AWS, see:

- [Deploy the Cluster in AWS Manually](#)
- [Deploy the Stack in AWS Using a CloudFormation Template](#)

Procedure

-
- Step 1** On the AWS Console, go to **Services > EC2**
 - Step 2** Click **Target Groups** to view the target groups page.
 - Step 3** Select the target group to which the threat defense virtual data interface IPs are registered. The target group details page is displayed, where you can enable the Target failover attributes.
 - Step 4** Go to the **Attributes** menu.
 - Step 5** Click **Edit** to edit the attributes.

Step 6 Toggle the **Rebalance flows** slider button to the right to enable target failover to configure GWLB to rebalance and forward the existing network packets to a healthy target node in the event of target failover or deregistration.

Deploy the Cluster in Azure

You can use the cluster with the Azure Gateway Load Balancer (GWLB), or with a non-native load-balancer. To deploy a cluster in Azure, use Azure Resource Manager (ARM) templates to deploy a Virtual Machine Scale Set.

Sample Topology for GWLB-based Cluster Deployment

Figure 246: Inbound Traffic Use Case and Topology with GWLB

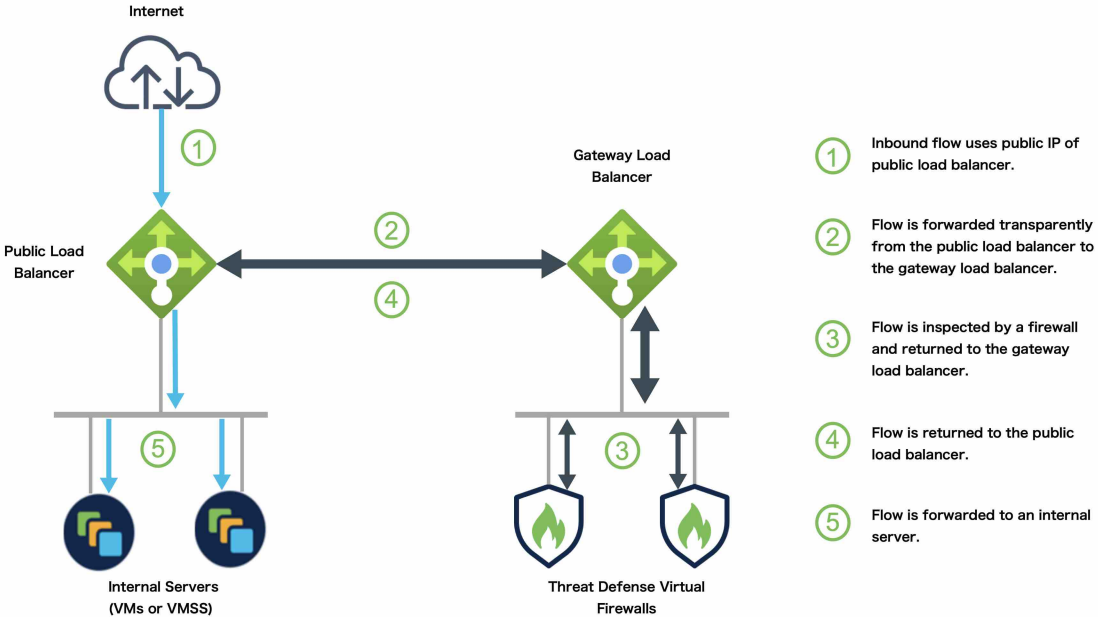

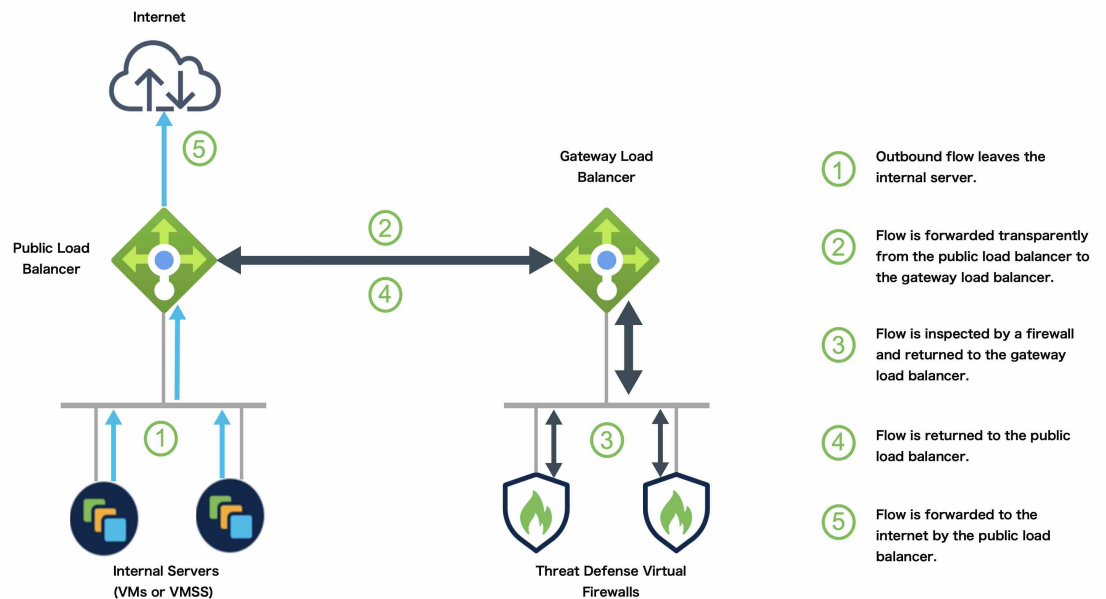

Figure 247: Outbound Traffic Use Case and Topology with GWLB

Azure Gateway Load Balancer and Paired Proxy

In an Azure service chain, Threat Defense Virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The Threat Defense Virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

The following figure shows traffic forwarded to the Azure Gateway Load Balancer from the Public Gateway Load Balancer on the external VXLAN segment. The Gateway Load Balancer balances traffic among multiple Threat Defense Virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer on the internal VXLAN segment. The Azure Gateway Load Balancer then sends the traffic back to the Public Gateway Load Balancer and to the destination.

Figure 248: Azure Gateway Load Balancer with Paired Proxy

Traffic flow between GWLB to GWLB (Geneve Single-Arm Proxy) in Azure

End-to-End Process for Deploying Threat Defense Virtual Cluster in Azure with GWLB

Template-based Deployment

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster in Azure with GWLB.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Modify <code>azure_ftdv_gwlb_cluster.json</code> and <code>azure_ftdv_gwlb_cluster_parameters.json</code> with the required parameters.
3	Azure Cloud	Create the resource group, virtual network, and subnets.

	Workspace	Steps
4	Azure Cloud	Deploy custom template.
5	Azure Cloud	Configure instance details.
6	Cluster Node	Verify cluster deployment.
7	Azure Cloud	Use the Function app to register the cluster with the Management Center.
8	Azure Cloud	Create FTPS credentials.
9	Local Host	Upload <i>Cluster_Function.zip</i> file to the Function app.

Manual Deployment

The following flowchart illustrates the workflow of manual deployment of Threat Defense Virtual cluster in Azure with GWLB.

	Workspace	Steps
1	Local Host	Create a VMSS from the Marketplace image.
2	Local Host	Attach interfaces.
3	Local Host	Add day 0 configuration in the customData field.
4	Local Host	Update scaling instance count.
5	Local Host	Configure GWLB.
6	Management Center	Add control node.

Templates

The templates given below are available in GitHub. The parameter values are self-explanatory with the parameter names, and values, given in the template.

From Secure Firewall version 7.4.1, you can deploy the cluster without the diagnostic interface. To deploy the cluster with only the Outside, Inside, Management, and CCL interfaces, use the withoutDiagnostic templates - [azure_withoutDiagnostic_ftdv_gwlb_cluster_parameters.json](#) and [azure_withoutDiagnostic_ftdv_gwlb_cluster.json](#) files.

Templates to deploy **with Diagnostic** Interface:

- [azure_ftdv_gwlb_cluster_parameters.json](#) – Template to enter parameters for the Threat Defense Virtual cluster with GWLB.
- [azure_ftdv_gwlb_cluster.json](#) – Template to deploy Threat Defense Virtual cluster with GWLB.

Templates to deploy **without Diagnostic** Interface:

- [azure_withoutDiagnostic_ftdv_gwlb_cluster_parameters.json](#) – Template to enter parameters for the Threat Defense Virtual cluster with GWLB deployment without Diagnostic interface.
- [azure_withoutDiagnostic_ftdv_gwlb_cluster.json](#) – Template to deploy Threat Defense Virtual cluster with GWLB without Diagnostic interface.

Prerequisites

- To allow the cluster to auto-register to the management center, create a user with Network Admin & Maintenance User privileges on the management center. Users with these privileges can use REST API. See the [Cisco Secure Firewall Management Center Administration Guide](#).
- Add an access policy in the management center that matches the name of the policy that you will specify during template deployment.
- Ensure that the Management Center Virtual is licensed appropriately.
- Perform the steps given below after the cluster is added to the Management Center Virtual:
 1. Configure platform settings with the health check port number in the Management Center. For more information on configuring this, see [Platform Settings](#).
 2. Create a static route for data traffic. For more information on creating a static route, see [Add a Static Route](#).

Sample static route configuration:

```
Network: any-ipv4
Interface: vxlan_tunnel
Leaked from Virtual Router: Global
Gateway: vxlan_tunnel_gw
Tunneled: false
Metric: 2
```

Note `vxlan_tunnel_gw` is the data subnet's gateway IP address.

Deploy Cluster on Azure with GWLB Using an Azure Resource Manager Template

Deploy the Virtual Machine Scale Set for Azure GWLB using the customized Azure Resource Manager (ARM) template.

Procedure

Step 1

Prepare the template.

- Clone the github repository to your local folder. See <https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/azure>.
- Modify `azure_ftdv_gwlb_cluster.json` and `azure_ftdv_gwlb_cluster_parameters.json` with the required parameters.

OR

Modify withoutDiagnostic templates, `azure_withoutDiagnostic_ftdv_gwlb_cluster_parameters.json` and `azure_withoutDiagnostic_ftdv_gwlb_cluster.json`, with the required parameter for deploying cluster without the diagnostic interface.

Step 2

Log into the Azure Portal: <https://portal.azure.com>.

Step 3

Create a Resource Group.

- In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
- Choose the required **Region**.

Step 4

Create a virtual network with 4 subnets: Management, Diagnostic, Outside, and Cluster Control Link (CCL).

From Secure Firewall version 7.4.1, you can deploy the cluster without the diagnostic interface. To deploy the cluster with only the Outside, Inside, Management, and CCL interfaces, use the withoutDiagnostic templates - `azure_withoutDiagnostic_ftdv_gwlb_cluster_parameters.json` and `azure_withoutDiagnostic_ftdv_gwlb_cluster.json` files.

- Create the virtual network.
 - In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
 - Choose the required **Region**. Click **Next: IP addresses**.

In the **IP Addresses** tab, click **Add subnet** and add the following subnets – Management, Diagnostic, Data, and Cluster Control Link.

If you are deploying the Threat Defense Virtual 7.4.1 cluster without a Diagnostic interface, then you must skip the Diagnostic subnet creation.

- Add the subnets.

Step 5

Deploy the custom template.

- a) Click **Create** > **Template deployment (deploy using custom templates)**.
- b) Click **Build your own template in the editor**.
- c) Click **Load File**, and upload **azure_ftdv_gwlb_cluster.json** or **azure_withoutDiagnostic_ftdv_gwlb_cluster.json**, if you have opted for without diagnostic interface deployment.
- d) Click **Save**.

Step 6 Configure the Instance details.

- a) Enter the required values and then click **Review + create**.
- b) Click **Create** after the validation is passed.

Step 7 After the instance is running, verify the cluster deployment by logging into any one of the nodes and entering the **show cluster info** command.

Figure 249: show cluster info

```
> show cluster info
Cluster gwlb-cluster-template-with-AN: On
Interface mode: individual
Cluster Member Limit : 16
This is "12" in state CONTROL_NODE
ID          : 0
Version    : 99.19(1)180
Serial No. : 9AKGFV8VH4G
CCL IP     : 10.1.1.12
CCL MAC    : 000d.3a55.5470
Module     : NGFWv
Resource   : 8 cores / 28160 MB RAM
Last join  : 11:13:24 UTC Sep 5 2022
Last leave : N/A
```

Step 8 In the Azure Portal, click the Function app to register the cluster with the Management Center.

Note If you do not want to use the Function app, you can alternatively register the control node to the management center directly by using **Add** > **Device** (not **Add** > **Cluster**). The rest of the cluster nodes will register automatically.

Step 9 Create FTPS Credentials by clicking **Deployment Center** > **FTPS credentials** > **User scope** > **Configure Username and Password**, and then click **Save**.

Step 10 Upload the Cluster_Function.zip file to the Function app by executing the following **curl** command in the local terminal.

```
curl -X POST -u username --data-binary @"Cluster_Function.zip" https://
Function_App_Name.scm.azurewebsites.net/api/zipdeploy
```

Note The **curl** command might take few minutes (~2 to 3 minutes) to complete command execution.

The function will be uploaded to the Function app. The function will start, and you can see the logs in the storage account's outqueue. The device registration with the Management Center will be initiated.

Figure 250: Functions

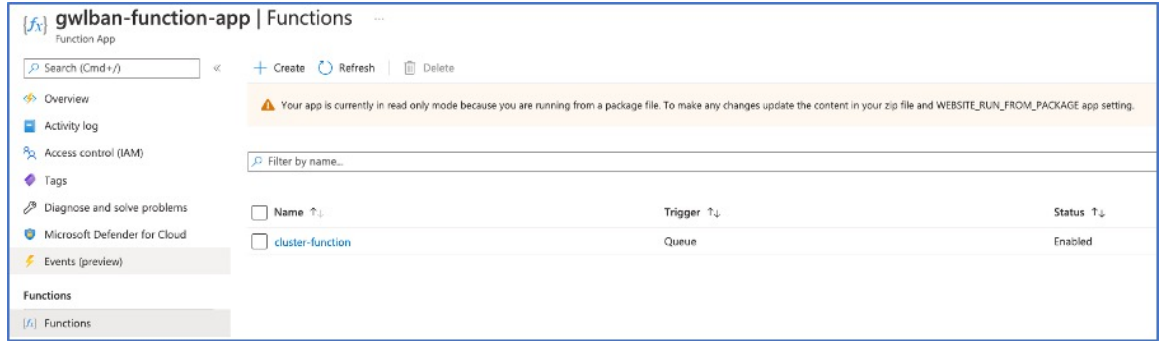

Figure 251: Queues

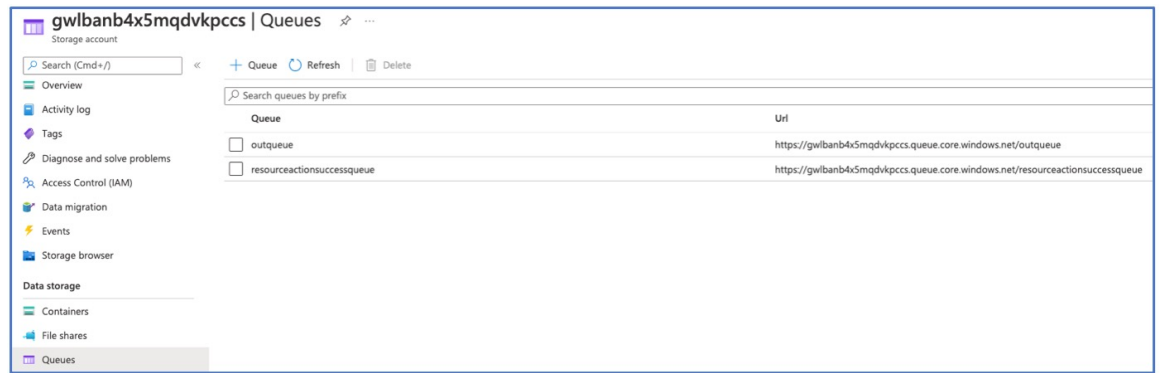

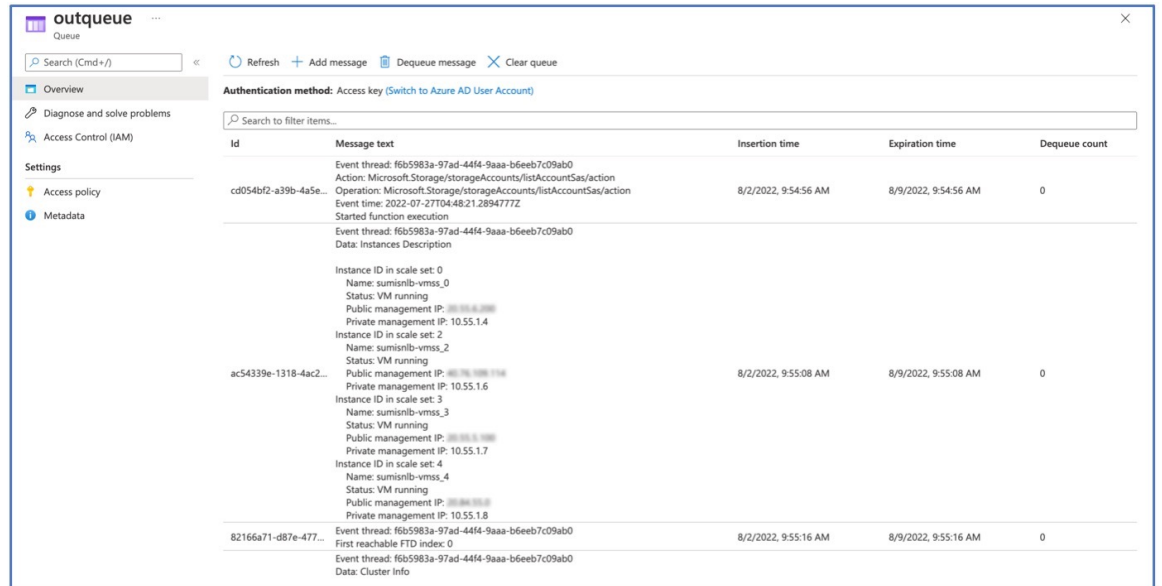

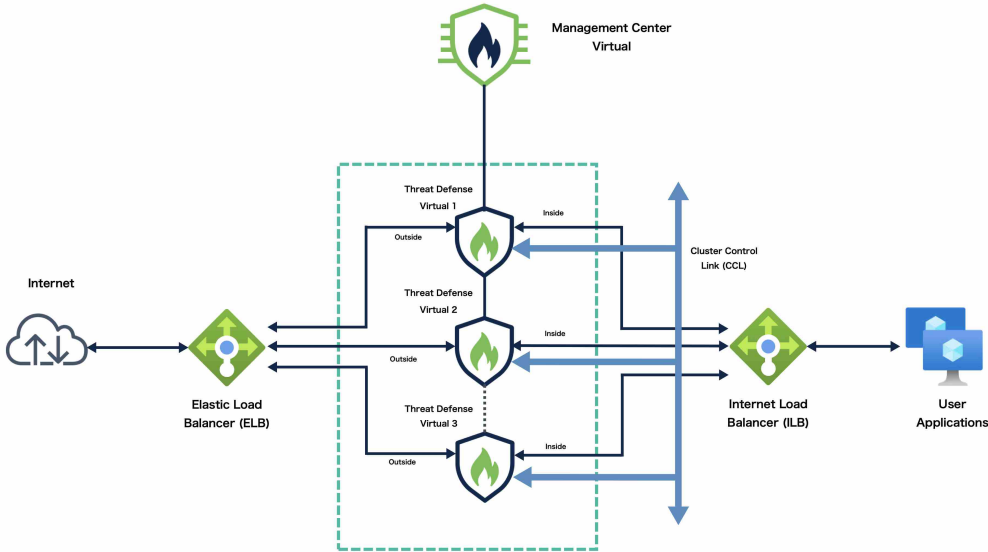

Figure 252: Outqueue

Sample Topology for NLB-based Cluster Deployment

This topology depicts both inbound and outbound traffic flow. The Threat Defense Virtual cluster is sandwiched between the internal and external load balancers. A Management Center Virtual instance is used to manage the cluster.

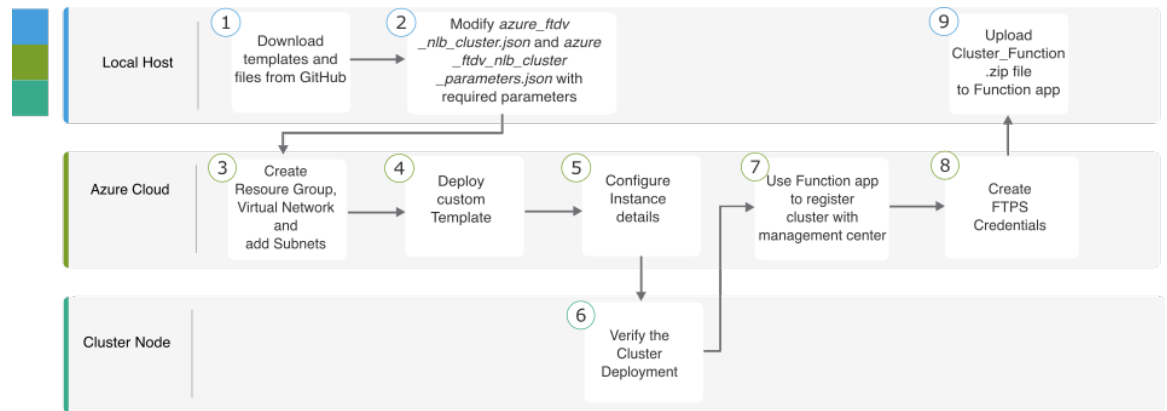

Inbound traffic from the internet goes to the external load balancer which then transmits the traffic to the Threat Defense Virtual cluster. After the traffic has been inspected by a Threat Defense Virtual instance in the cluster, it is forwarded to the application VM.

Outbound traffic from the application VM is transmitted to the internal load balancer. Traffic is then forwarded to the Threat Defense Virtual cluster and then sent out to the internet.

End-to-End Process for Deploying Threat Defense Virtual Cluster in Azure with NLB

Template-based Deployment

The following flowchart illustrates the workflow of template-based deployment of Threat Defense Virtual cluster in Azure with NLB.

	Workspace	Steps
①	Local Host	Download templates and files from GitHub.
②	Local Host	Modify <i>azure_ftdv_nlb_cluster.json</i> and <i>azure_ftdv_nlb_cluster_parameters.json</i> with the required parameters.
③	Azure Cloud	Create the resource group, virtual network, and subnets.
④	Azure Cloud	Deploy custom template.
⑤	Azure Cloud	Configure instance details.
⑥	Cluster Node	Verify cluster deployment.
⑦	Azure Cloud	Use the Function app to register the cluster with the Management Center.
⑧	Azure Cloud	Create FTPS credentials.
⑨	Local Host	Upload <i>Cluster_Function.zip</i> file to the Function app.

Manual Deployment

The following flowchart illustrates the workflow of manual deployment of Threat Defense Virtual cluster in Azure with NLB.

	Workspace	Steps
①	Local Host	Create a VMSS from the Marketplace image.
②	Local Host	Attach interfaces.
③	Local Host	Add day 0 configuration in the customData field.
④	Local Host	Update scaling instance count.
⑤	Local Host	Configure NLB.
⑥	Management Center	Add control node.

Templates

The templates given below are available in GitHub. The parameter values are self-explanatory with the parameter names, and values, given in the template.

From Secure Firewall version 7.4.1, you can deploy the cluster without the diagnostic interface. To deploy the cluster with only the Outside, Inside, Management, and CCL interfaces, use the withoutDiagnostic templates - [azure_withoutDiagnostic_ftdv_nlb_cluster_parameters.json](#) and [azure_withoutDiagnostic_ftdv_nlb_cluster.json](#) files.

Templates to deploy **with Diagnostic** Interface:

- [azure_ftdv_nlb_cluster_parameters.json](#) – Template to enter parameters for the Threat Defense Virtual cluster with NLB.
- [azure_ftdv_nlb_cluster.json](#) – Template to deploy Threat Defense Virtual cluster with NLB.

Templates to deploy **without Diagnostic** Interface:

- [azure_withoutDiagnostic_ftdv_nlb_cluster_parameters.json](#) – Template to enter parameters for the Threat Defense Virtual cluster with NLB deployment without Diagnostic interface.
- [azure_withoutDiagnostic_ftdv_nlb_cluster.json](#) – Template to deploy Threat Defense Virtual cluster with NLB without Diagnostic interface.

Prerequisites

- To allow the cluster to auto-register with the Management Center, create a user with Network Admin & Maintenance User privileges on the Management Center. Users with these privileges can use REST API. See the [Cisco Secure Firewall Management Center Administration Guide](#).
- Add an access policy in the Management Center that matches the name of the policy that you will specify during template deployment.
- Ensure that the Management Center Virtual is licensed appropriately.
- After the cluster is added to the Management Center Virtual:
 1. Configure platform settings with the health check port number in the Management Center. For more information on configuring this, see [Platform Settings](#).
 2. Create static routes for traffic from outside and inside interfaces. For more information on creating a static route, see [Add a Static Route](#).

Sample static route configuration for the outside interface:

```
Network: any-ipv4
Interface: outside
Leaked from Virtual Router: Global
Gateway: ftdv-cluster-outside
Tunneled: false
Metric: 10
```

Note *ftdv-cluster-outside* is the outside subnet's gateway IP address.

Sample static route configuration for the inside interface:

```
Network: any-ipv4
Interface: inside
Leaked from Virtual Router: Global
Gateway: ftdv-cluster-inside-gw
Tunneled: false
Metric: 11
```

Note *ftdv-cluster-inside-gw* is the inside subnet's gateway IP address.

3. Configure NAT rule for data traffic. For more information on configuring NAT rules, see [Network Address Translation](#).

Deploy Cluster on Azure with NLB Using an Azure Resource Manager Template

Deploy the cluster for Azure NLB using the customized Azure Resource Manager (ARM) template.

Procedure

Step 1

Prepare the template.

- a) Clone the github repository to your local folder. See <https://github.com/CiscoDevNet/cisco-ftdv/tree/master/cluster/azure>.
- b) Modify *azure_ftdv_nlb_cluster.json* and *azure_ftdv_nlb_cluster_parameters.json* with the required parameters.

Modify withoutDiagnostic templates, *azure_withoutDiagnostic_ftdv_nlb_cluster_parameters.json* and *azure_withoutDiagnostic_ftdv_nlb_cluster.json*, with the required parameter for deploying cluster without the diagnostic interface.

Step 2

Log into the Azure Portal: <https://portal.azure.com>.

Step 3

Create a Resource Group.

- a) In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
- b) Choose the required **Region**.

Step 4

Create a virtual network with 5 subnets: Management, Diagnostic, Inside, Outside, and Cluster Control Link.

From Secure Firewall version 7.4.1, you can deploy the cluster without the diagnostic interface. To deploy the cluster with only the Outside, Inside, Management, and Cluster Control Link interfaces, use the withoutDiagnostic templates - [azure_withoutDiagnostic_ftdv_nlb_cluster_parameters.json](#) and [azure_withoutDiagnostic_ftdv_nlb_cluster.json](#) files.

- a) Create the virtual network.
 1. In the **Basics** tab, choose the **Subscription** and **Resource Group** from the drop-down lists.
 2. b) Choose the required **Region**. Click **Next: IP addresses**.

- b) Add the subnets.

In the **IP Addresses** tab, click **Add subnet** and add the following subnets – Management, Diagnostic, Inside, Outside, and Cluster Control Link.

If you are deploying the Threat Defense Virtual 7.4.1 cluster without a Diagnostic interface, then you must skip the Diagnostic subnet creation.

Step 5

Deploy the custom template.

- a) Click **Create > Template deployment (deploy using custom templates)**.
- b) Click **Build your own template in the editor**.
- c) Click **Load File**, and upload *azure_ftdv_nlb_cluster.json* or *azure_withoutDiagnostic_ftdv_nlb_cluster.json*, if you have opted for without diagnostic interface deployment.
- d) Click **Save**.

Step 6

Configure the instance details.

- a) Enter the required values and then click **Review + create**.

Note For the cluster control link starting and ending addresses, specify only as many addresses as you need (up to 16). A larger range can affect performance.

- b) Click **Create** after the validation is passed.

- Step 7** After the instance is running, verify the cluster deployment by logging into any one of the nodes and using the **show cluster info** command.

Figure 253: show cluster info

```
> show cluster info
Cluster gwlb-cluster-template-with-AN: On
  Interface mode: individual
Cluster Member Limit : 16
  This is "12" in state CONTROL_NODE
  ID       : 0
  Version  : 99.19(1)180
  Serial No.: 9AKGFV8VH4G
  CCL IP   : 10.1.1.12
  CCL MAC  : 000d.3a55.5470
  Module   : NGFWv
  Resource : 8 cores / 28160 MB RAM
  Last join : 11:13:24 UTC Sep 5 2022
  Last leave: N/A
```

- Step 8** In the Azure Portal, click the Function app to register the cluster to the management center.

Note If you do not want to use the Function app, you can alternatively register the control node with the Management Center directly by using **Add > Device** (not **Add > Cluster**). The rest of the cluster nodes will register automatically.

- Step 9** Create FTPS Credentials by clicking **Deployment Center > FTPS credentials > User scope > Configure Username and Password**, and then click **Save**.

- Step 10** Upload the Cluster_Function.zip file to the Function app by executing the following **curl** command in the local terminal.

```
curl -X POST -u username --data-binary @"Cluster_Function.zip" https://
Function_App_Name.scm.azurewebsites.net/api/zipdeploy
```

Note The **curl** command might take a few minutes (~2 to 3 minutes) to complete command execution.

The function will be uploaded to the Function app. The function will start, and you can see the logs in the storage account's outqueue. The device registration with the Management Center will be initiated.

Deploy the Cluster in Azure Manually

To deploy the cluster manually, prepare the day0 configuration, deploy each node, and then add the control node to the management center.

Create the Day0 Configuration for Azure

You can use either a fixed configuration or a customized configuration.

Create the Day0 Configuration With a Fixed Configuration for Azure

The fixed configuration will auto-generate the cluster bootstrap configuration.

```
{
  "AdminPassword": "password",
  "FirewallMode": "Routed",
  "ManageLocally": "No",
  "Diagnostic": "OFF", //For deployment of version 7.4.1 and later without Diagnostics
```

```

template, set this parameter to OFF.
. "FmcIp": "<FMC_IP>",
  "FmcRegKey": "<REGISTRATION_KEY>",
  "FmcNatId": "<NAT_ID>",
  "Cluster": {
    "CclSubnetRange": "ip_address_start ip_address_end",
    "ClusterGroupName": "cluster_name",
    "HealthProbePort": "port_number",
    "GatewayLoadBalancerIP": "ip_address",
    "EncapsulationType": "vxlan",
    "InternalPort": "internal_port_number",
    "ExternalPort": "external_port_number",
    "InternalSegId": "internal_segment_id",
    "ExternalSegId": "external_segment_id"
  }
}

```

Example

A sample day 0 configuration is given below.

```

{
  "AdminPassword": "password",
  "FirewallMode": "routed",
  "ManageLocally": "No",
  "Diagnostic": "OFF", //For deployment of version 7.4.1 and later without Diagnostics
  template, set this parameter to OFF.
  "FmcIp": "<FMC_IP>",
  "FmcRegKey": "<REGISTRATION_KEY>",
  "FmcNatId": "<NAT_ID>",
  "Cluster": {
    "CclSubnetRange": "10.45.3.4 10.45.3.30", //mandatory user input
    "ClusterGroupName": "ngfwv-cluster", //mandatory user input
    "HealthProbePort": "7777", //mandatory user input
    "GatewayLoadBalanceIP": "10.45.2.4", //mandatory user input
    "EncapsulationType": "vxlan",
    "InternalPort": "2000",
    "ExternalPort": "2001",
    "InternalSegId": "800",
    "ExternalSegId": "801"
  }
}

```

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration

For the Azure health check settings, be sure to specify the **HealthProbePort** you set here.

For the **CclSubnetRange** variable, specify a range of IP addresses starting from x.x.x.4. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start and end IP addresses are given below.

Table 38: Examples of Start and End IP addresses

CIDR	Start IP Address	End IP Address
10.1.1.0/27	10.1.1.4	10.1.1.30
10.1.1.32/27	10.1.1.36	10.1.1.62

CIDR	Start IP Address	End IP Address
10.1.1.64/27	10.1.1.68	10.1.1.94
10.1.1.96/27	10.1.1.100	10.1.1.126
10.1.1.128/27	10.1.1.132	10.1.1.158
10.1.1.160/27	10.1.1.164	10.1.1.190
10.1.1.192/27	10.1.1.196	10.1.1.222
10.1.1.224/27	10.1.1.228	10.1.1.254

Create the Day0 Configuration With a Customized Configuration for Azure

You can enter the entire cluster bootstrap configuration using commands.

```
{
  "AdminPassword": "password",
  "FirewallMode": "Routed",
  "ManageLocally": "No",
  "Diagnostic": "OFF", //For deployment of version 7.4.1 and later without Diagnostics
  template, set this parameter to OFF.
  "FmcIp": "<FMC_IP>",
  "FmcRegKey": "<REGISTRATION_KEY>",
  "FmcNatId": "<NAT_ID>",
  "Cluster": {
    "CclSubnetRange": "ip_address_start ip_address_end",
    "ClusterGroupName": "cluster_name",
    "HealthProbePort": "port_number",
    "GatewayLoadBalancerIP": "ip_address",
    "EncapsulationType": "vxlan",
    "InternalPort": "internal_port_number",
    "ExternalPort": "external_port_number",
    "InternalSegId": "internal_segment_id",
    "ExternalSegId": "external_segment_id"
  }
}
```

Example

A sample day 0 configuration for **version 7.4 and later** is given below.

```
{
  "AdminPassword": "Sup3rnatural",
  "Hostname": "clusterftdv",
  "FirewallMode": "routed",
  "ManageLocally": "No",
  "Diagnostic": "OFF", //For deployment of version 7.4.1 and later without Diagnostics
  template, set this parameter to OFF.
  "FmcIp": "<FMC_IP>",
  "FmcRegKey": "<REGISTRATION_KEY>",
  "FmcNatId": "<NAT_ID>",
  "run_config": [
    "cluster interface-mode individual force",
    "policy-map global_policy",
    "class inspection_default",
    "no inspect h323 h225",
    "no inspect h323 ras",
    "no inspect rtsp",
  ]
}
```

```

"no inspect skinny",
"interface Management0/0",
"management-only",
"nameif management",
"security-level 0",
"ip address dhcp",
"interface GigabitEthernet0/0",
"no shutdown",
"nameif vxlan_tunnel",
"security-level 0",

"priority 1",
"enable",
"mtu vxlan_tunnel 1454",
"mtu ccl_link 1554"
]
}

```

Note If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration.

Deploy Cluster Nodes Manually - GWLB-based Deployment

Deploy the cluster nodes so they form a cluster.

Procedure

-
- Step 1** Create a Virtual Machine Scale Set from the Marketplace image with 0 instance count using the **az vmss create** CLI.
- ```
az vmss create --resource-group <ResourceGroupName> --name <VMSSName> --vm-sku <InstanceSize>
--image <FTDvImage> --instance-count 0 --admin-username <AdminUserName> --admin-password
<AdminPassword> --plan-name <ftdv-azure-byol/ftdv-azure-payg> --plan-publisher cisco --plan-product
cisco-ftdv --plan-promotion-code <ftdv-azure-byol/ftdv-azure-payg> --vnet-name <VirtualNetworkName>
--subnet <MgmtSubnetName>
```
- Step 2** Attach three interfaces—Diagnostic, Data, and Cluster Control Link.
- Step 3** Go to the virtual machine scale set you have created and perform the following steps:
- Under the **Operating system** section, add the day 0 configuration in the **customData** field.
  - Click **Save**.
  - Under the **Scaling** section, update the instance count with the required cluster node. You can set the instance count range of minimum 1 and maximum 16.
- Step 4** Configure the Azure Gateway Load Balancer. See [Auto Scale with Azure Gateway Load Balancer Use Case](#) for more information.
- Step 5** Add the control node to the management center. See [Add the Cluster to the Management Center \(Manual Deployment\)](#), on page 586.
- 

## Deploy Cluster Nodes Manually - NLB-based Deployment

Deploy the cluster nodes so they form a cluster.

### Procedure

- 
- Step 1** Create a Virtual Machine Scale Set from the Marketplace image with 0 instance count using the **az vmss create** CLI.
- ```
az vmss create --resource-group <ResourceGroupName> --name <VMSSName> --vm-sku <InstanceSize>
--image <FTDvImage> --instance-count 0 --admin-username <AdminUserName> --admin-password
<AdminPassword> --plan-name <ftdv-azure-byol/ftdv-azure-payg> --plan-publisher cisco --plan-product
cisco-ftdv --plan-promotion-code <ftdv-azure-byol/ftdv-azure-payg> --vnet-name <VirtualNetworkName>
--subnet <MgmtSubnetName>
```
- Step 2** Attach 4 interfaces—Diagnostic, Inside, Outside, and Cluster Control Link.
- Step 3** Go to the virtual machine scale set you have created and perform the following:
- Under the **Operating system** section, add the day0 configuration in the **customData** field.
 - Click **Save**.

- c) Under the **Scaling** section, update the instance count with the required cluster node. You can set the instance count range of minimum 1 and maximum 16.

Step 4 Add the control node to the Management Center. See [Add the Cluster to the Management Center \(Manual Deployment\)](#), on page 586.

Troubleshooting Cluster Deployment in Azure

- Issue: No traffic flow

Troubleshooting:

- Check if the health probe status of the Threat Defense Virtual instances deployed with a GWLB is healthy.
- If the Threat Defense Virtual instance's health probe status is unhealthy-
 - Check if the static route is configured in the Management Center Virtual.
 - Check if the default gateway is the data subnet's gateway IP.
 - Check if the Threat Defense Virtual instance is receiving health probe traffic.
 - Check if the access list configured in the Management Center Virtual allows health probe traffic.

- Issue: Cluster is not formed

Troubleshooting:

- Check the IP address of the nve-only cluster interface. Ensure that you can ping the nve-only cluster interface of other nodes.
- Check the IP address of the nve-only cluster interfaces are part of the object group.
- Ensure that the NVE interface is configured with the object group .
- Ensure that the cluster interface in the cluster group has the right VNI interface. This VNI interface has the NVE with the corresponding object group.
- Ensure that the nodes are pingable from each other. Since each node has its own cluster interface IP, these should be pingable from each other.
- Check if the CCL Subnet's Start and End Address mentioned during template deployment is correct. The start address should begin with the first available IP address in the subnet. For example, if the subnet is 192.168.1.0/24. The start address should be 192.168.1.4 (the three IP addresses at the start are reserved by Azure).
- Check if the Management Center Virtual has a valid license.

- Issue: Role-related error while deploying resources again in the same resource group.

Troubleshooting: Remove the roles given below by using the following commands on the terminal.

Error message:

```
"error": {
  "code": "RoleAssignmentUpdateNotPermitted",
  "message": "Tenant ID, application ID, principal ID, and scope are not allowed to be updated."}
```

- **az role assignment delete --resource-group <Resource Group Name> --role "Storage Queue Data Contributor"**
- **az role assignment delete --resource-group <Resource Group Name> --role "Contributor"**

Deploy the Cluster in GCP

To deploy a cluster in GCP, you can either manually deploy or use an instance template to deploy an instance group. You can use the cluster with native GCP load-balancers, or non-native load balancers such as the Cisco Cloud Services Router.

Note Outbound traffic requires interface NAT and is limited to 64K connections.

Sample Topology

This topology depicts both inbound and outbound traffic flow. The Threat Defense Virtual cluster is sandwiched between the internal and external load balancers. A Management Center Virtual instance is used to manage the cluster.

Inbound traffic from the internet goes to the external load balancer which then transmits the traffic to the Threat Defense Virtual cluster. After the traffic has been inspected by a Threat Defense Virtual instance in the cluster, it is forwarded to the application VM.

Outbound traffic from the application VM is transmitted to the internal load balancer. Traffic is then forwarded to the Threat Defense Virtual cluster and then sent out to the internet.

End-to-End Process for Deploying Threat Defense Virtual Cluster in GCP

Template-based Deployment

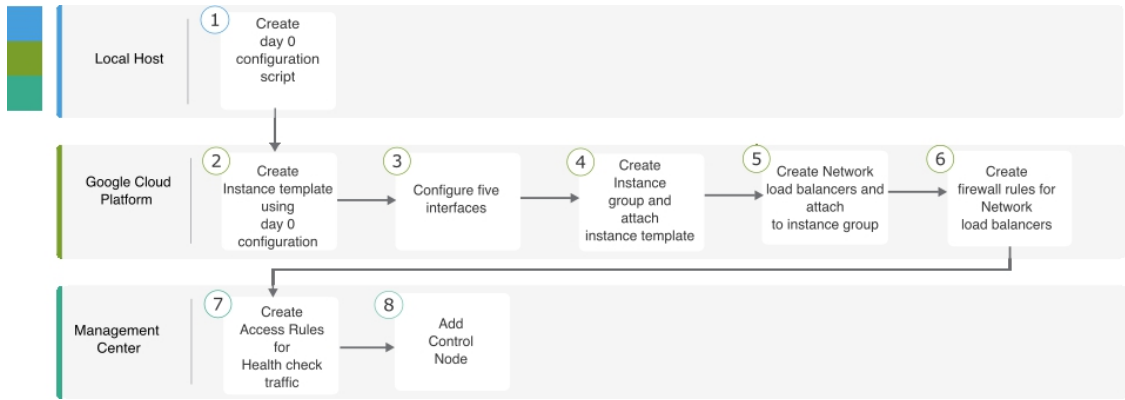

The following flowchart illustrates the workflow for template-based deployment of the Threat Defense Virtual cluster on GCP.

	Workspace	Steps
1	Local Host	Download templates and files from GitHub.
2	Local Host	Edit template parameters.
3	Google Cloud Platform	Create GCP bucket.
4	Local Host	Create Google Cloud function source archive file <i>ftdv_cluster_function.zip</i> .
5	Google Cloud Platform	Upload the Google function source archive file.
6	Google Cloud Platform	Deploy <i>infrastructure.yaml</i> .
7	Google Cloud Platform	If private IP addresses are used, create VPC connector.
8	Google Cloud Platform	If external IP addresses are used, set <i>deployWithExternalIP</i> to <i>True</i> in <i>cluster_function_infra.yaml</i> .
9	Google Cloud Platform	Deploy cluster function infrastructure template.
10	Google Cloud Platform	Deploy cluster.

Manual Deployment

The following flowchart illustrates the workflow for manual deployment of the Threat Defense Virtual cluster on GCP.

	Workspace	Steps
1	Local Host	Create the Day0 Configuration for GCP
2	Google Cloud Platform	Create instance template using day 0 configuration.
3	Google Cloud Platform	Configure the interfaces.
4	Google Cloud Platform	Create instance group and attach instance template.
5	Google Cloud Platform	Create NLB and attach to instance group.
6	Google Cloud Platform	Create firewall rules for NLB.
7	Management Center	Create access rules for health check traffic.
8	Management Center	Add control node.

Templates

The templates given below are available in GitHub. The parameter values are self-explanatory with the parameter names, and values, given in the template.

- Cluster deployment template for East-West traffic - [deploy_ngfw_cluster.yaml](#)
- Cluster deployment template for North-South traffic - [deploy_ngfw_cluster.yaml](#)

Deploy the Instance Group in GCP Using an Instance Template

Deploy the instance group in GCP using an instance template.

Before you begin

- Use Google Cloud Shell for deployment. Alternatively, you can use Google SDK on any macOS/Linux/Windows machine.
- To allow the cluster to auto-register with the Management Center, you need to create a user with administrative privileges on the Management Center that can use the REST API. See the [Cisco Secure Firewall Management Center Administration Guide](#).
- Add an access policy in the Management Center that matches the name of the policy that you specified in *cluster_function_infra.yaml*.

Procedure

-
- Step 1** Download the templates from [GitHub](#) to your local folder.
- Step 2** Edit **infrastructure.yaml**, **cluster_function_infra.yaml** and **deploy_ngfw_cluster.yaml** with the required *resourceNamePrefix* parameter (for example, ngfwcls) and other required user inputs.
- From Secure Firewall version 7.4.1, you can deploy the cluster without the diagnostic interface. To deploy the cluster with only the Outside, Inside, Management, and CCL interfaces, set the *withDiagnostic* variable to **False** in both the **infrastructure.yaml** and the **deploy_ngfw_cluster.yaml** files.
- Note that there is a **deploy_ngfw_cluster.yaml** file in both the **east-west** and **north-south** folders in GitHub. Download the appropriate template as per your traffic flow requirement.
- Step 3** Create a bucket using Google Cloud Shell to upload the Google cloud function source archive file *ftdv_cluster_function.zip*.
- ```
gsutil mb --pap enforced gs://resourceNamePrefix-ftdv-cluster-bucket/
```
- Ensure that the *resourceNamePrefix* variable here matches the *resourceNamePrefix* variable that you specified in **cluster\_function\_infra.yaml**.
- Step 4** Create an archive file for the cluster infrastructure.
- Example:**
- ```
zip -j ftdv_cluster_function.zip ./cluster-function/*
```
- Step 5** Upload the Google source archive that you created earlier.
- ```
gsutil cp ftdv_cluster_function.zip gs://resourceNamePrefix-ftdv-cluster-bucket/
```
- Step 6** Deploy infrastructure for the cluster.
- ```
gcloud deployment-manager deployments create cluster_name --config infrastructure.yaml
```
- Step 7** If you are using private IP addresses, perform the steps given below:
- Launch and set up the Management Center Virtual with a Threat Defense Virtual management VPC.
 - Create a VPC connector to connect the Google Cloud functions with the Threat Defense Virtual management VPC.
- ```
gcloud compute networks vpc-access connectors create vpc-connector-name --region us-central1 --subnet resourceNamePrefix-ftdv-mgmt-subnet28
```

**Step 8** If the Management Center is remote from the Threat Defense Virtual, and the Threat Defense Virtual needs an external IP address, ensure that you set `deployWithExternalIP` to `True` in `cluster_function_infra.yaml`.

**Step 9** Deploy the cluster function infrastructure.

```
gcloud deployment-manager deployments create cluster_name --config cluster_function_infra.yaml
```

**Step 10** Deploy the cluster.

a. For North-South topology deployment:

```
gcloud deployment-manager deployments create cluster_name --config
north-south/deploy_ngfw_cluster.yaml
```

b. For East-West topology deployment:

```
gcloud deployment-manager deployments create cluster_name --config
east-west/deploy_ngfw_cluster.yaml
```

## Deploy the Cluster in GCP Manually

To deploy the cluster manually, prepare the day0 configuration, deploy each node, and then add the control node to the management center.

### Create the Day0 Configuration for GCP

You can use either a fixed configuration or a customized configuration.

#### Create the Day0 Configuration With a Fixed Configuration for GCP

The fixed configuration will auto-generate the cluster bootstrap configuration.

```
{
 "AdminPassword": "password",
 "Hostname": "hostname",
 "FirewallMode": "Routed",
 "ManageLocally": "No",
 "Diagnostic": "OFF", //Optional user input from version 7.4.1 - use
to deploy cluster without Diagnostic interface
 "Cluster": {
 "CclSubnetRange": "ip_address_start ip_address_end",
 "ClusterGroupName": "cluster_name"
 }
}
```

For example:

```
{
 "AdminPassword": "DeanWlnche$ter",
 "Hostname": "ciscoftdv",
 "FirewallMode": "Routed",
 "ManageLocally": "No",
 "Cluster": {
 "CclSubnetRange": "10.10.55.2 10.10.55.253", //mandatory user input
 "ClusterGroupName": "ftdv-cluster" //mandatory user input
 }
}
```

**Note** If you are copying and pasting the configuration given above, ensure that you remove **//mandatory user input** from the configuration.

For the **CclSubnetRange** variable, note that you cannot use the first two IP addresses and the last two IP addresses in the subnet. See [Reserved IP addresses in IPv4 subnets](#) for more information. Ensure that you have at least 16 available IP addresses for clustering. Some examples of start and end IP addresses are given below.

**Table 39: Examples of Start and End IP addresses**

| CIDR          | Start IP Address | End IP Address |
|---------------|------------------|----------------|
| 10.1.1.0/27   | 10.1.1.2         | 10.1.1.29      |
| 10.1.1.32/27  | 10.1.1.34        | 10.1.1.61      |
| 10.1.1.64/27  | 10.1.1.66        | 10.1.1.93      |
| 10.1.1.96/27  | 10.1.1.98        | 10.1.1.125     |
| 10.1.1.128/27 | 10.1.1.130       | 10.1.1.157     |
| 10.1.1.160/27 | 10.1.1.162       | 10.1.1.189     |
| 10.1.1.192/27 | 10.1.1.194       | 10.1.1.221     |
| 10.1.1.224/27 | 10.1.1.226       | 10.1.1.253     |
| 10.1.1.0/24   | 10.1.1.2         | 10.1.1.253     |

## Create the Day0 Configuration With a Customized Configuration for GCP

You can enter the entire cluster bootstrap configuration using commands.

```
{
 "AdminPassword": "password",
 "Hostname": "hostname",
 "FirewallMode": "Routed",
 "ManageLocally": "No",
 "run_config": [comma_separated_threat_defense_configuration]
}
```

The following example creates a configuration with Management, Inside, and Outside interfaces, and a VXLAN interface for the cluster control link. Note the values in bold that need to be unique per node.

```
{
 "AdminPassword": "W1nch3sterBr0s",
 "Hostname": "ftdvl",
 "FirewallMode": "Routed",
 "ManageLocally": "No",
 "run_config": [
 "cluster interface-mode individual force",
 "interface Management0/0",
 "management-only",
 "nameif management",
]
}
```

```

 "ip address dhcp",
 "interface GigabitEthernet0/0",
 "no shutdown",
 "nameif outside",
 "ip address dhcp",
 "interface GigabitEthernet0/1",
 "no shutdown",
 "nameif inside",
 "ip address dhcp",
 "interface GigabitEthernet0/2",
 "nve-only cluster",
 "nameif ccl_link",
 "ip address dhcp",
 "no shutdown",
 "interface vni1",
 "description Clustering Interface",
 "segment-id 1",
 "vtep-nve 1",
 "object network ccl#link",
 "range 10.1.90.2 10.1.90.17",
 "object-group network cluster#group",
 "network-object object ccl#link",
 "nve 1",
 "encapsulation vxlan",
 "source-interface ccl_link",
 "peer-group cluster#group",
 "cluster group ftdv-cluster",
 "local-unit 1",
 "cluster-interface vni1 ip 10.1.1.1 255.255.255.0",
 "priority 1",
 "enable",
 "mtu outside 1400",
 "mtu inside 1400"
]
}

```

---

**Note** For the cluster control link network object, specify only as many addresses as you need (up to 16). A larger range can affect performance.

---

## Deploy Cluster Nodes Manually

Deploy the cluster nodes so they form a cluster. For clustering on GCP, you cannot use the 4 vCPU machine type. The 4 vCPU machine type only supports four interfaces, and five are needed. Use a machine type that supports five interfaces, such as c2-standard-8.

### Procedure

- 
- Step 1** Create an instance template using the day 0 configuration (in the **Metadata > Startup Script** section) with 5 interfaces: outside, inside, management, diagnostic, and cluster control link.  
See [Cisco Secure Firewall Threat Defense Virtual Getting Started Guide](#).
  - Step 2** Create an instance group, and attach the instance template.
  - Step 3** Create GCP network load balancers (internal and external), and attach the instance group.

- Step 4** For GCP network load balancers, allow health checks in your security policy on the Management Center. See [Allow Health Checks for GCP Network Load Balancers, on page 585](#).
- Step 5** Add the control node to the Management Center. See [Add the Cluster to the Management Center \(Manual Deployment\), on page 586](#).

## Allow Health Checks for GCP Network Load Balancers

Google Cloud provides health checks to determine if backends respond to traffic.

See <https://cloud.google.com/load-balancing/docs/health-checks> to create firewall rules for network load balancers. Then in the management center, create access rules to allow the health check traffic. See <https://cloud.google.com/load-balancing/docs/health-check-concepts> for the required network ranges. See [Access Control Rules, on page 1653](#).

You also need to configure dynamic manual NAT rules to redirect the health check traffic to the Google metadata server at 169.254.169.254. See [Configure Dynamic Manual NAT, on page 955](#).

### North-South NAT Rules Sample Configuration

```

nat (inside,outside) source dynamic GCP-HC ILB-SOUTH destination static ILB-SOUTH METADATA
nat (outside,outside) source dynamic GCP-HC ELB-NORTH destination static ELB-NORTH METADATA

nat (outside,inside) source static any interface destination static ELB-NORTH Ubuntu-App-VM
nat (inside,outside) source dynamic any interface destination static obj-any obj-any

object network Metadata
 host 169.254.169.254

object network ILB-SOUTH
 host <ILB_IP>
object network ELB-NORTH
 host <ELB_IP>

object-group network GCP-HC
 network-object 35.191.0.0 255.255.0.0
 network-object 130.211.0.0 255.255.252.0
 network-object 209.85.204.0 255.255.252.0
 network-object 209.85.152.0 255.255.252.0

```

| # | Direction | Type   | Source Interface Objects | Destination Interface Objects | Original Sources | Original Destinations | Original Services                 | Translated Sources | Translated Destinations | Translated Services | Options    |
|---|-----------|--------|--------------------------|-------------------------------|------------------|-----------------------|-----------------------------------|--------------------|-------------------------|---------------------|------------|
| 1 | ↔         | Dyn... | inside                   | outside                       | GCP-HC           | ILB-SOUTH             | ILB Health Check NAT rule         | ILB-SOUTH          | METADATA                |                     | Dns: false |
| 2 | ↔         | Dyn... | outside                  | outside                       | GCP-HC           | ELB-NORTH             |                                   | ELB-NORTH          | METADATA                |                     | Dns: false |

## Add the Cluster to the Management Center (Manual Deployment)

Use this procedure to add the cluster to the management center if you manually deployed the cluster. If you used a template, the cluster will auto-register on the management center.

Add one of the cluster units as a new device to the management center; the management center auto-detects all other cluster members.

### Before you begin

- All cluster units must be in a successfully-formed cluster prior to adding the cluster to the management center. You should also check which unit is the control unit. Use the threat defense **show cluster info** command.

### Procedure

- Step 1** In the management center, choose **Devices > Device Management**, and then choose **Add > Add Device** to add the control unit using the unit's management IP address.

Figure 254: Add Device

Add Device
?

---

CDO Managed Device

Host:†

Display Name:

Registration Key:\*\br/>

Group:

Access Control Policy:\*\br/>

**Smart Licensing**  
 Note: All virtual Firewall Threat Defense devices require a performance tier license. Make sure your Smart Licensing account contains the available licenses you need. It's important to choose the tier that matches the license you have in your account. Click [here](#) for information about the Firewall Threat Defense performance-tiered licensing. Until you choose a tier, your Firewall Threat Defense virtual defaults to the FTDv50 selection.

Performance Tier (only for Firewall Threat Defense virtual 7.0 and above):

Malware  
 Threat  
 URL Filtering

Advanced

Unique NAT ID:†

Transfer Packets

- a) In the **Host** field, enter the IP address or hostname of the control unit.

We recommend adding the control unit for the best performance, but you can add any unit of the cluster.

If you used a NAT ID during device setup, you may not need to enter this field. For more information, see [NAT Environments, on page 7](#).

- b) In the **Display Name** field, enter a name for the control unit as you want it to display in the management center.

This display name is not for the cluster; it is only for the control unit you are adding. You can later change the name of other cluster members and the cluster display name.

- c) In the **Registration Key** field, enter the same registration key that you used during device setup. The registration key is a one-time-use shared secret.
- d) (Optional) Add the device to a device **Group**.
- e) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.  
If you create a new policy, you create a basic policy only. You can later customize the policy as needed.

**New Policy**

Name:

Description:

Select Base Policy:

Default Action:  
 Block all traffic  
 Intrusion Prevention  
 Network Discovery

Snort3:

- f) Choose licenses to apply to the device.
- g) If you used a NAT ID during device setup, expand the **Advanced** section and enter the same NAT ID in the **Unique NAT ID** field.
- h) Check the **Transfer Packets** check box to allow the device to transfer packets to the management center.

This option is enabled by default. When events like IPS or Snort are triggered with this option enabled, the device sends event metadata information and packet data to the management center for inspection. If you disable it, only event information will be sent to the management center but packet data is not sent.

- i) Click **Register**.

The management center identifies and registers the control unit, and then registers all data units. If the control unit does not successfully register, then the cluster is not added. A registration failure can occur if the cluster was not up, or because of other connectivity issues. In this case, we recommend that you try re-adding the cluster unit.

The cluster name shows on the **Devices > Device Management** page; expand the cluster to see the cluster units.

**Figure 255: Cluster Management**

| Cluster                   | Unit                                                 | Model           | Version | Status | Policy                                        |
|---------------------------|------------------------------------------------------|-----------------|---------|--------|-----------------------------------------------|
| ftdcluster (2)<br>Cluster | 172.16.0.50(Control) Snort 3<br>172.16.0.50 - Routed | FTDv for VMware | 7.2.0   | Manage | Base, Threat (2 more...)<br>Default AC Policy |
|                           | 172.16.0.51 Snort 3<br>172.16.0.51 - Routed          | FTDv for VMware | 7.2.0   | N/A    | Base, Threat (2 more...)<br>Default AC Policy |

A unit that is currently registering shows the loading icon.

Figure 256: Node Registration

You can monitor cluster unit registration by clicking the **Notifications** icon and choosing **Tasks**. The management center updates the Cluster Registration task as each unit registers. If any units fail to register, see [Reconcile Cluster Nodes, on page 598](#).

**Step 2** Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not nodes in the cluster. For example, you can change the display name per node, but you can only configure interfaces for the whole cluster.

**Step 3** On the **Devices > Device Management > Cluster** screen, you see **General**, **License**, **System**, and **Health** settings.

See the following cluster-specific items:

- **General > Name**—Change the cluster display name by clicking the **Edit** (✎).

| General  |                                                                                     |
|---------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------|
| Name:      | TD_Cluster                                                                          |
| Transfer Packets:                                                                           | Yes                                                                                 |
| Status:                                                                                     |  |
| Control:                                                                                    | 10.10.1.13                                                                          |
| Cluster Live Status:                                                                        | <a href="#">View</a>                                                                |

Then set the **Name** field.

| General  |                                                |
|--------------------------------------------------------------------------------------------|------------------------------------------------|
| Name:                                                                                      | <input type="text" value="TD Native Cluster"/> |
| Transfer Packets:                                                                          | <input type="checkbox"/>                       |
| Compliance Mode:                                                                           |                                                |
| Performance Profile:                                                                       |                                                |
| TLS Crypto Acceleration:                                                                   |                                                |
| Force Deploy:                                                                              | <a href="#">→</a>                              |
| <input type="button" value="Cancel"/> <input type="button" value="Save"/>                  |                                                |

- **General > Cluster Live Status**—Click the **View** link to open the **Cluster Status** dialog box.

Cluster    Device    Routing    Interfaces    Inline Sets    DHCP    VTEP

---

**General** 

Name:  TD Native Cluster

Transfer Packets: Yes

Status: 

Control: 10.10.1.13

Cluster Live Status: 

The **Cluster Status** dialog box also lets you retry data unit registration by clicking **Reconcile**. You can also ping the cluster control link from a node. See [Perform a Ping on the Cluster Control Link, on page 607](#).

Cluster Status

- **License**—Click **Edit** (✎) to set license entitlements.

**Step 4** On the **Devices > Device Management > Devices**, you can choose each member in the cluster from the top right drop-down menu and configure the following settings.

- **General > Name**—Change the cluster member display name by clicking the **Edit** (✎).

| General                  |            | ✎ ⬆ ⬇ ⬆ |
|--------------------------|------------|---------|
| Name:                    | 10.89.5.21 |         |
| Transfer Packets:        | Yes        |         |
| Mode:                    | routed     |         |
| Compliance Mode:         | None       |         |
| TLS Crypto Acceleration: | Enabled    |         |

Then set the **Name** field.

| General                                                                   |                                         | ? |
|---------------------------------------------------------------------------|-----------------------------------------|---|
| Name:                                                                     | <input type="text" value="10.10.1.13"/> |   |
| Transfer Packets:                                                         | <input checked="" type="checkbox"/>     |   |
| Mode:                                                                     | routed                                  |   |
| Compliance Mode:                                                          | None                                    |   |
| Performance Profile:                                                      | Default                                 |   |
| TLS Crypto Acceleration:                                                  | Disabled                                |   |
| Force Deploy:                                                             | →                                       |   |
| <input type="button" value="Cancel"/> <input type="button" value="Save"/> |                                         |   |

- **Management > Host**—If you change the management IP address in the device configuration, you must match the new address in the management center so that it can reach the device on the network; edit the **Host** address in the **Management** area.

## Configure Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

**Figure 258: Cluster Health Monitor Settings**

The screenshot shows the 'Cluster Health Monitor Settings' configuration page. It is divided into three sections: Timeouts, Monitored Interfaces, and Auto-Rejoin Settings.

| Cluster Health Monitor Settings |          |                           |                    |
|---------------------------------|----------|---------------------------|--------------------|
| <b>Timeouts</b>                 |          |                           |                    |
| Hold Time                       |          |                           | 3 s                |
| Interface Debounce Time         |          |                           | 9000 ms            |
| <b>Monitored Interfaces</b>     |          |                           |                    |
| Service Application             |          |                           | Enabled            |
| Unmonitored Interfaces          |          |                           | None               |
| <b>Auto-Rejoin Settings</b>     |          |                           |                    |
|                                 | Attempts | Interval Between Attempts | Interval Variation |
| Cluster Interface               | -1       | 5                         | 1                  |
| Data Interface                  | 3        | 5                         | 2                  |
| System                          | 3        | 5                         | 2                  |

**Table 40: Cluster Health Monitor Settings Section Table Fields**

| Field           | Description                                                                                                                                                                                                                                                                                                                   |
|-----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Timeouts</b> |                                                                                                                                                                                                                                                                                                                               |
| Hold Time       | Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead. |

| Field                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Interface Debounce Time          | Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.                                                                                                                                                                                                                                          |
| <b>Monitored Interfaces</b>      | The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. |
| Service Application              | Shows whether the Snort and disk-full processes are monitored.                                                                                                                                                                                                                                                                                                                                                                            |
| Unmonitored Interfaces           | Shows unmonitored interfaces.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Auto-Rejoin Settings</b>      |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Cluster Interface                | Shows the auto-rejoin settings after a cluster control link failure.                                                                                                                                                                                                                                                                                                                                                                      |
| <i>Attempts</i>                  | Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.                                                                                                                                                                                                                                                                                                                                                  |
| <i>Interval Between Attempts</i> | Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.                                                                                                                                                                                                                                                                                                                             |
| <i>Interval Variation</i>        | Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.                                                                                                                                                                                                                                                                                                                     |
| Data Interfaces                  | Shows the auto-rejoin settings after a data interface failure.                                                                                                                                                                                                                                                                                                                                                                            |
| <i>Attempts</i>                  | Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.                                                                                                                                                                                                                                                                                                                                                               |
| <i>Interval Between Attempts</i> | Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.                                                                                                                                                                                                                                                                                                                             |
| <i>Interval Variation</i>        | Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.                                                                                                                                                                                                                                                                                                                     |
| System                           | Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.                                                                                                                                                                                                                                                                                  |
| <i>Attempts</i>                  | Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.                                                                                                                                                                                                                                                                                                                                                               |
| <i>Interval Between Attempts</i> | Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.                                                                                                                                                                                                                                                                                                                             |
| <i>Interval Variation</i>        | Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.                                                                                                                                                                                                                                                                                                                     |

**Note** If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

### Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the cluster you want to modify, click **Edit** (✎).
- Step 3** Click **Cluster**.
- Step 4** In the **Cluster Health Monitor Settings** section, click **Edit** (✎).
- Step 5** Disable the system health check by clicking the **Health Check** slider.

*Figure 259: Disable the System Health Check*

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

- Step 6** Configure the hold time and interface debounce time.
  - **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
  - **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce

time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

**Step 7** Customize the auto-rejoin cluster settings after a health check failure.

**Figure 260: Configure Auto-Rejoin Settings**

▼ Auto-Rejoin Settings

---

**Cluster Interface**

Attempts  Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts  Range: 2-60 minutes between rejoin attempts

Interval Variation  Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

**Data Interface**

Attempts  Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts  Range: 2-60 minutes between rejoin attempts

Interval Variation  Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

**System**

Attempts  Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts  Range: 2-60 minutes between rejoin attempts

Interval Variation  Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

**Step 8** Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

**Figure 261: Configure Monitored Interfaces**

▼ Monitored Interfaces

Monitored Interfaces

- GigabitEthernet0/0
- GigabitEthernet0/1
- GigabitEthernet0/2
- GigabitEthernet0/3
- GigabitEthernet0/4
- GigabitEthernet0/5
- GigabitEthernet0/6
- GigabitEthernet0/7
- Diagnostic0/0

Add

Unmonitored Interfaces 0

Enable Service Application Monitoring

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

**Step 9** Click **Save**.

**Step 10** Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

## Manage Cluster Nodes

### Disable Clustering

You may want to deactivate a node in preparation for deleting the node, or temporarily for maintenance. This procedure is meant to temporarily deactivate a node; the node will still appear in the management center device list. When a node becomes inactive, all data interfaces are shut down.

**Note** Do not power off the node without first disabling clustering.

**Procedure**

- Step 1** For the unit you want to disable, choose **Devices > Device Management**, click the **More** (⋮), and choose **Disable Node Clustering**.
- Step 2** Confirm that you want to disable clustering on the node.  
The node will show **(Disabled)** next to its name in the **Devices > Device Management** list.
- Step 3** To reenable clustering, see [Rejoin the Cluster, on page 598](#).

## Rejoin the Cluster

If a node was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. See [Rejoining the Cluster, on page 615](#) for more information about why a node can be removed from a cluster.

**Procedure**

- Step 1** For the unit you want to reactivate, choose **Devices > Device Management**, click the **More** (⋮), and choose **Enable Node Clustering**.
- Step 2** Confirm that you want to enable clustering on the node.

## Reconcile Cluster Nodes

If a cluster node fails to register, you can reconcile the cluster membership from the device to the management center. For example, a data node might fail to register if the management center is occupied with certain processes, or if there is a network issue.

**Procedure**

- Step 1** Choose **Devices > Device Management > More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.
- Step 2** Click **Reconcile All**.

Figure 262: Reconcile All

For more information about the cluster status, see [Monitoring the Cluster, on page 600](#).

## Unregister the Cluster or Nodes and Register to a New Management Center

You can unregister the cluster from the management center, which keeps the cluster intact. You might want to unregister the cluster if you want to add the cluster to a new management center.

You can also unregister a node from the management center without breaking the node from the cluster. Although the node is not visible in the management center, it is still part of the cluster, and it will continue to pass traffic and could even become the control node. You cannot unregister the current control node. You might want to unregister the node if it is no longer reachable from the management center, but you still want to keep it as part of the cluster while you troubleshoot management connectivity.

Unregistering a cluster:

- Severs all communication between the management center and the cluster.
- Removes the cluster from the **Device Management** page.
- Returns the cluster to local time management if the cluster's platform settings policy is configured to receive time from the management center using NTP.
- Leaves the configuration intact, so the cluster continues to process traffic.

Policies, such as NAT and VPN, ACLs, and the interface configurations remain intact.

Registering the cluster again to the same or a different management center causes the configuration to be removed, so the cluster will stop processing traffic at that point; the cluster configuration remains intact so

you can add the cluster as a whole. You can choose an access control policy at registration, but you will have to re-apply other policies after registration and then deploy the configuration before it will process traffic again.

### Before you begin

This procedure requires CLI access to one of the nodes.

### Procedure

---

- Step 1** Choose **Devices > Device Management**, click **More** (⋮) for the cluster or node, and choose **Unregister**.
- Step 2** You are prompted to unregister the cluster or node; click **Yes**.
- Step 3** You can register the cluster to a new (or the same) management center by adding one of the cluster members as a new device.
- You only need to add one of the cluster nodes as a device, and the rest of the cluster nodes will be discovered.
- Connect to one cluster node's CLI, and identify the new management center using the **configure manager add** command.
  - Choose **Devices > Device Management**, and then click **Add Device**.
- Step 4** To re-add a deleted node, see [Reconcile Cluster Nodes, on page 598](#).
- 

## Monitoring the Cluster

You can monitor the cluster in the management center and at the threat defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices > Device Management > More** (⋮) icon or from the **Devices > Device Management > Cluster** page > **General** area > **Cluster Live Status** link.

Figure 263: Cluster Status

Dated: 11:52:26 | 20 Dec 2021

The Control node has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- In Sync.—The node is registered with the management center.
- Pending Registration—The node is part of the cluster, but has not yet registered with the management center. If a node fails to register, you can retry registration by clicking **Reconcile All**.
- Clustering is disabled—The node is registered with the management center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the node from the cluster.
- Joining cluster...—The node is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the management center.

For each node, you can view the **Summary** or the **History**.

Figure 264: Node Summary

- **System** (⚙) > **Tasks** page.

The **Tasks** page shows updates of the Cluster Registration task as each node registers.

- **Devices** > **Device Management** > *cluster\_name*.

When you expand the cluster on the devices listing page, you can see all member nodes, including the control node shown with its role next to the IP address. For nodes that are still registering, you can see the loading icon.

- **show cluster** {*access-list [acl\_name]* | *conn [count]* | *cpu [usage]* | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [*auto-join* | *clients* | *conn-distribution* | **flow-mobility counters** | *goid [options]* | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | *trace [options]* | **transport** { *asp* | *cp* }]

To view cluster information, use the **show cluster info** command.

# Cluster Health Monitor Dashboard

## Cluster Health Monitor

When a threat defense is the control node of a cluster, the management center collects various metrics periodically from the device metric data collector. The cluster health monitor is comprised of the following components:

- Overview dashboard—Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the management center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

---

**Note** The CPU and memory metrics display the individual average of the data plane and snort usage.

---

- The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.
- Load Distribution dashboard—Displays load distribution across the cluster nodes in two widgets:
  - The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
  - The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.
- Member Performance dashboard—Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard—Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range—An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard—Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

## Viewing Cluster Health

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

### Before you begin

- Ensure you have created a cluster from one or more devices in the management center.

### Procedure

---

**Step 1** Choose **System** (⚙) > **Health** > **Monitor**.

Use the Monitoring navigation pane to access node-specific health monitors.

**Step 2** In the device list, click **Expand** (➤) and **Collapse** (▼) to expand and collapse the list of managed cluster devices.

**Step 3** To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
- Load Distribution — Traffic and packet distribution across the cluster nodes.
- Member Performance — Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL — Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, see [Cisco Secure Firewall Threat Defense Health Metrics](#).

**Step 4** You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

**Step 5** Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range.

The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

**Step 6** (For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

- Step 7** (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:
- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
  - CPU — CPU utilization, including the CPU usage by process and by physical cores.
  - Memory — Device memory utilization, including data plane and Snort memory usage.
  - Interfaces — Interface status and aggregate traffic statistics.
  - Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
  - Snort — Statistics that are related to the Snort process.
  - ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See [Cisco Secure Firewall Threat Defense Health Metrics](#) for a comprehensive list of the supported device metrics.

- Step 8** Click the plus sign (+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

## Cluster Metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

**Table 41: Cluster Metrics**

| Metric           | Description                                                                                  | Format     |
|------------------|----------------------------------------------------------------------------------------------|------------|
| CPU              | Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).    | percentage |
| Memory           | Average of memory metrics on the nodes of a cluster (individually for data plane and snort). | percentage |
| Data Throughput  | Incoming and outgoing data traffic statistics for a cluster.                                 | bytes      |
| CCL Throughput   | Incoming and outgoing CCL traffic statistics for a cluster.                                  | bytes      |
| Connections      | Count of active connections in a cluster.                                                    | number     |
| NAT Translations | Count of NAT translations for a cluster.                                                     | number     |
| Distribution     | Connection distribution count in the cluster for every second.                               | number     |

| Metric  | Description                                                | Format |
|---------|------------------------------------------------------------|--------|
| Packets | Packet distribution count in the cluster for every second. | number |

## Troubleshooting the Cluster

You can use the **CCL Ping** tool to make sure the cluster control link is operating correctly. You can also use the following tools that are available for devices and clusters:

- Troubleshooting files—If a node fails to join the cluster, a troubleshooting file is automatically generated. You can also generate and download troubleshooting files from the **Devices > Device Management > Cluster > General** area. See [Generate Troubleshooting Files, on page 42](#).

You can also generate files from the **Device Management** page by clicking **More** (☰) and choosing **Troubleshoot Files**.

- CLI output—From the **Devices > Device Management > Cluster > General** area, you can view a set of pre-defined CLI outputs that can help you troubleshoot the cluster. The following commands are automatically run for the cluster:

- **show running-config cluster**
- **show cluster info**
- **show cluster info health**
- **show cluster info transport cp**
- **show version**
- **show asp drop**
- **show counters**
- **show arp**
- **show int ip brief**
- **show blocks**
- **show cpu detailed**
- **show interface *ccl\_interface***
- **ping *ccl\_ip* size *ccl\_mtu* repeat 2**

You can also enter any **show** command in the Command field. See [View CLI Output, on page 45](#) for more information.

# Perform a Ping on the Cluster Control Link

You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.

## Procedure

**Step 1** Choose **Devices > Device Management**, click the **More** (⋮) icon next to the cluster, and choose **> Cluster Live Status**.

*Figure 266: Cluster Status*

Cluster Status ?

Overall Status: ✔ Cluster has all nodes in sync

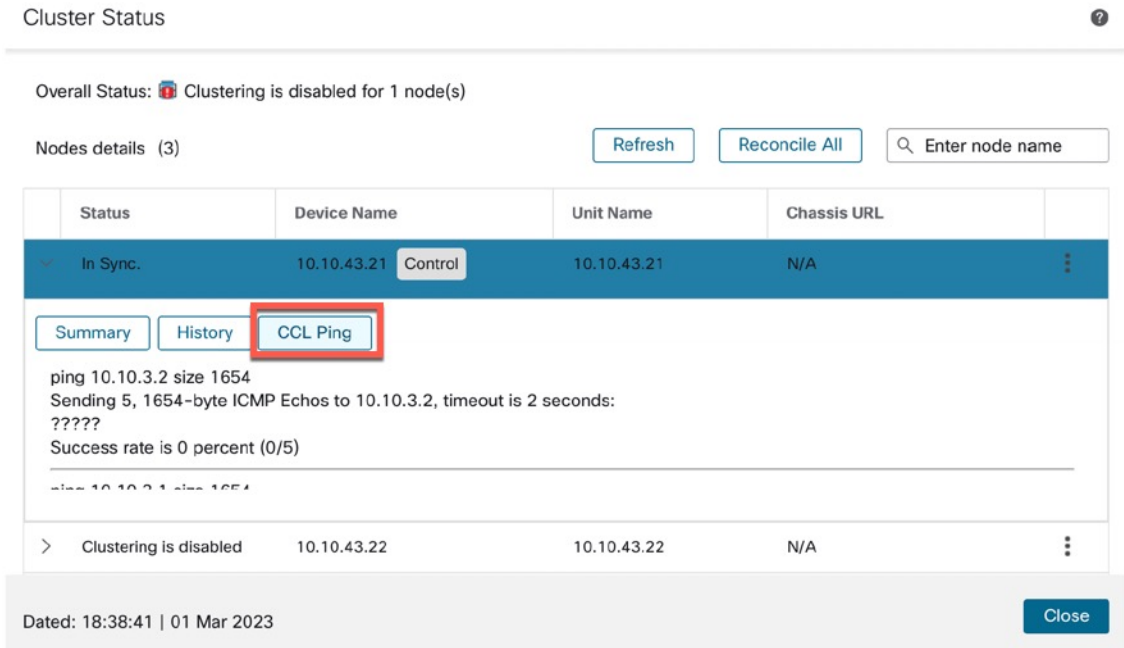

Nodes details (2) Refresh Reconcile All

|   | Status   | Device Name                                                                    | Unit Name   | Chassis URL |   |
|---|----------|--------------------------------------------------------------------------------|-------------|-------------|---|
| > | In Sync. | 172.16.0.50 <span style="background-color: #ccc; padding: 2px;">Control</span> | 172.16.0.50 | N/A         | ⋮ |
| > | In Sync. | 172.16.0.51                                                                    | 172.16.0.51 | N/A         | ⋮ |

Dated: 11:52:26 | 20 Dec 2021 Close

**Step 2** Expand one of the nodes, and click **CCL Ping**.

Figure 267: CCL Ping

The node sends a ping on the cluster control link to every other node using a packet size that matches the maximum MTU.

# Upgrading the Cluster

Perform the following steps to upgrade a threat defense virtual cluster:

### Procedure

- Step 1** Upload the target image version to the cloud image storage.
  - Step 2** Update the cloud instance template of the cluster with the updated target image version.
    - a) Create a copy of the instance template with the target image version.
    - b) Attach the newly created template to cluster instance group.
  - Step 3** Upload the target image version upgrade package to the management center.
  - Step 4** Perform readiness check on the cluster that you want to upgrade.
  - Step 5** After successful readiness check, initiate installation of upgrade package.
  - Step 6** The management center upgrades the cluster nodes one at a time.
  - Step 7** The management center displays a notification after successful upgrade of the cluster.
- There is no change in the serial number and UUID of the instance after the upgrade.

- Note**
- If you initiate the cluster upgrade from the management center, ensure that no threat defense virtual device is accidentally terminated or replaced by the auto scaling group during the post-upgrade reboot process. To prevent this, go to the AWS console, click **Auto scaling group** -> **Advanced configurations**, and suspend the processes - Health Check and Replace Unhealthy. After the upgrade is completed, go to **Advanced configurations** again and remove any suspended processes to detect unhealthy instances.
  - If you upgrade a cluster deployed on AWS from a major release to a patch release and then scale up the cluster, the new nodes will come up with the major release version instead of the patch release. You have to then manually upgrade each node to the patch release from the management center.

Alternatively, you can also create an Amazon Machine Image (AMI) from a snapshot of a standalone threat defense virtual instance on which the patch has been applied and which does not have a day 0 configuration. Use this AMI in the cluster deployment template. Any new nodes that come up when you scale up the cluster will have the patch release.

---

## Reference for Clustering

This section includes more information about how clustering operates.

### Threat Defense Features and Clustering

Some threat defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

### Unsupported Features and Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

---

**Note** To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2553](#).

---

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Management Center UCAPL/CC mode

## Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

---

**Note** Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

---

---

**Note** To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2553](#).

---

• The following application inspections:

- DCERPC
- ESMTTP
- NetBIOS
- PPTP
- RSH
- SQLNET
- SUNRPC
- TFTP
- XDMCP

• Static route monitoring

## Cisco Trustsec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

## Connection Settings and Clustering

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the

cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

## Dynamic Routing and Clustering

In Individual interface mode, each node runs the routing protocol as a standalone router, and routes are learned by each node independently.

**Figure 268: Dynamic Routing in Individual Interface Mode**

In the above diagram, Router A learns that there are 4 equal-cost paths to Router B, each through a node. ECMP is used to load balance traffic between the 4 paths. Each node picks a different router ID when talking to external routers.

You must configure a cluster pool for the router ID so that each node has a separate router ID.

## FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

## NAT and Clustering

For NAT usage, see the following limitations.

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different threat defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the threat defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- **No Proxy ARP**—For Individual interfaces, a proxy ARP reply is never sent for mapped addresses. This prevents the adjacent router from maintaining a peer relationship with an ASA that may no longer be in the cluster. The upstream router needs a static route or PBR with Object Tracking for the mapped addresses that points to the Main cluster IP address.
- **PAT with Port Block Allocation**—See the following guidelines for this feature:
  - **Maximum-per-host limit** is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - **Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.**
  - **On-the-fly PAT rule modifications**, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - **When operating in a cluster, you cannot simply change the block allocation size.** The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- **NAT pool address distribution for dynamic PAT**—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.
- **Reusing a PAT pool in multiple rules**—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- **No round-robin**—Round-robin for a PAT pool is not supported with clustering.
- **No extended PAT**—Extended PAT is not supported with clustering.

- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

## SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

## SNMP and Clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

## Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

## VPN and Clustering

Site-to-site VPN is a centralized feature; only the control node supports VPN connections.

---

**Note** Remote access VPN is not supported with clustering.

---

VPN functionality is limited to the control node and does not take advantage of the cluster high availability capabilities. If the control node fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control node is elected, you must reestablish the VPN connections.

For connections to an Individual interface when using PBR or ECMP, you must always connect to the Main cluster IP address, not a Local address.

VPN-related keys and certificates are replicated to all nodes.

## Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, if your model can handle approximately 10 Gbps of traffic when running alone, then for a cluster of 8 units, the maximum combined throughput will be approximately 80% of 80 Gbps (8 units x 10 Gbps): 64 Gbps.

## Control Node Election

Nodes of the cluster communicate over the cluster control link to elect a control node as follows:

1. When you enable clustering for a node (or when it first starts up with clustering already enabled), it broadcasts an election request every 3 seconds.
2. Any other nodes with a higher priority respond to the election request; the priority is set between 1 and 100, where 1 is the highest priority.
3. If after 45 seconds, a node does not receive a response from another node with a higher priority, then it becomes the control node.

---

**Note** If multiple nodes tie for the highest priority, the cluster node name and then the serial number is used to determine the control node.

---

4. If a node later joins the cluster with a higher priority, it does not automatically become the control node; the existing control node always remains as the control node unless it stops responding, at which point a new control node is elected.
5. In a "split brain" scenario when there are temporarily multiple control nodes, then the node with highest priority retains the role while the other nodes return to data node roles.

---

**Note** You can manually force a node to become the control node. For centralized features, if you force a control node change, then all connections are dropped, and you have to re-establish the connections on the new control node.

---

## High Availability within the Cluster

Clustering provides high availability by monitoring node and interface health and by replicating connection states between nodes.

### Node Health Monitoring

Each node periodically sends a broadcast heartbeat packet over the cluster control link. If the control node does not receive any heartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining nodes.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role.

### Interface Monitoring

Each node monitors the link status of all named hardware interfaces in use, and reports status changes to the control node.

All physical interfaces are monitored; only named interfaces can be monitored. You can optionally disable monitoring per interface.

A node is removed from the cluster if its monitored interfaces fail. The node is removed after 500 ms.

### Status After Failure

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The Threat Defense automatically tries to rejoin the cluster, depending on the failure event.

---

**Note** When the Threat Defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

---

### Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The threat defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The threat defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the threat defense application

disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.

- **Failed node**—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The threat defense application attempts to rejoin the cluster every 5 seconds.
- **Internal error**—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- **Failed configuration deployment**—If you deploy a new configuration from management center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.

## Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

**Table 42: Features Replicated Across the Cluster**

| Traffic                | State Support | Notes                              |
|------------------------|---------------|------------------------------------|
| Up time                | Yes           | Keeps track of the system up time. |
| ARP Table              | Yes           | —                                  |
| MAC address table      | Yes           | —                                  |
| User Identity          | Yes           | —                                  |
| IPv6 Neighbor database | Yes           | —                                  |
| Dynamic routing        | Yes           | —                                  |
| SNMP Engine ID         | No            | —                                  |

## How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

### Connection Roles

See the following roles defined for each connection:

- **Owner**—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- **Backup owner**—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- **Director**—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

ICMP/ICMPv6 hash details:

- For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- **Forwarder**—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

---

**Note** We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

---

- **Fragment Owner**—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be

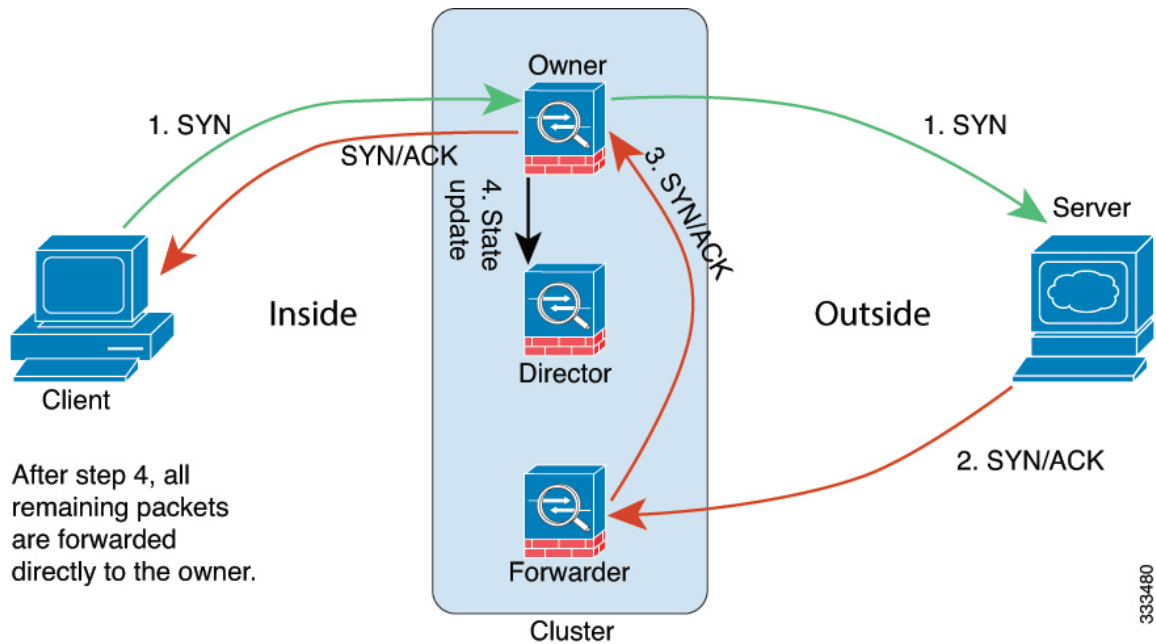

load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

## New Connection Ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

## Sample Data Flow for TCP

The following example shows the establishment of a new connection.

1. The SYN packet originates from the client and is delivered to one threat defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different threat defense (based on the load balancing method). This threat defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.

5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

## Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

### 1. Figure 269: ICMP and UDP Data Flow

The first UDP packet originates from the client and is delivered to one threat defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.

7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

# CHAPTER 13

## Clustering for the Firepower 4100/9300

Clustering lets you group multiple threat defense nodes together as a single logical device. A cluster provides all the convenience of a single device (management, integration into a network) while achieving the increased throughput and redundancy of multiple devices.

**Note** Some features are not supported when using clustering. See [Unsupported Features with Clustering, on page 677](#).

## About Clustering on the Firepower 4100/9300 Chassis

When you deploy a cluster on the Firepower 4100/9300 chassis, it does the following:

- For native instance clustering: Creates a *cluster-control link* (by default, port-channel 48) for node-to-node communication.

For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

For a cluster isolated to security modules within one Firepower 9300 chassis, this link utilizes the Firepower 9300 backplane for cluster communications.

For clustering with multiple chassis, you need to manually assign physical interface(s) to this EtherChannel for communications between chassis.

- Creates the cluster bootstrap configuration within the application.

When you deploy the cluster, the chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

- Assigns data interfaces to the cluster as *Spanned* interfaces.

For a cluster isolated to security modules within one Firepower 9300 chassis, spanned interfaces are not limited to EtherChannels, like it is for clustering with multiple chassis. The Firepower 9300 supervisor uses EtherChannel technology internally to load-balance traffic to multiple modules on a shared interface, so any data interface type works for Spanned mode. For clustering with multiple chassis, you must use Spanned EtherChannels for all data interfaces.

---

**Note** Individual interfaces are not supported, with the exception of a management interface.

---

- Assigns a management interface to all units in the cluster.

See the following sections for more information about clustering.

## Bootstrap Configuration

When you deploy the cluster, the Firepower 4100/9300 chassis supervisor pushes a minimal bootstrap configuration to each unit that includes the cluster name, cluster control link interface, and other cluster settings.

## Cluster Members

Cluster members work together to accomplish the sharing of the security policy and traffic flows.

One member of the cluster is the **control** unit. The control unit is determined automatically. All other members are **data** units.

You must perform all configuration on the control unit only; the configuration is then replicated to the data units.

Some features do not scale in a cluster, and the control unit handles all traffic for those features. .

## Cluster Control Link

For native instance clustering: The cluster control link is automatically created using the Port-channel 48 interface.

For multi-instance clustering: You should pre-configure subinterfaces on one or more cluster-type EtherChannels; each instance needs its own cluster control link.

For a cluster isolated to security modules within one Firepower 9300 chassis, this interface has no member interfaces. This Cluster type EtherChannel utilizes the Firepower 9300 backplane for cluster communications. For clustering with multiple chassis, you must add one or more interfaces to the EtherChannel.

For a cluster with two chassis, do not directly connect the cluster control link from one chassis to the other chassis. If you directly connect the interfaces, then when one unit fails, the cluster control link fails, and thus

the remaining healthy unit fails. If you connect the cluster control link through a switch, then the cluster control link remains up for the healthy unit.

Cluster control link traffic includes both control and data traffic.

## Size the Cluster Control Link

If possible, you should size the cluster control link to match the expected throughput of each chassis so the cluster control link can handle the worst-case scenarios.

Cluster control link traffic is comprised mainly of state update and forwarded packets. The amount of traffic at any given time on the cluster control link varies. The amount of forwarded traffic depends on the load-balancing efficacy or whether there is a lot of traffic for centralized features. For example:

- NAT results in poor load balancing of connections, and the need to rebalance all returning traffic to the correct units.
- When membership changes, the cluster needs to rebalance a large number of connections, thus temporarily using a large amount of cluster control link bandwidth.

A higher-bandwidth cluster control link helps the cluster to converge faster when there are membership changes and prevents throughput bottlenecks.

**Note** If your cluster has large amounts of asymmetric (rebalanced) traffic, then you should increase the cluster control link size.

## Cluster Control Link Redundancy

The following diagram shows how to use an EtherChannel as a cluster control link in a Virtual Switching System (VSS), Virtual Port Channel (vPC), StackWise, or StackWise Virtual environment. All links in the EtherChannel are active. When the switch is part of a redundant system, then you can connect firewall interfaces within the same EtherChannel to separate switches in the redundant system. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch. Note that this EtherChannel is device-local, not a Spanned EtherChannel.

## Cluster Control Link Reliability for Inter-Chassis Clustering

To ensure cluster control link functionality, be sure the round-trip time (RTT) between units is less than 20 ms. This maximum latency enhances compatibility with cluster members installed at different geographical sites. To check your latency, perform a ping on the cluster control link between units.

The cluster control link must be reliable, with no out-of-order or dropped packets; for example, for inter-site deployment, you should use a dedicated link.

## Cluster Control Link Network

The Firepower 4100/9300 chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: `127.2.chassis_id.slot_id`. For multi-instance clusters, which typically use different VLAN subinterfaces of the same EtherChannel, the same IP address can be used for different clusters because of VLAN separation. The cluster control link network cannot include any routers between units; only Layer 2 switching is allowed.

## Management Network

We recommend connecting all units to a single management network. This network is separate from the cluster control link.

## Management Interface

You must assign a Management type interface to the cluster. This interface is a special individual interface as opposed to a Spanned interface. The management interface lets you connect directly to each unit. This Management logical interface is separate from the other interfaces on the device. It is used to set up and register the device to the Secure Firewall Management Center. It uses its own local authentication, IP address, and static routing. Each cluster member uses a separate IP address on the management network that you set as part of the bootstrap configuration.

## Cluster Interfaces

For a cluster isolated to security modules within one Firepower 9300 chassis, you can assign both physical interfaces or EtherChannels (also known as port channels) to the cluster. Interfaces assigned to the cluster are Spanned interfaces that load-balance traffic across all members of the cluster.

For clustering with multiple chassis, you can only assign data EtherChannels to the cluster. These Spanned EtherChannels include the same member interfaces on each chassis; on the upstream switch, all of these interfaces are included in a single EtherChannel, so the switch does not know that it is connected to multiple devices.

You can use regular firewall interfaces or IPS-only interfaces (inline sets or passive interfaces).

Individual interfaces are not supported, with the exception of a management interface.

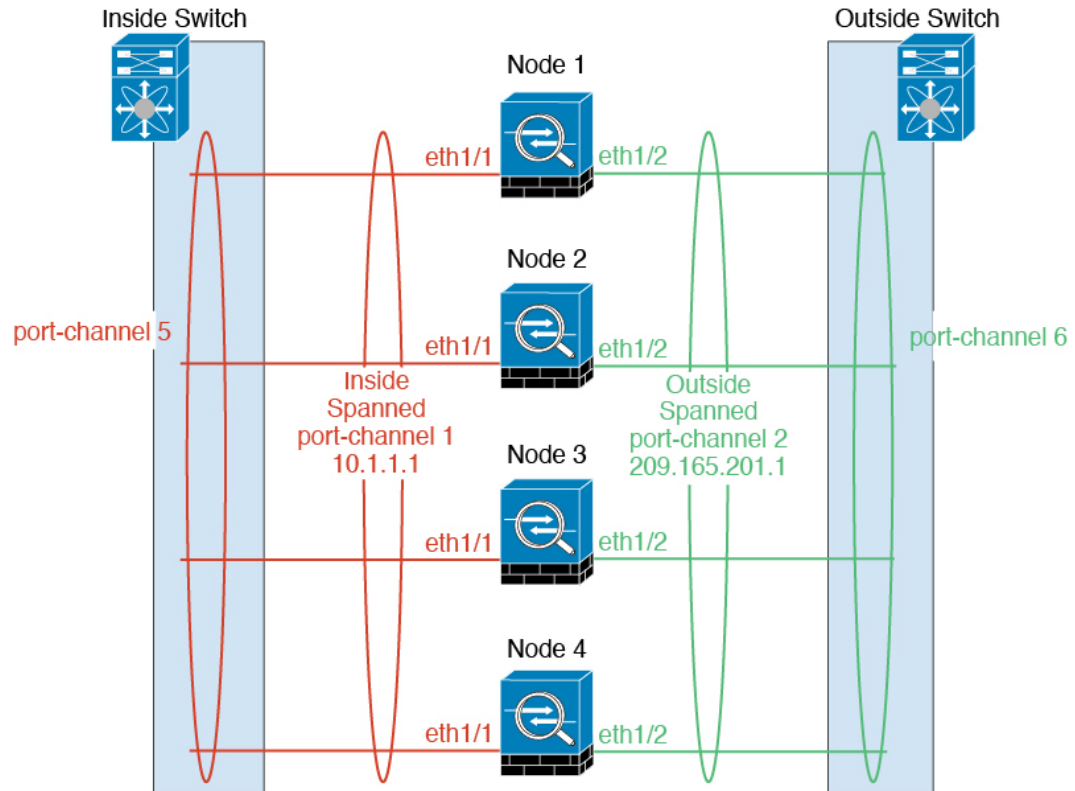

## Spanned EtherChannels

You can group one or more interfaces per chassis into an EtherChannel that spans all chassis in the cluster. The EtherChannel aggregates the traffic across all the available active interfaces in the channel.

For regular firewall interfaces: A Spanned EtherChannel can be configured in both routed and transparent firewall modes. In routed mode, the EtherChannel is configured as a routed interface with a single IP address. In transparent mode, the IP address is assigned to the BVI, not to the bridge group member interface.

The EtherChannel inherently provides load balancing as part of basic operation.

For multi-instance clusters, each cluster requires dedicated data EtherChannels; you cannot use shared interfaces or VLAN subinterfaces.

## Connecting to a Redundant Switch System

We recommend connecting EtherChannels to a redundant switch system such as a VSS, vPC, StackWise, or StackWise Virtual system to provide redundancy for your interfaces.

## Configuration Replication

All nodes in the cluster share a single configuration. You can only make configuration changes on the control node (with the exception of the bootstrap configuration), and changes are automatically synced to all other nodes in the cluster.

## Licenses for Clustering

You assign feature licenses to the cluster as a whole, not to individual nodes. However, each node of the cluster consumes a separate license for each feature. The clustering feature itself does not require any licenses.

When you add a cluster node to the management center, you can specify the feature licenses you want to use for the cluster. You can modify licenses for the cluster in the **Devices > Device Management > Cluster > License** area.

---

**Note** If you add the cluster before the management center is licensed (and running in Evaluation mode), then when you license the management center, you can experience traffic disruption when you deploy policy changes to the cluster. Changing to licensed mode causes all data units to leave the cluster and then rejoin.

---

## Requirements and Prerequisites for Clustering

### Cluster Model Support

The Threat Defense supports clustering on the following models:

- Firepower 9300— You can include up to 16 nodes in the cluster. For example, you can use 1 module in 16 chassis, or 2 modules in 8 chassis, or any combination that provides a maximum of 16 modules. Supports clustering with multiple chassis and clustering isolated to security modules within one chassis.
- Firepower 4100—Supported for up to 16 nodes using clustering with multiple chassis.

### User Roles

- Admin
- Access Admin
- Network Admin

### Clustering Hardware and Software Requirements

All chassis in a cluster:

- Native instance clustering—For the Firepower 4100: All chassis must be the same model. For the Firepower 9300: All security modules must be the same type. For example, if you use clustering, all modules in the Firepower 9300 must be SM-40s. You can have different quantities of installed security modules in each chassis, although all modules present in the chassis must belong to the cluster including any empty slots.
- Container instance clustering—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300 security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Must run the identical FXOS and application software except at the time of an image upgrade. Mismatched software versions can lead to poor performance, so be sure to upgrade all nodes in the same maintenance window.
- Must include the same interface configuration for interfaces you assign to the cluster, such as the same Management interface, EtherChannels, active interfaces, speed and duplex, and so on. You can use different network module types on the chassis as long as the capacity matches for the same interface IDs and interfaces can successfully bundle in the same spanned EtherChannel. Note that all data interfaces must be EtherChannels in clusters with multiple chassis. If you change the interfaces in FXOS after you enable clustering (by adding or removing interface modules, or configuring EtherChannels, for example), then perform the same changes on each chassis, starting with the data nodes, and ending with the control node.
- Must use the same NTP server. For threat defense, the management center must also use the same NTP server. Do not set the time manually.

**Multi-Instance Clustering Requirements**

- No intra-security-module/engine clustering—For a given cluster, you can only use a single container instance per security module/engine. You cannot add 2 container instances to the same cluster if they are running on the same module.

- Mix and match clusters and standalone instances—Not all container instances on a security module/engine need to belong to a cluster. You can use some instances as standalone or High Availability nodes. You can also create multiple clusters using separate instances on the same security module/engine.

- All 3 modules in a Firepower 9300 must belong to the cluster—For the Firepower 9300, a cluster requires a single container instance on all 3 modules. You cannot create a cluster using instances on module 1 and 2, and then use a native instance on module 3, or example.

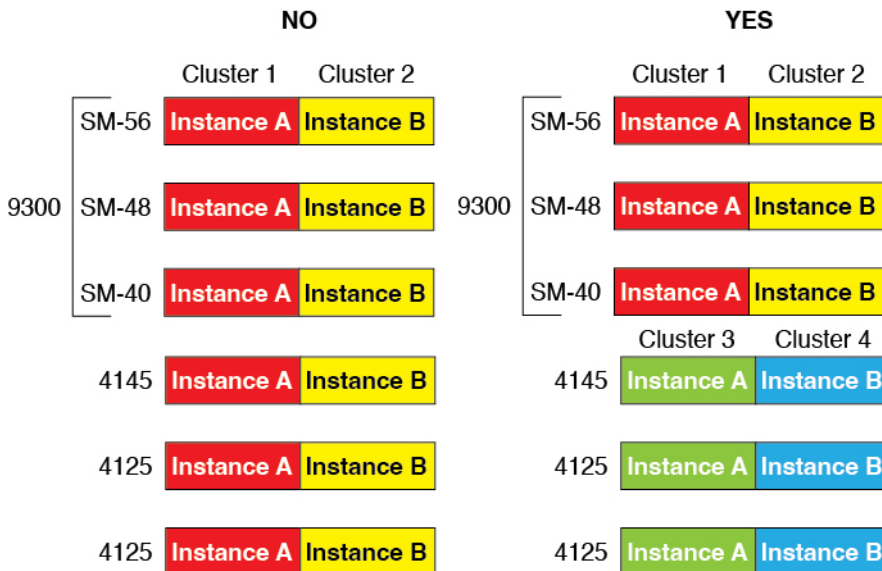

- Match resource profiles—We recommend that each node in the cluster use the same resource profile attributes; however, mismatched resources are allowed when changing cluster nodes to a different resource profile, or when using different models.
- Dedicated cluster control link—For clusters with multiple chassis, each cluster needs a dedicated cluster control link. For example, each cluster can use a separate subinterface on the same cluster-type EtherChannel, or use separate EtherChannels.

- No shared interfaces—Shared-type interfaces are not supported with clustering. However, the same Management and Eventing interfaces can be used by multiple clusters.
- No subinterfaces—A multi-instance cluster cannot use FXOS-defined VLAN subinterfaces. An exception is made for the cluster control link, which can use a subinterface of the Cluster EtherChannel.
- Mix chassis models—We recommend that you use the same security module or chassis model for each cluster instance. However, you can mix and match container instances on different Firepower 9300

security module types or Firepower 4100 models in the same cluster if required. You cannot mix Firepower 9300 and 4100 instances in the same cluster. For example, you can create a cluster using an instance on a Firepower 9300 SM-56, SM-48, and SM-40. Or you can create a cluster on a Firepower 4145 and a 4125.

- Maximum 6 nodes—You can use up to six container instances in a cluster.

### Switch Requirements

- Be sure to complete the switch configuration and successfully connect all the EtherChannels from the chassis to the switch(es) before you configure clustering on the Firepower 4100/9300 chassis.
- For supported switch characteristics, see [Cisco FXOS Compatibility](#).

## Clustering Guidelines and Limitations

### Switches for Clustering

- Make sure connected switches match the MTU for both cluster data interfaces and the cluster control link interface. You should configure the cluster control link interface MTU to be at least 100 bytes higher than the data interface MTU, so make sure to configure the cluster control link connecting switch appropriately. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead. In addition, we do not recommend setting the cluster control link MTU between 2561 and 8362; due to block pool handling, this MTU size is not optimal for system operation.
- For Cisco IOS XR systems, if you want to set a non-default MTU, set the IOS XR interface MTU to be 14 bytes higher than the cluster device MTU. Otherwise, OSPF adjacency peering attempts may fail unless the **mtu-ignore** option is used. Note that the cluster device MTU should match the IOS XR IPv4 MTU. This adjustment is not required for Cisco Catalyst and Cisco Nexus switches.

- On the switch(es) for the cluster control link interfaces, you can optionally enable Spanning Tree PortFast on the switch ports connected to the cluster unit to speed up the join process for new units.
- On the switch, we recommend that you use one of the following EtherChannel load-balancing algorithms: **source-dest-ip** or **source-dest-ip-port** (see the Cisco Nexus OS and Cisco IOS-XE **port-channel load-balance** command). Do not use a **vlan** keyword in the load-balance algorithm because it can cause unevenly distributed traffic to the devices in a cluster.
- If you change the load-balancing algorithm of the EtherChannel on the switch, the EtherChannel interface on the switch temporarily stops forwarding traffic, and the Spanning Tree Protocol restarts. There will be a delay before traffic starts flowing again.
- Switches on the cluster control link path should not verify the L4 checksum. Redirected traffic over the cluster control link does not have a correct L4 checksum. Switches that verify the L4 checksum could cause traffic to be dropped.
- Port-channel bundling downtime should not exceed the configured keepalive interval.
- On Supervisor 2T EtherChannels, the default hash distribution algorithm is adaptive. To avoid asymmetric traffic in a VSS design, change the hash algorithm on the port-channel connected to the cluster device to fixed:
 

```
router(config)# port-channel id hash-distribution fixed
```

Do not change the algorithm globally; you may want to take advantage of the adaptive algorithm for the VSS peer link.
- Firepower 4100/9300 clusters support LACP graceful convergence. So you can leave LACP graceful convergence enabled on connected Cisco Nexus switches.
- When you see slow bundling of a Spanned EtherChannel on the switch, you can enable LACP rate fast for an individual interface on the switch. FXOS EtherChannels have the LACP rate set to fast by default. Note that some switches, such as the Nexus series, do not support LACP rate fast when performing in-service software upgrades (ISSUs), so we do not recommend using ISSUs with clustering.

### EtherChannels for Clustering

- In Catalyst 3750-X Cisco IOS software versions earlier than 15.1(1)S2, the cluster unit did not support connecting an EtherChannel to a switch stack. With default switch settings, if the cluster unit EtherChannel is connected cross stack, and if the control unit switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- Spanned vs. Device-Local EtherChannel Configuration—Be sure to configure the switch appropriately for Spanned EtherChannels vs. Device-local EtherChannels.
  - Spanned EtherChannels—For cluster unit *Spanned* EtherChannels, which span across all members of the cluster, the interfaces are combined into a single EtherChannel on the switch. Make sure each interface is in the same channel group on the switch.

- Device-local EtherChannels—For cluster unit *Device-local* EtherChannels including any EtherChannels configured for the cluster control link, be sure to configure discrete EtherChannels on the switch; do not combine multiple cluster unit EtherChannels into one EtherChannel on the switch.

### Additional Guidelines

- When significant topology changes occur (such as adding or removing an EtherChannel interface, enabling or disabling an interface on the Firepower 4100/9300 chassis or the switch, adding an additional switch to form a VSS, vPC, StackWise, or StackWise Virtual) you should disable the health check feature, and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all units, you can re-enable the health check feature.
- When adding a unit to an existing cluster, or when reloading a unit, there will be a temporary, limited packet/connection drop; this is expected behavior. In some cases, the dropped packets can hang connections; for example, dropping a FIN/ACK packet for an FTP connection will make the FTP client hang. In this case, you need to reestablish the FTP connection.
- If you use a Windows 2003 server connected to a Spanned EtherChannel interface, when the syslog server port is down, and the server does not throttle ICMP error messages, then large numbers of ICMP messages are sent back to the cluster. These messages can result in some units of the cluster experiencing high CPU, which can affect performance. We recommend that you throttle ICMP error messages.
- We recommend connecting EtherChannels to a VSS, vPC, StackWise, or StackWise Virtual for redundancy.

- Within a chassis, you cannot cluster some security modules and run other security modules in standalone mode; you must include all security modules in the cluster.
- For decrypted TLS/SSL connections, the decryption states are not synchronized, and if the connection owner fails, then decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

### Defaults

- The cluster health check feature is enabled by default with the holdtime of 3 seconds. Interface health monitoring is enabled on all interfaces by default.
- The cluster auto-rejoin feature for a failed cluster control link is set to unlimited attempts every 5 minutes.
- The cluster auto-rejoin feature for a failed data interface is set to 3 attempts every 5 minutes, with the increasing interval set to 2.
- Connection replication delay of 5 seconds is enabled by default for HTTP traffic.

## Configure Clustering

You can easily deploy the cluster from the Firepower 4100/9300 supervisor. All initial configuration is automatically generated for each unit. You can then add the units to the management center and group them into a cluster.

### FXOS: Add a Threat Defense Cluster

In native mode: You can add a cluster to a single Firepower 9300 chassis that is isolated to security modules within the chassis, or you can use multiple chassis.

In multi-instance mode: You can add one or more clusters to a single Firepower 9300 chassis that are isolated to security modules within the chassis (you must include an instance on each module), or add one or more clusters on multiple chassis.

For clusters on multiple chassis, you must configure each chassis separately. Add the cluster on one chassis; you can then copy the bootstrap configuration from the first chassis to the next chassis for ease of deployment.

### Create a Threat Defense Cluster

You can easily deploy the cluster from the Firepower 4100/9300 chassis supervisor. All initial configuration is automatically generated for each unit.

For clustering on multiple chassis, you must configure each chassis separately. Deploy the cluster on one chassis; you can then copy the bootstrap configuration from the first chassis to the next chassis for ease of deployment.

In a Firepower 9300 chassis, you must enable clustering for all 3 module slots, or for container instances, a container instance in each slot, even if you do not have a module installed. If you do not configure all 3 modules, the cluster will not come up.

## Before you begin

- Download the application image you want to use for the logical device from Cisco.com, and then upload that image to the Firepower 4100/9300 chassis.
- For container instances, if you do not want to use the default profile, add a resource profile according to [Add a Resource Profile for Container Instances, on page 294](#).
- For container instances, before you can install a container instance for the first time, you must reinitialize the security module/engine so that the disk has the correct formatting. Choose **Security Modules** or **Security Engine**, and click the Reinitialize icon (Ⓢ). An existing logical device will be deleted and then reinstalled as a new device, losing any local application configuration. If you are replacing a native instance with container instances, you will need to delete the native instance in any case. You cannot automatically migrate a native instance to a container instance.
- Gather the following information:
  - Management interface ID, IP addresses, and network mask
  - Gateway IP address
  - management center IP address and/or NAT ID of your choosing
  - DNS server IP address
  - Threat Defense hostname and domain name

## Procedure

---

### Step 1

Configure interfaces.

- a) Add at least one Data type interface or EtherChannel (also known as a port-channel) before you deploy the cluster. See [Add an EtherChannel \(Port Channel\), on page 291](#) or [Configure a Physical Interface, on page 290](#).

For clustering on multiple chassis, all data interfaces must be Spanned EtherChannels with at least one member interface. Add the same EtherChannels on each chassis. Combine the member interfaces from all cluster units into a single EtherChannel on the switch. See [Clustering Guidelines and Limitations, on page 631](#) for more information about EtherChannels.

For multi-instance clustering, you cannot use FXOS-defined VLAN subinterfaces or data-sharing interfaces in the cluster. Only application-defined subinterfaces are supported. See [FXOS Interfaces vs. Application Interfaces, on page 258](#) for more information.

- b) Add a Management type interface or EtherChannel. See [Add an EtherChannel \(Port Channel\), on page 291](#) or [Configure a Physical Interface, on page 290](#).

The management interface is required. Note that this management interface is not the same as the chassis management interface that is used only for chassis management (in FXOS, you might see the chassis management interface displayed as MGMT, management0, or other similar names).

For clustering on multiple chassis, add the same Management interface on each chassis.

For multi-instance clustering, you can share the same management interface across multiple clusters on the same chassis, or with standalone instances.

- c) For clustering on multiple chassis, add a member interface to the cluster control link EtherChannel (by default, port-channel 48). See [Add an EtherChannel \(Port Channel\), on page 291](#).

Do not add a member interface for a cluster isolated to security modules within one Firepower 9300 chassis. If you add a member, the chassis assumes this cluster will be using multiple chassis, and will only allow you to use Spanned EtherChannels, for example.

On the **Interfaces** tab, the port-channel 48 cluster type interface shows the **Operation State** as **failed** if it does not include any member interfaces. For a cluster isolated to security modules within one Firepower 9300 chassis, this EtherChannel does not require any member interfaces, and you can ignore this Operational State.

Add the same member interfaces on each chassis. The cluster control link is a device-local EtherChannel on each chassis. Use separate EtherChannels on the switch per device. See [Clustering Guidelines and Limitations, on page 631](#) for more information about EtherChannels.

For multi-instance clustering, you can create additional Cluster type EtherChannels. Unlike the Management interface, the cluster control link is *not* sharable across multiple devices, so you will need a Cluster interface for each cluster. However, we recommend using VLAN subinterfaces instead of multiple EtherChannels; see the next step to add a VLAN subinterface to the Cluster interface.

- d) For multi-instance clustering, add VLAN subinterfaces to the cluster EtherChannel so you have a subinterface for each cluster. See [Add a VLAN Subinterface for Container Instances, on page 293](#).

If you add subinterfaces to a Cluster interface, you cannot use that interface for a native cluster.

- e) (Optional) Add an eventing interface. See [Add an EtherChannel \(Port Channel\), on page 291](#) or [Configure a Physical Interface, on page 290](#).

This interface is a secondary management interface for the threat defense devices. To use this interface, you must configure its IP address and other parameters at the threat defense CLI. For example, you can separate management traffic from events (such as web events). See the **configure network** commands in the threat defense command reference.

For clustering on multiple chassis, add the same eventing interface on each chassis.

## Step 2

Choose **Logical Devices**.

## Step 3

Click **Add > Cluster**, and set the following parameters:

**Figure 270: Native Cluster**

The screenshot shows a dialog box titled "Add Cluster" with a question mark icon and a close button in the top right corner. The dialog contains the following fields:

- I want to:** A dropdown menu with "Create New Cluster" selected.
- Device Name:** A text input field containing "cluster1".
- Template:** A dropdown menu with "Cisco Secure Firewall Threat Defense" selected.
- Image Version:** A dropdown menu with "7.3.0.1676" selected.
- Instance Type:** A dropdown menu with "Native" selected.

At the bottom of the dialog are two buttons: "OK" and "Cancel".

Figure 271: Multi-Instance Cluster

- a) Choose **I want to:** > **Create New Cluster**
- b) Provide a **Device Name**.

This name is used internally by the chassis supervisor to configure management settings and to assign interfaces; it is not the device name used in the application configuration.

- c) For the **Template**, choose **Cisco Firepower Threat Defense**.
- d) Choose the **Image Version**.
- e) For the **Instance Type**, choose either **Native** or **Container**.

A native instance uses all of the resources (CPU, RAM, and disk space) of the security module/engine, so you can only install one native instance. A container instance uses a subset of resources of the security module/engine, so you can install multiple container instances.

- f) (Container Instance only) For the **Resource Type**, choose one of the resource profiles from the drop-down list.

For the Firepower 9300, this profile will be applied to each instance on each security module. You can set different profiles per security module later in this procedure; for example, if you are using different security module types, and you want to use more CPUs on a lower-end model. We recommend choosing the correct profile before you create the cluster. If you need to create a new profile, cancel out of the cluster creation, and add one using [Add a Resource Profile for Container Instances, on page 294](#).

**Note** If you assign a different profile to instances in an established cluster, which allows mismatched profiles, then apply the new profile on the data nodes first; after they reboot and come back up, you can apply the new profile to the control node.

- g) Click **OK**.

You see the Provisioning - *device name* window.

**Step 4** Choose the interfaces you want to assign to this cluster.

For native mode clustering: All valid interfaces are assigned by default. If you defined multiple Cluster type interfaces, deselect all but one.

For multi-instance clustering: Choose each data interface you want to assign to the cluster, and also choose the Cluster type port-channel or port-channel subinterface.

**Step 5** Click the device icon in the center of the screen.

A dialog box appears where you can configure initial bootstrap settings. These settings are meant for initial deployment only, or for disaster recovery. For normal operation, you can later change most values in the application CLI configuration.

**Step 6** On the **Cluster Information** page, complete the following.

Figure 272: Native Cluster

Cisco Secure Firewall Threat Defense - Bootstrap Configuration

Cluster Information | Interface Information | Settings | Agreement

**Security Module**  
Security Module - 1, Security Module - 2, Security Module - 3

**Interface Information**

Chassis ID:

Site ID:

Cluster Key:

Confirm Cluster Key:

Cluster Group Name:

Management Interface:

CCL Subnet IP:

OK Cancel

Figure 273: Multi-Instance Cluster

Cisco Secure Firewall Threat Defense - Bootstrap Configuration

Cluster Information | Interface Information | Settings | Agreement

**Resource Profile Selection**

Security Module 1: (72 Cores Available)

Security Module 2: (46 Cores Available)

Security Module 3:

**Interface Information**

Chassis ID:

Site ID:

Cluster Key:

Confirm Cluster Key:

Cluster Group Name:

Management Interface:

CCL Subnet IP:

OK Cancel

- (Container Instance for the Firepower 9300 only) In the **Security Module (SM) and Resource Profile Selection** area, you can set a different resource profile per module; for example, if you are using different security module types, and you want to use more CPUs on a lower-end model.
- For clustering on multiple chassis, in the **Chassis ID** field, enter a chassis ID. Each chassis in the cluster must use a unique ID.

This field only appears if you added a member interface to cluster control link Port-Channel 48.

- For inter-site clustering, in the **Site ID** field, enter the site ID for this chassis between 1 and 8. FlexConfig feature. Additional inter-site cluster customizations to enhance redundancy and stability, such as director

localization, site redundancy, and cluster flow mobility, are only configurable using the management center FlexConfig feature.

- d) In the **Cluster Key** field, configure an authentication key for control traffic on the cluster control link.

The shared secret is an ASCII string from 1 to 63 characters. The shared secret is used to generate the key. This option does not affect datapath traffic, including connection state update and forwarded packets, which are always sent in the clear.

- e) Set the **Cluster Group Name**, which is the cluster group name in the logical device configuration.

The name must be an ASCII string from 1 to 38 characters.

**Important** From 2.4.1, spaces in cluster group name will be considered as special characters and may result in error while deploying the logical devices. To avoid this issue, you must rename the cluster group name without a space.

- f) Choose the **Management Interface**.

This interface is used to manage the logical device. This interface is separate from the chassis management port.

If you assign a Hardware Bypass-capable interface as the Management interface, you see a warning message to make sure your assignment is intentional.

- g) (Optional) Set the **CCL Subnet IP** as *a.b.0.0*.

By default, the cluster control link uses the 127.2.0.0/16 network. However, some networking deployments do not allow 127.2.0.0/16 traffic to pass. In this case, specify any /16 network address on a unique network for the cluster, except for loopback (127.0.0.0/8), multicast (224.0.0.0/4), and internal (169.254.0.0/16) addresses. If you set the value to 0.0.0.0, then the default network is used.

The chassis auto-generates the cluster control link interface IP address for each unit based on the chassis ID and slot ID: *a.b.chassis\_id.slot\_id*.

**Step 7** On the **Settings** page, complete the following.

Cisco Secure Firewall Threat Defense - Bootstrap Configuration

Cluster Information    Interface Information    Settings    Agreement

|                                          |               |
|------------------------------------------|---------------|
| Management type of application instance: | FMC           |
| Search domains:                          | cisco.com     |
| Firewall Mode:                           | Routed        |
| DNS Servers:                             | 10.89.5.67    |
| Fully Qualified Hostname:                | td2.cisco.com |
| Password:                                | .....         |
| Confirm Password:                        | .....         |
| Registration Key:                        | ....          |
| Confirm Registration Key:                | ....          |
| CDO Onboard:                             |               |
| Confirm CDO Onboard:                     |               |
| Firepower Management Center IP:          | 10.89.5.35    |
| Firepower Management Center NAT ID:      | test          |
| Eventing Interface:                      |               |

OK    Cancel

- a) In the **Registration Key** field, enter the key to be shared between the management center and the cluster members during registration.  
 You can choose any text string for this key between 1 and 37 characters; you will enter the same key on the management center when you add the threat defense.
- b) Enter a **Password** for the threat defense admin user for CLI access.
- c) In the **Firepower Management Center IP** field, enter the IP address of the managing management center. If you do not know the management center IP address, leave this field blank and enter a passphrase in the **Firepower Management Center NAT ID** field.
- d) (Optional) For a container instance, **Permit Expert mode from FTD SSH sessions: Yes or No**. Expert Mode provides threat defense shell access for advanced troubleshooting.

If you choose **Yes** for this option, then users who access the container instance directly from an SSH session can enter Expert Mode. If you choose **No**, then only users who access the container instance from the FXOS CLI can enter Expert Mode. We recommend choosing **No** to increase isolation between instances.

Use Expert Mode only if a documented procedure tells you it is required, or if the Cisco Technical Assistance Center asks you to use it. To enter this mode, use the **expert** command in the threat defense CLI.

- e) (Optional) In the **Search Domains** field, enter a comma-separated list of search domains for the management network.
- f) (Optional) From the **Firewall Mode** drop-down list, choose **Transparent** or **Routed**.

In routed mode, the threat defense is considered to be a router hop in the network. Each interface that you want to route between is on a different subnet. A transparent firewall, on the other hand, is a Layer 2 firewall that acts like a “bump in the wire,” or a “stealth firewall,” and is not seen as a router hop to connected devices.

The firewall mode is only set at initial deployment. If you re-apply the bootstrap settings, this setting is not used.

- g) (Optional) In the **DNS Servers** field, enter a comma-separated list of DNS servers.

The threat defense uses DNS if you specify a hostname for the management center, for example.

- h) (Optional) In the **Firepower Management Center NAT ID** field, enter a passphrase that you will also enter on the management center when you add the cluster as a new device.

Normally, you need both IP addresses (along with a registration key) for both routing purposes and for authentication: the management center specifies the device IP address, and the device specifies the management center IP address. However, if you only know one of the IP addresses, which is the minimum requirement for routing purposes, then you must also specify a unique NAT ID on both sides of the connection to establish trust for the initial communication and to look up the correct registration key. You can specify any text string as the NAT ID, from 1 to 37 characters. The management center and device use the registration key and NAT ID (instead of IP addresses) to authenticate and authorize for initial registration.

- i) (Optional) In the **Fully Qualified Hostname** field, enter a fully qualified name for the threat defense device.

Valid characters are the letters from a to z, the digits from 0 to 9, the dot (.), and the hyphen (-); maximum number of characters is 253.

- j) (Optional) From the **Eventing Interface** drop-down list, choose the interface on which events should be sent. If not specified, the management interface will be used.

To specify a separate interface to use for events, you must configure an interface as a *firepower-eventing* interface. If you assign a Hardware Bypass-capable interface as the Eventing interface, you see a warning message to make sure your assignment is intentional.

## Step 8

On the **Interface Information** page, configure a management IP address for each security module in the cluster. Select the type of address from the **Address Type** drop-down list and then complete the following for each security module.

**Note** You must set the IP address for all 3 module slots in a chassis, even if you do not have a module installed. If you do not configure all 3 modules, the cluster will not come up.

Cisco Secure Firewall Threat Defense - Bootstrap Configuration

Cluster Information **Interface Information** Settings Agreement

Address Type: IPv4 only

**Security Module 1**

Management IP: 10.89.5.20

Network Mask: 255.255.255.192

Gateway: 10.89.5.1

**Security Module 2**

Management IP: 10.89.5.21

Network Mask: 255.255.255.192

Gateway: 10.89.5.1

**Security Module 3**

Management IP: 10.89.5.22

Network Mask: 255.255.255.192

Gateway: 10.89.5.1

OK Cancel

- In the **Management IP** field, configure an IP address.  
Specify a unique IP address on the same network for each module.
- Enter a **Network Mask** or **Prefix Length**.
- Enter a **Network Gateway** address.

**Step 9** On the **Agreement** tab, read and accept the end user license agreement (EULA).

**Step 10** Click **OK** to close the configuration dialog box.

**Step 11** Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for the status of the new logical device. When the logical device shows its **Status** as **online**, you can add the remaining cluster chassis, or for a cluster isolated to security modules within one Firepower 9300 chassis, start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

**Step 12**

For clustering on multiple chassis, add the next chassis to the cluster:

- a) On the first chassis of the chassis manager, click the **Show Configuration icon** at the top right; copy the displayed cluster configuration.
- b) Connect to the chassis manager on the next chassis, and add a logical device according to this procedure.
- c) Choose **I want to: > Join an Existing Cluster**.
- d) Click **OK**.
- e) In the **Copy Cluster Details** box, paste in the cluster configuration from the first chassis, and click **OK**.
- f) Click the device icon in the center of the screen. The cluster information is mostly pre-filled, but you must change the following settings:
  - **Chassis ID**—Enter a unique chassis ID.
  - **Site ID**—For inter-site clustering, enter the site ID for this chassis between 1 and 8. Additional inter-site cluster customizations to enhance redundancy and stability, such as director localization, site redundancy, and cluster flow mobility, are only configurable using the management center FlexConfig feature.
  - **Cluster Key**—(Not prefilled) Enter the same cluster key.
  - **Management IP**—Change the management address for each module to be a unique IP address on the same network as the other cluster members.

Click **OK**.

- g) Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for each cluster member for the status of the new logical device. When the logical device for each cluster member shows its **Status as online**, you can start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

**Step 13**

Add the control unit to the management center using the management IP address.

All cluster units must be in a successfully-formed cluster on FXOS prior to adding them to management center.

The management center then automatically detects the data units.

## Add More Cluster Nodes

Add or replace the threat defense cluster node in an existing cluster. When you add a new cluster node in FXOS, the management center adds the node automatically.

**Note** The FXOS steps in this procedure only apply to adding a new *chassis*; if you are adding a new module to a Firepower 9300 where clustering is already enabled, the module will be added automatically.

### Before you begin

- In the case of a replacement, you must delete the old cluster node from the management center. When you replace it with a new node, it is considered to be a new device on the management center.
- The interface configuration must be the same on the new chassis. You can export and import FXOS chassis configuration to make this process easier.

### Procedure

**Step 1** If you previously upgraded the threat defense image using the management center, perform the following steps *on each chassis in the cluster*.

When you upgraded from the management center, the startup version in the FXOS configuration was not updated, and the standalone package was not installed on the chassis. Both of these items need to be set manually so the new node can join the cluster using the correct image version.

**Note** If you only applied a patch release, you can skip this step. Cisco does not provide standalone packages for patches.

- Install the running threat defense image on the chassis using the **System > Updates** page.
- Click **Logical Devices** and click the Set Version icon (🔧). For a Firepower 9300 with multiple modules, set the version for each module.

The **Startup Version** shows the original package you deployed with. The **Current Version** shows the version you upgraded to.

- In the **New Version** drop-down menu, choose the version that you uploaded. This version should match the **Current Version** displayed, and will set the startup version to match the new version.
- On the new chassis, make sure the new image package is installed.

**Step 2** On an existing cluster chassis chassis manager, click **Logical Devices**.

**Step 3** Click the **Show Configuration icon** at the top right; copy the displayed cluster configuration.

**Step 4** Connect to the chassis manager on the new chassis, and click **Add > Cluster**.

**Step 5** For the **Device Name**, provide a name for the logical device.

**Step 6** Click **OK**.

**Step 7** In the **Copy Cluster Details** box, paste in the cluster configuration from the first chassis, and click **OK**.

**Step 8** Click the device icon in the center of the screen. The cluster information is partly pre-filled, but you must fill in the following settings:

- **Chassis ID**—Enter a *unique* chassis ID.

- **Site ID**—For inter-site clustering, enter the site ID for this chassis between 1 and 8. This feature is only configurable using the management center FlexConfig feature.
- **Cluster Key**—Enter the *same* cluster key.
- **Management IP**—Change the management address for each module to be a *unique* IP address on the same network as the other cluster members.
- **Fully Qualified Hostname**—Enter the *same* hostname.
- **Password**—Enter the *same* password.
- **Registration Key**—Enter the *same* registration key.

Click **OK**.

**Step 9** Click **Save**.

The chassis deploys the logical device by downloading the specified software version and pushing the bootstrap configuration and management interface settings to the application instance. Check the **Logical Devices** page for each cluster member for the status of the new logical device. When the logical device for each cluster member shows its **Status** as **online**, you can start configuring the cluster in the application. You may see the "Security module not responding" status as part of the process; this status is normal and is temporary.

## Management Center: Add a Cluster

Add one of the cluster units as a new device to the Secure Firewall Management Center; the management center auto-detects all other cluster members.

### Before you begin

- All cluster units must be in a successfully-formed cluster on FXOS prior to adding the cluster to the management center. You should also check which unit is the control unit. Refer to the chassis manager **Logical Devices** screen or use the threat defense **show cluster info** command.

Procedure

Step 1

In the management center, choose **Devices > Device Management**, and then choose **Add > Add Device** to add the control unit using the unit's management IP address you assigned when you deployed the cluster.

Figure 277: Add Device

Add Device ?

Group:

Access Control Policy:\*

Smart Licensing  
 Note: All virtual Firewall Threat Defense devices require a performance tier license. Make sure your Smart Licensing account contains the available licenses you need. It's important to choose the tier that matches the license you have in your account. Click [here](#) for information about the Firewall Threat Defense performance-tiered licensing. Until you choose a tier, your Firewall Threat Defense virtual defaults to the FTDv50 selection.

Performance Tier (only for Firewall Threat Defense virtual 7.0 and above):

Malware  
 Threat  
 URL Filtering

Advanced  
 Unique NAT ID:†

Transfer Packets

- a) In the **Host** field, enter the IP address or hostname of the control unit.  
 We recommend adding the control unit for the best performance, but you can add any unit of the cluster.  
 If you used a NAT ID during device setup, you may not need to enter this field. For more information, see [NAT Environments, on page 7](#).

- b) In the **Display Name** field, enter a name for the control unit as you want it to display in the management center.

This display name is not for the cluster; it is only for the control unit you are adding. You can later change the name of other cluster members and the cluster display name.

- c) In the **Registration Key** field, enter the same registration key that you used when you deployed the cluster in FXOS. The registration key is a one-time-use shared secret.
- d) (Optional) Add the device to a device **Group**.
- e) Choose an initial **Access Control Policy** to deploy to the device upon registration, or create a new policy.

If you create a new policy, you create a basic policy only. You can later customize the policy as needed.

New Policy

Name:  
basic

Description:

Select Base Policy:  
None

Default Action:  
 Block all traffic  
 Intrusion Prevention  
 Network Discovery

Snort3:

- f) Choose licenses to apply to the device.
- g) If you used a NAT ID during device setup, expand the **Advanced** section and enter the same NAT ID in the **Unique NAT ID** field.
- h) Check the **Transfer Packets** check box to allow the device to transfer packets to the management center.

This option is enabled by default. When events like IPS or Snort are triggered with this option enabled, the device sends event metadata information and packet data to the management center for inspection. If you disable it, only event information will be sent to the management center but packet data is not sent.

- i) Click **Register**.

The management center identifies and registers the control unit, and then registers all data units. If the control unit does not successfully register, then the cluster is not added. A registration failure can occur if the cluster was not up on the chassis, or because of other connectivity issues. In this case, we recommend that you try re-adding the cluster unit.

The cluster name shows on the **Devices > Device Management** page; expand the cluster to see the cluster units.

| <input checked="" type="checkbox"/> | 10.10.1.12 | Deployment to device successful. | 1m 54s                |
| <input checked="" type="checkbox"/> | 10.10.1.13 | Deployment to device successful. | 1m 3s                 |
| <input checked="" type="checkbox"/> | TD_Cluster | Deployment to device successful. | 35s                   |

**Step 2** Configure device-specific settings by clicking the **Edit** (✎) for the cluster.

Most configuration can be applied to the cluster as a whole, and not member units in the cluster. For example, you can change the display name per unit, but you can only configure interfaces for the whole cluster.

**Step 3** On the **Devices > Device Management > Cluster** screen, you see **General**, **License**, **System**, and **Health** settings.

| TD Native Cluster                         |            |
|-------------------------------------------|------------|

## Management Center: Configure Cluster, Data Interfaces

This procedure configures basic parameters for each data interface that you assigned to the cluster when you deployed it in FXOS. For clustering on multiple chassis, data interfaces are always Spanned EtherChannel

interfaces. For the cluster control link interface for a cluster isolated to security modules within one Firepower 9300 chassis, you must increase the MTU from the default.

**Note** When using Spanned EtherChannels for clustering on multiple chassis, the port-channel interface will not come up until clustering is fully enabled. This requirement prevents traffic from being forwarded to a unit that is not an active unit in the cluster.

### Procedure

**Step 1** Choose **Devices > Device Management**, and click **Edit** (✎) next to the cluster.

**Step 2** Click **Interfaces**.

**Step 3** Configure the cluster control link.

For clustering on multiple chassis, set the cluster control link MTU to be at least 100 bytes higher than the highest MTU of the data interfaces. Because the cluster control link traffic includes data packet forwarding, the cluster control link needs to accommodate the entire size of a data packet plus cluster traffic overhead.

We suggest setting the MTU to the maximum of 9184; the minimum value is 1400 bytes. For example, because the maximum MTU is 9184, then the highest data interface MTU can be 9084, while the cluster control link can be set to 9184.

For native clusters: The cluster control link interface is Port-Channel48 by default. If you don't know which interface is the cluster control link, check the FXOS configuration for chassis for the Cluster-type interface assigned to the cluster.

- a) Click **Edit** (✎) for the cluster control link interface.
- b) On the **General** page, in the **MTU** field, enter a value between 1400 and 9184 but not between 2561 and 8362. Due to block pool handling, this MTU size is not optimal for system operation. We suggest using the maximum, 9184.
- c) Click **OK**.

**Step 4** Configure data interfaces.

- a) (Optional) For regular firewall interfaces, configure VLAN subinterfaces on the data interface. The rest of this procedure applies to the subinterfaces. See [Add a Subinterface, on page 759](#).
- b) Click **Edit** (✎) for the data interface.
- c) Configure the name and other parameters. For regular firewall interfaces, see [Configure Routed Mode Interfaces, on page 778](#) or, for transparent mode, [Configure Bridge Group Interfaces, on page 783](#). For IPS-only interfaces, see [Inline Sets and Passive Interfaces, on page 815](#).

**Note** If the cluster control link interface MTU is not at least 100 bytes higher than the data interface MTU, you will see an error that you must reduce the MTU of the data interface. See, [Step 3, on page 656](#) to increase the cluster control link MTU, after which you can continue configuring the data interfaces.

- d) For clustering on multiple chassis, set a manual global MAC address for the EtherChannel. Click **Advanced**, and in the **Active Mac Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

Do not set the **Standby Mac Address**; it is ignored.

You must configure a MAC address for a Spanned EtherChannel to avoid potential network connectivity problems. With a manually-configured MAC address, the MAC address stays with the current control unit. If you do not configure a MAC address, then if the control unit changes, the new control unit uses a new MAC address for the interface, which can cause a temporary network outage.

- e) Click **OK**. Repeat the above steps for other data interfaces.

**Step 5** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Management Center: Configure Cluster Health Monitor Settings

The **Cluster Health Monitor Settings** section of the **Cluster** page displays the settings described in the table below.

*Figure 279: Cluster Health Monitor Settings*

| Cluster Health Monitor Settings  |          |                           |                    |
|-----------------------------------------------------------------------------------------------------------------------|----------|---------------------------|--------------------|
| <b>Timeouts</b>                                                                                                       |          |                           |                    |
| Hold Time                                                                                                             |          |                           | 3 s                |

| Field           | Description |
|-----------------|-------------|
| <b>Timeouts</b> |             |

| Field                            | Description                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Hold Time                        | Between .3 and 45 seconds; The default is 3 seconds. To determine node system health, the cluster nodes send heartbeat messages on the cluster control link to other nodes. If a node does not receive any heartbeat messages from a peer node within the hold time period, the peer node is considered unresponsive or dead.                                                                                                             |
| Interface Debounce Time          | Between 300 and 9000 ms. The default is 500 ms. The interface debounce time is the amount of time before the node considers an interface to be failed, and the node is removed from the cluster.                                                                                                                                                                                                                                          |
| <b>Monitored Interfaces</b>      | The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. |
| Service Application              | Shows whether the Snort and disk-full processes are monitored.                                                                                                                                                                                                                                                                                                                                                                            |
| Unmonitored Interfaces           | Shows unmonitored interfaces.                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Auto-Rejoin Settings</b>      |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Cluster Interface                | Shows the auto-rejoin settings after a cluster control link failure.                                                                                                                                                                                                                                                                                                                                                                      |
| <i>Attempts</i>                  | Between -1 and 65535. The default is -1 (unlimited). Sets the number of rejoin attempts.                                                                                                                                                                                                                                                                                                                                                  |
| <i>Interval Between Attempts</i> | Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.                                                                                                                                                                                                                                                                                                                             |
| <i>Interval Variation</i>        | Between 1 and 3. The default is 1x the interval duration. Defines if the interval duration increases at each attempt.                                                                                                                                                                                                                                                                                                                     |
| Data Interfaces                  | Shows the auto-rejoin settings after a data interface failure.                                                                                                                                                                                                                                                                                                                                                                            |
| <i>Attempts</i>                  | Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.                                                                                                                                                                                                                                                                                                                                                               |
| <i>Interval Between Attempts</i> | Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.                                                                                                                                                                                                                                                                                                                             |
| <i>Interval Variation</i>        | Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt.                                                                                                                                                                                                                                                                                                                     |
| System                           | Shows the auto-rejoin settings after internal errors. Internal failures include: application sync timeout; inconsistent application statuses; and so on.                                                                                                                                                                                                                                                                                  |
| <i>Attempts</i>                  | Between -1 and 65535. The default is 3. Sets the number of rejoin attempts.                                                                                                                                                                                                                                                                                                                                                               |
| <i>Interval Between Attempts</i> | Between 2 and 60. The default is 5 minutes. Defines the interval duration in minutes between rejoin attempts.                                                                                                                                                                                                                                                                                                                             |

| Field                     | Description                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>Interval Variation</i> | Between 1 and 3. The default is 2x the interval duration. Defines if the interval duration increases at each attempt. |

**Note** If you disable the system health check, fields that do not apply when the system health check is disabled will not show.

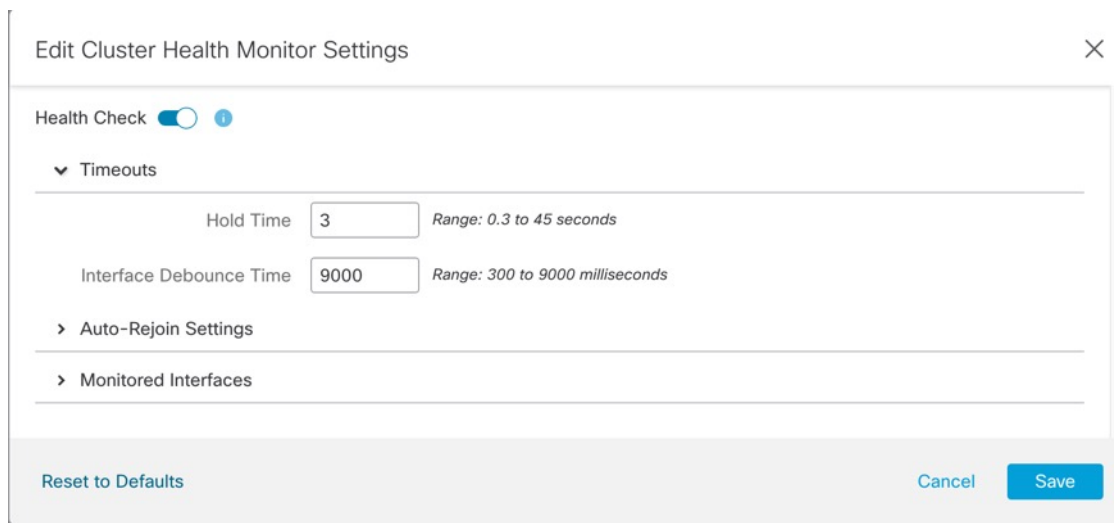

You can change these settings from this section.

You can monitor any port-channel ID, single physical interface ID, as well as the Snort and disk-full processes. Health monitoring is not performed on VLAN subinterfaces or virtual interfaces such as VNIs or BVIs. You cannot configure monitoring for the cluster control link; it is always monitored.

**Procedure**

- Step 1** Choose **Devices > Device Management**.
- Step 2** Next to the cluster you want to modify, click **Edit** (🔗).
- Step 3** Click **Cluster**.
- Step 4** In the **Cluster Health Monitor Settings** section, click **Edit** (🔗).
- Step 5** Disable the system health check by clicking the **Health Check** slider .

*Figure 280: Disable the System Health Check*

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

- Step 6** Configure the hold time and interface debounce time.

- **Hold Time**—Set the hold time to determine the amount of time between node heartbeat status messages, between .3 and 45 seconds; The default is 3 seconds.
- **Interface Debounce Time**—Set the debounce time between 300 and 9000 ms. The default is 500 ms. Lower values allow for faster detection of interface failures. Note that configuring a lower debounce time increases the chances of false-positives. When an interface status update occurs, the node waits the number of milliseconds specified before marking the interface as failed, and the node is removed from the cluster. In the case of an EtherChannel that transitions from a down state to an up state (for example, the switch reloaded, or the switch enabled an EtherChannel), a longer debounce time can prevent the interface from appearing to be failed on a cluster node just because another cluster node was faster at bundling the ports.

**Step 7**

Customize the auto-rejoin cluster settings after a health check failure.

**Figure 281: Configure Auto-Rejoin Settings**

▼ Auto-Rejoin Settings

---

**Cluster Interface**

Attempts  Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts  Range: 2-60 minutes between rejoin attempts

Interval Variation  Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

**Data Interface**

Attempts  Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts  Range: 2-60 minutes between rejoin attempts

Interval Variation  Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

**System**

Attempts  Range: 0-65535 (-1 for unlimited number of attempts)

Interval Between Attempts  Range: 2-60 minutes between rejoin attempts

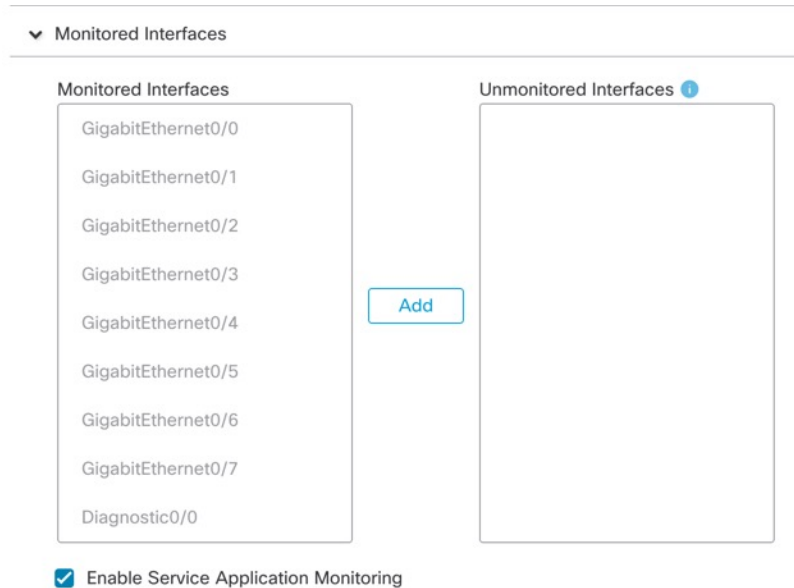

Interval Variation  Range: 1-3. Defines if the interval duration increases. 1 (no change); 2 (2 x the previous duration), or 3 (3 x the previous duration).

Set the following values for the **Cluster Interface**, **Data Interface**, and **System** (internal failures include: application sync timeout; inconsistent application statuses; and so on):

- **Attempts**—Sets the number of rejoin attempts, between -1 and 65535. **0** disables auto-rejoining. The default for the **Cluster Interface** is -1 (unlimited). The default for the **Data Interface** and **System** is 3.
- **Interval Between Attempts**—Defines the interval duration in minutes between rejoin attempts, between 2 and 60. The default value is 5 minutes. The maximum total time that the node attempts to rejoin the cluster is limited to 14400 minutes (10 days) from the time of last failure.
- **Interval Variation**—Defines if the interval duration increases. Set the value between 1 and 3: **1** (no change); **2** (2 x the previous duration), or **3** (3 x the previous duration). For example, if you set the interval duration to 5 minutes, and set the variation to 2, then the first attempt is after 5 minutes; the 2nd attempt is 10 minutes (2 x 5); the 3rd attempt 20 minutes (2 x 10), and so on. The default value is **1** for the **Cluster Interface** and **2** for the **Data Interface** and **System**.

- Step 8** Configure monitored interfaces by moving interfaces in the **Monitored Interfaces** or **Unmonitored Interfaces** window. You can also check or uncheck **Enable Service Application Monitoring** to enable or disable monitoring of the Snort and disk-full processes.

**Figure 282: Configure Monitored Interfaces**

The interface health check monitors for link failures. If all physical ports for a given logical interface fail on a particular node, but there are active ports under the same logical interface on other nodes, then the node is removed from the cluster. The amount of time before the node removes a member from the cluster depends on the type of interface and whether the node is an established node or is joining the cluster. Health check is enabled by default for all interfaces and for the Snort and disk-full processes.

You might want to disable health monitoring of non-essential interfaces.

When any topology changes occur (such as adding or removing a data interface, enabling or disabling an interface on the node or the switch, or adding an additional switch to form a VSS or vPC) you should disable the system health check feature and also disable interface monitoring for the disabled interfaces. When the topology change is complete, and the configuration change is synced to all nodes, you can re-enable the system health check feature and monitored interfaces.

- Step 9** Click **Save**.
- Step 10** Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

## FXOS: Remove a Cluster Node

The following sections describe how to remove nodes temporarily or permanently from the cluster.

## Temporary Removal

A cluster node will be automatically removed from the cluster due to a hardware or network failure, for example. This removal is temporary until the conditions are rectified, and it can rejoin the cluster. You can also manually disable clustering.

To check whether a device is currently in the cluster, check the cluster status on the chassis manager **Logical Devices** page:

| Gateway   | Management Port | Status |
|-----------|-----------------|--------|
| 10.89.5.1 | Ethernet1/4     | Online |

**Attributes**

- Cluster Operational Status : in-cluster
- FIREPOWER-MGMT-IP : 10.89.5.20
- CLUSTER-ROLE : control-node
- CLUSTER-IP : 127.2.1.1
- MGMT-URL : https://
- UUID : 95507f24-32aa-11ed-b9da-d0a0d37634c

For threat defense using the management center, you should leave the device in the management center device list so that it can resume full functionality after you reenables clustering.

- Disable clustering in the application—You can disable clustering using the application CLI. Enter the **cluster remove unit name** command to remove any node other than the one you are logged into. The bootstrap configuration remains intact, as well as the last configuration synced from the control node, so you can later re-add the node without losing your configuration. If you enter this command on a data node to remove the control node, a new control node is elected.

When a device becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, re-enable clustering. The Management interface remains up using the IP address the node received from the bootstrap configuration. However if you reload, and the node is still inactive in the cluster, the Management interface is disabled.

To reenables clustering, on the threat defense enter **cluster enable**.

- Disable the application instance—In the chassis manager on the **Logical Devices** page, click the **Slider enabled** () . You can later reenables it using the **Slider disabled** ().
- Shut down the security module/engine—In the chassis manager on the **Security Module/Engine** page, click the **Power Off icon**.
- Shut down the chassis—In the chassis manager on the **Overview** page, click the **Shut Down icon**.

## Permanent Removal

You can permanently remove a cluster node using the following methods.

For threat defense using the management center, be sure to remove the node from the management center device list after you disable clustering on the chassis.

- Delete the logical device—In the chassis manager on the **Logical Devices** page, click the **Delete** (  ). You can then deploy a standalone logical device, a new cluster, or even add a new logical device to the same cluster.
- Remove the chassis or security module from service—If you remove a device from service, you can add replacement hardware as a new node of the cluster.

## Management Center: Manage Cluster Members

After you deploy the cluster, you can change the configuration and manage cluster members.

### Add a New Cluster Member

When you add a new cluster member in FXOS, the Secure Firewall Management Center adds the member automatically.

#### Before you begin

- Make sure the interface configuration is the same on the replacement unit as for the other chassis.

#### Procedure

- 
- Step 1** Add the new unit to the cluster in FXOS. See the [FXOS configuration guide](#).
- Wait for the new unit to be added to the cluster. Refer to the chassis manager **Logical Devices** screen or use the threat defense **show cluster info** command to view cluster status.
- Step 2** The new cluster member is added automatically. To monitor the registration of the replacement unit, view the following:
- **Cluster Status** dialog box (which is available from the **Devices > Device Management More** (  ) icon or from the **Devices > Device Management > Cluster** tab > **General** area > **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the management center attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile**.
  - System status > **Tasks** —The management center shows all registration events and failures.
  - **Devices > Device Management**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.
-

# Replace a Cluster Member

You can replace a cluster member in an existing cluster. The management center auto-detects the replacement unit. However, you must manually delete the old cluster member in the management center. This procedure also applies to a unit that was reinitialized; in this case, although the hardware remains the same, it appears to be a new member.

**Before you begin**

- Make sure the interface configuration is the same on the replacement unit as for other chassis.

**Procedure**

**Step 1** For a new chassis, if possible, backup and restore the configuration from the old chassis in FXOS.

If you are replacing a module in a Firepower 9300, you do not need to perform these steps.

If you do not have a backup FXOS configuration from the old chassis, first perform the steps in [Add a New Cluster Member](#), on page 663.

For information about all of the below steps, see the [FXOS configuration guide](#).

- Use the configuration export feature to export an XML file containing logical device and platform configuration settings for your Firepower 4100/9300 chassis.
- Import the configuration file to the replacement chassis.
- Accept the license agreement.
- If necessary, upgrade the logical device application instance version to match the rest of the cluster.

**Step 2** In the management center for the old unit, choose **Devices > Device Management > More (⋮) > Delete**.

**Step 3** Confirm that you want to delete the unit.

The unit is removed from the cluster and from the management center devices list.

**Step 4** The new or reinitialized cluster member is added automatically. To monitor the registration of the replacement unit, view the following:

- **Cluster Status** dialog box (**Devices > Device Management > More (⋮)** icon or **Devices > Device Management > Cluster** page > **General** area > **Cluster Live Status** link)—A unit that is joining the cluster on the chassis shows "Joining cluster..." After it joins the cluster, the management center attempts to register it, and the status changes to "Available for Registration". After it completes registration, the status changes to "In Sync." If the registration fails, the unit will stay at "Available for Registration". In this case, force a re-registration by clicking **Reconcile All**.

- **System (⚙) > Tasks**—The management center shows all registration events and failures.

- **Devices > Device Management**—When you expand the cluster on the devices listing page, you can see when a unit is registering when it has the loading icon to the left.

## Deactivate a Member

You may want to deactivate a member in preparation for deleting the unit, or temporarily for maintenance. This procedure is meant to temporarily deactivate a member; the unit will still appear in the management center device list.

**Note** When a unit becomes inactive, all data interfaces are shut down; only the Management interface can send and receive traffic. To resume traffic flow, reenable clustering. The Management interface remains up using the IP address the unit received from the bootstrap configuration. However if you reload, and the unit is still inactive in the cluster, the management interface is disabled. You must use the console for any further configuration.

### Procedure

**Step 1** For the unit you want to deactivate, choose **Devices > Device Management > More (⋮) > Disable Clustering**.

| Unit Name                                     | IP Address | Model                   | Version | Security Module                           | Essentials, IPS             | Interfaces | Other |
|-----------------------------------------------|------------|-------------------------|---------|-------------------------------------------|-----------------------------|------------|-------|
| chassis1-mod1<br>10.89.5.20 - Routed          | Snort 3    | Firepower 9300 with FTD | 7.3.0   | fp9300-docs.cisco.com Security Module - 1 | Essentials, IPS (3 more...) | in-out     | N/A   |
| chassis2-mod1(Control)<br>10.89.5.11 - Routed | Snort 3    | Firepower 9300 with FTD | 7.3.0   | FP9300-2.cisco.com.4 Security Module - 1  | Essentials, IPS (3 more...) | in-out     | N/A   |
| chassis2-mod2<br>10.89.5.12 - Routed          | Snort 3    | Firepower 9300 with FTD | 7.3.0   | FP9300-2.cisco.com.4 Security Module - 2  | Essentials, IPS (3 more...) | in-out     | N/A   |

You can also deactivate a unit from the **Cluster Status** dialog box (**Devices > Device Management > More (⋮) > Cluster Live Status**).

**Step 2** Confirm that you want to disable clustering on the unit.

The unit will show **(Disabled)** next to its name in the **Devices > Device Management** list.

| Unit Name                                    | IP Address | Model | Version | Security Module | Essentials, IPS | Interfaces | Other |
|----------------------------------------------|------------|-------|---------|-----------------|-----------------|------------|-------|
| td-cluster1 (2)<br>Cluster                   |            |       |         |                 |                 |            |       |
| 10.89.5.21 (Disabled)<br>10.89.5.21 - Routed |            |       |         |                 |                 |            |       |
| 9300-1 (Master)<br>10.89.5.20 - Routed       |            |       |         |                 |                 |            |       |

**Step 3** To reenable clustering, see [Rejoin the Cluster](#), on page 666.

## Rejoin the Cluster

If a unit was removed from the cluster, for example for a failed interface or if you manually disabled clustering, you must manually rejoin the cluster. Make sure the failure is resolved before you try to rejoin the cluster. See [Rejoining the Cluster, on page 684](#) for more information about why a unit can be removed from a cluster.

### Procedure

**Step 1** For the unit you want to reactivate, choose **Devices > Device Management > More (⋮) > Enable Clustering**.

You can also reactivate a unit from the **Cluster Status** dialog box (**Devices > Device Management > More (⋮) > Cluster Live Status**).

**Step 2** Confirm that you want to enable clustering on the unit.

## Unregister a Data Node

If you need to permanently remove a cluster node (for example, if you remove a module on the Firepower 9300, or remove a chassis), then you should unregister it from the management center.

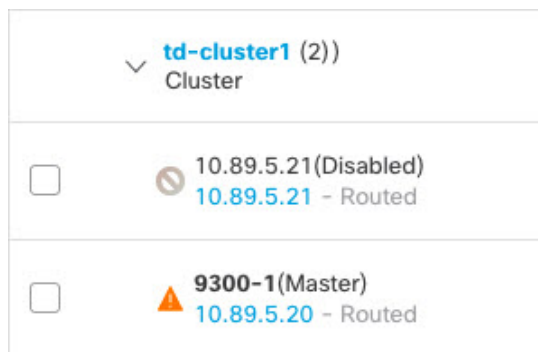

Do not unregister the node if it is still a healthy part of the cluster, or if you only want to disable the node temporarily. To remove it permanently from the cluster in FXOS, see [FXOS: Remove a Cluster Node, on page 661](#). If you unregister it from the management center, and it is still part of the cluster, it will continue to pass traffic, and could even become the control node—a control node that the management center can no longer manage.

### Before you begin

To manually deactivate the node, see [Deactivate a Member, on page 665](#). Before you unregister a node, the node must be inactive, either manually or because of a health failure.

### Procedure

**Step 1** Make sure the node is ready to be unregistered from the management center. On **Devices > Device Management**, make sure the node shows **(Disabled)**.

You can also view each node's status on the **Cluster Status** dialog box available from **More** (⋮). If the status is stale, click **Reconcile All** on the **Cluster Status** dialog box to force an update.

**Step 2** In the management center for the data node you want to delete, choose **Devices > Device Management > More** (⋮) > **Unregister**.

**Step 3** Confirm that you want to unregister the node.

The node is removed from the cluster and from the management center devices list.

## Change the Control Unit

**Caution** The best method to change the control unit is to disable clustering on the control unit, wait for a new control election, and then re-enable clustering. If you must specify the *exact* unit you want to become the control unit, use the procedure in this section. Note that for centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

To change the control unit, perform the following steps.

### Procedure

**Step 1** Open the **Cluster Status** dialog box by choosing **Devices > Device Management > More** (⋮) > **Cluster Live Status**.

You can also access the **Cluster Status** dialog box from **Devices > Device Management > Cluster page > General area > Cluster Live Status** link.

**Step 2** For the unit you want to become the control unit, choose **More** (⋮) > **Change Role to Control**.

**Step 3** You are prompted to confirm the role change. Check the checkbox, and click **OK**.

## Reconcile Cluster Members

If a cluster member fails to register, you can reconcile the cluster membership from the chassis to the Secure Firewall Management Center. For example, a data unit might fail to register if the management center is occupied with certain processes, or if there is a network issue.

### Procedure

---

**Step 1** Choose **Devices > Device Management > More** (⋮) for the cluster, and then choose **Cluster Live Status** to open the **Cluster Status** dialog box.

You can also open the **Cluster Status** dialog box from the **Devices > Device Management > Cluster** page > **General** area > **Cluster Live Status** link.

**Step 2** Click **Reconcile All**.

For more information about the cluster status, see [Management Center: Monitoring the Cluster, on page 668](#).

---

## Management Center: Monitoring the Cluster

You can monitor the cluster in Secure Firewall Management Center and at the threat defense CLI.

- **Cluster Status** dialog box, which is available from the **Devices > Device Management > More** (⋮) icon or from the **Devices > Device Management > Cluster** page > **General** area > **Cluster Live Status** link.

### Cluster Status ?

Overall Status:  Clustering is disabled for 1 node(s)

The Control unit has a graphic indicator identifying its role.

Cluster member **Status** includes the following states:

- **In Sync.**—The unit is registered with the management center.
- **Pending Registration**—The unit is part of the cluster, but has not yet registered with the management center. If a unit fails to register, you can retry registration by clicking **Reconcile All**.
- **Clustering is disabled**—The unit is registered with the management center, but is an inactive member of the cluster. The clustering configuration remains intact if you intend to later re-enable it, or you can delete the unit from the cluster.
- **Joining cluster...**—The unit is joining the cluster on the chassis, but has not completed joining. After it joins, it will register with the management center.

For each unit, you can view the **Summary** or the **History**.

For each unit from the **More** () menu, you can perform the following status changes:

- **Disable Clustering**
- **Enable Clustering**

- **Change Role to Control**

- **System** (⚙️) > **Tasks** page.

The **Tasks** page shows updates of the Cluster Registration task as each unit registers.

- **Devices** > **Device Management** > *cluster\_name*.

When you expand the cluster on the devices listing page, you can see all member units, including the control unit shown with its role next to the IP address. For units that are still registering, you can see the loading icon.

- **show cluster** {**access-list** [*acl\_name*] | **conn** [count] | **cpu** [usage] | **history** | **interface-mode** | **memory** | **resource usage** | **service-policy** | **traffic** | **xlate count**}

To view aggregated data for the entire cluster or other information, use the **show cluster** command.

- **show cluster info** [**auto-join** | **clients** | **conn-distribution** | **flow-mobility counters** | **goid** [*options*] | **health** | **incompatible-config** | **loadbalance** | **old-members** | **packet-distribution** | **trace** [*options*] | **transport** { **asp** | **cp**}]

To view cluster information, use the **show cluster info** command.

## Cluster Health Monitor Dashboard

### Cluster Health Monitor

When a threat defense is the control node of a cluster, the management center collects various metrics periodically from the device metric data collector. The cluster health monitor is comprised of the following components:

- **Overview dashboard**—Displays information about the cluster topology, cluster statistics, and metric charts:
  - The topology section displays a cluster's live status, the health of individual threat defense, threat defense node type (control node or data node), and the status of the device. The status of the device could be *Disabled* (when the device leaves the cluster), *Added out of box* (in a public cloud cluster, the additional nodes that do not belong to the management center), or *Normal* (ideal state of the node).
  - The cluster statistics section displays current metrics of the cluster with respect to the CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.

---

**Note** The CPU and memory metrics display the individual average of the data plane and snort usage.

---

- The metric charts, namely, CPU Usage, Memory Usage, Throughput, and Connections, diagrammatically display the statistics of the cluster over the specified time period.
- **Load Distribution dashboard**—Displays load distribution across the cluster nodes in two widgets:

- The Distribution widget displays the average packet and connection distribution over the time range across the cluster nodes. This data depicts how the load is being distributed by the nodes. Using this widget, you can easily identify any abnormalities in the load distribution and rectify it.
- The Node Statistics widget displays the node level metrics in table format. It displays metric data on CPU usage, memory usage, input rate, output rate, active connections, and NAT translations across the cluster nodes. This table view enables you to correlate data and easily identify any discrepancies.
- Member Performance dashboard—Displays current metrics of the cluster nodes. You can use the selector to filter the nodes and view the details of a specific node. The metric data include CPU usage, memory usage, input rate, output rate, active connections, and NAT translations.
- CCL dashboard—Displays, graphically, the cluster control link data namely, the input, and output rate.
- Troubleshooting and Links — Provides convenient links to frequently used troubleshooting topics and procedures.
- Time range—An adjustable time window to constrain the information that appears in the various cluster metrics dashboards and widgets.
- Custom Dashboard—Displays data on both cluster-wide metrics and node-level metrics. However, node selection only applies for the threat defense metrics and not for the entire cluster to which the node belongs.

## Viewing Cluster Health

You must be an Admin, Maintenance, or Security Analyst user to perform this procedure.

The cluster health monitor provides a detailed view of the health status of a cluster and its nodes. This cluster health monitor provides health status and trends of the cluster in an array of dashboards.

### Before you begin

- Ensure you have created a cluster from one or more devices in the management center.

### Procedure

- 
- Step 1** Choose **System** (⚙) > **Health** > **Monitor**.  
Use the Monitoring navigation pane to access node-specific health monitors.
- Step 2** In the device list, click **Expand** (>) and **Collapse** (v) to expand and collapse the list of managed cluster devices.
- Step 3** To view the cluster health statistics, click on the cluster name. The cluster monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:
- Overview — Highlights key metrics from the other predefined dashboards, including its nodes, CPU, memory, input and output rates, connection statistics, and NAT translation information.
  - Load Distribution — Traffic and packet distribution across the cluster nodes.

- Member Performance — Node-level statistics on CPU usage, memory usage, input throughput, output throughput, active connection, and NAT translation.
- CCL — Interface status and aggregate traffic statistics.

You can navigate through the various metrics dashboards by clicking on the labels. For a comprehensive list of the supported cluster metrics, see [Cisco Secure Firewall Threat Defense Health Metrics](#).

**Step 4** You can configure the time range from the drop-down in the upper-right corner. The time range can reflect a period as short as the last hour (the default) or as long as two weeks. Select **Custom** from the drop-down to configure a custom start and end date.

Click the refresh icon to set auto refresh to 5 minutes or to toggle off auto refresh.

**Step 5** Click on deployment icon for a deployment overlay on the trend graph, with respect to the selected time range. The deployment icon indicates the number of deployments during the selected time-range. A vertical band indicates the deployment start and end time. For multiple deployments, multiple bands/lines appear. Click on the icon on top of the dotted line to view the deployment details.

**Step 6** (For node-specific health monitor) View the **Health Alerts** for the node in the alert notification at the top of page, directly to the right of the device name.

Hover your pointer over the **Health Alerts** to view the health summary of the node. The popup window shows a truncated summary of the top five health alerts. Click on the popup to open a detailed view of the health alert summary.

**Step 7** (For node-specific health monitor) The device monitor reports health and performance metrics in several predefined dashboards by default. The metrics dashboards include:

- Overview — Highlights key metrics from the other predefined dashboards, including CPU, memory, interfaces, connection statistics; plus disk usage and critical process information.
- CPU — CPU utilization, including the CPU usage by process and by physical cores.
- Memory — Device memory utilization, including data plane and Snort memory usage.
- Interfaces — Interface status and aggregate traffic statistics.
- Connections — Connection statistics (such as elephant flows, active connections, peak connections, and so on) and NAT translation counts.
- Snort — Statistics that are related to the Snort process.
- ASP drops — Statistics related to the dropped packets against various reasons.

You can navigate through the various metrics dashboards by clicking on the labels. See [Cisco Secure Firewall Threat Defense Health Metrics](#) for a comprehensive list of the supported device metrics.

**Step 8** Click the plus sign (+) in the upper right corner of the health monitor to create a custom dashboard by building your own variable set from the available metric groups.

For cluster-wide dashboard, choose Cluster metric group, and then choose the metric.

---

## Cluster Metrics

The cluster health monitor tracks statistics that are related to a cluster and its nodes, and aggregate of load distribution, performance, and CCL traffic statistics.

**Table 44: Cluster Metrics**

| Metric           | Description                                                                                  | Format     |
|------------------|----------------------------------------------------------------------------------------------|------------|
| CPU              | Average of CPU metrics on the nodes of a cluster (individually for data plane and snort).    | percentage |
| Memory           | Average of memory metrics on the nodes of a cluster (individually for data plane and snort). | percentage |
| Data Throughput  | Incoming and outgoing data traffic statistics for a cluster.                                 | bytes      |
| CCL Throughput   | Incoming and outgoing CCL traffic statistics for a cluster.                                  | bytes      |
| Connections      | Count of active connections in a cluster.                                                    | number     |
| NAT Translations | Count of NAT translations for a cluster.                                                     | number     |
| Distribution     | Connection distribution count in the cluster for every second.                               | number     |
| Packets          | Packet distribution count in the cluster for every second.                                   | number     |

## Management Center: Troubleshooting the Cluster

You can use the **CCL Ping** tool to make sure the cluster control link is operating correctly. You can also use the following tools that are available for devices and clusters:

- Troubleshooting files—If a node fails to join the cluster, a troubleshooting file is automatically generated. You can also generate and download troubleshooting files from the **Devices > Device Management > Cluster > General** area. See [Generate Troubleshooting Files, on page 42](#).

You can also generate files from the **Device Management** page by clicking **More** (⋮) and choosing **Troubleshoot Files**.

- CLI output—From the **Devices > Device Management > Cluster > General** area, you can view a set of pre-defined CLI outputs that can help you troubleshoot the cluster. The following commands are automatically run for the cluster:
  - **show running-config cluster**
  - **show cluster info**
  - **show cluster info health**
  - **show cluster info transport cp**

- **show version**
- **show asp drop**
- **show counters**
- **show arp**
- **show int ip brief**
- **show blocks**
- **show cpu detailed**
- **show interface *ccl\_interface***
- **ping *ccl\_ip* size *ccl\_mtu* repeat 2**

You can also enter any **show** command in the Command field. See [View CLI Output, on page 45](#) for more information.

## Perform a Ping on the Cluster Control Link

You can check to make sure all the cluster nodes can reach each other over the cluster control link by performing a ping. One major cause for the failure of a node to join the cluster is an incorrect cluster control link configuration; for example, the cluster control link MTU may be set higher than the connecting switch MTUs.

### Procedure

---

- Step 1** Choose **Devices > Device Management**, click the **More** (⋮) icon next to the cluster, and choose **> Cluster Live Status**.

Figure 283: Cluster Status

Cluster Status ?

---

Overall Status: Cluster has all nodes in sync

Nodes details (2) Refresh Reconcile All

|   | Status   | Device Name                      | Unit Name   | Chassis URL |   |
|---|----------|----------------------------------|-------------|-------------|---|
| > | In Sync. | 172.16.0.50 <span>Control</span> | 172.16.0.50 | N/A         | ⋮ |
| > | In Sync. | 172.16.0.51                      | 172.16.0.51 | N/A         | ⋮ |

Dated: 11:52:26 | 20 Dec 2021 Close

**Step 2** Expand one of the nodes, and click **CCL Ping**.

The node sends a ping on the cluster control link to every other node using a packet size that matches the maximum MTU.

# Examples for Clustering

These examples include typical deployments.

## Firewall on a Stick

Data traffic from different security domains are associated with different VLANs, for example, VLAN 10 for the inside network and VLAN 20 for the outside network. Each has a single physical port connected to the external switch or router. Trunking is enabled so that all packets on the physical link are 802.1q encapsulated. This is the firewall between VLAN 10 and VLAN 20.

When using Spanned EtherChannels, all data links are grouped into one EtherChannel on the switch side. If the becomes unavailable, the switch will rebalance traffic between the remaining units.

## Traffic Segregation

You may prefer physical separation of traffic between the inside and outside network.

As shown in the diagram above, there is one Spanned EtherChannel on the left side that connects to the inside switch, and the other on the right side to outside switch. You can also create VLAN subinterfaces on each EtherChannel if desired.

## Reference for Clustering

This section includes more information about how clustering operates.

## Threat Defense Features and Clustering

Some threat defense features are not supported with clustering, and some are only supported on the control unit. Other features might have caveats for proper usage.

## Unsupported Features with Clustering

These features cannot be configured with clustering enabled, and the commands will be rejected.

---

**Note** To view FlexConfig features that are also not supported with clustering, for example WCCP inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2553](#).

---

- Remote access VPN (SSL VPN and IPsec VPN)
- DHCP client, server, and proxy. DHCP relay is supported.
- Virtual Tunnel Interfaces (VTIs)
- High Availability
- Integrated Routing and Bridging
- Management Center UCAPL/CC mode

## Centralized Features for Clustering

The following features are only supported on the control node, and are not scaled for the cluster.

---

**Note** Traffic for centralized features is forwarded from member nodes to the control node over the cluster control link.

If you use the rebalancing feature, traffic for centralized features may be rebalanced to non-control nodes before the traffic is classified as a centralized feature; if this occurs, the traffic is then sent back to the control node.

For centralized features, if the control node fails, all connections are dropped, and you have to re-establish the connections on the new control node.

---

---

**Note** To view FlexConfig features that are also centralized with clustering, for example RADIUS inspection, see the [ASA general operations configuration guide](#). FlexConfig lets you configure many ASA features that are not present in the management center GUI. See [FlexConfig Policies, on page 2553](#).

---

- The following application inspections:
  - DCERPC
  - ESMTTP
  - NetBIOS
  - PPTP
  - RSH
  - SQLNET
  - SUNRPC

- TFTP
- XDMCP
- Static route monitoring
- Site-to-site VPN
- IGMP multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- PIM multicast control plane protocol processing (data plane forwarding is distributed across the cluster)
- Dynamic routing

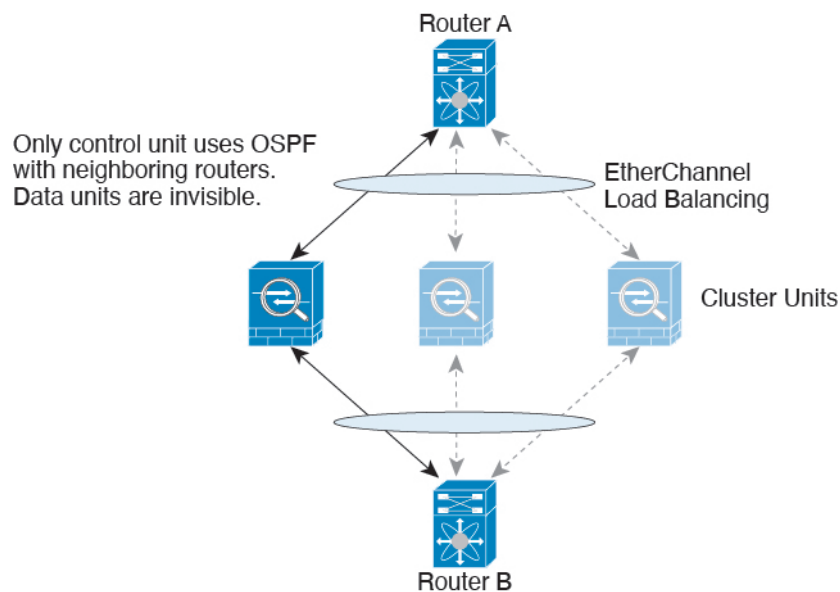

## Connection Settings

Connection limits are enforced cluster-wide. Each node has an estimate of the cluster-wide counter values based on broadcast messages. Due to efficiency considerations, the configured connection limit across the cluster might not be enforced exactly at the limit number. Each node may overestimate or underestimate the cluster-wide counter value at any given time. However, the information will get updated over time in a load-balanced cluster.

## Dynamic Routing and Clustering

The routing process only runs on the control unit, and routes are learned through the control unit and replicated to secondaries. If a routing packet arrives at a data unit, it is redirected to the control unit.

**Figure 285: Dynamic Routing**

After the data units learn the routes from the control unit, each unit makes forwarding decisions independently. The OSPF LSA database is not synchronized from the control unit to data units. If there is a control unit switchover, the neighboring router will detect a restart; the switchover is not transparent. The OSPF process picks an IP address as its router ID. Although not required, you can assign a static router ID to ensure a

consistent router ID is used across the cluster. See the OSPF Non-Stop Forwarding feature to address the interruption.

## FTP and Clustering

- If FTP data channel and control channel flows are owned by different cluster members, then the data channel owner will periodically send idle timeout updates to the control channel owner and update the idle timeout value. However, if the control flow owner is reloaded, and the control flow is re-hosted, the parent/child flow relationship will not longer be maintained; the control flow idle timeout will not be updated.

## Multicast Routing and Clustering

The control unit handles all multicast routing packets and data packets until fast-path forwarding is established. After the connection is established, each data unit can forward multicast data packets.

## NAT and Clustering

NAT can affect the overall throughput of the cluster. Inbound and outbound NAT packets can be sent to different threat defenses in the cluster, because the load balancing algorithm relies on IP addresses and ports, and NAT causes inbound and outbound packets to have different IP addresses and/or ports. When a packet arrives at the threat defense that is not the NAT owner, it is forwarded over the cluster control link to the owner, causing large amounts of traffic on the cluster control link. Note that the receiving node does not create a forwarding flow to the owner, because the NAT owner may not end up creating a connection for the packet depending on the results of security and policy checks.

If you still want to use NAT in clustering, then consider the following guidelines:

- PAT with Port Block Allocation—See the following guidelines for this feature:
  - Maximum-per-host limit is not a cluster-wide limit, and is enforced on each node individually. Thus, in a 3-node cluster with the maximum-per-host limit configured as 1, if the traffic from a host is load-balanced across all 3 nodes, then it can get allocated 3 blocks with 1 in each node.
  - Port blocks created on the backup node from the backup pools are not accounted for when enforcing the maximum-per-host limit.
  - On-the-fly PAT rule modifications, where the PAT pool is modified with a completely new range of IP addresses, will result in xlate backup creation failures for the xlate backup requests that were still in transit while the new pool became effective. This behavior is not specific to the port block allocation feature, and is a transient PAT pool issue seen only in cluster deployments where the pool is distributed and traffic is load-balanced across the cluster nodes.
  - When operating in a cluster, you cannot simply change the block allocation size. The new size is effective only after you reload each device in the cluster. To avoid having to reload each device, we recommend that you delete all block allocation rules and clear all xlates related to those rules. You can then change the block size and recreate the block allocation rules.
- NAT pool address distribution for dynamic PAT—When you configure a PAT pool, the cluster divides each IP address in the pool into port blocks. By default, each block is 512 ports, but if you configure port block allocation rules, your block setting is used instead. These blocks are distributed evenly among the nodes in the cluster, so that each node has one or more blocks for each IP address in the PAT pool. Thus, you could have as few as one IP address in a PAT pool for a cluster, if that is sufficient for the number

of PAT'ed connections you expect. Port blocks cover the 1024-65535 port range, unless you configure the option to include the reserved ports, 1-1023, on the PAT pool NAT rule.

- Reusing a PAT pool in multiple rules—To use the same PAT pool in multiple rules, you must be careful about the interface selection in the rules. You must either use specific interfaces in all rules, or "any" in all rules. You cannot mix specific interfaces and "any" across the rules, or the system might not be able to match return traffic to the right node in the cluster. Using unique PAT pools per rule is the most reliable option.
- No round-robin—Round-robin for a PAT pool is not supported with clustering.
- No extended PAT—Extended PAT is not supported with clustering.
- Dynamic NAT xlates managed by the control node—The control node maintains and replicates the xlate table to data nodes. When a data node receives a connection that requires dynamic NAT, and the xlate is not in the table, it requests the xlate from the control node. The data node owns the connection.
- Stale xlates—The xlate idle time on the connection owner does not get updated. Thus, the idle time might exceed the idle timeout. An idle timer value higher than the configured timeout with a refcnt of 0 is an indication of a stale xlate.
- No static PAT for the following inspections—
  - FTP
  - RSH
  - SQLNET
  - TFTP
  - XDMCP
  - SIP
- If you have an extremely large number of NAT rules, over ten thousand, you should enable the transactional commit model using the **asp rule-engine transactional-commit nat** command in the device CLI. Otherwise, the node might not be able to join the cluster.

## SIP Inspection and Clustering

A control flow can be created on any node (due to load balancing); its child data flows must reside on the same node.

## SNMP and Clustering

You should always use the Local address, and not the Main cluster IP address for SNMP polling. If the SNMP agent polls the Main cluster IP address, if a new control node is elected, the poll to the new control node will fail.

When using SNMPv3 with clustering, if you add a new cluster node after the initial cluster formation, then SNMPv3 users are not replicated to the new node. You must remove the users, and re-add them, and then redeploy your configuration to force the users to replicate to the new node.

## Syslog and Clustering

- Each node in the cluster generates its own syslog messages. You can configure logging so that each node uses either the same or a different device ID in the syslog message header field. For example, the hostname configuration is replicated and shared by all nodes in the cluster. If you configure logging to use the hostname as the device ID, syslog messages generated by all nodes look as if they come from a single node. If you configure logging to use the local-node name that is assigned in the cluster bootstrap configuration as the device ID, syslog messages look as if they come from different nodes.

## TLS/SSL Connections and Clustering

The decryption states of TLS/SSL connections are not synchronized, and if the connection owner fails, then the decrypted connections will be reset. New connections will need to be established to a new unit. Connections that are not decrypted (they match a do-not-decrypt rule) are not affected and are replicated correctly.

## Cisco TrustSec and Clustering

Only the control node learns security group tag (SGT) information. The control node then populates the SGT to data nodes, and data nodes can make a match decision for SGT based on the security policy.

## VPN and Clustering

Site-to-site VPN is a centralized feature; only the control unit supports VPN connections.

---

**Note** Remote access VPN is not supported with clustering.

---

VPN functionality is limited to the control unit and does not take advantage of the cluster high availability capabilities. If the control unit fails, all existing VPN connections are lost, and VPN users will see a disruption in service. When a new control unit is elected, you must reestablish the VPN connections.

When you connect a VPN tunnel to a Spanned interface address, connections are automatically forwarded to the control unit.

VPN-related keys and certificates are replicated to all units.

## Performance Scaling Factor

When you combine multiple units into a cluster, you can expect the total cluster performance to be approximately 80% of the maximum combined throughput.

For example, for TCP throughput, the Firepower 9300 with 3 SM-40 modules can handle approximately 135 Gbps of real world firewall traffic when running alone. For 2 chassis, the maximum combined throughput will be approximately 80% of 270 Gbps (2 chassis x 135 Gbps): 216 Gbps.

## Control Unit Election

Members of the cluster communicate over the cluster control link to elect a control unit as follows:

1. When you deploy the cluster, each unit broadcasts an election request every 3 seconds.

- Any other units with a higher priority respond to the election request; the priority is set when you deploy the cluster and is not configurable.
- If after 45 seconds, a unit does not receive a response from another unit with a higher priority, then it becomes the control unit.

---

**Note** If multiple units tie for the highest priority, the cluster unit name and then the serial number is used to determine the control unit.

---

- If a unit later joins the cluster with a higher priority, it does not automatically become the control unit; the existing control unit always remains as the control unit unless it stops responding, at which point a new control unit is elected.
- In a "split brain" scenario when there are temporarily multiple control units, then the unit with highest priority retains the role while the other units return to data unit roles.

---

**Note** You can manually force a unit to become the control unit. For centralized features, if you force a control unit change, then all connections are dropped, and you have to re-establish the connections on the new control unit.

---

## High Availability Within the Cluster

Clustering provides high availability by monitoring chassis, unit, and interface health and by replicating connection states between units.

### Chassis-Application Monitoring

Chassis-application health monitoring is always enabled. The Firepower 4100/9300 chassis supervisor checks the threat defense application periodically (every second). If the threat defense device is up and cannot communicate with the Firepower 4100/9300 chassis supervisor for 3 seconds, the threat defense device generates a syslog message and leaves the cluster.

If the Firepower 4100/9300 chassis supervisor cannot communicate with the application after 45 seconds, it reloads the threat defense device. If the threat defense device cannot communicate with the supervisor, it removes itself from the cluster.

### Unit Health Monitoring

Each unit periodically sends a broadcast keepaliveheartbeat packet over the cluster control link. If the control node does not receive any keepaliveheartbeat packets or other packets from a data node within the configurable timeout period, then the control node removes the data node from the cluster. If the data nodes do not receive packets from the control node, then a new control node is elected from the remaining node.

If nodes cannot reach each other over the cluster control link because of a network failure and not because a node has actually failed, then the cluster may go into a "split brain" scenario where isolated data nodes will elect their own control nodes. For example, if a router fails between two cluster locations, then the original control node at location 1 will remove the location 2 data nodes from the cluster. Meanwhile, the nodes at location 2 will elect their own control node and form their own cluster. Note that asymmetric traffic may fail

in this scenario. After the cluster control link is restored, then the control node that has the higher priority will keep the control node's role. See [Control Unit Election, on page 682](#) for more information.

## Interface Monitoring

Each node monitors the link status of all hardware interfaces in use, and reports status changes to the control node. For clustering on multiple chassis, Spanned EtherChannels use the cluster Link Aggregation Control Protocol (cLACP). Each chassis monitors the link status and the cLACP protocol messages to determine if the port is still active in the EtherChannel, and informs the threat defense application if the interface is down. When you enable health monitoring, all physical interfaces are monitored by default (including the main EtherChannel for EtherChannel interfaces). Only named interfaces that are in an Up state can be monitored. For example, all member ports of an EtherChannel must fail before a *named* EtherChannel is removed from the cluster. You can optionally disable monitoring per interface.

If a monitored interface fails on a particular node, but it is active on other nodes, then the node is removed from the cluster. The amount of time before the threat defense device removes a node from the cluster depends on whether the node is an established member or is joining the cluster. The threat defense device does not monitor interfaces for the first 90 seconds that a node joins the cluster. Interface status changes during this time will not cause the threat defense device to be removed from the cluster. For an established member, the node is removed after 500 ms.

For clustering on multiple chassis, if you add or delete an EtherChannel from the cluster, interface health-monitoring is suspended for 95 seconds to ensure that you have time to make the changes on each chassis.

## Decorator Application Monitoring

When you install a decorator application on an interface, such as the Radware DefensePro application, then both the threat defense device and the decorator application must be operational to remain in the cluster. The unit does not join the cluster until both applications are operational. Once in the cluster, the unit monitors the decorator application health every 3 seconds. If the decorator application is down, the unit is removed from the cluster.

## Status After Failure

When a node in the cluster fails, the connections hosted by that node are seamlessly transferred to other nodes; state information for traffic flows is shared over the control node's cluster control link.

If the control node fails, then another member of the cluster with the highest priority (lowest number) becomes the control node.

The threat defense automatically tries to rejoin the cluster, depending on the failure event.

---

**Note** When the threat defense becomes inactive and fails to automatically rejoin the cluster, all data interfaces are shut down; only the Management interface can send and receive traffic.

---

## Rejoining the Cluster

After a cluster member is removed from the cluster, how it can rejoin the cluster depends on why it was removed:

- Failed cluster control link when initially joining—After you resolve the problem with the cluster control link, you must manually rejoin the cluster by re-enabling clustering.
- Failed cluster control link after joining the cluster—The threat defense automatically tries to rejoin every 5 minutes, indefinitely.
- Failed data interface—The threat defense automatically tries to rejoin at 5 minutes, then at 10 minutes, and finally at 20 minutes. If the join is not successful after 20 minutes, then the threat defense application disables clustering. After you resolve the problem with the data interface, you have to manually enable clustering.
- Failed node—If the node was removed from the cluster because of a node health check failure, then rejoining the cluster depends on the source of the failure. For example, a temporary power failure means the node will rejoin the cluster when it starts up again as long as the cluster control link is up. The threat defense application attempts to rejoin the cluster every 5 seconds.
- Internal error—Internal failures include: application sync timeout; inconsistent application statuses; and so on.
- Failed configuration deployment—If you deploy a new configuration from management center, and the deployment fails on some cluster members but succeeds on others, then the nodes that failed are removed from the cluster. You must manually rejoin the cluster by re-enabling clustering. If the deployment fails on the control node, then the deployment is rolled back, and no members are removed. If the deployment fails on all data nodes, then the deployment is rolled back, and no members are removed.
- Failed Chassis-Application Communication—When the threat defense application detects that the chassis-application health has recovered, it tries to rejoin the cluster automatically.

## Data Path Connection State Replication

Every connection has one owner and at least one backup owner in the cluster. The backup owner does not take over the connection in the event of a failure; instead, it stores TCP/UDP state information, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner is usually also the director.

Some traffic requires state information above the TCP or UDP layer. See the following table for clustering support or lack of support for this kind of traffic.

**Table 45: Features Replicated Across the Cluster**

| Traffic                | State Support | Notes                              |
|------------------------|---------------|------------------------------------|
| Up time                | Yes           | Keeps track of the system up time. |
| ARP Table              | Yes           | —                                  |

## How the Cluster Manages Connections

Connections can be load-balanced to multiple nodes of the cluster. Connection roles determine how connections are handled in both normal operation and in a high availability situation.

### Connection Roles

See the following roles defined for each connection:

- **Owner**—Usually, the node that initially receives the connection. The owner maintains the TCP state and processes packets. A connection has only one owner. If the original owner fails, then when new nodes receive packets from the connection, the director chooses a new owner from those nodes.
- **Backup owner**—The node that stores TCP/UDP state information received from the owner, so that the connection can be seamlessly transferred to a new owner in case of a failure. The backup owner does not take over the connection in the event of a failure. If the owner becomes unavailable, then the first node to receive packets from the connection (based on load balancing) contacts the backup owner for the relevant state information so it can become the new owner.

As long as the director (see below) is not the same node as the owner, then the director is also the backup owner. If the owner chooses itself as the director, then a separate backup owner is chosen.

For clustering on the Firepower 9300, which can include up to 3 cluster nodes in one chassis, if the backup owner is on the same chassis as the owner, then an additional backup owner will be chosen from another chassis to protect flows from a chassis failure.

- **Director**—The node that handles owner lookup requests from forwarders. When the owner receives a new connection, it chooses a director based on a hash of the source/destination IP address and ports (see below for ICMP hash details), and sends a message to the director to register the new connection. If packets arrive at any node other than the owner, the node queries the director about which node is the owner so it can forward the packets. A connection has only one director. If a director fails, the owner chooses a new director.

As long as the director is not the same node as the owner, then the director is also the backup owner (see above). If the owner chooses itself as the director, then a separate backup owner is chosen.

ICMP/ICMPv6 hash details:

- For Echo packets, the source port is the ICMP identifier, and the destination port is 0.
  - For Reply packets, the source port is 0, and the destination port is the ICMP identifier.
  - For other packets, both source and destination ports are 0.
- **Forwarder**—A node that forwards packets to the owner. If a forwarder receives a packet for a connection it does not own, it queries the director for the owner, and then establishes a flow to the owner for any other packets it receives for this connection. The director can also be a forwarder. Note that if a forwarder receives the SYN-ACK packet, it can derive the owner directly from a SYN cookie in the packet, so it does not need to query the director. (If you disable TCP sequence randomization, the SYN cookie is not used; a query to the director is required.) For short-lived flows such as DNS and ICMP, instead of querying, the forwarder immediately sends the packet to the director, which then sends them to the owner. A connection can have multiple forwarders; the most efficient throughput is achieved by a good load-balancing method where there are no forwarders and all packets of a connection are received by the owner.

**Note** We do not recommend disabling TCP sequence randomization when using clustering. There is a small chance that some TCP sessions won't be established, because the SYN/ACK packet might be dropped.

- **Fragment Owner**—For fragmented packets, cluster nodes that receive a fragment determine a fragment owner using a hash of the fragment source IP address, destination IP address, and the packet ID. All fragments are then forwarded to the fragment owner over the cluster control link. Fragments may be load-balanced to different cluster nodes, because only the first fragment includes the 5-tuple used in the switch load balance hash. Other fragments do not contain the source and destination ports and may be load-balanced to other cluster nodes. The fragment owner temporarily reassembles the packet so it can determine the director based on a hash of the source/destination IP address and ports. If it is a new connection, the fragment owner will register to be the connection owner. If it is an existing connection, the fragment owner forwards all fragments to the provided connection owner over the cluster control link. The connection owner will then reassemble all fragments.

## New Connection Ownership

When a new connection is directed to a node of the cluster via load balancing, that node owns both directions of the connection. If any connection packets arrive at a different node, they are forwarded to the owner node over the cluster control link. If a reverse flow arrives at a different node, it is redirected back to the original node.

## Sample Data Flow for TCP

The following example shows the establishment of a new connection.

1. The SYN packet originates from the client and is delivered to one threat defense (based on the load balancing method), which becomes the owner. The owner creates a flow, encodes owner information into a SYN cookie, and forwards the packet to the server.
2. The SYN-ACK packet originates from the server and is delivered to a different threat defense (based on the load balancing method). This threat defense is the forwarder.
3. Because the forwarder does not own the connection, it decodes owner information from the SYN cookie, creates a forwarding flow to the owner, and forwards the SYN-ACK to the owner.
4. The owner sends a state update to the director, and forwards the SYN-ACK to the client.
5. The director receives the state update from the owner, creates a flow to the owner, and records the TCP state information as well as the owner. The director acts as the backup owner for the connection.
6. Any subsequent packets delivered to the forwarder will be forwarded to the owner.
7. If packets are delivered to any additional nodes, it will query the director for the owner and establish a flow.
8. Any state change for the flow results in a state update from the owner to the director.

## Sample Data Flow for ICMP and UDP

The following example shows the establishment of a new connection.

1. *Figure 286: ICMP and UDP Data Flow*

The first UDP packet originates from the client and is delivered to one threat defense (based on the load balancing method).

2. The node that received the first packet queries the director node that is chosen based on a hash of the source/destination IP address and ports.
3. The director finds no existing flow, creates a director flow and forwards the packet back to the previous node. In other words, the director has elected an owner for this flow.
4. The owner creates the flow, sends a state update to the director, and forwards the packet to the server.
5. The second UDP packet originates from the server and is delivered to the forwarder.
6. The forwarder queries the director for ownership information. For short-lived flows such as DNS, instead of querying, the forwarder immediately sends the packet to the director, which then sends it to the owner.
7. The director replies to the forwarder with ownership information.
8. The forwarder creates a forwarding flow to record owner information and forwards the packet to the owner.
9. The owner forwards the packet to the client.

## History for Clustering

# CHAPTER 14

## Interface Overview

---

The threat defense device includes data interfaces that you can configure in different modes, as well as a management interface.

- [Management Interface, on page 697](#)
- [Interface Mode and Types, on page 698](#)
- [Security Zones and Interface Groups, on page 700](#)
- [Auto-MDI/MDIX Feature, on page 701](#)
- [Default Settings for Interfaces, on page 702](#)
- [Create Security Zone and Interface Group Objects, on page 702](#)
- [Enable the Physical Interface and Configure Ethernet Settings, on page 703](#)
- [Configure EtherChannel Interfaces, on page 705](#)
- [Sync Interface Changes with the Management Center, on page 713](#)
- [Manage the Network Module for the Secure Firewall 3100/4200, on page 716](#)
- [Merge the Management and Diagnostic Interfaces, on page 730](#)
- [History for Interfaces, on page 737](#)

## Management Interface

In Version 7.3 and earlier, the physical management interface is shared between the Diagnostic logical interface and the Management logical interface. In Version 7.4 and later, the Diagnostic interface is merged with Management for a simplified user experience.

## Management Interface

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the management center. It uses its own IP address and static routing. You can configure its settings at the CLI using the **configure network** command. You can also view its status on the **Devices > Device Management > Devices > Interfaces** page. If you change the IP address at the CLI after you add it to the management center, you can match the IP address in the Secure Firewall Management Center in the **Devices > Device Management > Devices > Management** area.

You can alternatively manage the threat defense using a data interface instead of the Management interface.

## Diagnostic Interface

For new devices using 7.4 and later, you cannot use the legacy Diagnostic interface. Only the merged Management interface is available.

If you upgraded to 7.4 or later, and you did not have any configuration for the Diagnostic interface, then the interfaces will merge automatically.

If you upgraded to 7.4 or later, and you have configuration for the Diagnostic interface, then you have the choice to merge the interfaces manually, or you can continue to use the separate Diagnostic interface. Note that support for the Diagnostic interface will be removed in a later release, so you should plan to merge the interfaces as soon as possible. To manually merge the Management and Diagnostic interfaces, see [Merge the Management and Diagnostic Interfaces, on page 730](#). Configurations that prevent an automatic merge include the following:

- A data interface named "management"—This name is reserved for use with the merged Management interface.
- IP Address on Diagnostic
- DNS enabled on Diagnostic
- Syslog, SNMP, RADIUS or AD (for remote access VPN) source interface is Diagnostic
- RADIUS or AD (for remote access VPN) with no source interface specified, and there is at least one interface configured as management-only (including Diagnostic)—The default route lookup for these services has changed from the management-only routing table to the data routing table, with no fallback to management. Therefore, you cannot use a management-only interface other than Management.
- Static routes on Diagnostic
- Dynamic routing on Diagnostic
- HTTP server on Diagnostic
- ICMP on Diagnostic
- DDNS for Diagnostic
- FlexConfig using Diagnostic

For more information about how the legacy Diagnostic interface operates, see the 7.3 version of this guide.

## Interface Mode and Types

You can deploy threat defense interfaces in two modes: Regular firewall mode and IPS-only mode. You can include both firewall and IPS-only interfaces on the same device.

### Regular Firewall Mode

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See [Transparent or Routed Firewall Mode, on page 243](#) for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the threat defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the threat defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

### IPS-Only Mode

IPS-only mode interfaces bypass many firewall checks and only support IPS security policy. You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

---

**Note** The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes.

---

IPS-only interfaces can be deployed as the following types:

- Inline Set, with optional Tap mode—An inline set acts like a bump on the wire, and binds two interfaces together to slot into an existing network. This function allows the threat defense to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of an inline set unless explicitly dropped.

With tap mode, the threat defense is deployed inline, but the network traffic flow is undisturbed. Instead, the threat defense makes a copy of each packet so that it can analyze the packets. Note that rules of these types do generate intrusion events when they are triggered, and the table view of intrusion events indicates that the triggering packets would have dropped in an inline deployment. There are benefits to using tap mode with FTDs that are deployed inline. For example, you can set up the cabling between the threat defense and the network as if the threat defense were inline and analyze the kinds of intrusion events the threat defense generates. Based on the results, you can modify your intrusion policy and add the drop rules that best protect your network without impacting its efficiency. When you are ready to deploy the threat defense inline, you can disable tap mode and begin dropping suspicious traffic without having to reconfigure the cabling between the threat defense and the network.

---

**Note** Tap mode *significantly* impacts threat defense performance, depending on the traffic.

---

---

**Note** Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode or the firewall-type interfaces.

---

- Passive or ERSPAN Passive—Passive interfaces monitor traffic flowing across a network using a switch SPAN or mirror port. The SPAN or mirror port allows for traffic to be copied from other ports on the

switch. This function provides the system visibility within the network without being in the flow of network traffic. When you configure the threat defense in a passive deployment, the threat defense cannot take certain actions such as blocking or shaping traffic. Passive interfaces receive all traffic unconditionally, and no traffic received on these interfaces is retransmitted. Encapsulated remote switched port analyzer (ERSPAN) interfaces allow you to monitor traffic from source ports distributed over multiple switches, and uses GRE to encapsulate the traffic. ERSPAN interfaces are only allowed when the threat defense is in routed firewall mode.

---

**Note** Using SR-IOV interfaces as passive interfaces on NGFWv is not supported on some Intel network adapters (such as Intel X710 or 82599) using SR-IOV drivers due to a promiscuous mode restriction. In such cases, use a network adapter that supports this functionality. See [Intel Ethernet Products](#) for more information on Intel network adapters.

---

## Security Zones and Interface Groups

Each interface can be assigned to a *security zone* and/or *interface group*. You then apply your security policy based on zones or groups. For example, you can assign the "inside" interface on one or more devices to the "inside" zone; and the "outside" interfaces to the "outside" zone. You can then configure your access control policy to enable traffic to go from the inside zone to the outside zone for every device using the same zones.

To view the interfaces that belong to each object, choose **Objects > Object Management** and click **Interface**. This page lists the security zones and interface groups configured on your managed devices. You can expand each interface object to view the type of interfaces in each interface object.

---

**Note** Policies that apply to **any** zone (a global policy) apply to interfaces in zones as well as any interfaces that are not assigned to a zone.

---

---

**Note** The Management interface does not belong to a zone or interface group.

---

### Security Zones Vs. Interface Groups

There are two types of interface objects:

- Security zones—An interface can belong to only one security zone.
- Interface groups—An interface can belong to multiple interface groups (and to one security zone).

You can use interface groups in NAT policies, prefilter policies, and QoS policies, as well as features that let you specify the interface name directly, such as Syslog servers or DNS servers.

Some policies only support security zones, while other policies support zones and groups. Unless you need the functionality an interface group provides, you should default to using security zones because security zones are supported for all features.

You cannot change an existing security zone to an interface group or vice-versa; instead you must create a new interface object.

---

**Note** Although tunnel zones are not interface objects, you can use them in place of security zones in certain configurations; see [Tunnel Zones and Prefiltering, on page 1812](#).

---

### Interface Object Types

See the following interface object types:

- Passive—For IPS-only passive or ERSPAN interfaces.
- Inline—For IPS-only inline set interfaces.
- Switched—For regular firewall bridge group interfaces.
- Routed—For regular firewall routed interfaces.
- ASA—(Security zones only) For legacy ASA FirePOWER device interfaces.
- Management—(Interface groups only) For management-only interfaces.
- Loopback—(Interface groups only) For loopback interfaces.

All interfaces in an interface object must be of the same type. After you create an interface object, you cannot change the type of interfaces it contains.

### Interface Names

Note that the interface (or zone name) itself does not provide any default behavior in regards to the security policy. We recommend using names that are self-describing to avoid mistakes in future configuration. A good name signifies a logical segment or traffic specification, for example:

- Names of internal interfaces—InsideV110, InsideV160, InsideV195
- Names of DMZ interfaces—DMZV11, DMZV12, DMZV-TEST
- Names of external interfaces—Outside-ASN78, Outside-ASN91

## Auto-MDI/MDIX Feature

For RJ-45 interfaces, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. For Gigabit Ethernet, when the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

# Default Settings for Interfaces

This section lists default settings for interfaces.

## Default State of Interfaces

The default state of an interface depends on the type.

- Physical interfaces—Disabled. The exception is the Management interface that is enabled for initial setup.
- Redundant Interfaces—Enabled. However, for traffic to pass through the redundant interface, the member physical interfaces must also be enabled.
- VLAN subinterfaces—Enabled. However, for traffic to pass through the subinterface, the physical interface must also be enabled.
- EtherChannel port-channel interfaces (ISA 3000)—Enabled. However, for traffic to pass through the EtherChannel, the channel group physical interfaces must also be enabled.
- EtherChannel port-channel interfaces (Firepower and Secure Firewall models)—Disabled.

---

**Note** For the Firepower 4100/9300, you can administratively enable and disable interfaces in both the chassis and in the management center. For an interface to be operational, the interface must be enabled in both operating systems. Because the interface state is controlled independently, you may have a mismatch between the chassis and management center.

---

## Default Speed and Duplex

By default, the speed and duplex for copper (RJ-45) interfaces are set to auto-negotiate.

By default, the speed and duplex for fiber (SFP) interfaces are set to the maximum speed, with auto-negotiation enabled.

For the Secure Firewall 3100/4200, the speed is set to detect the installed SFP speed.

# Create Security Zone and Interface Group Objects

Add security zones and interface groups to which you can assign device interfaces.

---

**Tip** You can create empty interface objects and add interfaces to them later. To add an interface, the interface must have a name. You can also create security zones (but not interface groups) while configuring interfaces.

---

## Before you begin

Understand the usage requirements and restrictions for each type of interface object. See [Security Zones and Interface Groups](#), on page 700.

### Procedure

---

- Step 1** Choose **Objects > Object Management**.
- Step 2** Choose **Interface** from the list of object types.
- Step 3** Click **Add > Security Zone** or **Add > Interface Group**.
- Step 4** Enter a **Name**.
- Step 5** Choose an **Interface Type**.
- Step 6** (Optional) From the **Device > Interfaces** drop-down list, choose a device that contains interfaces you want to add.
- You do not need to assign interfaces on this screen; you can instead assign interfaces to the zone or group when you configure the interface.
- Step 7** Click **Save**.
- 

### What to do next

- If an active policy references your object, deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

## Enable the Physical Interface and Configure Ethernet Settings

This section describes how to:

- Enable the physical interface. By default, physical interfaces are disabled (with the exception of the Management interface).
- Set a specific speed and duplex. By default, speed and duplex are set to Auto.

This procedure only covers a small subset of Interface settings. Refrain from setting other parameters at this point. For example, you cannot name an interface that you want to use as part of an EtherChannel interface.

---

**Note** For the Firepower 4100/9300, you configure basic interface settings in FXOS. See [Configure a Physical Interface, on page 290](#) for more information.

---

---

**Note** For Firepower 1010 switch ports, see [Configure Firepower 1010 Switch Ports, on page 741](#).

---

### Before you begin

If you changed the physical interfaces on the device after you added it to the management center, you need to refresh the interface listing by clicking **Sync Interfaces from device** on the top left of **Interfaces**. For the Secure Firewall 3100/4200, which supports hot swapping, see [Manage the Network Module for the Secure Firewall 3100/4200, on page 716](#) before you change interfaces on a device.

## Procedure

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Enable the interface by checking the **Enabled** check box.
- Step 4** (Optional) Add a description in the **Description** field.  
The description can be up to 200 characters on a single line, without carriage returns.
- Step 5** (Optional) Set the duplex and speed by clicking **Hardware Configuration > Speed**.
- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
  - **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100/4200 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.
  - **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.
  - **Forward Error Correction Mode**—(Secure Firewall 3100/4200 only) For 25 Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

*Table 47: Default FEC for Auto Setting*

| Transceiver Type | Fixed Port Default FEC (Ethernet 1/9 through 1/16) | Network Module Default FEC |
|------------------|----------------------------------------------------|----------------------------|
| 25G-SR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 25G-LR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 10/25G-CSR       | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-AOCxM        | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-CU2.5/3M     | Auto-Negotiate                                     | Auto-Negotiate             |
| 25G-CU4/5M       | Auto-Negotiate                                     | Auto-Negotiate             |
| 25/50/100G       | Clause 91 RS-FEC                                   | Clause 91 RS-FEC           |

- Step 6** (Optional) (Firepower 1100/Secure Firewall 3100/4200) Enable Link Layer Discovery Protocol (LLDP) by clicking **Hardware Configuration > Network Connectivity**.
- **Enable LLDP Receive**—Enables the firewall to receive LLDP packets from its peers.
  - **Enable LLDP Transmit**—Enables the firewall to send LLDP packets to its peers.

**Step 7** (Optional) (Secure Firewall 3100/4200) Enable pause (XOFF) frames for flow control by clicking **Hardware Configuration > Network Connectivity**, and checking **Flow Control Send**.

Flow control enables connected Ethernet ports to control traffic rates during congestion by allowing congested nodes to pause link operation at the other end. If the threat defense port experiences congestion (exhaustion of queuing resources on the internal switch) and cannot receive any more traffic, it notifies the other port by sending a pause frame to stop sending until the condition clears. Upon receipt of a pause frame, the sending device stops sending any data packets, which prevents any loss of data packets during the congestion period.

**Note** The threat defense supports transmitting pause frames so that the remote peer can rate-control the traffic.

However, receiving of pause frames is not supported.

The internal switch has a global pool of 8000 buffers of 250 bytes each, and the switch allocates buffers dynamically to each port. A pause frame is sent out every interface with flowcontrol enabled when the buffer usage exceeds the global high-water mark (2 MB (8000 buffers)); and a pause frame is sent out of a particular interface when its buffer exceeds the port high-water mark (.3125 MB (1250 buffers)). After a pause is sent, an XON frame can be sent when the buffer usage is reduced below the low-water mark (1.25 MB globally (5000 buffers); .25 MB per port (1000 buffers)). The link partner can resume traffic after receiving an XON frame.

Only flow control frames defined in 802.3x are supported. Priority-based flow control is not supported.

**Step 8** In the **Mode** drop-down list, choose one of the following:

- **None**—Choose this setting for regular firewall interfaces and inline sets. The mode will automatically be changed to Routed, Switched, or Inline based on further configuration.
- **Passive**—Choose this setting for passive IPS-only interfaces.
- **Erspan**—Choose this setting for ERSPAN passive IPS-only interfaces.

**Step 9** In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to distribute the traffic across multiple egress interfaces.

**Step 10** Click **OK**.

**Step 11** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

**Step 12** Continue configuring interfaces.

- [Regular Firewall Interfaces, on page 741](#)
- [Inline Sets and Passive Interfaces, on page 815](#)

---

## Configure EtherChannel Interfaces

This section tells how to configure EtherChannel interfaces.

---

**Note** For the Firepower 4100/9300, you configure EtherChannels in FXOS. See [Add an EtherChannel \(Port Channel\)](#), on page 291 for more information.

---

## About EtherChannels

This section describes EtherChannels.

### About EtherChannels

An 802.3ad EtherChannel is a logical interface (called a port-channel interface) consisting of a bundle of individual Ethernet links (a channel group) so that you increase the bandwidth for a single network. A port channel interface is used in the same way as a physical interface when you configure interface-related features.

You can configure up to 48 EtherChannels, depending on how many interfaces your model supports.

### Channel Group Interfaces

Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.

All interfaces in the channel group must be the same type and speed. The first interface added to the channel group determines the correct type and speed.

The EtherChannel aggregates the traffic across all the available active interfaces in the channel. The interface is selected using a proprietary hash algorithm, based on source or destination MAC addresses, IP addresses, TCP and UDP port numbers and VLAN numbers.

### Connecting to an EtherChannel on Another Device

The device to which you connect the threat defense EtherChannel must also support 802.3ad EtherChannels; for example, you can connect to the Catalyst 6500 switch or the Cisco Nexus 7000.

When the switch is part of a Virtual Switching System (VSS) or Virtual Port Channel (vPC), then you can connect threat defense interfaces within the same EtherChannel to separate switches in the VSS/vPC. The switch interfaces are members of the same EtherChannel port-channel interface, because the separate switches act like a single switch.

Figure 287: Connecting to a VSS/vPC

**Note** If the threat defense device is in transparent firewall mode, and you place the threat defense device between two sets of VSS/vPC switches, then be sure to disable Unidirectional Link Detection (UDLD) on any switch ports connected to the threat defense device with an EtherChannel. If you enable UDLD, then a switch port may receive UDLD packets sourced from both switches in the other VSS/vPC pair. The receiving switch will place the receiving interface in a down state with the reason "UDLD Neighbor mismatch".

If you use the threat defense device in an Active/Standby failover deployment, then you need to create separate EtherChannels on the switches in the VSS/vPC, one for each threat defense device. On each threat defense device, a single EtherChannel connects to both switches. Even if you could group all switch interfaces into a single EtherChannel connecting to both threat defense devices (in this case, the EtherChannel will not be established because of the separate threat defense system IDs), a single EtherChannel would not be desirable because you do not want traffic sent to the standby threat defense device.

Figure 288: Active/Standby Failover and VSS/vPC

### Link Aggregation Control Protocol

The Link Aggregation Control Protocol (LACP) aggregates interfaces by exchanging the Link Aggregation Control Protocol Data Units (LACPDU) between two network devices.

You can configure each physical interface in an EtherChannel to be:

- **Active**—Sends and receives LACP updates. An active EtherChannel can establish connectivity with either an active or a passive EtherChannel. You should use the active mode unless you need to minimize the amount of LACP traffic.
- **Passive**—Receives LACP updates. A passive EtherChannel can only establish connectivity with an active EtherChannel. Not supported on hardware models.
- **On**—The EtherChannel is always on, and LACP is not used. An “on” EtherChannel can only establish a connection with another “on” EtherChannel.

LACP coordinates the automatic addition and deletion of links to the EtherChannel without user intervention. It also handles misconfigurations and checks that both ends of member interfaces are connected to the correct channel group. “On” mode cannot use standby interfaces in the channel group when an interface goes down, and the connectivity and configurations are not checked.

## Load Balancing

The threat defense device distributes packets to the interfaces in the EtherChannel by hashing the source and destination IP address of the packet (this criteria is configurable). The resulting hash is divided by the number of active links in a modulo operation where the resulting remainder determines which interface owns the flow. All packets with a *hash\_value mod active\_links* result of 0 go to the first interface in the EtherChannel, packets with a result of 1 go to the second interface, packets with a result of 2 go to the third interface, and so on. For example, if you have 15 active links, then the modulo operation provides values from 0 to 14. For 6 active links, the values are 0 to 5, and so on.

If an active interface goes down and is not replaced by a standby interface, then traffic is rebalanced between the remaining links. The failure is masked from both Spanning Tree at Layer 2 and the routing table at Layer 3, so the switchover is transparent to other network devices.

## EtherChannel MAC Address

All interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links.

### Firepower and Secure Firewall Hardware

The port-channel interface uses the MAC address of the internal interface Internal-Data 0/1. Alternatively you can manually configure a MAC address for the port-channel interface. All EtherChannel interfaces on a chassis use the same MAC address, so be aware that if you use SNMP polling, for example, multiple interfaces will have the same MAC address.

---

**Note** Member interfaces only use the Internal-Data 0/1 MAC address after a reboot. Prior to rebooting, the member interface uses its own MAC address. If you add a new member interface after a reboot, you will have to perform another reboot to update its MAC address.

---

# Guidelines for EtherChannels

## Bridge Group

In routed mode, Management Center-defined EtherChannels are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.

## High Availability

- When you use an EtherChannel interface as a High Availability link, it must be pre-configured on both units in the High Availability pair; you cannot configure it on the primary unit and expect it to replicate to the secondary unit because *the High Availability link itself is required for replication*.
- If you use an EtherChannel interface for the state link, no special configuration is required; the configuration can replicate from the primary unit as normal. For the Firepower 4100/9300 chassis, all interfaces, including EtherChannels, need to be pre-configured on both units.
- You can monitor EtherChannel interfaces for High Availability. When an active member interface fails over to a standby interface, this activity does not cause the EtherChannel interface to appear to be failed when being monitored for device-level High Availability. Only when all physical interfaces fail does the EtherChannel interface appear to be failed (for an EtherChannel interface, the number of member interfaces allowed to fail is configurable).
- If you use an EtherChannel interface for a High Availability or state link, then to prevent out-of-order packets, only one interface in the EtherChannel is used. If that interface fails, then the next interface in the EtherChannel is used. You cannot alter the EtherChannel configuration while it is in use as a High Availability link. To alter the configuration, you need to temporarily disable High Availability, which prevents High Availability from occurring for the duration.

## Model Support

- You cannot add EtherChannels in the management center for the Firepower 4100/9300 or the threat defense virtual. The Firepower 4100/9300 supports EtherChannels, but you must perform all hardware configuration of EtherChannels in FXOS on the chassis.
- You cannot use Firepower 1010 switch ports or VLAN interfaces in EtherChannels.

## General EtherChannel Guidelines

- You can configure up to 48 EtherChannels, depending on how many interfaces are available on your model.
- Each channel group can have up to 8 active interfaces, except for the ISA 3000, which supports 16 active interfaces. For switches that support only 8 active interfaces, you can assign up to 16 interfaces to a channel group: while only 8 interfaces can be active, the remaining interfaces can act as standby links in case of interface failure.
- All interfaces in the channel group must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, except for the Secure Firewall 3100/4200, which supports different interface capacities as long as the speed is set to Detect SFP; in this case the lowest common speed is used.

- The device to which you connect the threat defense EtherChannel must also support 802.3ad EtherChannels.
- The threat defense device does not support LACPDU s that are VLAN-tagged. If you enable native VLAN tagging on the neighboring switch using the Cisco IOS **vlan dot1Q tag native** command, then the threat defense device will drop the tagged LACPDUs. Be sure to disable native VLAN tagging on the neighboring switch.
- The LACP rate depends on the model. When you set the rate (normal or fast), the device requests that rate from the connecting switch. In return, the device will send at the rate requested by the connecting switch. We recommend that you set the same rate on both sides.
  - Firepower 4100/9300—The LACP rate is set to fast by default in FXOS, but you can configure it as normal (also known as slow).
  - Secure Firewall 3100/4200—The LACP rate is set to normal (slow) by default, but you can configure it as fast on the device.
  - All other models—The LACP rate set to normal (also known as slow), and it is not configurable, which means the device will always request a slow rate from the connecting switch. We recommend setting the rate on the switch to slow, so both sides send LACP messages at the same rate.
- In Cisco IOS software versions earlier than 15.1(1)S2, threat defense did not support connecting an EtherChannel to a switch stack. With default switch settings, if the threat defense EtherChannel is connected cross stack, and if the primary switch is powered down, then the EtherChannel connected to the remaining switch will not come up. To improve compatibility, set the **stack-mac persistent timer** command to a large enough value to account for reload time; for example, 8 minutes or 0 for indefinite. Or, you can upgrade to more a more stable switch software version, such as 15.1(1)S2.
- All the threat defense configuration refers to the logical EtherChannel interface instead of the member physical interfaces.

## Configure an EtherChannel

This section describes how to create an EtherChannel port-channel interface, assign interfaces to the EtherChannel, and customize the EtherChannel.

### Guidelines

- You can configure up to 48 EtherChannels, depending on the number of interfaces for your model.
- Each channel group can have up to 8 active interfaces.
- All interfaces in the channel group must be the same media type and speed capacity. The media type can be either RJ-45 or SFP; SFPs of different types (copper and fiber) can be mixed. You cannot mix interface capacities (for example 1GB and 10GB interfaces) by setting the speed to be lower on the larger-capacity interface, except for the Secure Firewall 3100/4200, which supports different interface capacities as long as the speed is set to Detect SFP; in this case the lowest common speed is used.

---

**Note** For the Firepower 4100/9300, you configure EtherChannels in FXOS. See [Add an EtherChannel \(Port Channel\), on page 291](#) for more information.

---

### Before you begin

- You cannot add a physical interface to the channel group if you configured a name for it. You must first remove the name.

**Note** If you are using a physical interface already in your configuration, removing the name will clear any configuration that refers to the interface.

### Procedure

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Enable the member interfaces according to [Enable the Physical Interface and Configure Ethernet Settings, on page 703](#).
- Step 3** Click **Add Interfaces > Ether Channel Interface**.
- Step 4** On the **General** tab, set the **Ether Channel ID** to a number between 1 and 48 (1 and 8 for the Firepower 1010).

*Figure 289: Add EtherChannel Interface*

**Add Ether Channel Interface**

General IPv4 IPv6 Hardware Configuration Path Monitoring Advanced

Name: dmz

Enabled  
 Management Only

Description:

Mode: None

Security Zone: dmz\_zone

MTU: 1500  
(64 - 9198)

Priority: 0  
(0 - 65535)

Propagate Security Group Tag:

Ether Channel ID \*: 1

Cancel OK

**Step 5** In the **Available Interfaces** area, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members.

Make sure all interfaces are the same type and speed capability.

**Figure 290: Available Interfaces**

The screenshot shows a configuration window for an EtherChannel. At the top, there is a field for 'Ether Channel ID \*' with the value '1'. Below this, there are two main sections: 'Available Interfaces' and 'Selected Interfaces'. The 'Available Interfaces' section has a search bar and a list containing 'Ethernet1/1', which is highlighted in blue. An 'Add' button is located to the right of this list. The 'Selected Interfaces' section is currently empty. At the bottom left, there is a checkbox labeled 'NVE Only' which is unchecked. At the bottom right, there are 'Cancel' and 'OK' buttons.

**Step 6** (Optional) Click the **Advanced** tab to customize the EtherChannel. Set the following parameters on the **Information** sub-tab:

**Figure 291: Advanced**

The screenshot shows the 'Add Ether Channel Interface' dialog box with the 'Advanced' tab selected. Under the 'Information' sub-tab, the 'LACP Mode' is set to 'Active'. There are two empty input fields for 'Active Mac Address' and 'Standby Mac Address'. The dialog has a title bar with a question mark icon and a tabbed interface with 'General', 'IPv4', 'IPv6', 'Hardware Configuration', 'Path Monitoring', and 'Advanced' tabs.

- **(ISA 3000 only) Load Balancing**—Select the criteria used to load balance the packets across the group channel interfaces. By default, the threat defense device balances the packet load on interfaces according to the source and destination IP address of the packet. If you want to change the properties on which the packet is categorized, choose a different set of criteria. For example, if your traffic is biased heavily towards the same source and destination IP addresses, then the traffic assignment to interfaces in the EtherChannel will be unbalanced. Changing to a different algorithm can result in more evenly distributed traffic. For more information about load balancing, see [Load Balancing, on page 708](#).
- **LACP Mode**—Choose Active, Passive, or On. We recommend using Active mode (the default). Passive mode is only available for the ISA 3000 only.

- (Secure Firewall 3100/4200 only) **LACP Rate**—Choose Default, Normal, or Fast. The default is Normal (also known as slow). Sets the LACP data unit receive rate for a physical interface in the channel group. We recommend that you set the same rate on both sides.
- (ISA 3000 only) **Active Physical Interface: Range**—From the left drop-down list, choose the minimum number of active interfaces required for the EtherChannel to be active, between 1 and 16. The default is 1. From the right drop-down list, choose the maximum number of active interfaces allowed in the EtherChannel, between 1 and 16. The default is 16. If your switch does not support 16 active interfaces, be sure to set this command to 8 or fewer.
- **Active Mac Address**—Set a manual MAC address if desired. The mac\_address is in H.H.H format, where H is a 16-bit hexadecimal digit. For example, the MAC address 00-0C-F1-42-4C-DE is entered as 000C.F142.4CDE.

**Step 7** Click the **Hardware Configuration** tab and set the Duplex and Speed for all member interfaces.

**Step 8** Click **OK**.

**Step 9** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

**Step 10** (Optional) For regular firewall interfaces, add a VLAN subinterface. See [Add a Subinterface, on page 759](#).

**Step 11** For regular firewall interfaces, configure the routed or transparent mode interface parameters: [Configure Routed Mode Interfaces, on page 778](#) or [Configure Bridge Group Interfaces, on page 783](#). For IPS-only interfaces, see [Inline Sets and Passive Interfaces, on page 815](#).

---

## Sync Interface Changes with the Management Center

Interface configuration changes on the device can cause the management center and the device to get out of sync. The management center can detect interface changes by one of the following methods:

- Event sent from the device
- Sync when you deploy from the management center

If the management center detects interface changes when it attempts to deploy, the deploy will fail. You must first accept the interface changes.

- Manual sync

There are two types of interface changes performed outside of management center that need to be synced:

- Addition or deletion of physical interfaces—Adding a new interface, or deleting an unused interface has minimal impact on the threat defense configuration. However, deleting an interface that is used in your security policy will impact the configuration. Interfaces can be referenced directly in many places in the threat defense configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected. You can also edit the membership of an allocated EtherChannel without affecting the logical device or requiring a sync on the management center.

When the management center detects changes, the **Interface** page shows status (removed, changed, or added) to the left of each interface.

- Management Center access interface changes—If you configure a data interface for managing management center using the **configure network management-data-interface** command, you must manually make matching configuration changes in management center and then acknowledge the changes. These interface changes cannot be made automatically.

This procedure describes how to manually sync device changes if required and how to acknowledge the detected changes. If device changes are temporary, you should not save the changes in the management center; you should wait until the device is stable, and then re-sync.

### Before you begin

- User Roles:
  - Admin
  - Access Admin
  - Network Admin

### Procedure

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** If required, click **Sync Device** on the top left of **Interfaces**.
- Step 3** After the changes are detected, see the following steps.

#### Addition or Deletion of Physical Interfaces

- You will see a red banner on **Interfaces** indicating that the interface configuration has changed. Click the **Click to know more** link to view the interface changes.
- Click **Validate Changes** to make sure your policy will still work with the interface changes.  
If there are any errors, you need to change your policy and rerun the validation.
- Click **Save**.  
You can now go to **Deploy > Deployment** and deploy the policy to assigned devices.

#### FMC Access Interface Changes

- You will see a yellow banner in the top right of the **Device** page indicating that the management center access configuration has changed. Click the **View details** link to view the interface changes.

The **FMC Access - Configuration Details** dialog box opens.

- b) Take note of all highlighted configurations, especially the pink highlighted ones. You need to match any values on the threat defense by manually configuring them on the management center.

For example, the pink highlights below show configuration that exists on the threat defense but not yet on the management center.

**FMC Access - Configuration Details** ? x

FMC Access configuration on device have been updated outside of FMC. Review the differences and update FMC values accordingly.

Legend: Above configurations will be ■ added, ■ modified or ■ disassociated from FMC Access interface on next deploy to FTD.

- c) Click **Acknowledge**.

We recommend that you do not click **Acknowledge** until you have finished the management center configuration, and are ready to deploy. Clicking **Acknowledge** removes the block on deployment. The next time you deploy, the management center configuration will overwrite any remaining conflicting settings on the threat defense. It is your responsibility to manually fix the configuration in the management center before you re-deploy.

- d) You can now go to **Deploy > Deployment** and deploy the policy to assigned devices.

## Manage the Network Module for the Secure Firewall 3100/4200

If you install a network module before you first power on the device, no action is required; the network module is enabled and ready for use.

To view physical interface details for the device, and to manage the network module, open the **Chassis Operations** page. From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit. The **Chassis Operations** page opens for the device.

---

### Physical Interfaces

This view lists only the physical interfaces to perform chassis related advanced operations. To view complete list of physical and logical interfaces, navigate to [Interface page in device details](#)

| Interface Name | Duplex | Auto Negotiation | Admin FEC | Admin Speed | Media Type |
|----------------|--------|------------------|-----------|-------------|------------|
| Ethernet1/1    | FULL   | No               | AUTO      | 1gbps       | rj45       |
| Ethernet1/2    | FULL   | No               | AUTO      | 1gbps       | rj45       |
| Ethernet1/3    | FULL   | No               | AUTO      | 1gbps       | rj45       |
| Ethernet1/4    | FULL   | No               | AUTO      | 1gbps       | rj45       |

Click **Refresh** to refresh interface status. Click **Sync Modules** if you made a hardware change on the device that you need to detect.

If you need to make changes to your network module installation after initial bootup, then see the following procedures.

## Configure Breakout Ports

You can configure 10GB breakout ports for each 40GB or higher interface. This procedure tells you how to break out and rejoin the ports. Breakout ports can be used just like any other physical Ethernet port, including being added to EtherChannels.

Changes are immediate; you do not need to deploy to the device. After you break or rejoin, you cannot roll back to the previous interface state.

### Before you begin

- You must use a supported breakout cable. See the hardware installation guide for more information.
- The interface cannot be in use for the following before breaking or rejoining:
  - Failover link
  - Cluster control link
  - Have a subinterface
  - EtherChannel member
  - BVI member
  - Manager access interface
- Breaking or rejoining an interface that is used directly in your security policy can impact the configuration; however, the action is not blocked.

### Procedure

- Step 1** From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

*Figure 293: Manage Chassis*

| <input type="checkbox"/> | Name                                             | Model                        | Version | Chassis                |
|--------------------------|--------------------------------------------------|------------------------------|---------|------------------------|
| <input type="checkbox"/> | Ungrouped (2)                                    |                              |         |                        |
| <input type="checkbox"/> | 172.16.0.51 Snort 3<br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <a href="#">Manage</a> |

The **Chassis Operations** page opens for the device (in multi-instance mode, this page is called **Chassis Manager**). This page shows physical interface details for the device.

- Step 2** Break out 10GB ports from a 40GB or higher interface.

- a) click **Break** (🔌) to the right of the interface.

Click **Yes** on the confirmation dialog box. If the interface is in use, you will see an error message. You must resolve any use cases before you can retry the breakout.

For example, to break out the Ethernet2/1 40GB interface, the resulting child interfaces will be identified as Ethernet2/1/1, Ethernet2/1/2, Ethernet2/1/3, and Ethernet2/1/4.

On the interfaces graphic, a port that is broken out has this appearance:

**Figure 294: Breakout Ports**

- b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

**Figure 295: Go to Interface Page**

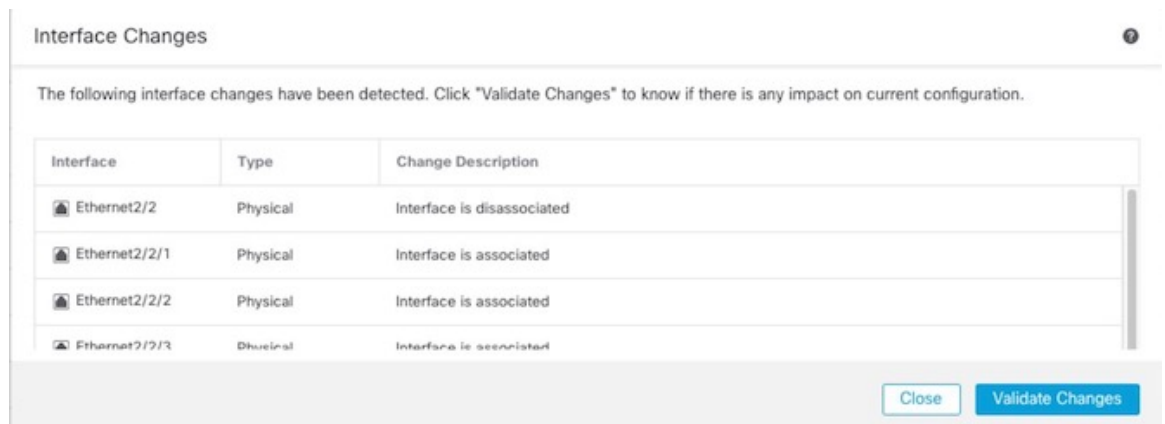

▲ This device has configuration changes that were performed directly on the device. Visit [Interface page in device details](#)

- c) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

**Figure 296: View Interface Changes**

Interface configuration has changed on device. [Click to know more.](#)

**Figure 297: Interface Changes**

- d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Replacing the parent interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity

rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

- e) Click **Close** to return to the **Interfaces** page.
- f) Click **Save** to save the interface changes to the firewall.
- g) If you had to change any configuration, go to **Deploy > Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

**Step 3** Rejoin breakout ports.

You must rejoin all child ports for the interface.

- a) Click **Join** (🔗) to the right of the interface.  
Click **Yes** on the confirmation dialog box. If any child ports are in use, you will see an error message. You must resolve any use cases before you can retry the rejoin.
- b) Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

**Figure 298: Go to Interface Page**

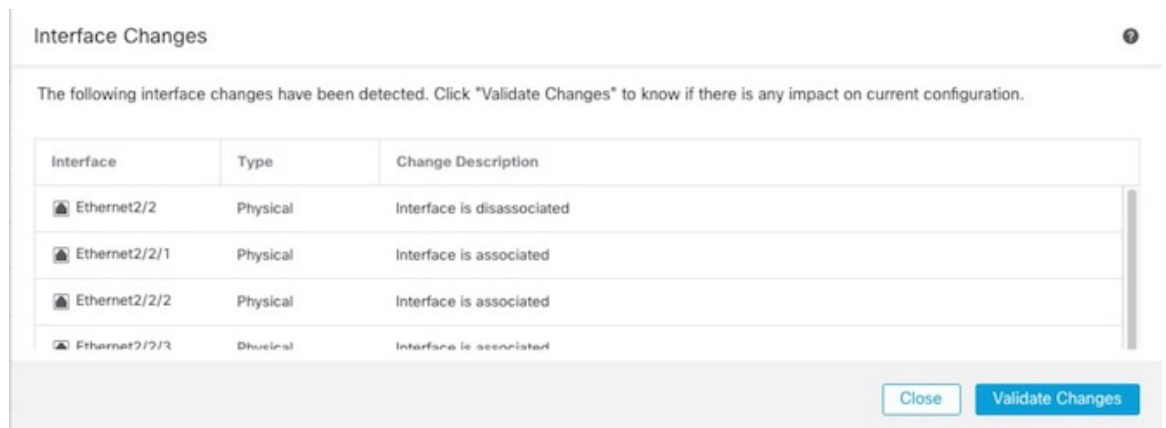

- c) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

**Figure 299: View Interface Changes**

**Figure 300: Interface Changes**

- d) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Replacing the child interfaces that are used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

- e) Click **Close** to return to the **Interfaces** page.
- f) Click **Save** to save the interface changes to the firewall.
- g) If you had to change any configuration, go to **Deploy > Deployment** and deploy the policy.

You do not need to deploy just to save the breakout port changes.

## Add a Network Module

To add a network module to a firewall after initial bootup, perform the following steps. Adding a new module requires a reboot.

### Procedure

- Step 1** Install the network module according to the hardware installation guide.  
For clustering or High Availability, install the network module on all nodes.
- Step 2** Reboot the firewall; see [Shut Down or Restart the Device, on page 39](#).  
For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node (see [Change the Control Node, on page 445](#)) or active unit (see [Switch the Active Peer in the Threat Defense High Availability Pair, on page 399](#)), and reboot the former control node/active unit.
- Step 3** From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

*Figure 301: Manage Chassis*

| <input type="checkbox"/> | Name                                             | Model                        | Version | Chassis                |
|--------------------------|--------------------------------------------------|------------------------------|---------|------------------------|
| <input type="checkbox"/> | Ungrouped (2)                                    |                              |         |                        |
| <input type="checkbox"/> | 172.16.0.51 Snort 3<br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <a href="#">Manage</a> |

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

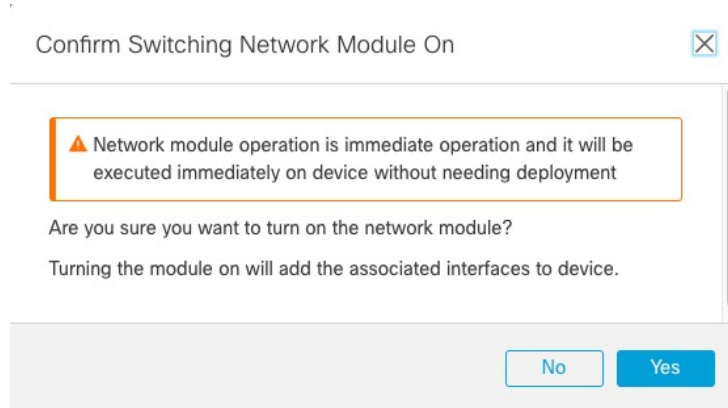

- Step 4** Click **Sync Modules** to update the page with the new network module details.
- Step 5** On the interfaces graphic, click the slider () to enable the network module.

Figure 302: Enable the Network Module

**Step 6** You are prompted to confirm that you want to turn the network module on. Click **Yes**.

Figure 303: Confirm Enable

**Step 7** You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

Figure 304: Go to Interface Page

**Step 8** (Optional) At the top of the **Interfaces** page, you see a message that the interface configuration has changed. You can click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 305: View Interface Changes

Figure 306: Interface Changes

Interface Changes

The following interface changes have been detected. Click "Validate Changes" to know if there is any impact on current configuration.

| Interface   | Type     | Change Description      |
|-------------|----------|-------------------------|
| Ethernet2/1 | Physical | Interface is associated |
| Ethernet2/2 | Physical | Interface is associated |
| Ethernet2/5 | Physical | Interface is associated |
| Ethernet2/6 | Physical | Interface is associated |
| Ethernet2/7 | Physical | Interface is associated |
| Ethernet2/8 | Physical | Interface is associated |

Close Validate Changes

Click **Close** to return to the **Interfaces** page. (Because you are adding a new module, there shouldn't be any configuration impact, so you do not need to click **Validate Changes**.)

**Step 9** Click **Save** to save the interface changes to the firewall.

## Hot Swap the Network Module

You can hot swap a network module for a new module of the same type without having to reboot. However, you must shut down the current module to remove it safely. This procedure describes how to shut down the old module, install a new module, and enable it.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit. You cannot disable a network module if the cluster control link/failover link is on the module.

### Before you begin

### Procedure

**Step 1** For clustering or High Availability, perform the following steps.

- **Clustering**—Ensure the unit you want to perform the hot swap on is a data node (see [Change the Control Node, on page 445](#)); then break the node so it is no longer in the cluster. See [Break a Node, on page 442](#).

You will add the node back to the cluster after you perform the hot swap. Alternatively, you can perform all operations on the control node, and the network module changes will sync to all data nodes. However, you will lose use of those interfaces on all nodes during the hot swap.

- **High Availability**—To avoid failing over when you disable the network module:
  - If the failover link is on the network module, you must break High Availability. See [Break a High Availability Pair, on page 403](#). Disabling the network module with an active failover link is not allowed.

- Disable interface monitoring for interfaces on the network module. See [Configure Standby IP Addresses and Interface Monitoring, on page 397](#).

**Step 2** From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

**Figure 307: Manage Chassis**

| <input type="checkbox"/> | Name                                             | Model                        | Version | Chassis       |
|--------------------------|--------------------------------------------------|------------------------------|---------|---------------|
| <input type="checkbox"/> | Ungrouped (2)                                    |                              |         |               |
| <input type="checkbox"/> | 172.16.0.51 Snort 3<br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <b>Manage</b> |

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

**Step 3** On the interfaces graphic, click the slider (  ) to disable the network module.

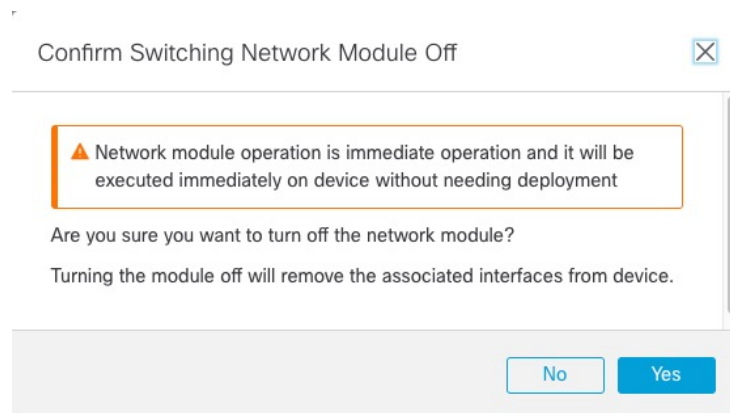

**Figure 308: Disable the Network Module**

Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

**Step 4** You are prompted to confirm that you want to turn the network module off. Click **Yes**.

**Figure 309: Confirm Disable**

**Step 5** On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.

**Step 6** In the management center, enable the new module by clicking the slider (  ).

**Figure 310: Enable the Network Module**

**Step 7** You are prompted to confirm that you want to turn the network module on. Click **Yes**.

**Figure 311: Confirm Enable**

**Step 8** For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster. See [Add a New Cluster Node, on page 440](#).
- **High Availability**—
  - If you broke High Availability, then reform High Availability. See [Add a High Availability Pair, on page 395](#).
  - Reenable interface monitoring for interfaces on the network module. See [Configure Standby IP Addresses and Interface Monitoring, on page 397](#).

## Replace the Network Module with a Different Type

If you replace a network module with a different type, then a reboot is required. If the new module has fewer interfaces than the old module, you will have to manually remove any configuration related to interfaces that will no longer be present.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit.

### Before you begin

For High Availability, you cannot disable a network module if the failover link is on the module. You will have to break High Availability (see [Break a High Availability Pair, on page 403](#)), which means you will have downtime when you reboot the active unit. After the units finish rebooting, you can reform High Availability.

### Procedure

#### Step 1

For clustering or High Availability, perform the following steps.

- **Clustering**—To avoid downtime, you can break each node one at a time so it is no longer in the cluster while you perform the network module replacement. See [Break a Node, on page 442](#).

You will add the node back to the cluster after you perform the replacement.

- **High Availability**—To avoid failing over when you replace the network module, disable interface monitoring for interfaces on the network module. See [Configure Standby IP Addresses and Interface Monitoring, on page 397](#).

#### Step 2

From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

**Figure 312: Manage Chassis**

| <input type="checkbox"/> | Name                                             | Model                        | Version | Chassis                |
|--------------------------|--------------------------------------------------|------------------------------|---------|------------------------|
| <input type="checkbox"/> | ▼ Ungrouped (2)                                  |                              |         |                        |
| <input type="checkbox"/> | 172.16.0.51 Short 3<br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <a href="#">Manage</a> |

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

#### Step 3

On the interfaces graphic, click the slider () to disable the network module.

**Figure 313: Disable the Network Module**

Do not save any changes on the **Interfaces** page. Because you are replacing the network module, you do not want to disrupt any existing configuration.

#### Step 4

You are prompted to confirm that you want to turn the network module off. Click **Yes**.

Figure 314: Confirm Disable

**Step 5** On the device, remove the old network module and replace it with the new network module according to the hardware installation guide.

**Step 6** Reboot the firewall; see [Shut Down or Restart the Device](#), on page 39.

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node (see [Change the Control Node](#), on page 445) or active unit (see [Switch the Active Peer in the Threat Defense High Availability Pair](#), on page 399), and reboot the former control node/active unit.

**Step 7** In the management center, click **Sync Modules** to update the page with the new network module details.

**Step 8** Enable the new module by clicking the slider ()

Figure 315: Enable the Network Module

**Step 9** You are prompted to confirm that you want to turn the network module on. Click **Yes**.

**Figure 316: Confirm Enable**

**Step 10** Click the link in the message at the top of the screen to go to the **Interfaces** page to save the interface changes.

**Figure 317: Go to Interface Page**

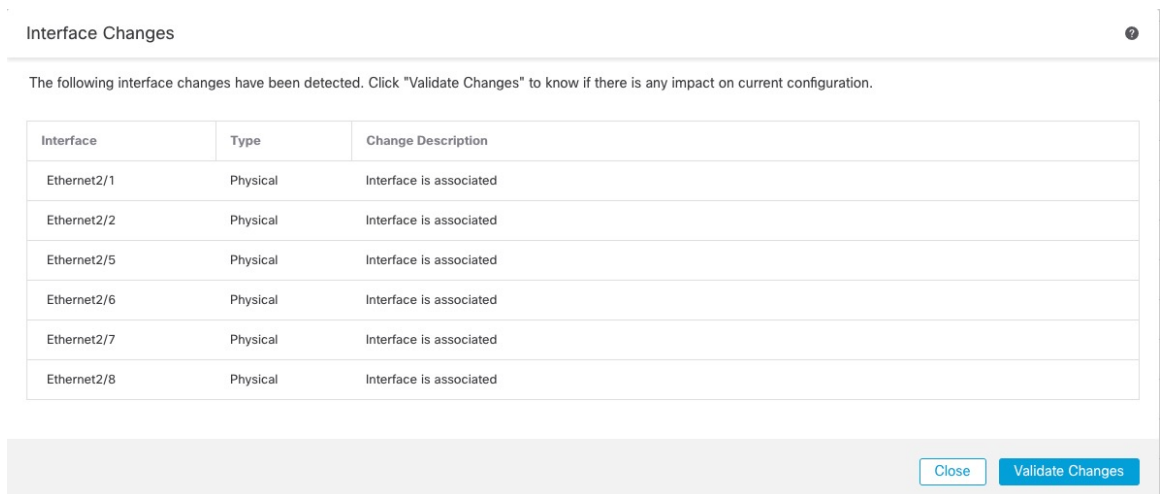

**Step 11** If the network module has *fewer* interfaces:  
 a) At the top of the **Interfaces** page, click **Click to know more**. The **Interface Changes** dialog box opens.

**Figure 318: View Interface Changes**

**Figure 319: Interface Changes**

b) Click **Validate Changes** to make sure your policy will still work with the interface changes.  
 If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

c) Click **Close** to return to the **Interfaces** page.

**Step 12** To change the interface speed, see [Enable the Physical Interface and Configure Ethernet Settings, on page 703](#).

The default speed is set to Detect SFP, which detects the correct speed from the SFP installed. You only need to fix the speed if you manually set the speed to a particular value and you now need a new speed.

**Step 13** Click **Save** to save the interface changes to the firewall.

**Step 14** If you had to change any configuration, go to **Deploy > Deployment** and deploy the policy.

You do not need to deploy just to save the network module changes.

**Step 15** For clustering or High Availability, perform the following steps.

- **Clustering**—Add the node back to the cluster. See [Add a New Cluster Node, on page 440](#).
- **High Availability**—Reenable interface monitoring for interfaces on the network module. See [Configure Standby IP Addresses and Interface Monitoring, on page 397](#).

## Remove the Network Module

If you want to permanently remove the network module, follow these steps. Removing a network module requires a reboot.

For clustering or High Availability, you can only perform chassis operations on the control node/active unit.

### Before you begin

For clustering or High Availability, make sure the cluster/failover link is not on the network module.

### Procedure

**Step 1** From **Devices > Device Management**, click **Manage** in the **Chassis** column. For clustering or High Availability, this option is only available for the control node/active unit; network module changes are replicated to all nodes.

*Figure 320: Manage Chassis*

| <input type="checkbox"/> | Name                                                            | Model                        | Version | Chassis       |
|--------------------------|-----------------------------------------------------------------|------------------------------|---------|---------------|
| <input type="checkbox"/> | ▽ Ungrouped (2)                                                 |                              |         |               |
| <input type="checkbox"/> | 172.16.0.51 <small>Snort 3</small><br>172.16.0.51 - Transparent | Firewall 3120 Threat Defense | 7.1.0   | <b>Manage</b> |

The **Chassis Operations** page opens for the device. This page shows physical interface details for the device.

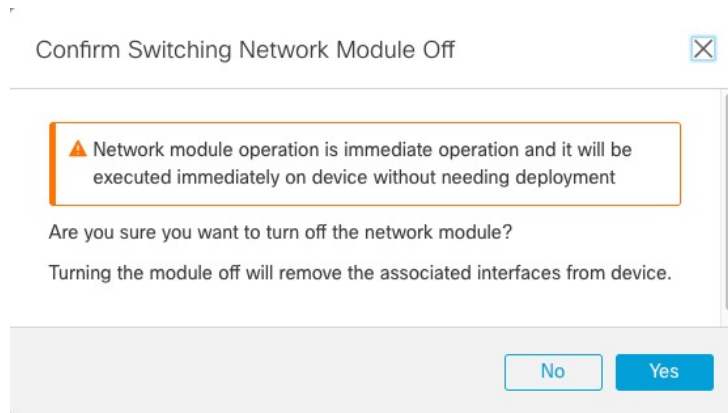

**Step 2** On the interfaces graphic, click the slider (  ) to disable the network module.

**Figure 321: Disable the Network Module**

**Step 3** You are prompted to confirm that you want to turn the network module off. Click **Yes**.

**Figure 322: Confirm Disable**

**Step 4** You see a message at the top of the screen; click the link to go to the **Interfaces** page to save the interface changes.

**Figure 323: Go to Interface Page**

 This device has configuration changes that were performed directly on the device. Visit [Interface page in device details](#)

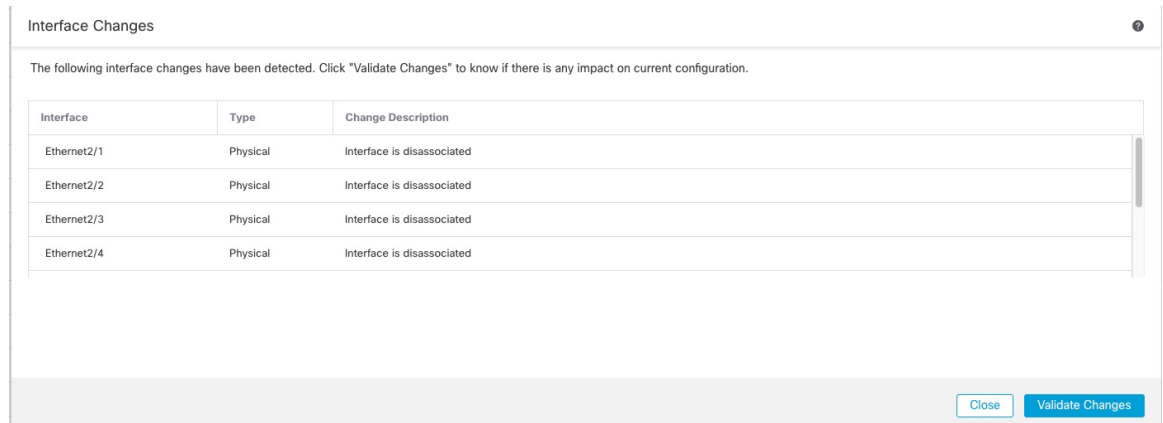

**Step 5** At the top of the **Interfaces** page, you see a message that the interface configuration has changed.

**Figure 324: View Interface Changes**

Interface configuration has changed on device. [Click to know more.](#)

a) Click **Click to know more** to open the **Interface Changes** dialog box to view the changes.

Figure 325: Interface Changes

- b) Click **Validate Changes** to make sure your policy will still work with the interface changes.

If there are any errors, you need to change your policy and rerun the validation.

Deleting an interface that is used in your security policy can impact the configuration. Interfaces can be referenced directly in many places in the configuration, including access rules, NAT, SSL, identity rules, VPN, DHCP server, and so on. Deleting an interface will delete any configuration associated with that interface. Policies that refer to security zones are not affected.

- c) Click **Close** to return to the **Interfaces** page.

**Step 6** Click **Save** to save the interface changes to the firewall.

**Step 7** If you had to change any configuration, go to **Deploy > Deployment** and deploy the policy.

**Step 8** Reboot the firewall; see [Shut Down or Restart the Device, on page 39](#).

For clustering or High Availability, reboot the data nodes/standby unit first, and wait for them to come back up. Then you can change the control node (see [Change the Control Node, on page 445](#)) or active unit (see [Switch the Active Peer in the Threat Defense High Availability Pair, on page 399](#)), and reboot the former control node/active unit.

## Merge the Management and Diagnostic Interfaces

Threat Defense 7.4 and later supports a merged Management and Diagnostic interface. If you have any configuration using the Diagnostic interface, then the interfaces will not be merged automatically, and you will need to perform the following procedure. This procedure requires you to acknowledge configuration changes, and in some cases, manually fix the configuration.

The Backup/Restore and management center configuration rollback functions save and restore the merged state, either non-merged or merged. For example, if you merge the interfaces, and then restore an old non-merged configuration, then the restored configuration will be in a non-merged state.

The following table shows the available configuration on the legacy Diagnostic interface, and how the merge is completed.

Table 48: Management Center Merged Management Interface Support

| Legacy Diagnostic Interface Configuration                           | Merge Behavior                                                                                                                                                      | Supported on Management?                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| DNS server                                | Automatically moved to Management interface. | Yes.<br>If you checked the <b>Enable DNS Lookup via diagnostic interface also</b> check box, then it will be moved to use Management. There is a routing lookup change when you do not choose any interfaces or check the <b>Enable DNS Lookup via diagnostic/management interface also</b> check box: the threat defense uses the data routing table only, and does not fall back to using the management-only routing table. Therefore, you cannot use a management-only interface for DNS other than the Management interface.<br><b>Note</b> The Management interface also has a separate DNS lookup setting for its management traffic only. Set at the CLI using the <b>configure network dns</b> command. |
| FlexConfig                                | Manual removal required.                     | <b>No support.</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the threat defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

The following output shows that the Management interfaces are not merged:

```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

## Procedure

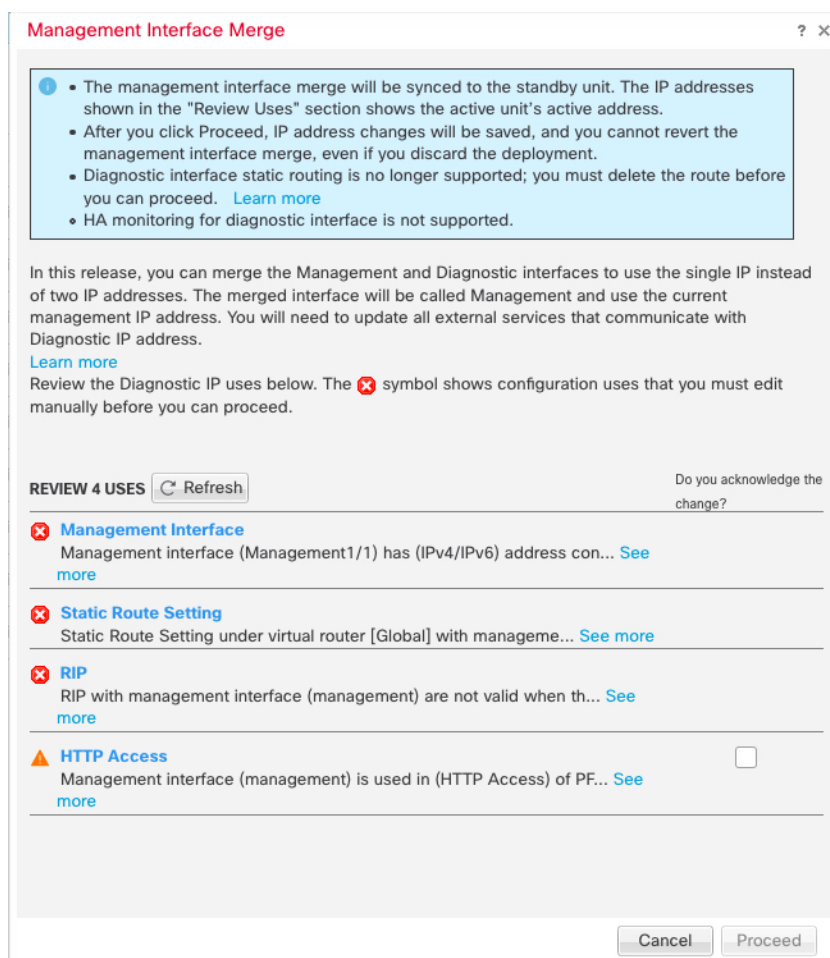

**Step 1** Choose **Devices > Device Management**, and click **Edit** (✎) for your threat defense. The **Interfaces** page is selected by default. .

**Step 2** Edit the Diagnostic interface, and remove the IP address.

You cannot complete the merge until after you have removed the Diagnostic IP address.

**Step 3** Click **Management Interface Merge** in the **Management Interface action needed** area.

The **Management Interface Merge** dialog box shows all the occurrences of the Diagnostic interface in the configuration. For any occurrences that require you to manually remove or change the configuration, they will appear with a warning icon. Platform Settings that will no longer work on your device are marked with a caution icon and require your acknowledgement.

**Step 4** If you need to manually remove or change any listed configurations, do the following.

- Click **Cancel** to close the **Management Interface Merge** dialog box.
- Navigate to the feature area. You can then delete the item, or choose a data interface instead.
- Reopen the **Management Interface Merge** dialog box.

There should no longer be any warnings.

**Step 5** For each configuration caution, click the box in **Do you acknowledge the change?** column, and then click **Proceed**.

**Management Interface Merge** ? x

- The management interface merge will be synced to the standby unit. The IP addresses shown in the "Review Uses" section shows the active unit's active address.
- After you click Proceed, IP address changes will be saved, and you cannot revert the management interface merge, even if you discard the deployment.
- Diagnostic interface static routing is no longer supported; you must delete the route before you can proceed. [Learn more](#)
- HA monitoring for diagnostic interface is not supported.

In this release, you can merge the Management and Diagnostic interfaces to use the single IP instead of two IP addresses. The merged interface will be called Management and use the current management IP address. You will need to update all external services that communicate with Diagnostic IP address.  
[Learn more](#)

Review the Diagnostic IP uses below. The symbol shows configuration uses that you must edit manually before you can proceed.

**REVIEW 2 USES**  Do you acknowledge the change?

|                                                                                                                    |                                     |
|--------------------------------------------------------------------------------------------------------------------|-------------------------------------|
| <b>HTTP Access</b><br>Management interface (management) is used in (HTTP Access) of PF... <a href="#">See more</a> | <input checked="" type="checkbox"/> |
| <b>ICMP Access</b><br>Management interface (management) is used in (ICMP Access) of PF... <a href="#">See more</a> | <input checked="" type="checkbox"/> |

After the configuration is merged, you see a success banner:

The Management interface merge was saved and is ready to be deployed.  
Note that you cannot undo the configuration changes related to merge; you must manually reconfigure the Diagnostic interface and related configuration.

**Step 6** Deploy the new merged configuration.

**Caution** After you deploy the merged configuration, you can unmerge the interfaces from management center; however the Diagnostic interface will have to be reconfigured manually. See [Unmerge the Management Interface, on page 736](#). Also, if you restore a configuration that is unmerged, or roll back to an unmerged configuration, then the device will revert to that unmerged configuration.

After the merge, the Management interface is shown on the **Interfaces** page, although it is read-only.

**Step 7** After the merge, if you had any external services that communicated with the Diagnostic interface, you need to change their configuration to use the Management interface IP address.

For example:

- SNMP client

- RADIUS server—RADIUS servers often verify the IP address for incoming traffic, so you need to change that IP address to the Management address. Moreover, for a High Availability pair, you need to allow both the primary and secondary Management IP addresses; the Diagnostic interface used to support a single "floating" IP address that stayed with the active unit, but Management does not support that functionality.

## Unmerge the Management Interface

The threat defense 7.4 and later supports a merged Management and Diagnostic interface. If you need to unmerge your interfaces, perform this procedure. We recommend using unmerged mode temporarily while you migrate your network to a merged mode deployment. Separate Management and Diagnostic interfaces may not be supported in all future releases.

Unmerging the interfaces does not restore your original Diagnostic configuration (if you upgraded and then merged your interfaces). You will need to reconfigure the Diagnostic interface manually. Also, the Management interface will now be named "management"; you cannot rename it "diagnostic."

Alternatively, if you used the Backup function to save an old unmerged configuration, you can restore that configuration or you can use the or management center configuration rollback feature, and the device will be in an unmerged state with the Diagnostic configuration intact.

### Before you begin

- To view the current mode of the device, enter the **show management-interface convergence** command at the threat defense CLI. The following output shows that the Management interfaces are merged:

```
> show management-interface convergence
management-interface convergence
>
```

The following output shows that the Management interfaces are not merged:

```
> show management-interface convergence
no management-interface convergence
>
```

- For High Availability pairs and clusters, perform this task on the active/control unit. The merged configuration will be replicated automatically to the standby/data units.

### Procedure

**Step 1** Choose **Devices > Device Management**, and click **Edit** (✎) for your threat defense. The **Interfaces** page is selected by default. .

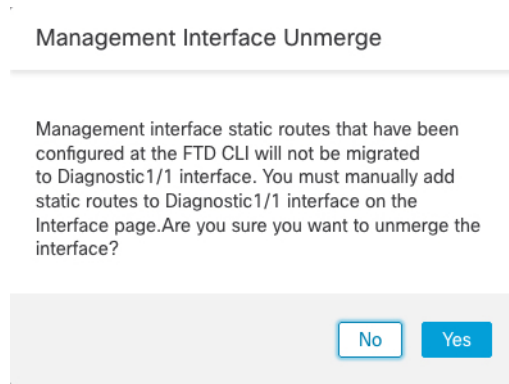

**Step 2** For the Management interface, click **Unmerge Management Interface** (↺).

*Figure 326: Management Interface Selection*

**Step 3** Click **Yes** to confirm that you want to unmerge the interface.

*Figure 327: Unmerge Confirmation*

**Step 4** Deploy the new unmerged configuration.

**Note** If you restore a configuration that is merged, or roll back to a merged configuration, then the device will revert to that merged configuration.

After the merge, the Management interface is no longer shown on the **Interfaces** page.

## History for Interfaces

| Feature                                              | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

# CHAPTER 15

## Regular Firewall Interfaces

This chapter includes regular firewall threat defense interface configuration including EtherChannels, VLAN subinterfaces, IP addressing, and more.

**Note** For initial interface configuration on the Firepower 4100/9300, see [Configure Interfaces, on page 289](#).

## Requirements and Prerequisites for Regular Firewall Interfaces

### Model Support

Threat Defense

### User Roles

- Admin
- Access Admin
- Network Admin

## Configure Firepower 1010 Switch Ports

You can configure each Firepower 1010 interface to run as a regular firewall interface or as a Layer 2 hardware switch port. This section includes tasks for starting your switch port configuration, including enabling or

disabling the switch mode and creating VLAN interfaces and assigning them to switch ports. This section also describes how to customize Power over Ethernet (PoE) on supported interfaces.

## About Firepower 1010 Switch Ports

This section describes the switch ports of the Firepower 1010.

### Understanding Switch Ports and Interfaces

#### Ports and Interfaces

For each physical Firepower 1010 interface, you can set its operation as a firewall interface or as a switch port. See the following information about physical interface and port types as well as logical VLAN interfaces to which you assign switch ports:

- **Physical firewall interface**—In routed mode, these interfaces forward traffic between networks at Layer 3, using the configured security policy to apply firewall and VPN services. In transparent mode, these interfaces are bridge group members that forward traffic between the interfaces on the same network at Layer 2, using the configured security policy to apply firewall services. In routed mode, you can also use Integrated Routing and Bridging with some interfaces as bridge group members and others as Layer 3 interfaces. By default, the Ethernet 1/1 interface is configured as a firewall interface. You can also configure these interfaces to be IPS-only (inline sets and passive interfaces).
- **Physical switch port**—Switch ports forward traffic at Layer 2, using the switching function in hardware. Switch ports on the same VLAN can communicate with each other using hardware switching, and traffic is not subject to the threat defense security policy. Access ports accept only untagged traffic, and you can assign them to a single VLAN. Trunk ports accept untagged and tagged traffic, and can belong to more than one VLAN. By default, Ethernet 1/2 through 1/8 are configured as access switch ports on VLAN 1. You cannot configure the Management interface as a switch port.
- **Logical VLAN interface**—These interfaces operate the same as physical firewall interfaces, with the exception being that you cannot create subinterfaces, IPS-only interfaces (inline sets and passive interfaces), or EtherChannel interfaces. When a switch port needs to communicate with another network, then the threat defense device applies the security policy to the VLAN interface and routes to another logical VLAN interface or firewall interface. You can even use Integrated Routing and Bridging with VLAN interfaces as bridge group members. Traffic between switch ports on the same VLAN are not subject to the threat defense security policy, but traffic between VLANs in a bridge group are subject to the security policy, so you may choose to layer bridge groups and switch ports to enforce the security policy between certain segments.

#### Power Over Ethernet

Power over Ethernet+ (PoE+) is supported on the following ports:

- On Firepower 1010, Ethernet 1/7 and Ethernet 1/8 support Power over Ethernet+ (PoE+).

### Auto-MDI/MDIX Feature

For all switch ports, the default auto-negotiation setting also includes the Auto-MDI/MDIX feature. Auto-MDI/MDIX eliminates the need for crossover cabling by performing an internal crossover when a straight cable is detected during the auto-negotiation phase. Either the speed or duplex must be set to auto-negotiate to enable Auto-MDI/MDIX for the interface. If you explicitly set both the speed and duplex

to a fixed value, thus disabling auto-negotiation for both settings, then Auto-MDI/MDIX is also disabled. When the speed and duplex are set to 1000 and full, then the interface always auto-negotiates; therefore Auto-MDI/MDIX is always enabled and you cannot disable it.

## Guidelines and Limitations for Switch Ports

### High Availability and Clustering

- No cluster support.
- You should not use the switch port functionality when using High Availability. Because the switch ports operate in hardware, they continue to pass traffic on both the active *and* the standby units. High Availability is designed to prevent traffic from passing through the standby unit, but this feature does not extend to switch ports. In a normal High Availability network setup, active switch ports on both units will lead to network loops. We suggest that you use external switches for any switching capability. Note that VLAN interfaces can be monitored by failover, while switch ports cannot. Theoretically, you can put a single switch port on a VLAN and successfully use High Availability, but a simpler setup is to use physical firewall interfaces instead.
- You can only use a firewall interface as the failover link.

### Logical VLAN Interfaces

- You can create up to 60 VLAN interfaces.
- If you also use VLAN subinterfaces on a firewall interface, you cannot use the same VLAN ID as for a logical VLAN interface. VLAN 1 is reserved for the logical VLAN interface.
- MAC Addresses:
  - Routed firewall mode—All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See [Configure the MAC Address, on page 804](#).
  - Transparent firewall mode—Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See [Configure the MAC Address, on page 804](#).

### Bridge Groups

You cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.

### VLAN Interface and Switch Port Unsupported Features

VLAN interfaces and switch ports do not support:

- Dynamic routing
- Multicast routing
- Equal-Cost Multi-Path routing (ECMP)
- Inline sets or Passive interfaces

- EtherChannels
- Failover and state link
- Security group tagging (SGT)

### Other Guidelines and Limitations

- You can configure a maximum of 60 named interfaces on the Firepower 1010.
- You cannot configure the Management interface as a switch port.

### Default Settings

- Ethernet 1/1 is a firewall interface.
- Ethernet 1/2 through Ethernet 1/8 are switch ports assigned to VLAN 1.
- Default Speed and Duplex—By default, the speed and duplex are set to auto-negotiate.

## Configure Switch Ports and Power Over Ethernet

To configure switch ports and PoE, complete the following tasks.

### Enable or Disable Switch Port Mode

You can set each interface independently to be either a firewall interface or a switch port. By default, Ethernet 1/1 is a firewall interface, and the remaining Ethernet interfaces are configured as switch ports.

#### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Set the switch port mode by clicking the slider in the **SwitchPort** column so it shows as **Slider enabled** (🔵) or **Slider disabled** (⚪).

By default, switch ports are set to access mode in VLAN 1. You must manually add a logical VLAN 1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the threat defense security policy (see [Configure a VLAN Interface, on page 745](#)). You cannot set the Management interface to switch port mode. When you change the switch port mode, all unsupported configuration is removed:

## Configure a VLAN Interface

This section describes how to configure VLAN interfaces for use with associated switch ports. By default, switch ports are assigned to VLAN1; however, you must manually add the logical VLAN1 interface (or whichever VLAN you set for these switch ports) for traffic to be routed and to participate in the threat defense security policy.

### Procedure

---

- Step 1** Select **Devices > Device Management** and click **Edit** (🔗) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Add Interfaces > VLAN Interface**.
- Step 3** On **General**, set the following VLAN-specific parameters:

### Add VLAN Interface ?

General
IPv4
IPv6
Advanced

Name:

Enabled

Description:

Mode:

Security Zone:

MTU:  
  
(64 - 9198)

Priority:  
 (0 - 65535)

VLAN ID \*:  
  
(1 - 4070)

Disable Forwarding on Interface VLAN:

| Associated Interface  | Port Mode |
|-----------------------|-----------|
| No records to display |           |

If you are editing an existing VLAN interface, the **Associated Interface** table shows switch ports on this VLAN.

- a) Set the **VLAN ID**, between 1 and 4070, excluding IDs in the range 3968 to 4047, which are reserved for internal use.

You cannot change the VLAN ID after you save the interface; the VLAN ID is both the VLAN tag used, and the interface ID in your configuration.

- b) (Optional) Choose a VLAN ID for **Disable Forwarding on Interface VLAN** to disable forwarding to another VLAN.

For example, you have one VLAN assigned to the outside for internet access, one VLAN assigned to an inside business network, and a third VLAN assigned to your home network. The home network does not need to access the business network, so you can disable forwarding on the home VLAN; the business network can access the home network, but the home network cannot access the business network.

- Step 4** To complete the interface configuration, see one of the following procedures:
- [Configure Routed Mode Interfaces, on page 778](#)
  - [Configure General Bridge Group Member Interface Parameters, on page 783](#)

**Step 5** Click **OK**.

**Step 6** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure Switch Ports as Access Ports

To assign a switch port to a single VLAN, configure it as an access port. Access ports accept only untagged traffic. By default, Ethernet1/2 through Ethernet 1/8 switch ports are assigned to VLAN 1.

---

**Note** The device does not support Spanning Tree Protocol for loop detection in the network. Therefore you must ensure that any connection with the threat defense does not end up in a network loop.

---

### Procedure

---

- Step 1** Select **Devices > Device Management** and click **Edit** (🔗) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (🔗) for the interface you want to edit.

Figure 328: Edit Physical Interface

Edit Physical Interface

General Hardware Configuration

Interface ID:  
Ethernet1/2

Enabled

Description:

Port Mode:  
Access ▼

VLAN ID:  
1  
(1 - 4070)

Protected:

**Step 3** Enable the interface by checking the **Enabled** check box.

**Step 4** (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

**Step 5** Set the **Port Mode** to **Access**.

**Step 6** In the **VLAN ID** field, set the VLAN for this switch port, between 1 and 4070.

The default VLAN ID is 1.

**Step 7** (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

**Step 8** (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

Figure 329: Hardware Configuration

The screenshot shows the 'Edit Physical Interface' configuration page. The 'Hardware Configuration' tab is selected. Under the 'Speed' section, the 'Duplex' dropdown is set to 'full' and the 'Speed' dropdown is set to '1gbps'. The 'Auto-negotiation' checkbox is checked.

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

**Step 9** Click **OK**.

**Step 10** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure Switch Ports as Trunk Ports

This procedure describes how to create a trunk port that can carry multiple VLANs using 802.1Q tagging. Trunk ports accept untagged and tagged traffic. Traffic on allowed VLANs pass through the trunk port unchanged.

When the trunk receives untagged traffic, it tags it to the native VLAN ID so that the ASA can forward the traffic to the correct switch ports, or can route it to another firewall interface. When the ASA sends native VLAN ID traffic out of the trunk port, it removes the VLAN tag. Be sure to set the same native VLAN on the trunk port on the other switch so that the untagged traffic will be tagged to the same VLAN.

### Procedure

**Step 1** Select **Devices > Device Management** and click **Edit** (🔗) for your threat defense device. The **Interfaces** page is selected by default.

**Step 2** Click **Edit** (🔗) for the interface you want to edit.

Figure 330: Set Trunk Port Mode

Edit Physical Interface

General Hardware Configuration

Interface ID:  
Ethernet1/2

Enabled

Description:

Port Mode:  
Trunk ▼

Native VLAN ID:  
  
(1 - 4070)

Allowed VLAN IDs:  
  
(1 - 4070)

Protected:

**Step 3** Enable the interface by checking the **Enabled** check box.

**Step 4** (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

**Step 5** Set the **Port Mode** to **Trunk**.

**Step 6** In the **Native VLAN ID** field, set the native VLAN for this switch port, between 1 and 4070.

The default native VLAN ID is 1.

Each port can only have one native VLAN, but every port can have either the same or a different native VLAN.

**Step 7** In the **Allowed VLAN IDs** field, enter the VLANs for this trunk port between 1 and 4070.

You can identify up to 20 IDs in one of the following ways:

- A single number (n)
- A range (n-x)
- Numbers and ranges separated by commas, for example:

5,7-10,13,45-100

You can enter spaces instead of commas.

If you include the native VLAN in this field, it is ignored; the trunk port always removes the VLAN tagging when sending native VLAN traffic out of the port. Moreover, it will not receive traffic that still has native VLAN tagging.

**Step 8** (Optional) Check the **Protected** check box to set this switch port as protected, so you can prevent the switch port from communicating with other protected switch ports on the same VLAN.

You might want to prevent switch ports from communicating with each other if: the devices on those switch ports are primarily accessed from other VLANs; you do not need to allow intra-VLAN access; and you want to isolate the devices from each other in case of infection or other security breach. For example, if you have a DMZ that hosts three web servers, you can isolate the web servers from each other if you enable **Protected** on each switch port. The inside and outside networks can both communicate with all three web servers, and vice versa, but the web servers cannot communicate with each other.

**Step 9** (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The screenshot shows a window titled "Edit Physical Interface" with a "Hardware Configuration" tab selected. Under "Duplex:", the dropdown menu is set to "auto". Under "Speed:", the dropdown menu is also set to "auto". The "Auto-negotiation:" checkbox is checked. At the bottom right, there are "OK" and "Cancel" buttons.

Check the **Auto-negotiation** check box (the default) to auto-detect the speed and duplex. If you uncheck it, you can set the speed and duplex manually:

- **Duplex**—Choose **Full** or **Half**.
- **Speed**—Choose **10mbps**, **100mbps**, or **1gbps**.

**Step 10** Click **OK**.

**Step 11** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure Power Over Ethernet

Ethernet 1/7 and Ethernet 1/8 support Power over Ethernet (PoE) for devices such as IP phones or wireless access points. The Firepower 1010 supports both IEEE 802.3af (PoE) and 802.3at (PoE+). PoE+ uses Link Layer Discovery Protocol (LLDP) to negotiate the power level. PoE+ can deliver up to 30 watts to a powered device. Power is only supplied when needed.

If you shut down the switch port, or configure the port as a firewall interface, then you disable power to the device.

PoE is enabled by default on Ethernet 1/7 and Ethernet 1/8. This procedure describes how to disable and enable PoE and how to set optional parameters.

## Procedure

- Step 1** Select **Devices > Device Management** and click **Edit** (🔗) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (🔗) for Ethernet1/7 or 1/8.
- Step 3** Click **PoE**.

**Figure 331: PoE**

The screenshot shows the 'Edit Physical Interface' configuration page with the 'PoE' tab selected. The 'Enable PoE' checkbox is checked. The 'Auto Negotiate' checkbox is also checked. The 'Consumption Wattage' field is empty, with a range of (4000 - 30000)mW indicated.

- Step 4** Check the **Enable PoE** check box.  
PoE is enabled by default.
- Step 5** (Optional) Uncheck the **Auto Negotiate Consumption Wattage** check box, and enter the **Consumption Wattage** if you know the exact wattage you need.  
By default, PoE delivers power automatically to the powered device using a wattage appropriate to the class of the powered device. The Firepower 1010 uses LLDP to further negotiate the correct wattage. If you know the specific wattage and want to disable LLDP negotiation, enter a value from 4000 to 30000 milliwatts.
- Step 6** Click **OK**.
- Step 7** Click **Save**.  
You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

# Configure Loopback Interfaces

This section tells how to configure loopback interfaces.

## About Loopback Interfaces

A loopback interface is a software-only interface that emulates a physical interface. This interface is reachable on IPv4 and IPv6 through multiple physical interfaces. The loopback interface helps to overcome path failures; it is accessible from any physical interface, so if one goes down, you can access the loopback interface from another.

Loopback interfaces can be used for:

- AAA

- BGP
- DNS
- HTTP
- ICMP
- IPsec flow offload—Secure Firewall 3100 and 4200 only
- NetFlow
- SNMP
- SSH
- Static and dynamic VTI tunnels
- Syslog

The threat defense can distribute the loopback address using dynamic routing protocols, or you can configure a static route on the peer device to reach the loopback IP address through one of the threat defense's physical interfaces. You cannot configure a static route on the threat defense that specifies the loopback interface.

#### Related Topics

[Guidelines and Limitations for Loopback Interfaces](#), on page 753

[Configure a Loopback Interface](#), on page 753

## Guidelines and Limitations for Loopback Interfaces

#### Firewall Mode

- Supported in routed mode only.

#### High Availability and Clustering

- No clustering support.

#### Additional Guidelines and Limitations

- TCP sequence randomization is always disabled for traffic from the physical interface to the loopback interface.

## Configure a Loopback Interface

To add a loopback interface for a device:

#### Procedure

---

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

- Step 2** From the **Add Interfaces** drop-down list, choose **Loopback Interface**.
- Step 3** In the **General** tab, configure the following parameters:
- Name**—Enter a name for the loopback interface.
  - Enabled**—Check the check box to enable the loopback interface.
  - Loopback ID**—Enter the loopback ID between 1 to 1024.
  - Description**—Enter a description for the loopback interface.
- Step 4** Configure the routed mode interface parameters. See [Configure Routed Mode Interfaces, on page 778](#).

## Rate-Limit Traffic to the Loopback Interface

### Before you begin

You should rate-limit traffic going to the loopback interface IP address to prevent excessive load on the system. You can add a connection limit rule to the global service policy.

### Procedure

- Step 1** Create an extended access list identifying traffic to the loopback interface IP address(es).
- Choose **Objects > Object Management** and choose **Access Control Lists > Extended** from the table of contents.
  - Click **Add Extended Access List** to create a new ACL.
  - In the **New Extended Access List Object** dialog box, enter a name for the ACL (no spaces allowed), and click **Add** to create a new entry.

**Figure 332: Name ACL and Add Entry**

The screenshot shows a dialog box titled "New Extended Access List Object". It has a "Name" input field containing the text "rate-limiting", which is highlighted with a red rectangular box. Below the name field is a label "Entries (0)". To the right of the dialog box is a blue "Add" button, also highlighted with a red rectangular box.

- Configure the source (any) and destination addresses (loopback IP addresses) on the **Network** tab.

Figure 333: Source and Destination Networks

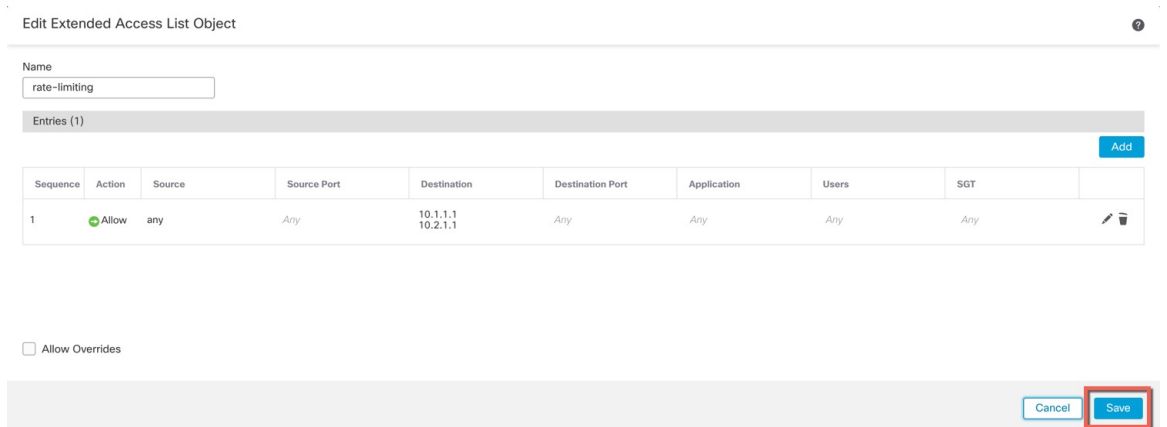

**Note** Keep the default **Action** as **Allow** (match) and other settings as-is.

- **Source**—Select **any** from the **Available Networks** list, and click **Add to Source**. You can also narrow this access list by specifying the source IP addresses instead of **any**.
- **Destination**—Type an address in the edit box below the **Destination Networks** list and click **Add**. Repeat for each loopback interface.

- Click **Add** to add the entry to the ACL.
- Click **Save** to save the ACL.

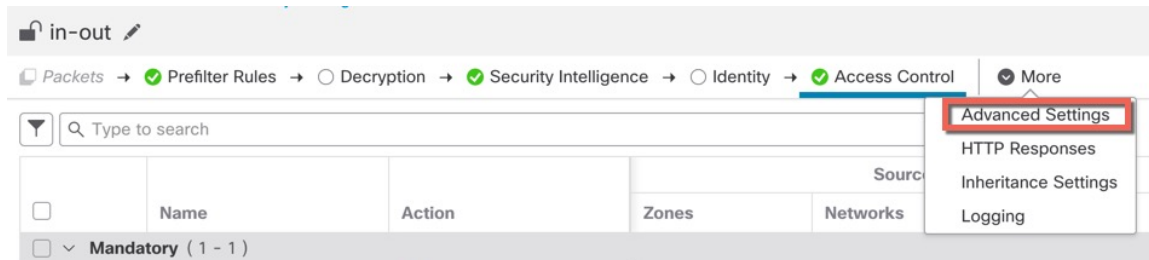

Figure 334: Save ACL

**Step 2** Choose **Policies > Access Control > Access Control**, and click **Edit** (✎) for the access control policy assigned to your device.

**Step 3** Click **Advanced Settings** from the **More** drop-down arrow at the end of the packet flow line.

*Figure 335: Advanced Settings*

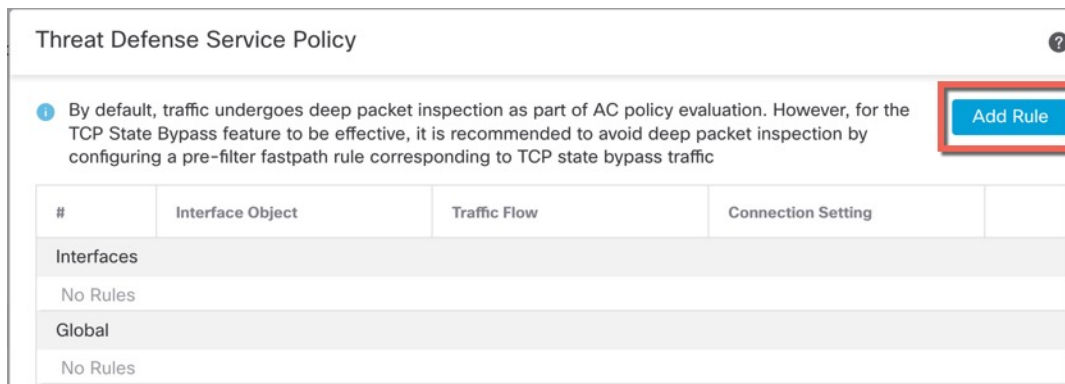

**Step 4** Click **Edit** (✎) in the **Threat Defense Service Policy** group.

*Figure 336: Threat Defense Service Policy*

**Step 5** Click **Add Rule** to create a new rule.

*Figure 337: Add Rule*

The service policy rule wizard opens to step you through the process of configuring the rule.

**Step 6** In the **Interface Object** step, click **Global** to create a global rule, which applies to all interfaces, then click **Next**.

**Figure 338: Global Policy**

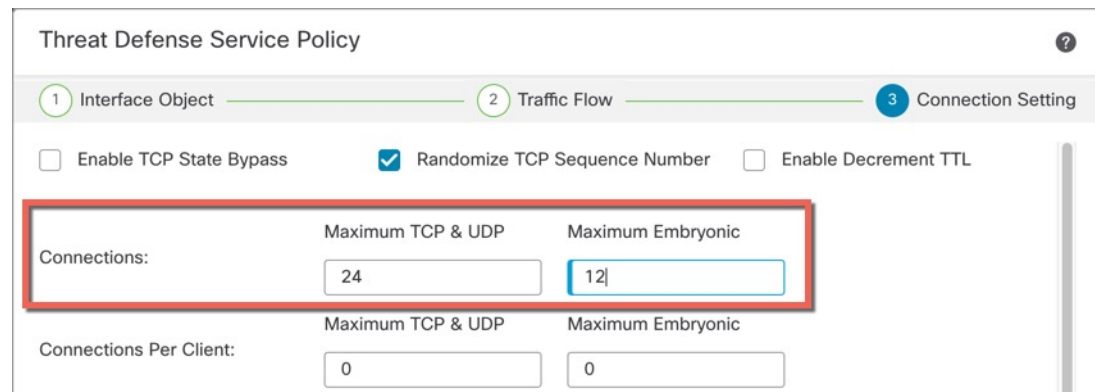

**Step 7** In the **Traffic Flow** step, select the extended access list object you created in [Step 1, on page 754](#), and then click **Next**.

**Figure 339: Choose Extended Access List**

**Step 8** In the **Connection Setting** step, set the **Connections** limits.

**Figure 340: Set Connection Limits**

Set the **Maximum TCP & UDP** connections to the expected number of connections for the loopback interface, and the **Maximum Embryonic** connections to a lower number. For example, you can set it to 5/2, or 10/5, or 1024/512, depending on the expected loopback interface sessions you need.

Setting the embryonic connection limit enables TCP Intercept, which protects the system from a DoS attack perpetrated by flooding an interface with TCP SYN packets.

**Step 9** Click **Finish** to save your changes.

**Step 10** Click **OK**.

**Step 11** Click **Save** on the **Advanced Settings** window.

**Step 12** You can now deploy the changes to the affected devices.

# Configure VLAN Subinterfaces and 802.1Q Trunking

VLAN subinterfaces let you divide a physical, redundant, or EtherChannel interface into multiple logical interfaces that are tagged with different VLAN IDs. An interface with one or more VLAN subinterfaces is automatically configured as an 802.1Q trunk. Because VLANs let you keep traffic separate on a given physical interface, you can increase the number of interfaces available to your network without adding additional physical interfaces or devices.

## Guidelines and Limitations for VLAN Subinterfaces

### Model Support

- Firepower 1010—VLAN subinterfaces are not supported on switch ports or VLAN interfaces.
- Firepower 1010—You cannot create a subinterface using interface ID 1 or VLAN ID 1. VLAN 1 is reserved for the logical VLAN interface for switch ports.

### High Availability and Clustering

You cannot use a subinterface for the failover or state link or for the cluster control link. The exception is for multi-instance mode: you can use a *chassis*-defined subinterface for these links.

### Additional Guidelines

- Preventing untagged packets on the physical interface—If you use subinterfaces, you typically do not also want the physical interface to pass traffic, because the physical interface passes untagged packets. This property is also true for the active physical interface in a redundant interface pair and for EtherChannel links. Because the physical, redundant, or EtherChannel interface must be enabled for the subinterface to pass traffic, ensure that the physical, redundant, or EtherChannel interface does not pass traffic by not configuring a name for the interface. If you want to let the physical, redundant, or EtherChannel interface pass untagged packets, you can configure the name as usual.
- You cannot configure subinterfaces on the Management interface, either the dedicated Management interface configured at the CLI nor a data interface used for manager access.
- All subinterfaces on the same parent interface must be either bridge group members or routed interfaces; you cannot mix and match.
- The threat defense does not support the Dynamic Trunking Protocol (DTP), so you must configure the connected switch port to trunk unconditionally.
- You might want to assign unique MAC addresses to subinterfaces defined on the threat defense, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the threat defense.

## Maximum Number of VLAN Subinterfaces by Device Model

The device model limits the maximum number of VLAN subinterfaces that you can configure. Note that you can configure subinterfaces on data interfaces only, you cannot configure them on the management interface.

The following table explains the limits for each device model.

| Model                      | Maximum VLAN Subinterfaces |
|----------------------------|----------------------------|
| Firepower 1010             | 60                         |
| Firepower 1120             | 512                        |
| Firepower 1140, 1150       | 1024                       |
| Secure Firewall 3100, 4200 | 1024                       |
| Firepower 4100             | 1024                       |
| Firepower 9300             | 1024                       |
| Threat Defense Virtual     | 50                         |
| ISA 3000                   | 100                        |

## Add a Subinterface

Add one or more subinterfaces to a physical, redundant, or port-channel interface.

For the Firepower 4100/9300, you can configure subinterfaces in FXOS for use with container instances; see [Add a VLAN Subinterface for Container Instances, on page 293](#). These subinterfaces appear in the management center interface list. You can also add subinterfaces in management center, but only on parent interfaces that do not already have subinterfaces defined in FXOS.

**Note** The parent physical interface passes untagged packets. You may not want to pass untagged packets, so be sure not to include the parent interface in your security policy.

### Procedure

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Enable the parent interface according to [Enable the Physical Interface and Configure Ethernet Settings, on page 703](#).
- Step 3** Click **Add Interfaces > Sub Interface**.
- Step 4** On **General**, set the following parameters:

Figure 341: Add Subinterface

**Add Sub Interface**

General IPv4 IPv6 Path Monitoring Advanced

Name:  
inside-100

Enabled  
 Management Only

Description:

Security Zone:  
inside\_zone

MTU:  
1500  
(64 - 9198)

Priority:  
0  
(0 - 65535)

Propagate Security Group Tag:

Interface \*:  
Ethernet1/1

Enabled

Sub-Interface ID \*:  
100  
(1 - 4294967295)

VLAN ID:  
100  
(1 - 4094)

Cancel OK

- Interface**—Choose the physical, redundant, or port-channel interface to which you want to add the subinterface.
- Sub-Interface ID**—Enter the subinterface ID as an integer between 1 and 4294967295. The number of subinterfaces allowed depends on your platform. You cannot change the ID after you set it.
- VLAN ID**—Enter the VLAN ID between 1 and 4094 that will be used to tag the packets on this subinterface.

This VLAN ID must be unique.

**Step 5** Click **OK**.

**Step 6** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

- Step 7** Configure the routed or transparent mode interface parameters. See [Configure Routed Mode Interfaces, on page 778](#) or [Configure Bridge Group Interfaces, on page 783](#).
- 

## Configure VXLAN Interfaces

This chapter tells how to configure Virtual eXtensible LAN (VXLAN) interfaces. VXLAN interfaces act as Layer 2 virtual networks over Layer 3 physical networks to stretch Layer 2 networks.

### About VXLAN Interfaces

VXLAN provides the same Ethernet Layer 2 network services as VLAN does, but with greater extensibility and flexibility. Compared to VLAN, VXLAN offers the following benefits:

- Flexible placement of multitenant segments throughout the data center.
- Higher scalability to address more Layer 2 segments: up to 16 million VXLAN segments.

This section describes how VXLAN works. For detailed information about VXLAN, see RFC 7348. For detailed information about Geneve, see RFC 8926.

### Encapsulation

The threat defense supports two types of VXLAN encapsulation:

- VXLAN (all models)—VXLAN uses MAC Address-in-User Datagram Protocol (MAC-in-UDP) encapsulation. The original Layer 2 frame has a VXLAN header added and is then placed in a UDP-IP packet.
- Geneve (threat defense virtual only)—Geneve has a flexible inner header that is not limited to the MAC address. Geneve encapsulation is required for transparent routing of packets between an Amazon Web Services (AWS) Gateway Load Balancer and appliances, and for sending extra information.

### VXLAN Tunnel Endpoint

VXLAN tunnel endpoint (VTEP) devices perform VXLAN encapsulation and decapsulation. Each VTEP has two interface types: one or more virtual interfaces called VXLAN Network Identifier (VNI) interfaces to which you apply your security policy, and a regular interface called the VTEP source interface that tunnels the VNI interfaces between VTEPs. The VTEP source interface is attached to the transport IP network for VTEP-to-VTEP communication.

The following figure shows two threat defenses and Virtual Server 2 acting as VTEPs across a Layer 3 network, extending the VNI 1, 2, and 3 networks between sites. The threat defenses act as bridges or gateways between VXLAN and non-VXLAN networks.

The underlying IP network between VTEPs is independent of the VXLAN overlay. Encapsulated packets are routed based on the outer IP address header, which has the initiating VTEP as the source IP address and the terminating VTEP as the destination IP address. For VXLAN encapsulation: The destination IP address can be a multicast group when the remote VTEP is not known. With Geneve, the threat defense only supports static peers. The destination port for VXLAN is UDP port 4789 by default (user configurable). The destination port for Geneve is 6081.

## VTEP Source Interface

The VTEP source interface is a regular interface (physical, EtherChannel, or even VLAN) with which you plan to associate all VNI interfaces. You can configure one VTEP source interface per threat defense virtual. Because you can only configure one VTEP source interface, you cannot configure both VXLAN and Geneve interfaces on the same device. There is an exception for threat defense virtual clustering on AWS or Azure, where you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve (AWS) or VXLAN (Azure) interface can be used for the Gateway Load Balancer.

The VTEP source interface can be devoted wholly to VXLAN traffic, although it is not restricted to that use. If desired, you can use the interface for regular traffic and apply a security policy to the interface for that traffic. For VXLAN traffic, however, all security policy must be applied to the VNI interfaces. The VTEP interface serves as a physical port only.

In transparent firewall mode, the VTEP source interface is not part of a BVI, and you do configure an IP address for it, similar to the way the management interface is treated.

## VNI Interfaces

VNI interfaces are similar to VLAN interfaces: they are virtual interfaces that keep network traffic separated on a given physical interface by using tagging. You apply your security policy directly to each VNI interface.

You can only add one VTEP interface, and all VNI interfaces are associated with the same VTEP interface. There is an exception for threat defense virtual clustering on AWS or Azure. For AWS clustering, you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a Geneve interface can be used for the AWS Gateway Load Balancer. For Azure clustering, you can have two VTEP source interfaces: a VXLAN interface is used for the cluster control link, and a second VXLAN interface can be used for the Azure Gateway Load Balancer.

## VXLAN Packet Processing

### VXLAN

Traffic entering and exiting the VTEP source interface is subject to VXLAN processing, specifically encapsulation or decapsulation.

Encapsulation processing includes the following tasks:

- The VTEP source interface encapsulates the inner MAC frame with the VXLAN header.
- The UDP checksum field is set to zero.
- The Outer frame source IP is set to the VTEP interface IP.
- The Outer frame destination IP is decided by a remote VTEP IP lookup.

Decapsulation; the threat defense only decapsulates a VXLAN packet if:

- It is a UDP packet with the destination port set to 4789 (this value is user configurable).
- The ingress interface is the VTEP source interface.
- The ingress interface IP address is the same as the destination IP address.
- The VXLAN packet format is compliant with the standard.

### Geneve

Traffic entering and exiting the VTEP source interface is subject to Geneve processing, specifically encapsulation or decapsulation.

Encapsulation processing includes the following tasks:

- The VTEP source interface encapsulates the inner MAC frame with the Geneve header.
- The UDP checksum field is set to zero.
- The Outer frame source IP is set to the VTEP interface IP.
- The Outer frame destination IP is set the peer IP address that you configured.

Decapsulation; the ASA only decapsulates a Geneve packet if:

- It is a UDP packet with the destination port set to 6081 (this value is user configurable).
- The ingress interface is the VTEP source interface.
- The ingress interface IP address is the same as the destination IP address.
- The Geneve packet format is compliant with the standard.

## Peer VTEPs

When the threat defense sends a packet to a device behind a peer VTEP, the threat defense needs two important pieces of information:

- The destination MAC address of the remote device

- The destination IP address of the peer VTEP

The threat defense maintains a mapping of destination MAC addresses to remote VTEP IP addresses for the VNI interfaces.

### VXLAN Peer

There are two ways in which the threat defense can find this information:

- A single peer VTEP IP address can be statically configured on the threat defense.

For IPv4: The threat defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC address.

For IPv6: The threat defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A group of peer VTEP IP addresses can be statically configured on the threat defense.

For IPv4: The threat defense then sends a VXLAN-encapsulated ARP broadcast to the VTEP to learn the end node MAC addresses.

For IPv6: The threat defense then sends an IPv6 Neighbor Solicitation message to the IPv6 solicited-node multicast address. The peer VTEP responds with an IPv6 Neighbor Advertisement message with its link-local address.

- A multicast group can be configured on each VNI interface (or on the VTEP as a whole).

For IPv4: The threat defense sends a VXLAN-encapsulated ARP broadcast packet within an IP multicast packet through the VTEP source interface. The response to this ARP request enables the threat defense to learn both the remote VTEP IP address along with the destination MAC address of the remote end node.

For IPv6: The threat defense sends a Multicast Listener Discovery (MLD) Report message through the VTEP source interface to indicate that the threat defense is listening on the VTEP interface for the multicast address traffic.

This option is not supported with Geneve.

### Geneve Peer

The threat defense virtual only supports statically defined peers. You can define the threat defense virtual peer IP address on the AWS Gateway Load Balancer. Because the threat defense virtual never initiates traffic to the Gateway Load Balancer, you do not also have to specify the Gateway Load Balancer IP address on the threat defense virtual; it learns the peer IP address when it receives Geneve traffic. Multicast groups are not supported with Geneve.

## VXLAN Use Cases

This section describes the use cases for implementing VXLAN on the threat defense.

### VXLAN Bridge or Gateway Overview

Each threat defense VTEP acts as a bridge or gateway between end nodes such as VMs, servers, and PCs and the VXLAN overlay network. For incoming frames received with VXLAN encapsulation over the VTEP

source interface, the threat defense strips out the VXLAN header and forwards it to a physical interface connected to a non-VXLAN network based on the destination MAC address of the inner Ethernet frame.

The threat defense always processes VXLAN packets; it does not just forward VXLAN packets untouched between two other VTEPs.

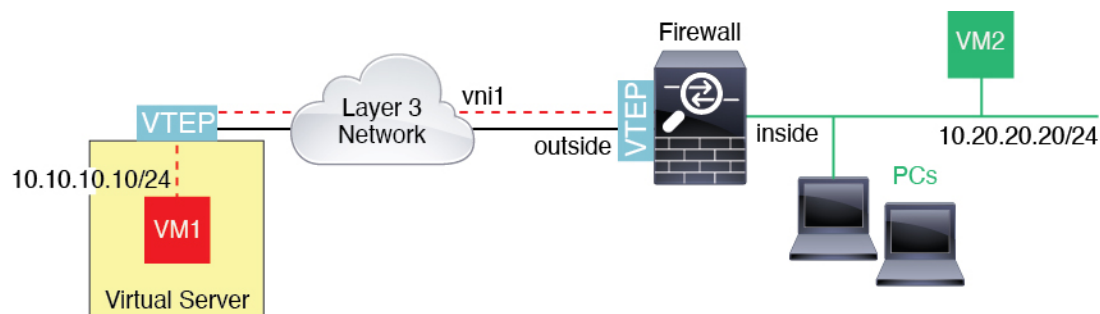

**VXLAN Bridge**

When you use a bridge group (transparent firewall mode, or optionally routed mode), the threat defense can serve as a VXLAN bridge between a (remote) VXLAN segment and a local segment where both are in the same network. In this case, one member of the bridge group is a regular interface while the other member is a VNI interface.

**VXLAN Gateway (Routed Mode)**

The threat defense can serve as a router between VXLAN and non-VXLAN domains, connecting devices on different networks.

## Router Between VXLAN Domains

With a VXLAN-stretched Layer 2 domain, a VM can point to an threat defense as its gateway while the threat defense is not on the same rack, or even when the threat defense is far away over the Layer 3 network.

See the following notes about this scenario:

1. For packets from VM3 to VM1, the destination MAC address is the threat defense MAC address, because the threat defense is the default gateway.
2. The VTEP source interface on Virtual Server 2 receives packets from VM3, then encapsulates the packets with VNI 3's VXLAN tag and sends them to the threat defense.
3. When the threat defense receives the packets, it decapsulates the packets to get the inner frames.
4. The threat defense uses the inner frames for route lookup, then finds that the destination is on VNI 2. If it does not already have a mapping for VM1, the threat defense sends an encapsulated ARP broadcast on the multicast group IP on VNI 2.

**Note** The threat defense must use dynamic VTEP peer discovery because it has multiple VTEP peers in this scenario.

5. The threat defense encapsulates the packets again with the VXLAN tag for VNI 2 and sends the packets to Virtual Server 1. Before encapsulation, the threat defense changes the inner frame destination MAC address to be the MAC of VM1 (multicast-encapsulated ARP might be needed for the threat defense to learn the VM1 MAC address).
6. When Virtual Server 1 receives the VXLAN packets, it decapsulates the packets and delivers the inner frames to VM1.

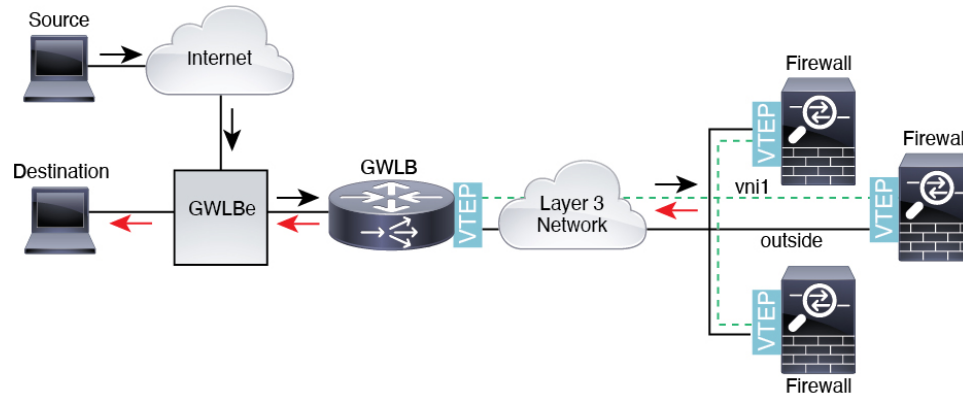

## Geneve Single-Arm Proxy

**Note** This use case is the only currently supported use case for Geneve interfaces.

The AWS Gateway Load Balancer combines a transparent network gateway and a load balancer that distributes traffic and scales virtual appliances on demand. The threat defense virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint). The following figure shows traffic forwarded to the Gateway Load Balancer from the Gateway Load Balancer endpoint. The Gateway Load Balancer balances traffic among multiple threat defense virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway Load Balancer (U-turn traffic). The Gateway Load Balancer then sends the traffic back to the Gateway Load Balancer endpoint and to the destination.

**Figure 342: Geneve Single-Arm Proxy**

## AWS Gateway Load Balancer and Geneve Dual-Arm Proxy

**Note** This use case is the only supported use case for Geneve interfaces.

The threat defense virtual supports the Gateway Load Balancer centralized control plane with a distributed data plane (Gateway Load Balancer endpoint) in single-arm and dual-arm mode. The following figure shows outbound traffic (traffic inspected by threat defense virtual) directly forwarded to the destination (internet) without the need for traffic hop to the GWLB and GWLB endpoint. The threat defense virtual inspect the outbound traffic and perform NAT before either dropping it or sending it back to the internet through NAT

gateway. Dual-arm proxy provides a common egress path for multi-VPC deployment. The firewall inspects the outbound traffic from multiple VPCs, and it exits from a single point to the internet, making it a cost-effective infrastructure solution.

Figure 343: Geneve Dual-Arm Proxy: Egress Traffic from Single VPC

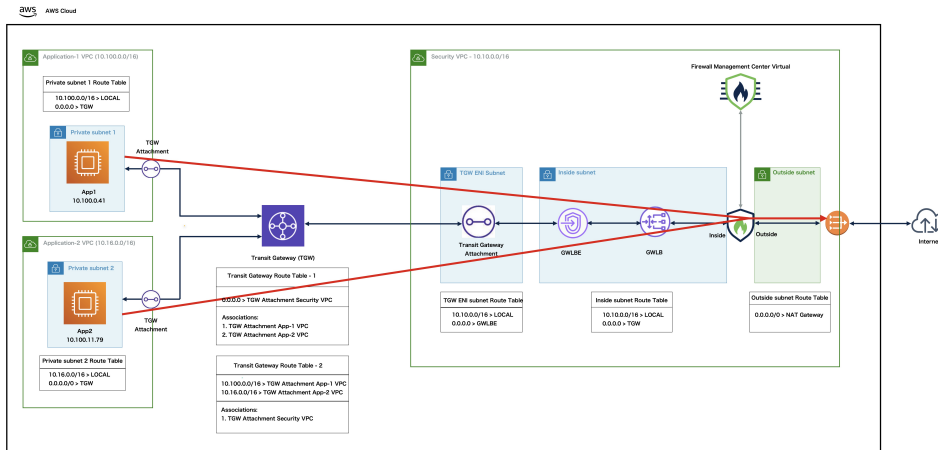

Figure 344: Geneve Dual-Arm Proxy: Egress Traffic from Multiple VPCs

### Azure Gateway Load Balancer and Paired Proxy

In an Azure service chain, threat defense virtuals act as a transparent gateway that can intercept packets between the internet and the customer service. The threat defense virtual defines an external interface and an internal interface on a single NIC by utilizing VXLAN segments in a paired proxy.

The following figure shows traffic forwarded to the Azure Gateway Load Balancer from the Public Gateway Load Balancer on the external VXLAN segment. The Gateway Load Balancer balances traffic among multiple threat defense virtuals, which inspect the traffic before either dropping it or sending it back to the Gateway

Load Balancer on the internal VXLAN segment. The Azure Gateway Load Balancer then sends the traffic back to the Public Gateway Load Balancer and to the destination.

**Figure 345: Azure Gateway Load Balancer with Paired Proxy**

## Requirements and Prerequisites for VXLAN Interfaces

### Model Requirements

- VXLAN encapsulation is supported on all models.
- Geneve encapsulation is supported for the following models:
  - Threat Defense Virtual in Amazon Web Services (AWS)
- VXLAN in *paired proxy mode* is supported for the following models:
  - Threat Defense Virtual in Azure
- Firepower 1010 switch ports and VLAN interfaces are not supported as VTEP interfaces.

## Guidelines for VXLAN Interfaces

### Firewall Mode

- Geneve interfaces are only supported in routed firewall mode.

- Paired proxy VXLAN interfaces are only supported in routed firewall mode.

### IPv6

- The VNI interface supports both IPv4 and IPv6 traffic.
- For VXLAN encapsulation, the VTEP source interface supports both IPv4 and IPv6. The threat defense virtual cluster control link VTEP source interface only supports IPv4.

For Geneve, the VTEP source interface only supports IPv4.

### Clustering

- Clustering does not support VXLAN in Individual Interface mode except for the cluster control link (threat defense virtual only) Only Spanned EtherChannel mode supports VXLAN.

An exception is made for AWS, which can use an additional Geneve interface for use with the GWLB and for Azure, which can use an additional paired proxy VXLAN interface for use with the GWLB.

### Routing

- Only static routing or Policy Based Routing is supported on the VNI interface; dynamic routing protocols are not supported.

### MTU

- VXLAN encapsulation—If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the threat defense automatically raises the MTU to 1554 bytes or 1574 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 54 bytes for IPv4 or +64 bytes for IPv6. For the threat defense virtual, this MTU requires a restart to enable jumbo frame reservation.
- Geneve encapsulation—If the source interface MTU is less than 1806 bytes, then the threat defense automatically raises the MTU to 1806 bytes. In this case, the entire Ethernet datagram is being encapsulated, so the new packet is larger and requires a larger MTU. If the MTU used by other devices is larger, then you should set the source interface MTU to be the network MTU + 306 bytes. This MTU requires a restart to enable jumbo frame reservation.

## Configure VXLAN or Geneve Interfaces

You can configure either VXLAN or Geneve interfaces.

### Configure VXLAN Interfaces

To configure VXLAN, perform the following steps.

---

**Note** You can configure either VXLAN or Geneve (threat defense virtual only). For Geneve interfaces, see [Configure Geneve Interfaces, on page 773](#).

---

**Note** For Azure GWLB, the VXLAN interface is configured when you deploy the VM using the ARM template. You can use this section to change your configuration.

1. [Configure the VTEP Source Interface, on page 771.](#)
2. [Configure the VNI Interface, on page 772.](#)
3. (Azure GWLB) [Allow Gateway Load Balancer Health Checks, on page 775.](#)

## Configure the VTEP Source Interface

You can configure one VTEP source interface per threat defense device. The VTEP is defined as a Network Virtualization Endpoint (NVE). VXLAN is the default encapsulation type. An exception is made for clustering on the threat defense virtual in Azure, where you can use one VTEP source interface for the cluster control link and a second one for the data interface connected to the Azure GWLB.

### Procedure

- Step 1** If you want to specify a group of peer VTEPs, add a network object with the peer IP addresses. See [Creating Network Objects, on page 1301](#).
- Step 2** Choose **Devices > Device Management**.
- Step 3** Click **Edit** (✎) next to the device on which you want to configure VXLAN.
- Step 4** (Optional) Specify that the source interface is NVE-only.  
This setting is optional for routed mode where this setting restricts traffic to VXLAN and common management traffic only on this interface. This setting is automatically enabled for transparent firewall mode.
  - a) Click **Interfaces**.
  - b) Click **Edit** (✎) for the VTEP source interface.
  - c) On the **General** page, check the check box of **NVE Only**.
- Step 5** Click **VTEP** if it is not already displaying.
- Step 6** Check **Enable NVE**.
- Step 7** Click **Add VTEP**.
- Step 8** For the **Encapsulation Type**, choose **VxLAN**.  
For AWS, you can choose between **VxLAN** and **Geneve**. Other platforms have **VxLAN** chosen automatically.
- Step 9** Enter the value for the **Encapsulation port** within the specified range.  
The default value is 4789.
- Step 10** Select the **VTEP Source Interface**.  
Select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1554 bytes for IPv4 or 1574 bytes for IPv6, then the management center automatically raises the MTU to 1554 bytes or 1574 bytes.
- Step 11** Select the **Neighbor Address**. The available options are:

- **None**—No neighbor address is specified.
- **Peer VTEP**—Specify a peer VTEP address.
- **Peer Group**—Specify a network object with the peer IP addresses.
- **Default Multicast**—Specify a default multicast group for all associated VNI interfaces. If you do not configure the multicast group per VNI interface, then this group is used. If you configure a group at the VNI interface level, then that group overrides this setting.

**Step 12** Click **OK**.

**Step 13** Click **Save**.

**Step 14** Configure the routed interface parameters. See [Configure Routed Mode Interfaces](#).

## Configure the VNI Interface

Add a VNI interface, associate it with the VTEP source interface, and configure basic interface parameters.

For the threat defense virtual in Azure, you can configure either a regular VXLAN interface, or you can configure a paired proxy mode VXLAN interface for use with the Azure GWLB. Paired proxy mode is the only supported mode with clustering.

### Procedure

**Step 1** Choose **Devices > Device Management**.

**Step 2** Click **Edit** (✎) next to the device on which you want to configure VXLAN.

**Step 3** Click **Interfaces**.

**Step 4** Click **Add Interfaces**, and then choose **VNI Interface**.

**Step 5** Enter the interface **Name** and **Description**.

**Step 6** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

**Step 7** Enter a value for the **Priority** field within the specified range. By default, 0 is selected.

**Step 8** Enter a value for the **VNI ID** between 1 and 10000.

This ID is only an internal interface identifier.

**Step 9** (Paired Proxy VXLAN for Azure GWLB) Enable proxy paired mode and set the required parameters.

- Check **Proxy Paired**.
- Set the **Internal Port** between 1024 and 65535.
- Set the **Internal Segment ID** between 1 and 16777215.
- Set the **External Port** between 1024 and 65535.
- Set the **External Segment ID** between 1 and 16777215.

**Step 10** (Regular VXLAN) Enter a value for the **VNI Segment ID** between 1 and 16777215.

The segment ID is used for VXLAN tagging.

**Step 11** Enter the **Multicast Group IP Address**.

If you do not set the multicast group for the VNI interface, the default group from the VTEP source interface configuration is used, if available. If you manually set a VTEP peer IP for the VTEP source interface, you cannot specify a multicast group for the VNI interface.

- Step 12** Check **NVE Mapped to VTEP Interface**.  
This option associates this interface with the VTEP source interface.
- Step 13** Click **OK**.
- Step 14** Click **Save** to save the interface configuration.
- Step 15** Configure the routed or transparent interface parameters. See [Configure Routed and Transparent Mode Interfaces, on page 775](#).

## Configure Geneve Interfaces

To configure Geneve interfaces for threat defense virtual, perform the following steps.

**Note** You can configure either VXLAN or Geneve. For information about VXLAN interfaces, see [Configure VXLAN Interfaces, on page 770](#).

1. [Configure the VTEP Source Interface, on page 773](#).
2. [Configure the VNI, on page 774](#).
3. [Allow Gateway Load Balancer Health Checks, on page 775](#).

### Configure the VTEP Source Interface

You can configure one VTEP source interface per threat defense virtual device. The VTEP is defined as a Network Virtualization Endpoint (NVE).

#### Procedure

- Step 1** Choose **Devices > Device Management**.
- Step 2** Click **Edit** (✎) next to the device on which you want to configure Geneve.
- Step 3** Click **VTEP**.
- Step 4** Check **Enable NVE**.
- Step 5** Click **Add VTEP**.
- Step 6** For the **Encapsulation Type**, choose **Geneve**.
- Step 7** Enter the value for the **Encapsulation port** within the specified range.  
We do not recommend changing the Geneve port; AWS requires a port of 6081.
- Step 8** Select the **VTEP Source Interface**.  
You can select from the list of available physical interfaces present on the device. If the source interface MTU is less than 1806 bytes, then the management center automatically raises the MTU to 1806 bytes.

- Step 9** Click **OK**.
  - Step 10** Click **Save**.
  - Step 11** Configure the routed interface parameters. See [Configure Routed Mode Interfaces](#).
- 

## Configure the VNI

Add a VNI, associate it with (VTEP) source interface, and configure basic interface parameters.

### Procedure

---

- Step 1** Choose **Devices > Device Management**.
- Step 2** Click **Edit** (✎) next to the device on which you want to configure Geneve.
- Step 3** Click **Interfaces**.
- Step 4** Click **Add Interfaces**, and then choose **VNI Interface**.
- Step 5** In the **Name** and **Description** fields, provide relevant information.
- Step 6** In the **VNI ID** field, enter a value between 1 and 10000.

**Note** This ID is only an internal interface identifier.

- Step 7** Check the **Enable Proxy** check box.

This option enables single-arm proxy mode or dual-arm proxy mode. Single-arm proxy mode allows traffic to exit the same interface it entered (U-turn traffic) while the dual-arm proxy mode enables the virtual devices to perform the NAT of the inspected traffic and then directly forward the outbound traffic to the internet without returning it to the GWLB and GWLB endpoint. If you edit the interface later, you cannot disable single-arm proxy mode or dual-arm proxy mode. To do that, you need to delete the existing interface and create a new VNI.

This option is only available for a Geneve VTEP.

- Step 8** From the **Proxy type** drop-down list, choose the proxy mode you want to enable for the interface. If you do not specify the proxy mode for the interface, then by default, single-arm proxy mode is considered.
- Step 9** Select **NVE Mapped to VTEP Interface**.

This option associates this interface with the VTEP source interface.

- Step 10** Click **OK**.
  - Step 11** Click **Save**.
- 

### What to do next

Configure the routed interface parameters. See [Configure Routed Mode Interfaces](#).

## Allow Gateway Load Balancer Health Checks

The AWS or Azure GWLB requires appliances to answer a health check properly. The GWLB will only send traffic to appliances that are considered healthy. You must configure the threat defense virtual to respond to an SSH, HTTP, or HTTPS health check.

Configure one of the following methods.

### Procedure

---

**Step 1** Configure SSH. See [Configure Secure Shell](#)

Allow SSH from the GWLB IP address. The GWLB will attempt to establish a connection to the threat defense virtual, and the threat defense virtual's prompt to log in is taken as proof of health. An SSH login attempt will time out after 1 minute. You will need to configure a longer health check interval on the GWLB to accommodate this timeout.

**Step 2** Configure HTTP(S) Redirection Using Static Interface NAT with Port Translation.

You can configure the threat defense virtual to redirect health checks to a metadata HTTP(S) server. For HTTP(S) health checks, the HTTP(S) server must reply to the GWLB with a status code in the range 200 to 399. Because the threat defense virtual has limits on the number of simultaneous management connections, you may choose to offload the health check to an external server.

Static interface NAT with port translation lets you redirect a connection to a port (such as port 80) to a different IP address. For example, translate an HTTP packet from the GWLB with a destination of the threat defense virtual outside interface so that it appears to be from the threat defense virtual outside interface with a destination of the HTTP server. The threat defense virtual then forwards the packet to the mapped destination address. The HTTP server responds to the threat defense virtual outside interface, and then the threat defense virtual forwards the response back to the GWLB. You need an access rule that allows traffic from the GWLB to the HTTP server.

- a) Permit HTTP(S) traffic on the outside interface from the GWLB network in an access rule. See [Access Control Rules, on page 1653](#).
  - b) For HTTP(S), translate the source GWLB IP address to the threat defense virtual outside interface IP address; then translate the destination of the outside interface IP address to the HTTP(S) server IP address. See [Configure Static Manual NAT, on page 972](#).
- 

## Configure Routed and Transparent Mode Interfaces

This section includes tasks to complete the regular interface configuration for all models in routed or transparent firewall mode.

### About Routed and Transparent Mode Interfaces

Firewall mode interfaces subject traffic to firewall functions such as maintaining flows, tracking flow states at both IP and TCP layers, IP defragmentation, and TCP normalization. You can also optionally configure IPS functions for this traffic according to your security policy.

The types of firewall interfaces you can configure depends on the firewall mode set for the device: routed or transparent mode. See [Transparent or Routed Firewall Mode, on page 243](#) for more information.

- Routed mode interfaces (routed firewall mode only)—Each interface that you want to route between is on a different subnet.
- Bridge group interfaces (routed and transparent firewall mode)—You can group together multiple interfaces on a network, and the threat defense device uses bridging techniques to pass traffic between the interfaces. Each bridge group includes a Bridge Virtual Interface (BVI) to which you assign an IP address on the network. In routed mode, the threat defense device routes between BVIs and regular routed interfaces. In transparent mode, each bridge group is separate and cannot communicate with each other.

## Dual IP Stack (IPv4 and IPv6)

The threat defense device supports both IPv6 and IPv4 addresses on an interface. Make sure you configure a default route for both IPv4 and IPv6.

## 31-Bit Subnet Mask

For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. The 31-bit subnet includes only 2 addresses; normally, the first and last address in the subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4. For example, the failover link between 2 threat defenses only requires 2 addresses; any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog.

### 31-Bit Subnet and Clustering

You can use a 31-bit subnet mask for cluster interfaces, excluding the management interface and the Cluster Control Link.

### 31-Bit Subnet and Failover

For failover, when you use a 31-bit subnet for the threat defense interface IP address, you cannot configure a standby IP address for the interface because there are not enough addresses. Normally, an interface for failover should have a standby IP address so the active unit can perform interface tests to ensure standby interface health. Without a standby IP address, the threat defense cannot perform any network tests; only the link state can be tracked.

For the failover and optional separate state link, which are point-to-point connections, you can also use a 31-bit subnet.

### 31-Bit Subnet and Management

If you have a directly-connected management station, you can use a point-to-point connection for SSH or HTTP on the threat defense, or for SNMP or Syslog on the management station.

### 31-Bit Subnet Unsupported Features

The following features do not support the 31-Bit subnet:

- BVI interfaces for bridge groups—The bridge group requires at least 3 host addresses: the BVI, and two hosts connected to two bridge group member interfaces. you must use a /29 subnet or smaller.

- Multicast Routing

## Guidelines and Limitations for Routed and Transparent Mode Interfaces

### High Availability, Clustering, and Multi-Instance

- Do not configure failover links with the procedures in this chapter. See the High Availability chapter for more information.
- For cluster interfaces, see the clustering chapter for requirements.
- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- When you use High Availability, you must set the IP address and standby address for data interfaces manually; DHCP and PPPoE are not supported. Set the standby IP addresses on the **Devices > Device Management > High Availability** tab in the **Monitored Interfaces** area. See the High Availability chapter for more information.

### IPv6

- IPv6 is supported on all interfaces.
- You can only configure IPv6 addresses manually in transparent mode.
- The threat defense device does not support IPv6 anycast addresses.
- DHCPv6 and prefix delegation options are not supported with transparent mode, clustering, or High Availability.

### Model Guidelines

- For the threat defense virtual on VMware with bridged ixgbevf interfaces, bridge groups are not supported.

### Transparent Mode and Bridge Group Guidelines

- You can create up to 250 bridge groups, with 64 interfaces per bridge group.
- Each directly-connected network must be on the same subnet.
- The threat defense device does not support traffic on secondary networks; only traffic on the same network as the BVI IP address is supported.
- An IP address for the BVI is required for each bridge group for to-the-device and from-the-device management traffic, as well as for data traffic to pass through the threat defense device. For IPv4 traffic, specify an IPv4 address. For IPv6 traffic, specify an IPv6 address.
- You can only configure IPv6 addresses manually.
- The BVI IP address must be on the same subnet as the connected network. You cannot set the subnet to a host subnet (255.255.255.255).
- Management interfaces are not supported as bridge group members.

- For multi-instance mode, shared interfaces are not supported for bridge group member interfaces (in transparent mode or routed mode).
- For the threat defense virtual on VMware with bridged ixgbevf interfaces, transparent mode is not supported, and bridge groups are not supported in routed mode.
- For the Firepower 1010, you cannot mix logical VLAN interfaces and physical firewall interfaces in the same bridge group.
- For the Firepower 4100/9300, data-sharing interfaces are not supported as bridge group members.
- In transparent mode, you must use at least 1 bridge group; data interfaces must belong to a bridge group.
- In transparent mode, do not specify the BVI IP address as the default gateway for connected devices; devices need to specify the router on the other side of the threat defense as the default gateway.
- In transparent mode, the *default* route, which is required to provide a return path for management traffic, is only applied to management traffic from one bridge group network. This is because the default route specifies an interface in the bridge group as well as the router IP address on the bridge group network, and you can only define one default route. If you have management traffic from more than one bridge group network, you need to specify a regular static route that identifies the network from which you expect management traffic.
- Transparent mode is not supported on threat defense virtual instances deployed on Amazon Web Services, Microsoft Azure, Google Cloud Platform, and Oracle Cloud Infrastructure.
- In routed mode, to route between bridge groups and other routed interfaces, you must name the BVI.
- In routed mode, threat defense-defined EtherChannel interfaces are not supported as bridge group members. EtherChannels on the Firepower 4100/9300 can be bridge group members.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the threat defense when using bridge group members. If there are two neighbors on either side of the threat defense running BFD, then the threat defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.

### Additional Guidelines and Requirements

- The threat defense supports only one 802.1Q header in a packet and does not support multiple headers (known as Q-in-Q support) for firewall interfaces. **Note:** For inline sets and passive interfaces, the FTD supports Q-in-Q up to two 802.1Q headers in a packet, with the exception of the Firepower 4100/9300, which only supports one 802.1Q header.

## Configure Routed Mode Interfaces

This procedure describes how to set the name, security zone, and IPv4 address.

---

**Note** Not all fields are supported for all interface types.

---

### Before you begin

- **Firepower 4100/9300**

1. [Configure a Physical Interface, on page 290](#)
  2. (Optional) Configure any special interfaces.
    - [Add an EtherChannel \(Port Channel\), on page 291](#)
    - [Add a VLAN Subinterface for Container Instances, on page 293](#) in FXOS
    - [Configure a Loopback Interface, on page 753](#)
    - [Add a Subinterface, on page 759](#) in management center
    - [Configure VXLAN Interfaces, on page 770](#)
- (Optional) **All other models:**
    - [Configure an EtherChannel, on page 710](#)
    - [Configure a Loopback Interface, on page 753](#)
    - [Add a Subinterface, on page 759](#)
    - [Configure VXLAN Interfaces, on page 770](#)
    - Threat Defense Virtual on AWS: [Configure Geneve Interfaces, on page 773](#)
    - Firepower 1010: [Configure a VLAN Interface, on page 745](#)

## Procedure

---

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** In the **Name** field, enter a name up to 48 characters in length.  
You cannot start the name with the phrase "cluster". It is reserved for internal use.
- Step 4** Enable the interface by checking the **Enabled** check box.
- Step 5** (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.
- Step 6** (Optional) Add a description in the **Description** field.  
The description can be up to 200 characters on a single line, without carriage returns.
- Step 7** In the **Mode** drop-down list, choose **None**.  
Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types.
- Step 8** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.  
The routed interface is a Routed-type interface, and can only belong to Routed-type zones.
- Step 9** See [Configure the MTU, on page 803](#) for information about the **MTU**.
- Step 10** In the **Priority** field, enter a number ranging from 0–65535.

This value is used in the policy based routing configuration. The priority is used to determine how you want to route the traffic across multiple egress interfaces. For more information, see [Configure Policy-Based Routing Policy, on page 1237](#).

**Step 11** Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list. High Availability, clustering, and loopback interfaces only support static IP address configuration; DHCP and PPPoE are not supported.

- **Use Static IP**—Enter the IP address and subnet mask. For point-to-point connections, you can specify a 31-bit subnet mask (255.255.255.254 or /31). In this case, no IP addresses are reserved for the network or broadcast addresses. You cannot set the standby IP address in this case. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices > Device Management > High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- **Use DHCP**—Configure the following optional parameters:
  - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
  - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.
- **Use PPPoE**—If the interface is connected to a DSL, cable modem, or other connection to your ISP, and your ISP uses PPPoE to provide your IP address, configure the following parameters:
  - **VPDN Group Name**—Specify a group name of your choice to represent this connection.
  - **PPPoE User Name**—Specify the username provided by your ISP.
  - **PPPoE Password/Confirm Password**—Specify and confirm the password provided by your ISP.
  - **PPP Authentication**—Choose **PAP**, **CHAP**, or **MSCHAP**.

PAP passes a cleartext username and password during authentication and is not secure. With CHAP, the client returns the encrypted [challenge plus password], with a cleartext username in response to the server challenge. CHAP is more secure than PAP, but it does not encrypt data. MSCHAP is similar to CHAP but is more secure because the server stores and compares only encrypted passwords rather than cleartext passwords as in CHAP. MSCHAP also generates a key for data encryption by MPPE.

- **PPPoE route metric**—Assign an administrative distance to the learned route. Valid values are from 1 to 255. By default, the administrative distance for the learned routes is 1.
- **Enable Route Settings**—To manually configure the PPPoE IP address, check this box and then enter the **IP Address**.

If you select the **Enable Route Settings** check box and leave the **IP Address** blank, the **ip address pppoe setroute** command is applied as shown in this example:

```
interface GigabitEthernet0/2
nameif inside2_pppoe
cts manual
 propagate sgt preserve-untag
 policy static sgt disabled trusted
security-level 0
pppoe client vpdn group test
pppoe client route distance 10
ip address pppoe setroute
```

- **Store Username and Password in Flash**—Stores the username and password in flash memory. The threat defense device stores the username and password in a special location of NVRAM.

- Step 12** (Optional) See [Configure IPv6 Addressing, on page 787](#) to configure IPv6 addressing on the **IPv6** tab.
- Step 13** (Optional) See [Configure the MAC Address, on page 804](#) to manually configure the MAC address on the **Advanced** tab.
- Step 14** (Optional) Set the duplex and speed by clicking **Hardware Configuration > Speed**.
- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.
  - **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100/4200 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.
  - **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.
  - **Forward Error Correction Mode**—(Secure Firewall 3100/4200 only) For 25 Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

*Table 49: Default FEC for Auto Setting*

| Transceiver Type | Fixed Port Default FEC (Ethernet 1/9 through 1/16) | Network Module Default FEC |
|------------------|----------------------------------------------------|----------------------------|
| 25G-SR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 25G-LR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 10/25G-CSR       | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-AOCxM        | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-CU2.5/3M     | Auto-Negotiate                                     | Auto-Negotiate             |
| 25G-CU4/5M       | Auto-Negotiate                                     | Auto-Negotiate             |
| 25/50/100G       | Clause 91 RS-FEC                                   | Clause 91 RS-FEC           |

- Step 15** (Optional) Enable management center manager access on a data interface on the **Manager Access** page. You can enable manager access from a data interface when you first setup the threat defense. If you want to enable or disable manager access after you added the threat defense to the management center, see:
- Enable manager access: [Change the Manager Access Interface from Management to Data, on page 59](#)
- Note** You cannot enable manager access unless you first initiate the manager interface migration from Management to a data interface. After you initiate the migration, you can enable manager access on the **Manager Access** page and save the configuration successfully.
- Disable manager access: [Change the Manager Access Interface from Data to Management, on page 63](#)

If you want to change the manager access interface from one data interface to another data interface, you must disable manager access on the original data interface, but do not disable the interface itself yet; the original data interface must be used to perform the deployment. If you want to use the same IP address on the new manager access interface, you can delete or change the IP configuration on the original interface; this change should not affect the deployment. If you use a different IP address for the new interface, then also change the device IP address shown in the management center; see [Update the Hostname or IP Address in the Management Center, on page 53](#). Be sure to also update related configuration to use the new interface such as static routes, DDNS, and DNS settings.

Manager access from a data interface has the following limitations:

- You can only enable manager access on a physical, data interface. You cannot use a subinterface or EtherChannel, nor can you create a subinterface on the manager access interface. You can also use the management center to enable manager access on a single secondary interface for redundancy.
- This interface cannot be management-only.
- Routed firewall mode only, using a routed interface.
- PPPoE is not supported. If your ISP requires PPPoE, you will have to put a router with PPPoE support between the threat defense and the WAN modem.
- The interface must be in the global VRF only.
- SSH is not enabled by default for data interfaces, so you will have to enable SSH later using the management center. Because the Management interface gateway will be changed to be the data interfaces, you also cannot SSH to the Management interface from a remote network unless you add a static route for the Management interface using the **configure network static-routes** command. For threat defense virtual on Amazon Web Services, a console port is not available, so you should maintain your SSH access to the Management interface: add a static route for Management before you continue with your configuration. Alternatively, be sure to finish all CLI configuration (including the **configure manager add** command) before you configure the data interface for manager access and you are disconnected.
- You cannot use separate management and event-only interfaces.
- Clustering is not supported. You must use the Management interface in this case.

Figure 346: Manager Access

Enable management on this interface for the Manager

Available Networks  +

- any-ipv4
- any-ipv6
- IPv4-Benchmark-Tests
- IPv4-Link-Local
- IPv4-Multicast
- IPv4-Private-10.0.0.0-8

Add

Allowed Management Networks

- any

Cancel OK

- Check **Enable management on this interface for the manager** to use this data interface for management instead of the dedicated Management interface.
- (Optional) In the **Allowed Management Networks** box, add the networks from which you want to allow manager access. By default, any networks are allowed.

**Step 16** Click **OK**.

**Step 17** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure Bridge Group Interfaces

A bridge group is a group of interfaces that the Secure Firewall Threat Defense device bridges instead of routes. Bridge groups are supported in both transparent and routed firewall mode. For more information about bridge groups, see [About Bridge Groups, on page 245](#).

To configure bridge groups and associated interfaces, perform these steps.

### Configure General Bridge Group Member Interface Parameters

This procedure describes how to set the name and security zone for each bridge group member interface. The same bridge group can include different types of interfaces: physical interfaces, VLAN subinterfaces, Firepower 1010 VLAN interfaces, EtherChannels, and redundant interfaces. The Management interface is not supported. In routed mode, EtherChannels are not supported. For the Firepower 4100/9300, data-sharing type interfaces are not supported.

**Before you begin**• **Firepower 4100/9300**

1. [Configure a Physical Interface, on page 290](#)
2. (Optional) Configure any special interfaces.
  - [Add an EtherChannel \(Port Channel\), on page 291](#)
  - [Add a VLAN Subinterface for Container Instances, on page 293](#) in FXOS
  - [Add a Subinterface, on page 759](#) in management center

• (Optional) **All other models:**

- [Configure an EtherChannel, on page 710](#)
- [Add a Subinterface, on page 759](#)
- Firepower 1010: [Configure a VLAN Interface, on page 745](#)

**Procedure**

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** In the **Name** field, enter a name up to 48 characters in length.  
You cannot start the name with the phrase "cluster". It is reserved for internal use.
- Step 4** Enable the interface by checking the **Enabled** check box.
- Step 5** (Optional) Set this interface to **Management Only** to limit traffic to management traffic; through-the-box traffic is not allowed.
- Step 6** (Optional) Add a description in the **Description** field.  
The description can be up to 200 characters on a single line, without carriage returns.
- Step 7** In the **Mode** drop-down list, choose **None**.  
Regular firewall interfaces have the mode set to None. The other modes are for IPS-only interface types. After you assign this interface to a bridge group, the mode will show as **Switched**.
- Step 8** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.  
The bridge group member interface is a Switched-type interface, and can only belong to Switched-type zones. Do not configure any IP address settings for this interface. You will set the IP address for the Bridge Virtual Interface (BVI) only. Note that the BVI does not belong to a zone, and you cannot apply access control policies to the BVI.
- Step 9** See [Configure the MTU, on page 803](#) for information about the **MTU**.
- Step 10** (Optional) Set the duplex and speed by clicking **Hardware Configuration > Speed**.
- **Duplex**—Choose **Full** or **Half**. SFP interfaces only support **Full** duplex.

- **Speed**—Choose a speed (varies depending on the model). (Secure Firewall 3100/4200 only) Choose **Detect SFP** to detect the speed of the installed SFP module and use the appropriate speed. Duplex is always Full, and auto-negotiation is always enabled. This option is useful if you later change the network module to a different model, and want the speed to update automatically.
- **Auto-negotiation**—Set the interface to negotiate the speed, link status, and flow control.
- **Forward Error Correction Mode**—(Secure Firewall 3100/4200 only) For 25 Gbps and higher interfaces, enable Forward Error Correction (FEC). For an EtherChannel member interface, you must configure FEC before you add it to the EtherChannel. The setting chosen when you use **Auto** depends on the transceiver type and whether the interface is fixed (built-in) or on a network module.

Table 50: Default FEC for Auto Setting

| Transceiver Type | Fixed Port Default FEC (Ethernet 1/9 through 1/16) | Network Module Default FEC |
|------------------|----------------------------------------------------|----------------------------|
| 25G-SR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 25G-LR           | Clause 74 FC-FEC                                   | Clause 108 RS-FEC          |
| 10/25G-CSR       | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-AOCxM        | Clause 74 FC-FEC                                   | Clause 74 FC-FEC           |
| 25G-CU2.5/3M     | Auto-Negotiate                                     | Auto-Negotiate             |
| 25G-CU4/5M       | Auto-Negotiate                                     | Auto-Negotiate             |
| 25/50/100G       | Clause 91 RS-FEC                                   | Clause 91 RS-FEC           |

- Step 11** (Optional) See [Configure IPv6 Addressing, on page 787](#) to configure IPv6 addressing on the **IPv6** tab.
- Step 12** (Optional) See [Configure the MAC Address, on page 804](#) to manually configure the MAC address on the **Advanced** tab.
- Step 13** Click **OK**.
- Step 14** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure the Bridge Virtual Interface (BVI)

Each bridge group requires a BVI for which you configure an IP address. The threat defense uses this IP address as the source address for packets originating from the bridge group. The BVI IP address must be on the same subnet as the connected network. For IPv4 traffic, the BVI IP address is required to pass any traffic. For IPv6 traffic, you must, at a minimum, configure the link-local addresses to pass traffic, but a global management address is recommended for full functionality, including remote management and other management operations.

For routed mode, if you provide a name for the BVI, then the BVI participates in routing. Without a name, the bridge group remains isolated as in transparent firewall mode.

**Before you begin**

You cannot add the BVI to a security zone; therefore, you cannot apply Access Control policies to the BVI. You must apply your policy to the bridge group member interfaces based on their zones.

**Procedure**

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Choose **Add Interfaces > Bridge Group Interface**.
- Step 3** (Routed Mode) In the **Name** field, enter a name up to 48 characters in length.
- You must name the BVI if you want to route traffic outside the bridge group members, for example, to the outside interface or to members of other bridge groups. The name is not case-sensitive.
- Step 4** In the **Bridge Group ID** field, enter the bridge group ID between 1 and 250.
- Step 5** In the **Description** field, enter a description for this bridge group.
- Step 6** On the **Interfaces** tab, click an interface and then click **Add** to move it to the **Selected Interfaces** area. Repeat for all interfaces that you want to make members of the bridge group.
- Step 7** (Transparent Mode) Click the **IPv4** tab. In the **IP Address** field, enter the IPv4 address and subnet mask.
- Do not assign a host address (/32 or 255.255.255.255) to the BVI. Also, do not use other subnets that contain fewer than 3 host addresses (one each for the upstream router, downstream router, and transparent firewall) such as a /30 subnet (255.255.255.252). The threat defense device drops all ARP packets to or from the first and last addresses in a subnet. For example, if you use a /30 subnet and assign a reserved address from that subnet to the upstream router, then the threat defense device drops the ARP request from the downstream router to the upstream router.
- For High Availability, set the standby IP address on the **Devices > Device Management > High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
- Step 8** (Routed Mode) Click the **IPv4** tab. To set the IP address, use one of the following options from the **IP Type** drop-down list.
- High Availability and clustering interfaces only support static IP address configuration; DHCP is not supported.
- **Use Static IP**—Enter the IP address and subnet mask. For High Availability, you can only use a static IP address. Set the standby IP address on the **Devices > Device Management > High Availability** tab in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.
  - **Use DHCP**—Configure the following optional parameters:
    - **Obtain default route using DHCP**—Obtains the default route from the DHCP server.
    - **DHCP route metric**—Assigns an administrative distance to the learned route, between 1 and 255. The default administrative distance for the learned routes is 1.
- Step 9** (Optional) See [Configure IPv6 Addressing, on page 787](#) to configure IPv6 addressing.
- Step 10** (Optional) See [Add a Static ARP Entry, on page 805](#) and [Add a Static MAC Address and Disable MAC Learning for a Bridge Group, on page 806](#) (for transparent mode only) to configure the **ARP** and **MAC** settings.

**Step 11** Click **OK**.

**Step 12** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure IPv6 Addressing

This section describes how to configure IPv6 addressing in routed and transparent mode.

### About IPv6

This section includes information about IPv6.

#### IPv6 Addressing

You can configure two types of unicast addresses for IPv6:

- **Global**—The global address is a public address that you can use on the public network. For a bridge group, this address needs to be configured for the BVI, and not per member interface. You can also configure a global IPv6 address for the management interface in transparent mode.
- **Link-local**—The link-local address is a private address that you can only use on the directly-connected network. Routers do not forward packets using link-local addresses; they are only for communication on a particular physical network segment. They can be used for address configuration or for the Neighbor Discovery functions such as address resolution. In a bridge group, only member interfaces have link-local addresses; the BVI does not have a link-local address.

At a minimum, you need to configure a link-local address for IPv6 to operate. If you configure a global address, a link-local address is automatically configured on the interface, so you do not also need to specifically configure a link-local address. For bridge group member interfaces, when you configure the global address on the BVI, the threat defense device automatically generates link-local addresses for member interfaces. If you do not configure a global address, then you need to configure the link-local address, either automatically or manually.

#### Modified EUI-64 Interface IDs

RFC 3513: Internet Protocol Version 6 (IPv6) Addressing Architecture requires that the interface identifier portion of all unicast IPv6 addresses, except those that start with binary value 000, be 64 bits long and be constructed in Modified EUI-64 format. The threat defense device can enforce this requirement for hosts attached to the local link.

When this feature is enabled on an interface, the source addresses of IPv6 packets received on that interface are verified against the source MAC addresses to ensure that the interface identifiers use the Modified EUI-64 format. If the IPv6 packets do not use the Modified EUI-64 format for the interface identifier, the packets are dropped and the following system log message is generated:

```
325003: EUI-64 source address check failed.
```

The address format verification is only performed when a flow is created. Packets from an existing flow are not checked. Additionally, the address verification can only be performed for hosts on the local link.

## Configure the IPv6 Prefix Delegation Client

The threat defense can act as a DHCPv6 Prefix Delegation client so that the client interface, for example the outside interface connected to a cable modem, can receive one or more IPv6 prefixes that the threat defense can then subnet and assign to its inside interfaces.

### About IPv6 Prefix Delegation

The threat defense can act as a DHCPv6 Prefix Delegation client so that the client interface, for example the outside interface connected to a cable modem, can receive one or more IPv6 prefixes that the threat defense can then subnet and assign to its inside interfaces. Hosts connected to the inside interfaces can then use Stateless Address Auto Configuration (SLAAC) to obtain global IPv6 addresses. Note that the inside threat defense interfaces do not in turn act as Prefix Delegation servers; the threat defense can only provide global IP addresses to SLAAC clients. For example, if a router is connected to the threat defense, it can act as a SLAAC client to obtain its IP address. But if you want to use a subnet of the delegated prefix for the networks behind the router, you must manually configure those addresses on the router's inside interfaces.

The threat defense includes a light DHCPv6 server so the threat defense can provide information such as the DNS server and domain name to SLAAC clients when they send Information Request (IR) packets to the threat defense. The threat defense only accepts IR packets, and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the threat defense received using Prefix Delegation.

### *IPv6 Prefix Delegation /64 Subnet Example*

The following example shows the threat defense receiving an IP address on the outside interface using the DHCPv6 address client. It also gets a delegated prefix using the DHCPv6 Prefix Delegation client. The threat defense subnets the delegated prefix into /64 networks and assigns global IPv6 addresses to its inside interfaces dynamically using the delegated prefix plus a manually configured subnet (::0, ::1, or ::2) and IPv6 address (0:0:0:1) per interface. SLAAC clients connected to those inside interfaces obtain IPv6 addresses on each /64 subnet.

*IPv6 Prefix Delegation /62 Subnet Example*

The following example shows the threat defense subnetting the prefix into 4 /62 subnets: 2001:DB8:ABCD:1230::/62, 2001:DB8:ABCD:1234::/62, 2001:DB8:ABCD:1238::/62, and 2001:DB8:ABCD:123C::/62. The threat defense uses one of 4 available /64 subnets on 2001:DB8:ABCD:1230::/62 for its inside network (::0). You can then manually use additional /62 subnets for downstream routers. The router shown uses 3 of 4 available /64 subnets on 2001:DB8:ABCD:1234::/62 for its inside interfaces (::4, ::5, and ::6). In this case, the inside router interfaces cannot dynamically obtain the delegated prefix, so you need to view the delegated prefix on the threat defense, and then use that prefix for your router configuration. Usually, ISPs delegate the same prefix to a given client when the lease expires, but if the threat defense receives a new prefix, you will have to modify the router configuration to use the new prefix. The DHCP unique identifier (DUID) is persistent across reboots.

## Enable the IPv6 Prefix Delegation Client

Enable the DHCPv6 Prefix Delegation client on one or more interfaces. The threat defense obtains one or more IPv6 prefixes that it can subnet and assign to inside networks. Typically, the interface on which you enable the prefix delegation client obtains its IP address using the DHCPv6 address client; only other threat defense interfaces use addresses derived from the delegated prefix.

This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

### Before you begin

When you use Prefix Delegation, you must set the threat defense IPv6 neighbor discovery router advertisement interval to be much lower than the preferred lifetime of the prefix assigned by the DHCPv6 Server to prevent IPv6 traffic interruption. For example, if the DHCPv6 server sets the preferred Prefix Delegation lifetime to 300 seconds, you should set the threat defense RA interval to be 150 seconds. To set the preferred lifetime, use the **show ipv6 general-prefix** command. To set the threat defense RA interval, see [Configure IPv6 Neighbor Discovery, on page 796](#); the default is 200 seconds.

## Procedure

- Step 1** Select **Devices > Device Management** and click **Edit** (🔗) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (🔗) for the interface you want to edit.
- Step 3** Click the **IPv6** page, and then click **DHCP**.
- Step 4** Click **Client PD Prefix Name** and enter a name for this prefix.

*Figure 347: Enable the Prefix Delegation Client*

Client PD Prefix Name

Outside-Prefix

Client PD Hint Prefixes

Add

2001:DB8:ABCD:1230::/60

The name can be up to 200 characters.

- Step 5** (Optional) Enter the prefix and prefix length in the **Client PD Hint Prefixes** field to provide one or more hints to the DHCP server about the delegated prefix you want to receive, then click **Add**.  
Typically you want to request a particular prefix length, such as `::/60`, or if you have received a particular prefix before and want to ensure you get it again when the lease expires, you can enter the whole prefix as the hint. If you enter multiple hints (different prefixes or lengths), then it is up to the DHCP server which hint to honor, or whether to honor the hint at all.
- Step 6** Click **OK**.
- Step 7** Click **Save**.  
You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure a Global IPv6 Address

To configure a global IPv6 address for any routed mode interface and for the transparent or routed mode BVI, perform the following steps.

**Note** Configuring the global address automatically configures the link-local address, so you do not need to configure it separately. For bridge groups, configuring the global address on the BVI automatically configures link-local addresses on all member interfaces.

For subinterfaces defined on the threat defense, we recommend that you also set the MAC address manually, because they use the same burned-in MAC address of the parent interface. IPv6 link-local addresses are generated based on the MAC address, so assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the threat defense. See [Configure the MAC Address, on page 804](#).

### Before you begin

For IPv6 neighbor discovery for bridge groups, you must explicitly allow Neighbor Solicitation (ICMPv6 type 135) and Neighbor Advertisement (ICMPv6 type 136) packets through the threat defense bridge group member interfaces using a bidirectional access rule.

### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Click the **IPv6** page.
- For routed mode, the **Basic** page is selected by default. For transparent mode, the **Address** page is selected by default.
- Step 4** (Optional) On the **Basic** page, check **Enable IPv6**.
- Use this option if you want to only configure the link-local addresses. Otherwise, configuring an IPv6 address enabled IPv6 processing automatically.
- Step 5** Configure the global IPv6 address using one of the following methods.
- For failover and clustering, and for loopback interfaces, you must set the IP address manually. For clustering, manually configuring the link-local address is also not supported.
- (Routed interface) Stateless autoconfiguration—Check the **Autoconfiguration** check box.
 

Enabling stateless autoconfiguration on the interface configures IPv6 addresses based upon prefixes received in Router Advertisement messages. A link-local address, based on the Modified EUI-64 interface ID, is automatically generated for the interface when stateless autoconfiguration is enabled.

Although RFC 4862 specifies that hosts configured for stateless autoconfiguration do not send Router Advertisement messages, the threat defense device does send Router Advertisement messages in this case. Uncheck the **IPv6 > Settings > Enable RA** check box to suppress messages.
  - Manual configuration—To manually configure a global IPv6 address:
    - a. Click the **Address** page, and click (⊕) **Add Address**.
 

The **Add Address** dialog box appears.

- b. In the **Address** field, enter either a full global IPv6 address, including the interface ID, or enter the IPv6 prefix, along with the IPv6 prefix length. (Routed Mode) If you only enter the prefix, then be sure to check the **Enforce EUI 64** check box to generate the interface ID using the Modified EUI-64 format. For example, 2001:0DB8::BA98:0:3210/48 (full address) or 2001:0DB8::/48 (prefix, with EUI 64 checked).

For High Availability (if you did not set **Enforce EUI 64**), set the standby IP address on the **Devices > Device Management > High Availability** page in the **Monitored Interfaces** area. If you do not set the standby IP address, the active unit cannot monitor the standby interface using network tests; it can only track the link state.

- (Routed interface) Obtain an address using DHCPv6—To use DHCPv6:

**Figure 348: Enable the DHCPv6 Client**

The screenshot shows the 'Edit Physical Interface' configuration page. The 'IPv6' tab is selected, and the 'DHCP' sub-tab is active. Two checkboxes are checked: 'Enable DHCP Client' and 'Enable default route using DHCP'. There are also two unchecked checkboxes labeled 'Enable...' on the right side of the page.

- a. Click the **DHCP** page.
- b. Check the check box of **Enable DHCP Client**.
- c. (Optional) Check the check box of **Enable default route using DHCP** to obtain a default route from Router Advertisements.

- (Routed interface) Use a delegated prefix—To assign an IPv6 address using the delegated prefix:

This feature requires the threat defense to have the DHCPv6 Prefix Delegation client enabled *on a different interface*. See [Enable the IPv6 Prefix Delegation Client, on page 790](#).

- a. Click the **DHCP** page.
- b. Click **Add (+)**.

Figure 349: Use a Delegated Prefix

Prefixes

Prefix Name: Outside-Prefix

Prefix Length: ::1:0:0:0:1/64

Cancel OK

- d. Enter the IPv6 address and **Prefix Length**.

Typically, the delegated prefix will be /60 or smaller so you can subnet to multiple /64 networks. /64 is the supported subnet length if you want to support SLAAC for connected clients. You should specify an address that completes the /60 subnet, for example ::1:0:0:0:1. Enter :: before the address in case the prefix is smaller than /60. For example, if the delegated prefix is 2001:DB8:1234:5670::/60, then the global IP address assigned to this interface is 2001:DB8:1234:5671::1/64. The prefix that is advertised in router advertisements is 2001:DB8:1234:5671::/64. In this example, if the prefix is smaller than /60, the remaining bits of the prefix will be 0's as indicated by the leading ::. For example, if the prefix is 2001:DB8:1234::/48, then the IPv6 address will be 2001:DB8:1234::1:0:0:0:1/64.

- e. Click **OK**.

Figure 351: Prefix Delegation Table

| Prefix Name    | Prefix Length  |                                                                                     |
|----------------|----------------|-------------------------------------------------------------------------------------|
| Outside-Prefix | ::1:0:0:0:1/64 |  |

+ Add

- f. Optionally enable the DHCPv6 stateless server on this interface (see [Enable the DHCPv6 Stateless Server, on page 835](#)). If you do so, we recommend that you also check the **Enable DHCP for non-address config** option.

**Step 6**

For Routed interfaces, you can optionally set the following values on the **Basic** page:

- To enforce the use of Modified EUI-64 format interface identifiers in IPv6 addresses on a local link, check the **Enforce EUI-64** check box.
- To manually set the link-local address, enter an address in the **Link-Local address** field.

A link-local address should start with FE8, FE9, FEA, or FEB, for example fe80::20d:88ff:feee:6a82. If you do not want to configure a global address, and only need to configure a link-local address, you have the option of manually defining the link-local address. Note that we recommend automatically assigning the link-local address based on the Modified EUI-64 format. For example, if other devices enforce the use of the Modified EUI-64 format, then a manually-assigned link-local address may cause packets to be dropped.

Clustering does not support manual link-local addresses.

**Step 7**

For Routed interfaces, you can optionally set the following values on the **DHCP** page:

- Check the **Enable DHCP for address config** check box to set the Managed Address Config flag in the IPv6 router advertisement packet.

This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain addresses, in addition to the derived stateless autoconfiguration address.

- Check the **Enable DHCP for non-address config** check box to set the Other Address Config flag in the IPv6 router advertisement packet.

This flag in IPv6 router advertisements informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address. Use this option when using the DHCPv6 stateless server with DHCPv6 prefix delegation.

**Step 8**

For Routed interfaces, see [Configure IPv6 Neighbor Discovery, on page 796](#) to configure settings on the **Prefixes** and **Settings** pages. For BVI interfaces, see the following parameters on the **Settings** page:

- **DAD attempts**—The maximum number of DAD attempts, between 1 and 600. Set the value to 0 to disable duplicate address detection (DAD) processing. This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses. 1 attempt is the default.
- **NS Interval**—The interval between IPv6 neighbor solicitation retransmissions on an interface, between 1000 and 3600000 ms. The default value is 1000 ms.

- **Reachable Time**—The amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred, between 0 and 3600000 ms. The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value. The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

**Step 9** Click **OK**.

**Step 10** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure IPv6 Neighbor Discovery

The IPv6 neighbor discovery process uses ICMPv6 messages and solicited-node multicast addresses to determine the link-layer address of a neighbor on the same network (local link), verify the readability of a neighbor, and keep track of neighboring routers.

Nodes (hosts) use neighbor discovery to determine the link-layer addresses for neighbors known to reside on attached links and to quickly purge cached values that become invalid. Hosts also use neighbor discovery to find neighboring routers that are willing to forward packets on their behalf. In addition, nodes use the protocol to actively keep track of which neighbors are reachable and which are not, and to detect changed link-layer addresses. When a router or the path to a router fails, a host actively searches for functioning alternates.

### Before you begin

Supported in Routed mode only. For IPv6 neighbor settings supported in transparent mode, see [Configure a Global IPv6 Address, on page 791](#).

### Procedure

**Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

**Step 2** Click **Edit** (✎) for the interface you want to edit.

**Step 3** Click **IPv6**, and then **Prefixes**.

**Step 4** (Optional) To configure which IPv6 prefixes are included in IPv6 router advertisements, perform the following steps:

- Click **(+)Add Prefix**.
- In the **Address** field, enter the IPv6 address with the prefix length or check the **Default** check box to use the default prefix.
- (Optional) Uncheck the **Advertisement** check box to indicate that the IPv6 prefix is not advertised.
- Check the **Off Link** check box to indicate that the specified prefix is assigned to the link. Nodes sending traffic to addresses that contain the specified prefix consider the destination to be locally reachable on the link. This prefix should not be used for on-link determination.
- To use the specified prefix for autoconfiguration, check the **Autoconfiguration** check box.

f) For the **Prefix Lifetime**, click **Duration** or **Expiration Date**.

- **Duration**—Enter a **Preferred Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being valid. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default is 2592000 (30 days). Enter a **Valid Lifetime** for the prefix in seconds. This setting is the amount of time that the specified IPv6 prefix is advertised as being preferred. The maximum value represents infinity. Valid values are from 0 to 4294967295. The default setting is 604800 (seven days). Alternatively, check the **Infinite** check box to set an unlimited duration.
- **Expiration Date**—Choose a **Valid** and **Preferred** date and time.

g) Click **OK**.

#### Step 5

Click **Settings**.

#### Step 6

(Optional) Set the maximum number of **DAD attempts**, between 1 and 600. 1 attempt is the default. Set the value to 0 to disable duplicate address detection (DAD) processing.

This setting configures the number of consecutive neighbor solicitation messages that are sent on an interface while DAD is performed on IPv6 addresses.

During the stateless autoconfiguration process, Duplicate Address Detection verifies the uniqueness of new unicast IPv6 addresses before the addresses are assigned to interfaces.

When a duplicate address is identified, the state of the address is set to **DUPLICATE**, the address is not used, and the following error message is generated:

```
325002: Duplicate address ipv6_address/MAC_address on interface
```

If the duplicate address is the link-local address of the interface, the processing of IPv6 packets is disabled on the interface. If the duplicate address is a global address, the address is not used.

#### Step 7

(Optional) Configure the interval between IPv6 neighbor solicitation retransmissions in the **NS Interval** field, between 1000 and 3600000 ms.

The default value is 1000 ms.

Neighbor solicitation messages (ICMPv6 Type 135) are sent on the local link by nodes attempting to discover the link-layer addresses of other nodes on the local link. After receiving a neighbor solicitation message, the destination node replies by sending a neighbor advertisement message (ICMPv6 Type 136) on the local link.

After the source node receives the neighbor advertisement, the source node and destination node can communicate. Neighbor solicitation messages are also used to verify the reachability of a neighbor after the link-layer address of a neighbor is identified. When a node wants to verify the reachability of a neighbor, the destination address in a neighbor solicitation message is the unicast address of the neighbor.

Neighbor advertisement messages are also sent when there is a change in the link-layer address of a node on a local link.

#### Step 8

(Optional) Configure the amount of time that a remote IPv6 node is considered reachable after a reachability confirmation event has occurred in the **Reachable Time** field, between 0 and 3600000 ms.

The default value is 0 ms. When 0 is used for the value, the reachable time is sent as undetermined. It is up to the receiving devices to set and track the reachable time value.

The neighbor reachable time enables detecting unavailable neighbors. Shorter configured times enable detecting unavailable neighbors more quickly, however, shorter times consume more IPv6 network bandwidth and

processing resources in all IPv6 network devices. Very short configured times are not recommended in normal IPv6 operation.

**Step 9** (Optional) To suppress the router advertisement transmissions, uncheck the **Enable RA** check box. If you enable router advertisement transmissions, you can set the RA lifetime and interval.

Router advertisement messages (ICMPv6 Type 134) are automatically sent in response to router solicitation messages (ICMPv6 Type 133). Router solicitation messages are sent by hosts at system startup so that the host can immediately autoconfigure without needing to wait for the next scheduled router advertisement message.

You may want to disable these messages on any interface for which you do not want the threat defense to supply the IPv6 prefix (for example, the outside interface).

- **RA Lifetime**—Configure the router lifetime value in IPv6 router advertisements, between 0 and 9000 seconds.

The default is 1800 seconds.

- **RA Interval**—Configure the interval between IPv6 router advertisement transmissions, between 3 and 1800 seconds.

The default is 200 seconds.

**Step 10** Click **OK**.

**Step 11** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure Advanced Interface Settings

This section describes how to configure MAC addresses for regular firewall mode interfaces, how to set the maximum transmission unit (MTU), and how to set other advanced parameters.

### About Advanced Interface Configuration

This section describes advanced interface settings.

#### About MAC Addresses

You can manually assign MAC addresses to override the default. For container instances, the FXOS chassis automatically generates unique MAC addresses for all interfaces.

**Note** You might want to assign unique MAC addresses to subinterfaces defined on the threat defense, because they use the same burned-in MAC address of the parent interface. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the threat defense device.

**Note** For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

## Default MAC Addresses

### For native instances:

Default MAC address assignments depend on the type of interface.

- Physical interfaces—The physical interface uses the burned-in MAC address.
- VLAN interfaces (Firepower 1010)—Routed firewall mode: All VLAN interfaces share a MAC address. Ensure that any connected switches can support this scenario. If the connected switches require unique MAC addresses, you can manually assign MAC addresses. See [Configure the MAC Address, on page 804](#).  
  
Transparent firewall mode: Each VLAN interface has a unique MAC address. You can override the generated MAC addresses if desired by manually assigning MAC addresses. See [Configure the MAC Address, on page 804](#).
- EtherChannels (Firepower Models)—For an EtherChannel, all interfaces that are part of the channel group share the same MAC address. This feature makes the EtherChannel transparent to network applications and users, because they only see the one logical connection; they have no knowledge of the individual links. The port-channel interface uses a unique MAC address from a pool; interface membership does not affect the MAC address.
- EtherChannels (ASA Models)—The port-channel interface uses the lowest-numbered channel group interface MAC address as the port-channel MAC address. Alternatively you can configure a MAC address for the port-channel interface. We recommend configuring a unique MAC address in case the group channel interface membership changes. If you remove the interface that was providing the port-channel MAC address, then the port-channel MAC address changes to the next lowest numbered interface, thus causing traffic disruption.
- Subinterfaces (threat defense-defined)—All subinterfaces of a physical interface use the same burned-in MAC address. You might want to assign unique MAC addresses to subinterfaces. For example, your service provider might perform access control based on the MAC address. Also, because IPv6 link-local addresses are generated based on the MAC address, assigning unique MAC addresses to subinterfaces allows for unique IPv6 link-local addresses, which can avoid traffic disruption in certain instances on the threat defense.

### For container instances:

- MAC addresses for all interfaces are taken from a MAC address pool. For subinterfaces, if you decide to manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification. See [Automatic MAC Addresses for Container Instance Interfaces, on page 277](#).

## About the MTU

The MTU specifies the maximum frame *payload* size that the threat defense device can transmit on a given Ethernet interface. The MTU value is the frame size *without* Ethernet headers, VLAN tagging, or other

overhead. For example, when you set the MTU to 1500, the expected frame size is 1518 bytes including the headers, or 1522 when using VLAN. Do not set the MTU value higher to accommodate these headers.

For Geneve, the entire Ethernet datagram is being encapsulated, so the new IP packet is larger and requires a larger MTU: you should set the ASA VTEP source interface MTU to be the network MTU + 306 bytes.

## Path MTU Discovery

The threat defense device supports Path MTU Discovery (as defined in RFC 1191), which lets all devices in a network path between two hosts coordinate the MTU so they can standardize on the lowest MTU in the path.

## Default MTU

The default MTU on the threat defense device is 1500 bytes. This value does not include the 18-22 bytes for the Ethernet header, VLAN tagging, or other overhead.

## MTU and Fragmentation

For IPv4, if an outgoing IP packet is larger than the specified MTU, it is fragmented into 2 or more frames. Fragments are reassembled at the destination (and sometimes at intermediate hops), and fragmentation can cause performance degradation. For IPv6, packets are typically not allowed to be fragmented at all. Therefore, your IP packets should fit within the MTU size to avoid fragmentation.

For TCP packets, the endpoints typically use their MTU to determine the TCP maximum segment size (MTU - 40, for example). If additional TCP headers are added along the way, for example for site-to-site VPN tunnels, then the TCP MSS might need to be adjusted down by the tunneling entity. See [About the TCP MSS, on page 800](#).

For UDP or ICMP, the application should take the MTU into account to avoid fragmentation.

---

**Note** The threat defense device can receive frames larger than the configured MTU as long as there is room in memory.

---

## MTU and Jumbo Frames

A larger MTU lets you send larger packets. Larger packets might be more efficient for your network. See the following guidelines:

- Matching MTUs on the traffic path—We recommend that you set the MTU on all threat defense interfaces and other device interfaces along the traffic path to be the same. Matching MTUs prevents intermediate devices from fragmenting the packets.
- Accommodating jumbo frames—You can set the MTU 9000 bytes or higher when you enable jumbo frames. The maximum depends on the model.

## About the TCP MSS

The TCP maximum segment size (MSS) is the size of the TCP payload *before* any TCP and IP headers are added. UDP packets are not affected. The client and the server exchange TCP MSS values during the three-way handshake when establishing the connection.

You can set the TCP MSS on the threat defense device for through traffic using the Sysopt\_Basic object in FlexConfig; see [#unique\\_236](#); by default, the maximum TCP MSS is set to 1380 bytes. This setting is useful when the threat defense device needs to add to the size of the packet for IPsec VPN encapsulation. However, for non-IPsec endpoints, you should disable the maximum TCP MSS on the threat defense device.

If you set a maximum TCP MSS, if either endpoint of a connection requests a TCP MSS that is larger than the value set on the threat defense device, then the threat defense device overwrites the TCP MSS in the request packet with the threat defense device maximum. If the host or server does not request a TCP MSS, then the threat defense device assumes the RFC 793-default value of 536 bytes (IPv4) or 1220 bytes (IPv6), but does not modify the packet. For example, you leave the default MTU as 1500 bytes. A host requests an MSS of 1500 minus the TCP and IP header length, which sets the MSS to 1460. If the threat defense device maximum TCP MSS is 1380 (the default), then the threat defense device changes the MSS value in the TCP request packet to 1380. The server then sends packets with 1380-byte payloads. The threat defense device can then add up to 120 bytes of headers to the packet and still fit in the MTU size of 1500.

You can also configure the minimum TCP MSS; if a host or server requests a very small TCP MSS, the threat defense device can adjust the value up. By default, the minimum TCP MSS is not enabled.

For to-the-box traffic, including for SSL VPN connections, this setting does not apply. The threat defense device uses the MTU to derive the TCP MSS: MTU - 40 (IPv4) or MTU - 60 (IPv6).

## Default TCP MSS

By default, the maximum TCP MSS on the threat defense device is 1380 bytes. This default accommodates IPv4 IPsec VPN connections where the headers can equal up to 120 bytes; this value fits within the default MTU of 1500 bytes.

## Suggested Maximum TCP MSS Setting

The default TCP MSS assumes the threat defense device acts as an IPv4 IPsec VPN endpoint and has an MTU of 1500. When the threat defense device acts as an IPv4 IPsec VPN endpoint, it needs to accommodate up to 120 bytes for TCP and IP headers.

If you change the MTU value, use IPv6, or do not use the threat defense device as an IPsec VPN endpoint, then you should change the TCP MSS setting using the Sysopt\_Basic object in FlexConfig.

---

**Note** Even if you explicitly set an MSS, if a component such as TLS/SSL decryption or server discovery needs a particular MSS, it will set that MSS based on the interface MTU and ignore your MSS setting.

---

See the following guidelines:

- Normal traffic—Disable the TCP MSS limit and accept the value established between connection endpoints. Because connection endpoints typically derive the TCP MSS from the MTU, non-IPsec packets usually fit this TCP MSS.
- IPv4 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 120. For example, if you use jumbo frames and set the MTU to 9000, then you need to set the TCP MSS to 8880 to take advantage of the new MTU.
- IPv6 IPsec endpoint traffic—Set the maximum TCP MSS to the MTU - 140.

## ARP Inspection for Bridge Group Traffic

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the threat defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the threat defense device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the threat defense device to either forward the packet out all interfaces (flood), or to drop the packet.

---

**Note** The dedicated Management interface never floods packets even if this parameter is set to flood.

---

## MAC Address Table

When you use bridge groups, the threat defense learns and builds a MAC address table in a similar way as a normal bridge or switch: when a device sends a packet through the bridge group, the threat defense adds the MAC address to its table. The table associates the MAC address with the source interface so that the threat defense knows to send any packets addressed to the device out the correct interface. Because traffic between bridge group members is subject to the threat defense security policy, if the destination MAC address of a packet is not in the table, the threat defense does not flood the original packet on all interfaces as a normal bridge does. Instead, it generates the following packets for directly-connected devices or for remote devices:

- Packets for directly-connected devices—The threat defense generates an ARP request for the destination IP address, so that it can learn which interface receives the ARP response.
- Packets for remote devices—The threat defense generates a ping to the destination IP address so that it can learn which interface receives the ping reply.

The original packet is dropped.

## Default Settings

- If you enable ARP inspection, the default setting is to flood non-matching packets.
- The default timeout value for dynamic MAC address table entries is 5 minutes.

- By default, each interface automatically learns the MAC addresses of entering traffic, and the threat defense device adds corresponding entries to the MAC address table.

---

**Note** Secure Firewall Threat Defense device generates a reset packet to reset a connection that is denied by a stateful inspection engine. Here, the destination MAC address of the packet is not determined based on the ARP table lookup but instead it is taken directly from the packets (connections) that are being denied.

---

## Guidelines for ARP Inspection and the MAC Address Table

- ARP inspection is only supported for bridge groups.
- MAC address table configuration is only supported for bridge groups.

## Configure the MTU

Customize the MTU on the interface, for example, to allow jumbo frames.

For the ISA 3000 and the threat defense virtual: Changing the MTU above 1500 bytes automatically enables jumbo-frame reservation. You must restart the system before you can use jumbo frames. For the threat defense virtual that supports clustering, you can enable jumbo-frame reservation in the Day0 configuration, so in that case, you do not need to restart. After you restart, you cannot disable jumbo-frame reservation. An exception is for the threat defense virtual, where you can disable jumbo-frame reservation in the Day0 configuration, if supported. If you use an interface in an inline set, the MTU setting is not used. However, the jumbo-frame reservation setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo-frame reservation, you must set the MTU of *any* interface above 1500 bytes.

Jumbo frames are enabled by default on other platforms.

---

**Caution** Changing the highest MTU value on the device for a data interface restarts the Snort process when you deploy configuration changes, temporarily interrupting traffic inspection. Inspection is interrupted on all data interfaces, not just the interface you modified. Whether this interruption drops traffic or passes it without further inspection depends on the model of the managed device and the interface type. This caution does not apply to management-only interfaces. See [Snort Restart Traffic Behavior, on page 212](#) for more information.

---

### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (🔗) for your threat defense device. The **Interfaces** page is selected by default.
  - Step 2** Click **Edit** (🔗) for the interface you want to edit.
  - Step 3** On the **General** tab, set the **MTU**. The minimum and maximum depends on your platform. The default is 1500 bytes.
  - Step 4** Click **OK**.

**Step 5** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

**Step 6** For the ISA 3000 and the threat defense virtual, if you set the MTU above 1500 bytes, restart the system to enable jumbo-frame reservation. See [Shut Down or Restart the Device, on page 39](#).

## Configure the MAC Address

You might need to manually assign a MAC address. You can also set the Active and Standby MAC addresses on the **Devices > Device Management > High Availability** tab. If you set the MAC address for an interface on both screens, the addresses on the **Interfaces > Advanced** tab take precedence.

**Note** For container instances, even if you are not sharing a subinterface, if you manually configure MAC addresses, make sure you use unique MAC addresses for all subinterfaces on the same parent interface to ensure proper classification.

### Procedure

**Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

**Step 2** Click **Edit** (✎) for the interface you want to edit.

**Step 3** Click the **Advanced** tab.  
The **Information** tab is selected.

**Step 4** (For clustering in individual interface mode) Choose a MAC address pool from the drop-down list.  
You can add MAC address pools according to [Address Pools, on page 1272](#).

**Step 5** (For other modes) Set the active and standby MAC addresses.

a) In the **Active MAC Address** field, enter a MAC address in H.H.H format, where H is a 16-bit hexadecimal digit.

For example, the MAC address 00-0C-F1-42-4C-DE would be entered as 000C.F142.4CDE. The MAC address must not have the multicast bit set, that is, the second hexadecimal digit from the left cannot be an odd number.

b) In the **Standby MAC Address** field, enter a MAC address for use with High Availability.

If the active unit fails over and the standby unit becomes active, the new active unit starts using the active MAC addresses to minimize network disruption, while the old active unit uses the standby address.

**Step 6** Click **OK**.

**Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Add a Static ARP Entry

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection (see [ARP Inspection, on page 865](#)). ARP inspection compares ARP packets with *static* ARP entries in the ARP table.

For routed interfaces, you can enter static ARP entries, but normally dynamic entries are sufficient. For routed interfaces, the ARP table is used to deliver packets to directly-connected hosts. Although senders identify a packet destination by an IP address, the actual delivery of the packet on Ethernet relies on the Ethernet MAC address. When a router or host wants to deliver a packet on a directly connected network, it sends an ARP request asking for the MAC address associated with the IP address, and then delivers the packet to the MAC address according to the ARP response. The host or router keeps an ARP table so it does not have to send ARP requests for every packet it needs to deliver. The ARP table is dynamically updated whenever ARP responses are sent on the network, and if an entry is not used for a period of time, it times out. If an entry is incorrect (for example, the MAC address changes for a given IP address), the entry needs to time out before it can be updated with the new information.

For transparent mode, the threat defense only uses dynamic ARP entries in the ARP table for traffic to and from the threat defense device, such as management traffic.

### Before you begin

This screen is only available for named interfaces.

### Procedure

---

- Step 1** Select **Devices > Device Management** and click **Edit** (🔗) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (🔗) for the interface you want to edit.
- Step 3** Click the **Advanced** tab, and then click the **ARP** tab (called **ARP and MAC** for transparent mode).
- Step 4** Click (+) **Add ARP Config**.  
The **Add ARP Config** dialog box appears.
- Step 5** In the **IP Address** field, enter the IP address of the host.
- Step 6** In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b.
- Step 7** To perform proxy ARP for this address, check the **Enable Alias** check box.  
  
If the threat defense device receives an ARP request for the specified IP address, then it responds with the specified MAC address.
- Step 8** Click **OK**, and then click **OK** again to exit the Advanced settings.
- Step 9** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Add a Static MAC Address and Disable MAC Learning for a Bridge Group

Normally, MAC addresses are added to the MAC address table dynamically as traffic from a particular MAC address enters an interface. You can disable MAC address learning; however, unless you statically add MAC addresses to the table, no traffic can pass through the threat defense device. You can also add static MAC addresses to the MAC address table. One benefit to adding static entries is to guard against MAC spoofing. If a client with the same MAC address as a static entry attempts to send traffic to an interface that does not match the static entry, then the threat defense device drops the traffic and generates a system message. When you add a static ARP entry (see [Add a Static ARP Entry, on page 805](#)), a static MAC address entry is automatically added to the MAC address table.

### Before you begin

This screen is only available for named BVIs in transparent mode.

### Procedure

---

- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Click the **Advanced** tab, and then click the **ARP and MAC** tab.
- Step 4** (Optional) Disable MAC learning by unchecking the **Enable MAC Learning** check box.
- Step 5** To add a static MAC address, click **Add MAC Config**. The **Add MAC Config** dialog box appears.
- Step 6** In the **MAC Address** field, enter the MAC address of the host; for example, 00e0.1e4e.3d8b. Click **OK**.
- Step 7** Click **OK** to exit the Advanced settings.
- Step 8** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Set Security Configuration Parameters

This section describes how to prevent IP spoofing, allow full fragment reassembly, and override the default fragment setting set for at the device level in **Platform Settings**.

### Anti-Spoofing

This section lets you enable Unicast Reverse Path Forwarding on an interface. Unicast RPF guards against IP spoofing (a packet uses an incorrect source IP address to obscure its true source) by ensuring that all packets have a source IP address that matches the correct source interface according to the routing table.

Normally, the threat defense device only looks at the destination address when determining where to forward the packet. Unicast RPF instructs the device to also look at the source address; this is why it is called Reverse Path Forwarding. For any traffic that you want to allow through the threat defense device, the device routing table must include a route back to the source address. See RFC 2267 for more information.

For outside traffic, for example, the threat defense device can use the default route to satisfy the Unicast RPF protection. If traffic enters from an outside interface, and the source address is not known to the routing table, the device uses the default route to correctly identify the outside interface as the source interface.

If traffic enters the outside interface from an address that is known to the routing table, but is associated with the inside interface, then the threat defense device drops the packet. Similarly, if traffic enters the inside interface from an unknown source address, the device drops the packet because the matching route (the default route) indicates the outside interface.

Unicast RPF is implemented as follows:

- ICMP packets have no session, so each packet is checked.
- UDP and TCP have sessions, so the initial packet requires a reverse route lookup. Subsequent packets arriving during the session are checked using an existing state maintained as part of the session. Non-initial packets are checked to ensure they arrived on the same interface used by the initial packet.

### Fragment per Packet

By default, the threat defense device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments through the threat defense device. Fragmented packets are often used as DoS attacks.

### Fragment Reassembly

The threat defense device performs the following fragment reassembly processes:

- IP fragments are collected until a fragment set is formed or until a timeout interval has elapsed.
- If a fragment set is formed, integrity checks are performed on the set. These checks include no overlapping, no tail overflow, and no chain overflow.
- IP fragments that terminate at the threat defense device are always fully reassembled.
- If **Full Fragment Reassembly** is disabled (the default), the fragment set is forwarded to the transport layer for further processing.
- If **Full Fragment Reassembly** is enabled, the fragment set is first coalesced into a single IP packet. The single IP packet is then forwarded to the transport layer for further processing.

### Before you begin

This screen is only available for named interfaces.

### Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** Click the **Advanced** tab, and then click the **Security Configuration** tab.
- Step 4** To enable Unicast Reverse Path Forwarding, check the **Enable Anti Spoofing** check box.
- Step 5** To enable full fragment reassembly, check the **Allow Full Fragment Reassembly** check box.
- Step 6** To change the number of fragments allowed per packet, check the **Override Default Fragment Setting** check box, and set the following values:
- **Size**—Set the maximum number of packets that can be in the IP reassembly database waiting for reassembly. The default is 200. Set this value to 1 to disable fragments.
  - **Chain**—Set the maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets.
  - **Timeout**—Set the maximum number of seconds to wait for an entire fragmented packet to arrive. The timer starts after the first fragment of a packet arrives. If all fragments of the packet do not arrive by the number of seconds specified, all fragments of the packet that were already received will be discarded. The default is 5 seconds.
- Step 7** Click **OK**.
- Step 8** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## History for Regular Firewall Interfaces for Secure Firewall Threat Defense

| Feature                                                            | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------------------------------------------------------|---------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Secure Firewall supports Dual-Arm Deployment Mode on AWS with GWLB | 7.6                       | 7.6                    | The Secure Firewall supports the dual-arm deployment mode on AWS with GWLB. This mode enables the firewall to directly forward internet-bound traffic to the internet through the internet gateway after traffic inspection, while also performing network address translation (NAT).                                                                                                                                                                                                                  |
| VXLAN VTEP IPv6 support                                            | 7.4                       | Any                    | <p>You can now specify an IPv6 address for the VXLAN VTEP interface. IPv6 is not supported for the threat defense virtual cluster control link or for Geneve encapsulation.</p> <p>New/Modified screens:</p> <ul style="list-style-type: none"> <li>• <b>Devices &gt; Device Management &gt; Edit &gt; VTEP &gt; Add VTEP</b></li> <li>• <b>Devices &gt; Device Management &gt; Edit &gt; Interfaces &gt; Add Interfaces &gt; VNI Interface</b></li> </ul> <p>Requires threat defense version 7.4.</p> |

| Geneve support for the Threat Defense Virtual | 7.1                       | Any                    | <p>Geneve encapsulation support was added for the threat defense virtual to support single-arm proxy for the Amazon Web Services (AWS) Gateway Load Balancer. The AWS Gateway Load Balancer combines a transparent network gateway (with a single entry and exit point for all traffic) and a load balancer that distributes traffic and scales threat defense virtual to match the traffic demand.</p> <p>This feature requires Snort 3.</p> <p>New/Modified screens:</p> <ul style="list-style-type: none"> <li>• <b>Devices &gt; Device Management &gt; Device &gt; VTEP</b></li> <li>• <b>Devices &gt; Device Management &gt; Device &gt; Interfaces &gt; Add Interfaces &gt; VNI Interface</b></li> <li>• <b>Devices &gt; Device Management &gt; Device &gt; Interfaces edit physical interface &gt; General</b></li> </ul> <p>Supported platforms: Threat Defense Virtual in AWS</p>                                        |
| 31-bit Subnet Mask                            | 7.0                       | Any                    | <p>For routed interfaces, you can configure an IP address on a 31-bit subnet for point-to-point connections. The 31-bit subnet includes only 2 addresses; normally, the first and last address in the subnet is reserved for the network and broadcast, so a 2-address subnet is not usable. However, if you have a point-to-point connection and do not need network or broadcast addresses, a 31-bit subnet is a useful way to preserve addresses in IPv4. For example, the failover link between 2 FTDs only requires 2 addresses; any packet that is transmitted by one end of the link is always received by the other, and broadcasting is unnecessary. You can also have a directly-connected management station running SNMP or Syslog. This feature is not supported for BVIs for bridge groups or with multicast routing.</p> <p>New/Modified screens:</p> <p><b>Devices &gt; Device Management &gt; Interfaces</b></p> |

| Synchronization between the threat defense operational link state and the physical link state for the Firepower 4100/9300 | 6.7                       | Any                    | <p>The Firepower 4100/9300 chassis can now synchronize the threat defense operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The threat defense application interface admin state is not considered. Without synchronization from threat defense, data interfaces can be in an Up state physically before the threat defense application has completely come online, for example, or can stay Up for a period of time after you initiate a threat defense shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the threat defense before the threat defense can handle it. This feature is disabled by default, and can be enabled per logical device in FXOS.</p> <p><b>Note</b> This feature is not supported for clustering, container instances, or threat defense with a Radware vDP decorator. It is also not supported for ASA.</p> <p>New/Modified Firepower Chassis Manager screens: <b>Logical Devices &gt; Enable Link State</b></p> <p>New/Modified FXOS commands: <b>set link-state-sync enabled, show interface expand detail</b></p> <p>Supported platforms: Firepower 4100/9300</p> |

| Integrated Routing and Bridging | 6.2.0                     | Any                    | <p>Integrated Routing and Bridging provides the ability to route between a bridge group and a routed interface. A bridge group is a group of interfaces that the threat defense bridges instead of routes. The threat defense is not a true bridge in that the threat defense continues to act as a firewall: access control between interfaces is controlled, and all of the usual firewall checks are in place.</p> <p>Previously, you could only configure bridge groups in transparent firewall mode, where you cannot route between bridge groups. This feature lets you configure bridge groups in routed firewall mode, and to route between bridge groups and between a bridge group and a routed interface. The bridge group participates in routing by using a Bridge Virtual Interface (BVI) to act as a gateway for the bridge group. Integrated Routing and Bridging provides an alternative to using an external Layer 2 switch if you have extra interfaces on the threat defense to assign to the bridge group. In routed mode, the BVI can be a named interface and can participate separately from member interfaces in some features, such as access rules and DHCP server.</p> <p>The following features that are supported in transparent mode are not supported in routed mode: clustering. The following features are also not supported on BVIs: dynamic routing and multicast routing.</p> <p>New/Modified screens:</p> <ul style="list-style-type: none"> <li>• <b>Devices &gt; Device Management &gt; Interfaces &gt; Edit Physical Interface</b></li> <li>• <b>Devices &gt; Device Management &gt; Interfaces &gt; Add Interfaces &gt; Bridge Group Interface</b></li> </ul> <p>Supported platforms: All except for the Firepower 2100 and the threat defense virtual</p> |

# CHAPTER 16

## Inline Sets and Passive Interfaces

You can configure IPS-only passive interfaces, passive ERSPAN interfaces, and inline sets. IPS-only mode interfaces bypass many firewall checks and only support IPS security policy. You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

- [About IPS Interfaces, on page 815](#)
- [Requirements and Prerequisites for Inline Sets, on page 817](#)
- [Guidelines for Inline Sets and Passive Interfaces, on page 819](#)
- [Configure a Passive Interface, on page 821](#)
- [Configure an Inline Set, on page 822](#)

### About IPS Interfaces

This section describes IPS interfaces.

### IPS Interface Types

IPS-only mode interfaces bypass many firewall checks and only support IPS security policy. You might want to implement IPS-only interfaces if you have a separate firewall protecting these interfaces and do not want the overhead of firewall functions.

---

**Note** The firewall mode only affects regular firewall interfaces, and not IPS-only interfaces such as inline sets or passive interfaces. IPS-only interfaces can be used in both firewall modes.

---

IPS-only interfaces can be deployed as the following types:

- **Inline Set, with optional Tap mode**—An inline set acts like a bump on the wire, and binds two interfaces together to slot into an existing network. This function allows the threat defense to be installed in any network environment without the configuration of adjacent network devices. Inline interfaces receive all traffic unconditionally, but all traffic received on these interfaces is retransmitted out of an inline set unless explicitly dropped.

With tap mode, the threat defense is deployed inline, but the network traffic flow is undisturbed. Instead, the threat defense makes a copy of each packet so that it can analyze the packets. Note that rules of these

types do generate intrusion events when they are triggered, and the table view of intrusion events indicates that the triggering packets would have dropped in an inline deployment. There are benefits to using tap mode with FTDs that are deployed inline. For example, you can set up the cabling between the threat defense and the network as if the threat defense were inline and analyze the kinds of intrusion events the threat defense generates. Based on the results, you can modify your intrusion policy and add the drop rules that best protect your network without impacting its efficiency. When you are ready to deploy the threat defense inline, you can disable tap mode and begin dropping suspicious traffic without having to reconfigure the cabling between the threat defense and the network.

---

**Note** Tap mode *significantly* impacts threat defense performance, depending on the traffic.

---

---

**Note** Inline sets might be familiar to you as "transparent inline sets," but the inline interface type is unrelated to the transparent firewall mode or the firewall-type interfaces.

---

- Passive or ERSPAN Passive—Passive interfaces monitor traffic flowing across a network using a switch SPAN or mirror port. The SPAN or mirror port allows for traffic to be copied from other ports on the switch. This function provides the system visibility within the network without being in the flow of network traffic. When you configure the threat defense in a passive deployment, the threat defense cannot take certain actions such as blocking or shaping traffic. Passive interfaces receive all traffic unconditionally, and no traffic received on these interfaces is retransmitted. Encapsulated remote switched port analyzer (ERSPAN) interfaces allow you to monitor traffic from source ports distributed over multiple switches, and uses GRE to encapsulate the traffic. ERSPAN interfaces are only allowed when the threat defense is in routed firewall mode.

---

**Note** Using SR-IOV interfaces as passive interfaces on NGFWv is not supported on some Intel network adapters (such as Intel X710 or 82599) using SR-IOV drivers due to a promiscuous mode restriction. In such cases, use a network adapter that supports this functionality. See [Intel Ethernet Products](#) for more information on Intel network adapters.

---

## About Hardware Bypass for Inline Sets

For certain interface modules on the supported models (see [Requirements and Prerequisites for Inline Sets, on page 817](#)), you can enable the Hardware Bypass feature. Hardware Bypass ensures that traffic continues to flow between an inline interface pair during a power outage. This feature can be used to maintain network connectivity in the case of software or hardware failures.

### Hardware Bypass Triggers

Hardware Bypass can be triggered in the following scenarios:

- Threat Defense crash

- Threat Defense reboot
- Security Module reboot
- Chassis crash
- Chassis reboot
- Manual trigger
- Chassis power loss
- Security Module power loss

---

**Note** Hardware bypass is intended for unplanned/unexpected failure scenarios, and is not automatically triggered during planned software upgrades. Hardware bypass only engages at the end of a planned upgrade process, when the threat defense application reboots.

---

## Hardware Bypass Switchover

When switching from normal operation to hardware bypass or from hardware bypass back to normal operation, traffic may be interrupted for several seconds. A number of factors can affect the length of the interruption; for example, copper port auto-negotiation; behavior of the optical link partner such as how it handles link faults and de-bounce timing; spanning tree protocol convergence; dynamic routing protocol convergence; and so on. During this time, you may experience dropped connections.

You may also experience dropped connections due to application identification errors when analyzing connections midstream after the return to normal operations.

## Snort Fail Open vs. Hardware Bypass

For inline sets other than those in tap mode, you can use the Snort Fail Open option to either drop traffic or allow traffic to pass without inspection when the Snort process is busy or down. Snort Fail Open is supported on all inline sets except those in tap mode, not just on interfaces that support Hardware Bypass.

The Hardware Bypass functionality allows traffic to flow during a hardware failure, including a complete power outage, and certain limited software failures. A software failure that triggers Snort Fail Open does not trigger a Hardware Bypass.

## Hardware Bypass Status

If the system has power, then the Bypass LED indicates the Hardware Bypass status. See the Firepower chassis hardware installation guide for LED descriptions.

# Requirements and Prerequisites for Inline Sets

### User Roles

- Admin
- Access Admin

- Network Admin

### Hardware Bypass Support

The threat defense supports Hardware Bypass for interface pairs on specific network modules on the following models:

- Secure Firewall 3100
- Firepower 4100
- Secure Firewall 4200
- Firepower 9300

---

**Note** You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.

---

The supported Hardware Bypass network modules for these models include:

- Secure Firewall 3100:
  - 6-port 1G SFP Fail-to-Wire Network Module, SX (multimode) (FPR3K-XNM-6X1SXF)
  - 6-port 10G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-6X10SRF)
  - 6-port 10G SFP Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X10LRF)
  - 6-port 25G SFP Fail-to-Wire Network Module, SR (multimode) (FPR3K-XNM-X25SRF)
  - 6-port 25G Fail-to-Wire Network Module, LR (single mode) (FPR3K-XNM-6X25LRF)
  - 8-port 1G Copper Fail-to-Wire Network Module, RJ45 (copper) (FPR3K-XNM-8X1GF)
- Secure Firewall 4200:
  - 6-port 1G SFP Fail-to-Wire Network Module, SX (multimode) (FPR4K-XNM-6X1SXF)
  - 6-port 10G SFP Fail-to-Wire Network Module, SR (multimode) (FPR4K-XNM-6X10SRF)
  - 6-port 10G SFP Fail-to-Wire Network Module, LR (single mode) (FPR4K-XNM-6X10LRF)
  - 6-port 25G SFP Fail-to-Wire Network Module, SR (multimode) (FPR4K-XNM-X25SRF)
  - 6-port 25G Fail-to-Wire Network Module, LR (single mode) (FPR4K-XNM-6X25LRF)
  - 8-port 1G Copper Fail-to-Wire Network Module, RJ45 (copper) (FPR4K-XNM-8X1GF)
- Firepower 4100:
  - Firepower 6-port 1G SX FTW Network Module single-wide (FPR4K-NM-6X1SX-F)
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR4K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR4K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR4K-NM-2X40G-F)

- Firepower 8-port 1G Copper FTW Network Module single-wide (FPR-NM-8X1G-F)
- Firepower 9300:
  - Firepower 6-port 10G SR FTW Network Module single-wide (FPR9K-NM-6X10SR-F)
  - Firepower 6-port 10G LR FTW Network Module single-wide (FPR9K-NM-6X10LR-F)
  - Firepower 2-port 40G SR FTW Network Module single-wide (FPR9K-NM-2X40G-F)

Hardware Bypass can only use the following port pairs:

- 1 & 2
- 3 & 4
- 5 & 6
- 7 & 8

## Guidelines for Inline Sets and Passive Interfaces

### Firewall Mode

- ERSPAN interfaces are only allowed when the device is in routed firewall mode.

### Clustering

- Link State Propagation for an inline set is not supported with clustering.
- IPS-only interfaces are not supported in Individual interface mode.

### Multi-Instance Mode

- Multi-instance shared interfaces are not supported. You must use an unshared interface.
- Multi-instance chassis-defined subinterfaces are not supported. You must use a physical interface or EtherChannel.

### General Guidelines

- Inline sets and passive interfaces support physical interfaces and EtherChannels only, and cannot use VLANs or other virtual interfaces, including multi-instance chassis-defined subinterfaces.
- Bidirectional Forwarding Detection (BFD) echo packets are not allowed through the threat defense when using inline sets. If there are two neighbors on either side of the threat defense running BFD, then the threat defense will drop BFD echo packets because they have the same source and destination IP address and appear to be part of a LAND attack.
- For inline sets and passive interfaces, the threat defense supports up to two 802.1Q headers in a packet (also known as Q-in-Q support), with the exception of the Firepower 4100/9300, which only supports

one 802.1Q header. **Note:** Firewall-type interfaces do not support Q-in-Q, and only support one 802.1Q header.

### Hardware Bypass Guidelines

- Hardware Bypass ports are supported only for inline sets.
- Hardware Bypass ports cannot be part of an EtherChannel.
- Hardware Bypass is not supported in high availability mode.
- Hardware Bypass ports are supported with intra-chassis clustering on the Firepower 9300. Ports are placed in Hardware Bypass mode when the last unit in the chassis fails. Inter-chassis clustering is not supported, because inter-chassis clustering only supports Spanned EtherChannels; Hardware Bypass ports cannot be part of an EtherChannel.
- If all modules in an intra-chassis cluster on the Firepower 9300 fail, then Hardware Bypass is triggered on the final unit, and traffic continues to pass. When units come back up, Hardware Bypass returns to standby mode. However, when you use rules that match application traffic, those connections may be dropped and need to be reestablished. Connections are dropped because state information is not retained on the cluster unit, and the unit cannot identify the traffic as belonging to an allowed application. To avoid a traffic drop, use a port-based rule instead of an application-based rule, if appropriate for your deployment.
- You can use Hardware Bypass interfaces as regular interfaces without the Hardware Bypass feature enabled.
- Do not enable Hardware Bypass and link state propagation for the same inline set.

### Unsupported Firewall Features on IPS Interfaces

- DHCP server
- DHCP relay
- DHCP client
- TCP Intercept
- Routing
- NAT
- VPN
- Application inspection
- QoS
- NetFlow
- VXLAN

# Configure a Passive Interface

This section describes how to:

- Enable the interface. By default, interfaces are disabled.
- Set the interface mode to Passive or ERSPAN. For ERSPAN interfaces, you will set the ERSPAN parameters and the IP address.
- Change the MTU. By default, the MTU is set to 1500 bytes. For more information about the MTU, see [About the MTU, on page 799](#).
- Set a specific speed and duplex (if available). By default, speed and duplex are set to Auto.

---

**Note** For the Secure Firewall Threat Defense on the FXOS chassis, you configure basic interface settings on the Firepower 4100/9300. See [Configure a Physical Interface, on page 290](#) for more information.

---

## Before you begin

- If you are using EtherChannels, add them according to [Configure an EtherChannel, on page 710](#).

## Procedure

- 
- Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (✎) for the interface you want to edit.
- Step 3** In the **Mode** drop-down list, choose **Passive** or **Ersparn**.
- Step 4** Enable the interface by checking the **Enabled** check box.
- Step 5** In the **Name** field, enter a name up to 48 characters in length.
- Step 6** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.
- Step 7** (Optional) Add a description in the **Description** field.  
The description can be up to 200 characters on a single line, without carriage returns.
- Step 8** (Optional) On **General**, set the **MTU** between 64 and 9198 bytes; for the Secure Firewall Threat Defense Virtual and Secure Firewall Threat Defense on the FXOS chassis, the maximum is 9000 bytes.  
The default is 1500 bytes.
- Step 9** For ERSPAN interfaces, set the following parameters:
- **Flow Id**—Configure the ID used by the source and destination sessions to identify the ERSPAN traffic, between 1 and 1023. This ID must also be entered in the ERSPAN destination session configuration.
  - **Source IP**—Configure the IP address used as the source of the ERSPAN traffic.
- Step 10** For ERSPAN interfaces, set the IPv4 address and mask on **IPv4**.

**Step 11** (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.
- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.

**Step 12** Click **OK**.

**Step 13** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure an Inline Set

This section enables and names two physical interfaces or EtherChannels that you can add to an inline set. You can also optionally enable Hardware Bypass for supported interface pairs.

**Note** For the Firepower 4100/9300, you configure basic interface settings in FXOS on the chassis. See [Configure a Physical Interface, on page 290](#) for more information.

### Before you begin

- If you are using EtherChannels, add them according to [Configure an EtherChannel, on page 710](#).
- We recommend that you set STP PortFast for STP-enabled switches that connect to the threat defense inline pair interfaces. This setting is especially useful for Hardware Bypass configurations and can reduce bypass times.

### Procedure

**Step 1** Select **Devices > Device Management** and click **Edit** (✎) for your threat defense device. The **Interfaces** page is selected by default.

**Step 2** Click **Edit** (✎) for the interface you want to edit.

**Step 3** In the **Mode** drop-down list, choose **None**.

After you add this interface to an inline set, this field will show Inline for the mode.

**Step 4** Enable the interface by checking the **Enabled** check box.

**Step 5** In the **Name** field, enter a name up to 48 characters in length.

Do not set the security zone yet; you must set it after you create the inline set later in this procedure.

**Step 6** (Optional) Add a description in the **Description** field.

The description can be up to 200 characters on a single line, without carriage returns.

**Step 7** (Optional) Set the duplex and speed by clicking **Hardware Configuration**.

The exact speed and duplex options depend on your hardware.

- **Duplex**—Choose **Full**, **Half**, or **Auto**. Auto is the default.
- **Speed**—Choose **10**, **100**, **1000**, or **Auto**. Auto is the default.

**Step 8** Click **OK**.

Do not set any other settings for this interface.

**Step 9** Click **Edit** (✎) for the second interface you want to add to the inline set.

**Step 10** Configure the settings as for the first interface.

**Step 11** Click **Inline Sets**.

**Step 12** Click **Add Inline Set**.

The **Add Inline Set** dialog box appears with **General** selected.

**Step 13** In the **Name** field, enter a name for the set.

**Step 14** (Optional) Change the **MTU** to enable jumbo frames.

For inline sets, the MTU setting is not used. However, the jumbo frame setting *is* relevant to inline sets; jumbo frames enable the inline interfaces to receive packets up to 9000 bytes. To enable jumbo frames, you must set the MTU of *any* interface on the device above 1500 bytes.

**Step 15** Configure Hardware Bypass.

**Note** Do not enable **Bypass** and **Propagate Link State** for the same inline set.

a) For the **Bypass** mode, choose one of the following options:

- **Disabled**—Set Hardware Bypass to disabled for interfaces where Hardware Bypass is supported, or use interfaces where Hardware Bypass is not supported.
- **Standby**—Set Hardware Bypass to the standby state on supported interfaces. Only pairs of Hardware Bypass interfaces are shown. In the standby state, the interfaces remain in normal operation until there is a trigger event.
- **Bypass-Force**—Manually forces the interface pair to go into a bypass state. **Inline Sets** shows **Yes** for any interface pairs that are in Bypass-Force mode.

b) In the **Available Interfaces Pairs** area, click a pair and then click **Add** to move it to the **Selected Interface Pair** area.

All possible pairings between named and enabled interfaces with the mode set to None show in this area.

**Step 16** (Optional) Click **Advanced** to set the following optional parameters:

- **Tap Mode**—Set to inline tap mode.

Note that you cannot enable this option and strict TCP enforcement on the same inline set.

**Note** If you need to enable or disable the Tap mode, you should do so during a maintenance window. Changing the mode while the device is passing traffic can cause traffic disruption.

**Note** Tap mode *significantly* impacts the threat defense performance, depending on the traffic.

- **Propagate Link State**—Configure link state propagation.

Link state propagation automatically brings down the second interface in the inline interface pair when one of the interfaces in an inline set goes down. When the downed interface comes back up, the second interface automatically comes back up, also. In other words, if the link state of one interface changes, the device senses the change and updates the link state of the other interface to match it. Note that devices require up to 4 seconds to propagate link state changes. Link state propagation is especially useful in resilient network environments where routers are configured to reroute traffic automatically around network devices that are in a failure state.

**Note** Do not enable **Bypass** and **Propagate Link State** for the same inline set.

Do not enable **Propagate Link State** when using clustering.

- **Snort Fail Open**—Enable or disable either or both of the **Busy** and **Down** options if you want new and existing traffic to pass without inspection (enabled) or drop (disabled) when the Snort process is busy or down.

By default, traffic passes without inspection when the Snort process is down, and drops when it is busy.

When the Snort process is:

- **Busy**—It cannot process traffic fast enough because traffic buffers are full, indicating that there is more traffic than the device can handle, or because of other software resource issues.
- **Down**—It is restarting because you deployed a configuration that requires it to restart. See [Configurations that Restart the Snort Process When Deployed or Activated, on page 214](#).

When the Snort process is down and comes back up, it inspects *new* connections. To prevent false positives and false negatives, it does not inspect existing connections on inline, routed, or transparent interfaces because initial session information might have been lost while it was down.

**Note** When Snort fails open, features that rely on the Snort process do not function. These include application control and deep inspection. The system performs only basic access control using simple, easily determined transport and network layer characteristics.

**Note** The **Strict TCP Enforcement** option is not supported.

**Step 17** Click **Interfaces**.

**Step 18** Click **Edit** (✎) for one of the member interfaces.

**Step 19** From the **Security Zone** drop-down list, choose a security zone or add a new one by clicking **New**.

You can only set the zone after you add the interface to the inline set; adding it to an inline set configures the mode to Inline and lets you choose inline-type security zones.

**Step 20** Click **OK**.

**Step 21** Set the security zone for the second interface.

**Step 22** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## History for Inline Sets and Passive Interfaces

| Feature                                                                                                                   | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Synchronization between the threat defense operational link state and the physical link state for the Firepower 4100/9300 | 6.7                       | Any                    | <p>The Firepower 4100/9300 chassis can now synchronize the threat defense operational link state with the physical link state for data interfaces. Currently, interfaces will be in an Up state as long as the FXOS admin state is up and the physical link state is up. The threat defense application interface admin state is not considered. Without synchronization from threat defense, data interfaces can be in an Up state physically before the threat defense application has completely come online, for example, or can stay Up for a period of time after you initiate a shutdown. For inline sets, this state mismatch can result in dropped packets because external routers may start sending traffic to the threat defense before the threat defense can handle it. This feature is disabled by default, and can be enabled per logical device in FXOS.</p> <p><b>Note</b> This feature is not supported for clustering, container instances, or threat defense with a Radware vDP decorator. It is also not supported for ASA.</p> <p>New/Modified Firepower Chassis Manager screens: <b>Logical Devices &gt; Enable Link State</b></p> <p>New/Modified FXOS commands: <b>set link-state-sync enabled, show interface expand detail</b></p> <p>Supported platforms: Firepower 4100/9300</p> |
| Hardware bypass support on the Firepower 2130 and 2140 for supported network modules                                      | 6.3.0                     | Any                    | <p>The Firepower 2130 and 2140 now support hardware bypass functionality when using the hardware bypass network modules.</p> <p>New/Modified screens:</p> <p><b>Devices &gt; Device Management &gt; Interfaces &gt; Edit Physical Interface</b></p> <p>Supported platforms: Firepower 2130 and 2140</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Support for EtherChannels in threat defense inline sets or passive interface                                              | 6.2.0                     | Any                    | <p>You can now use EtherChannels in a threat defense inline set or passive interface.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Feature                                                                          | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

# CHAPTER 17

## DHCP and DDNS

The following topics explain DHCP and DDNS services and how to configure them on Threat Defense devices.

- [About DHCP and DDNS Services, on page 827](#)
- [Requirements and Prerequisites for DHCP and DDNS, on page 829](#)
- [Guidelines for DHCP and DDNS Services, on page 829](#)
- [Configure the DHCPv4 Server, on page 830](#)
- [Configure the DHCPv6 Stateless Server, on page 832](#)
- [Configure the DHCP Relay Agent, on page 836](#)
- [Configure Dynamic DNS, on page 837](#)
- [History for DHCP and DDNS, on page 843](#)

## About DHCP and DDNS Services

The following topics describe the DHCP server, DHCP relay agent, and DDNS update.

### About the DHCPv4 Server

DHCP provides network configuration parameters, such as IP addresses, to DHCP clients. The threat defense device can provide a DHCP server to DHCP clients attached to threat defense device interfaces. The DHCP server provides network configuration parameters directly to DHCP clients.

An IPv4 DHCP client uses a broadcast rather than a multicast address to reach the server. The DHCP client listens for messages on UDP port 68; the DHCP server listens for messages on UDP port 67.

The DHCP server for IPv6 is not supported; you can, however, enable DHCP relay for IPv6 traffic.

### DHCP Options

DHCP provides a framework for passing configuration information to hosts on a TCP/IP network. The configuration parameters are carried in tagged items that are stored in the Options field of the DHCP message and the data are also called options. Vendor information is also stored in Options, and all of the vendor information extensions can be used as DHCP options.

For example, Cisco IP Phones download their configuration from a TFTP server. When a Cisco IP Phone starts, if it does not have both the IP address and TFTP server IP address preconfigured, it sends a request with option 150 or 66 to the DHCP server to obtain this information.

- DHCP option 150 provides the IP addresses of a list of TFTP servers.
- DHCP option 66 gives the IP address or the hostname of a single TFTP server.
- DHCP option 3 sets the default route.

A single request might include both options 150 and 66. In this case, the ASA DHCP server provides values for both options in the response if they are already configured on the ASA.

You can use advanced DHCP options to provide DNS, WINS, and domain name parameters to DHCP clients; DHCP option 15 is used for the DNS domain suffix. You can also use the DHCP automatic configuration setting to obtain these values or define them manually. When you use more than one method to define this information, it is passed to DHCP clients in the following sequence:

1. Manually configured settings.
2. Advanced DHCP options settings.
3. DHCP automatic configuration settings.

For example, you can manually define the domain name that you want the DHCP clients to receive and then enable DHCP automatic configuration. Although DHCP automatic configuration discovers the domain together with the DNS and WINS servers, the manually defined domain name is passed to DHCP clients with the discovered DNS and WINS server names, because the domain name discovered by the DHCP automatic configuration process is superseded by the manually defined domain name.

## About the DHCPv6 Stateless Server

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature ([Enable the IPv6 Prefix Delegation Client, on page 790](#)), you can configure the threat defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the threat defense by defining a DHCP IPv6 Pool and assigning it to the DHCPv6 server. The threat defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the threat defense received using Prefix Delegation.

## About the DHCP Relay Agent

You can configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers. DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the threat defense device because it does not forward broadcast traffic. The DHCP relay agent lets you configure the interface of the threat defense device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another interface.

# Requirements and Prerequisites for DHCP and DDNS

## Model Support

Threat Defense

## User Roles

- Admin
- Access Admin
- Network Admin

# Guidelines for DHCP and DDNS Services

This section includes guidelines and limitations that you should check before configuring DHCP and DDNS services.

## Firewall Mode

- DHCP Relay is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCP Server is supported in transparent firewall mode on a bridge group member interface. In routed mode, the DHCP server is supported on the BVI interface, not the bridge group member interface. The BVI must have a name for the DHCP server to operate.
- DDNS is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.
- DHCPv6 stateless server is not supported in transparent firewall mode or in routed mode on the BVI or bridge group member interface.

## Clustering

- DHCPv6 stateless server is not supported with clustering.

## IPv6

Supports IPv6 for DHCP stateless server and DHCP Relay.

## DHCPv4 Server

- The maximum available DHCP pool is 256 addresses.
- You can configure a DHCP server on any interface with a name and IP address, such as a physical interface, a subinterface, or a BVI in routed mode.

- You can configure only one DHCP server on each interface. Each interface can have its own pool of addresses to use. However the other DHCP settings, such as DNS servers, domain name, options, ping timeout, and WINS servers, are configured globally and used by the DHCP server on all interfaces.
- You cannot configure an interface as a DHCP client if that interface also has DHCP server enabled; you must use a static IP address.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- The threat defense does not support QIP DHCP servers for use with the DHCP proxy service.
- The DHCP server does not support BOOTP requests.

### DHCPv6 Server

The DHCPv6 Stateless server cannot be configured on an interface where the DHCPv6 address, Prefix Delegation client, or DHCPv6 relay is configured.

### DHCP Relay

- You can configure a maximum of 10 DHCPv4 relay servers per virtual router, global (VRF) and interface-specific servers combined, with a maximum of 4 servers per interface.
- You can configure a maximum of 10 DHCPv6 relay servers per virtual router. Interface-specific servers for IPv6 are not supported.
- You cannot configure both a DHCP server and DHCP relay on the same device, even if you want to enable them on different interfaces; you can only configure one type of service.
- DHCP relay services are not available in transparent firewall mode or in routed mode on the BVI or bridge group member interface. You can, however, allow DHCP traffic through using an access rule. To allow DHCP requests and replies through the threat defense, you need to configure two access rules, one that allows DHCP requests from the inside interface to the outside (UDP destination port 67), and one that allows the replies from the server in the other direction (UDP destination port 68).
- For IPv4, clients must be directly-connected to the threat defense and cannot send requests through another relay agent or a router. For IPv6, the threat defense supports packets from another relay server.
- The DHCP clients must be on different interfaces from the DHCP servers to which the threat defense relays requests.
- You cannot enable DHCP Relay on an interface in a traffic zone.

### DDNS Service

The firewall's DDNS supports only DynDNS service. Hence, ensure that the DDNS is configured with update URL in the following syntax:

**https://username:password@provider-domain/path?hostname=<h>&myip=<a>**

## Configure the DHCPv4 Server

See the following steps to configure a DHCPv4 server.

## Procedure

---

- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Select **DHCP > DHCP Server**.
- Step 3** Configure the following DHCP server options:
- **Ping Timeout**—The amount of time in milliseconds that threat defense device waits to time out a DHCP ping attempt. Valid values range from 10 to 10000 milliseconds. The default value is 50 milliseconds.  
To avoid address conflicts, the threat defense device sends two ICMP ping packets to an address before assigning that address to a DHCP client.
  - **Lease Length**—The amount of time in seconds that the client may use its allocated IP address before the lease expires. Valid values range from 300 to 1048575 seconds. The default value is 3600 seconds (1 hour).
  - (Routed mode) **Auto-configuration**—Enables DHCP auto configuration on the threat defense device. Auto-configuration enables the DHCP server to provide the DHCP clients with the DNS server, domain name, and WINS server information obtained from a DHCP client running on the specified interface. Otherwise, you can disable auto configuration and add the values yourself in Step 4.
  - (Routed mode) **Interface**—Specifies the interface to be used for auto configuration. For a device with virtual routing capability, this interface can only be a global virtual router interface.
- Step 4** To override auto-configured settings, do the following:
- Enter the domain name of the interface. For example, your device may be in the Your\_Company domain.
  - From the drop-down list, choose the DNS servers (primary and secondary) configured for the interface. To add a new DNS server, see [Creating Network Objects, on page 1301](#).
  - From the drop-down list, choose the WINS servers (primary and secondary) configured for the interface. To add a new WINS server, see [Creating Network Objects, on page 1301](#).
- Step 5** Select **Server**, click **Add**, and configure the following options:
- **Interface**—Choose the interface from the drop-down list. In transparent mode, specify a named bridge group member interface. In routed mode, specify a named routed interface or a named BVI; do not specify the bridge group member interface. Note that each bridge group member interface for the BVI must also be named for the DHCP server to operate.
  - **Address Pool**—The range of IP addresses from lowest to highest that is used by the DHCP server. The range of IP addresses must be on the same subnet as the selected interface and cannot include the IP address of the interface itself.
  - **Enable DHCP Server**—Enables the DHCP server on the selected interface.
- Step 6** Click **OK** to save the DHCP server configuration.
- Step 7** (Optional) Select **Advanced**, click **Add**, and specify the type of information you want the option to return to the DHCP client:
- **Option Code**—The threat defense device supports the DHCP options listed in RFC 2132, RFC 2562, and RFC 5510 to send information. All DHCP options (1 through 255) are supported except for 1, 12,

50–54, 58–59, 61, 67, and 82. See [About the DHCPv4 Server, on page 827](#) for more information on DHCP option codes.

**Note** The threat defense device does not verify that the option type and value that you provide match the expected type and value for the option code, as defined in RFC 2132. For more information about option codes and their associated types and expected values, see RFC 2132.

- **Type**—DHCP option type. Available options include **IP**, **ASCII**, and **HEX**. If you chose IP, you must add IP addresses in the IP Address fields. If you chose ASCII, you must add the ASCII value in the ASCII field. If you chose HEX, you must add the HEX value in the HEX field.
- **IP Address 1** and **IP Address 2**—The IP address(es) to be returned with this option code. To add a new IP address, see [Creating Network Objects, on page 1301](#).
- **ASCII**—The ASCII value that is returned to the DHCP client. The string cannot include spaces.
- **HEX**—The HEX value that is returned to the DHCP client. The string must have an even number of digits and no spaces. You do not need to use a 0x prefix.

**Step 8** Click **OK** to save the option code configuration.

**Step 9** Click **Save** on the DHCP page to save your changes.

**Step 10** To view DHCP bindings, use the following command.

**show dhcpd binding**

**Example:**

```
> show dhcpd binding
IP Address Client-id Lease Expiration Type
10.0.1.100 0100.a0c9.868e.43 84985 seconds automatic
```

## Configure the DHCPv6 Stateless Server

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature, you can configure the threat defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the threat defense.

### Create the DHCP IPv6 Pool

Create a DHCP IPv6 Pool for use with the DHCPv6 server. The DHCPv6 server provides information such as the DNS server or domain name when they clients send Information Request (IR) packets to the threat defense. The DHCP IPv6 Pool defines the parameters to sent in IR messages.

This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

#### Procedure

**Step 1** Choose **Objects > Object Management**.

**Step 2** Choose **DHCP IPv6 Pool** from the list of object types.

**Step 3** Click **Add** ()

**Step 4** Configure the **DNS Server** and **Domain Name**.

You can either manually define the values and click **Add**, or you can check **Import** to use one or more parameters that the threat defense obtained from the DHCPv6 server on the Prefix Delegation client interface. You can mix and match manually-configured parameters with imported parameters; however, you cannot configure the same parameter manually and also use **Import**.

*Figure 352: Manually Define Values*

Add DHCP IPv6 Pool

*Figure 353: Import Values*

Add DHCP IPv6 Pool

Name  
pool1

DNS Server  
Add

Domain Name  
Add

Import  Import

**Step 5** Define **Other Server Options**.

You can define the domain name and IP address for the following servers:

- NIS
- NISP

- SIP
- SNTTP

a) Click **Add** ()

**Figure 354: Other Server Options**

b) Choose the server type under **Option**, and either manually define the **Domain Name** and **Address**, or check **Import**.

**Figure 355: Define Server Domain Name and Address**

The 'Add Server Option' dialog box contains the following fields and controls:

- Option:** A dropdown menu with 'NIS' selected.
- Domain Name:** A text input field containing 'eng.example.com' and a trash icon to its right. An 'Add' button is to the right of the input field.
- Import:** An unchecked checkbox labeled 'Import'.
- Address:** A text input field that is currently empty. An 'Add' button is to the right of the input field.
- Import (bottom):** A checked checkbox labeled 'Import'.
- Buttons:** 'Cancel' and 'Save' buttons at the bottom right.

**Import** uses one or more parameters that the threat defense obtained from the DHCPv6 server on the Prefix Delegation client interface. You can mix and match manually-configured parameters with imported parameters; however, you cannot configure the same parameter manually and also use **Import**.

c) Click **Save**.

d) Repeat for each server type.

**Step 6** Click **Save**.

**Step 7** Use this pool with the DHCPv6 server. See [Enable the DHCPv6 Stateless Server, on page 835](#).

## Enable the DHCPv6 Stateless Server

For clients that use StateLess Address Auto Configuration (SLAAC) in conjunction with the Prefix Delegation feature ([Enable the IPv6 Prefix Delegation Client, on page 790](#)), you can configure the threat defense to provide information such as the DNS server or domain name when they send Information Request (IR) packets to the threat defense. The threat defense only accepts IR packets and does not assign addresses to the clients. You will configure the client to generate its own IPv6 address by enabling IPv6 autoconfiguration on the client. Enabling stateless autoconfiguration on a client configures IPv6 addresses based on prefixes received in Router Advertisement messages; in other words, based on the prefix that the threat defense received using Prefix Delegation.

This feature is only supported in routed mode. This feature is not supported in clustering or High Availability.

### Before you begin

Add a DHCP IPv6 Pool object. See [Create the DHCP IPv6 Pool, on page 832](#). This object defines the server parameters included in the IR messages.

### Procedure

- Step 1** Select **Devices > Device Management** and click **Edit** (🔗) for your threat defense device. The **Interfaces** page is selected by default.
- Step 2** Click **Edit** (🔗) for the interface you want to edit.
- Step 3** Click the **IPv6** page, and then click **DHCP**.
- Step 4** Click **DHCP Server Pool**, and choose the object you created earlier.

*Figure 356: Enable the DHCPv6 Server*

Edit Physical Interface

| General                                                  | IPv4    | IPv6                                                                   | Path Monitoring | Hardware Configuration | Manager Access |
|----------------------------------------------------------|---------|------------------------------------------------------------------------|-----------------|------------------------|----------------|
| Basic                                                    | Address | Prefixes                                                               | Settings        | DHCP                   |                |
| <input type="checkbox"/> Enable DHCP Client              |         | <input type="checkbox"/> Enable DHCP for address config                |                 |                        |                |
| <input type="checkbox"/> Enable default route using DHCP |         | <input checked="" type="checkbox"/> Enable DHCP for non-address config |                 |                        |                |
| <input checked="" type="radio"/> DHCP Server pool        |         | <input type="radio"/> Client PD Prefix Name                            |                 |                        |                |
| <input type="text" value="pool1"/>                       |         | <input type="text"/>                                                   |                 |                        |                |

- Step 5** Check **Enable DHCP for non-address config** to inform SLAAC clients about the DHCPv6 server.

This flag informs IPv6 autoconfiguration clients that they should use DHCPv6 to obtain additional information from DHCPv6, such as the DNS server address.

**Step 6** Click **OK**.

**Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Configure the DHCP Relay Agent

You can configure a DHCP relay agent to forward DHCP requests received on an interface to one or more DHCP servers. DHCP clients use UDP broadcasts to send their initial DHCPDISCOVER messages because they do not have information about the network to which they are attached. If the client is on a network segment that does not include a server, UDP broadcasts normally are not forwarded by the threat defense device because it does not forward broadcast traffic.

You can remedy this situation by configuring the interface of the threat defense device that is receiving the broadcasts to forward DHCP requests to a DHCP server on another interface.

---

**Note** DHCP Relay is not supported in transparent firewall mode.

---

### Procedure

---

**Step 1** Choose **Devices > Device Management**, and edit the threat defense device.

**Step 2** Select **DHCP > DHCP Relay**.

**Step 3** In the **IPv4 Relay Timeout** and **IPv6 Relay Timeout** fields, enter the amount of time in seconds that the threat defense device waits to time out the DHCP relay agent. Valid values range from 1 to 3600 seconds. The default value is 60 seconds.

The timeout is for address negotiation through the local DHCP Relay agent.

**Step 4** (Optional) Check **Trust All Information** to set all client interfaces as trusted.

You can configure interfaces as trusted interfaces to preserve DHCP Option 82. DHCP Option 82 is used by downstream switches and routers for DHCP snooping and IP Source Guard. Normally, if the threat defense DHCP relay agent receives a DHCP packet with Option 82 already set, but the giaddr field (which specifies the DHCP relay agent address that is set by the relay agent before it forwards the packet to the server) is set to 0, then the threat defense will drop that packet by default. You can preserve Option 82 and forward the packet by identifying an interface as a trusted interface.

**Step 5** On **DHCP Relay Agent**, click **Add**, and configure the following options:

- **Interface**—The interface connected to the DHCP clients.
- **Enable IPv4 Relay**—Enables IPv4 DHCP Relay for this interface.

- **Set Route**—(For IPv4) Changes the default gateway address in the DHCP message from the server to that of the threat defense device interface that is closest to the DHCP client, which relayed the original DHCP request. This action allows the client to set its default route to point to the threat defense device even if the DHCP server specifies a different router. If there is no default router option in the packet, the threat defense device adds one containing the interface address.
- **Enable IPv6 Relay**—Enables IPv6 DHCP Relay for this interface.

**Step 6** Click **OK** to save the DHCP relay agent changes.

**Step 7** On **DHCP Servers**, click **Add**, and configure the following options:

Add the IPv4 and IPv6 server addresses as separate entries, even if they belong to the same server.

- **Server**—The IP address of the DHCP server. Chose an IP address from the drop-down list. To add a new one, see [Creating Network Objects, on page 1301](#)
- **Interface**—The interface to which the specified DHCP server is attached. The DHCP Relay agent and the DHCP server cannot be configured on the same interface.

**Step 8** Click **OK** to save the DHCP server changes.

**Step 9** Click **Save** on the DHCP page to save your changes.

---

## Configure Dynamic DNS

When an interface uses DHCP IP addressing, the assigned IP address can change when the DHCP lease is renewed. When the interface needs to be reachable using a fully qualified domain name (FQDN), the IP address change can cause the DNS server resource records (RRs) to become stale. Dynamic DNS (DDNS) provides a mechanism to update DNS RRs whenever the IP address or hostname changes. You can also use DDNS for static or PPPoE IP addressing.

DDNS updates the following RRs on the DNS server: the A RR includes the name-to-IP address mapping, while the PTR RR maps addresses to names.

The threat defense supports the following DDNS update methods:

- **Standard DDNS**—The standard DDNS update method is defined by RFC 2136.

With this method, the threat defense and the DHCP server use DNS requests to update the DNS RRs. The threat defense or DHCP server sends a DNS request to its local DNS server for information about the hostname and, based on the response, determines the main DNS server that owns the RRs. The threat defense or DHCP server then sends an update request directly to the main DNS server. See the following typical scenarios.

- The threat defense updates the A RR, and the DHCP server updates the PTR RR.

Typically, the threat defense "owns" the A RR, while the DHCP server "owns" the PTR RR, so both entities need to request updates separately. When the IP address or hostname changes, the threat defense sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request a PTR RR update.

- The DHCP server updates both the A and PTR RR.

Use this scenario if the threat defense does not have the authority to update the A RR. When the IP address or hostname changes, the threat defense sends a DHCP request (including the FQDN option) to the DHCP server to inform it that it needs to request an A and PTR RR update.

You can configure different ownership depending on your security needs and the requirements of the main DNS server. For example, for a static address, the threat defense should own the updates for both records.

- **Web**—The Web update method uses the DynDNS Remote API specification (<https://help.dyn.com/remote-access-api/>).

With this method when the IP address or hostname changes, the threat defense sends an HTTP request directly to a DNS provider with which you have an account.

---

**Note** For devices that were registered using zero-touch provisioning from the outside interface, DDNS is automatically enabled using the "fmcOnly" method, which is similar to the Web method. This method is only available for zero-touch provisioning devices. You can edit some options for this method using this screen, or delete the method and configure a different one. For more information about zero-touch provisioning, see [Add a Device to the Management Center Using the Serial Number \(Zero-Touch Provisioning\)](#), on page 31.

---

The **DDNS** page also supports setting DHCP server settings relating to DDNS.

---

**Note** DDNS is not supported on the BVI or bridge group member interfaces.

---

### Before you begin

- Configure a DNS server group on **Objects > Object Management > DNS Server Group**, and then enable the group for the interface on **Devices > Platform Settings > DNS**. See [DNS](#), on page 867.
- Configure the device hostname. You can configure the hostname when you perform the threat defense initial setup, or by using the **configure network hostname** command. If you do not specify the hostname per interface, then the device hostname is used.

### Procedure

---

- Step 1** Choose **Devices > Device Management**, and edit the threat defense device.
- Step 2** Choose **DHCP > DDNS**.
- Step 3** Standard DDNS method: Configure a DDNS update method to enable DNS requests from the threat defense. You do not need to configure a DDNS update method if the DHCP server will perform all requests.
- On **DDNS Update Methods**, click **Add**.
  - Set the **Method Name**.
  - Click **DDNS**.

- d) (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.
- e) Set the **Update Records** you want the threat defense to update.

This setting only affects the records you want to update directly from the threat defense; to determine the records you want the DHCP server to update, configure the DHCP client settings per interface or globally. See, [Step 5, on page 839](#).

- **Not Defined**—Disables DNS updates from the threat defense.
- **Both A and PTR Records**—Sets the threat defense to update both A and PTR RRs. Use this option for static or PPPoE IP addressing.
- **A Records**—Sets the threat defense to update the A RR only. Use this option if you want the DHCP server to update the PTR RR.

- f) Click **OK**.
- g) Assign this method to the interface in [Step 5, on page 839](#).

**Step 4** Web method: Configure a DDNS update method to enable HTTP update requests from the threat defense.

- a) On **DDNS Update Methods**, click **Add**.
- b) Set the **Method Name**.
- c) Click **Web**.
- d) Set the **Web Update Type** to update IPv4, IPv6, or both types of addresses.
- e) Set the **Web URL**. Specify the update URL. Check with your DNS provider for the URL required.

Use the following syntax:

**https://username:password@provider-domain/path?hostname=<h>&myip=<a>**

**Example:**

https://jcrichon:pa\$\$w0rd17@domains.example.com/nic/update?hostname=<h>&myip=<a>

- f) (Optional) Configure the **Update Interval** between DNS requests. By default when all values are set to 0, update requests are sent whenever the IP address or hostname changes. To send requests regularly, set the **Days** (0-364), **Hours**, **Minutes**, and **Seconds**.
- g) Click **OK**.
- h) Assign this method to the interface in [Step 5, on page 839](#).
- i) The web type method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection. See, [Step 9, on page 841](#).

**Step 5** Configure interface settings for DDNS, including setting the update method, DHCP client settings, and the hostname for this interface.

- a) On **DDNS Interface Settings**, click **Add**.
- b) Choose the **Interface** from the drop-down list.
- c) Choose the **Method Name** that you created on the **DDNS Update Methods** page.

(Standard DDNS method) You do not need to assign a method if you want the DHCP server to perform all updates.

- d) Set the **Host Name** for this interface.

If you do not set the hostname, the device hostname is used. If you do not specify an FQDN, then the default domain from the DNS server group is appended (for static or PPPoE IP addressing) or the domain name from the DHCP server is appended (for DHCP IP addressing).

- e) Standard DDNS method: Configure the **DHCP Client requests DHCP server to update requests** to determine which records you want the DHCP server to update.

The threat defense sends DHCP client requests to the DHCP server. Note that the DHCP server must also be configured to support DDNS. The server can be configured to honor the client requests, or it can override the client (in which case, it will reply to the client so the client does not also try to perform updates that the server is performing).

For static or PPPoE IP addressing, these settings are ignored.

**Note** You can also set these values globally for all interfaces on the **DDNS** page. The per-interface settings take precedence over the global settings.

- **Not Selected**—Disables DDNS requests to the DHCP server. Even if the client does not request DDNS updates, the DHCP server can be configured to send updates anyway.
- **No Update**—Requests the DHCP server not to perform updates. This setting works in conjunction with a DDNS update method with **Both A and PTR Records** enabled.
- **Only PTR**—Requests that the DHCP server perform the PTR RR update. This setting works in conjunction with a DDNS update method with **A Records** enabled.
- **Both A and PTR Records**—Requests that the DHCP server perform both A and PTR RR updates. This setting does not require a DDNS update method to be associated with the interface.

- f) Click **OK**.

**Note** The **Dynamic DNS Update** settings relate to DHCP server settings when you enable a DHCP server on the threat defense. See, [Step 6, on page 840](#) for more information.

**Step 6** If you enable the DHCP server on an threat defense, you can configure DHCP server settings for DDNS.

To enable the DHCP server, see [Configure the DHCPv4 Server, on page 830](#)). You can configure the server behavior when DHCP clients use the standard DDNS update method. If the server performs any updates, then if the client lease expires (and is not renewed), the server will request that the DNS server remove the RRs for which it was responsible.

- a) You can configure server settings globally or per interface. For global settings, see the main **DDNS** page. For per-interface settings, see the **DDNS Interface Settings** page. Interface settings take precedence over global settings.
- b) Configure which DNS RRs you want the DHCP server to update under **Dynamic DNS Update**.
- **Not Selected**—DDNS updates are disabled, even if the client requests them.
  - **Only PTR**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will only update the PTR RR. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.
  - **Both A and PTR Records**—Enables DDNS updates. If you enable the **Override DHCP Client Requests** setting, then the server will update both the A and PTR RRs. Otherwise, the server will update RRs that the client requests. If the client does not send an update request with the FQDN

option, the server will request an update for both A and PTR RRs using the hostname discovered in DHCP option 12.

- c) To override the update actions requested by the DHCP client, check **Override DHCP Client Requests**. The server will reply to the client that the request was overridden, so the client does not also try to perform updates that the server is performing.

**Step 7** (Optional) Configure general DHCP client settings. These settings are not related to DDNS, but are related to how the DHCP client behaves.

- a) On the **DDNS** page, check **Enable DHCP Client Broadcast** to request that the DHCP server broadcast the DHCP reply (DHCP option 1).
- b) To force a MAC address to be stored inside a DHCP request packet for option 61 instead of the default internally generated string, on **DDNS > DHCP Client ID Interface**, choose the interface from the **Available Interfaces** list, and then click **Add** to move it to the **Selected Interfaces** list.

Some ISPs expect option 61 to be the interface MAC address. If the MAC address is not included in the DHCP request packet, then an IP address will not be assigned. This setting does not directly relate to DDNS, but is a general DHCP client setting.

**Step 8** Click **Save** on the Device page to save your changes.

**Step 9** The Web method for DDNS also requires you to identify the DDNS server root CA to validate the DDNS server certificate for the HTTPS connection.

The following example shows how to add a DDNS server's CA as a trustpoint.

- a) Obtain the DDNS server CA certificate. This procedure shows a manual import using PEM format, but you can also use PKCS12.
- b) In management center, choose **Devices > Certificates**, and click **Add**.
- c) Select a **Device**, and click **Add (+)**.

The **Add Cert Enrollment** dialog box appears.

- d) Enter the following fields, and click **Save**:

### Add Cert Enrollment ?

Name\*

Description

[CA Information](#)  
 [Certificate Parameters](#)  
 [Key](#)  
 [Revocation](#)

Enrollment Type:

**CA Only**  
*Check this option if you do not require an identity certificate to be created from this CA*

```

TkL4Eq1ZKR4O
fdX4lld
oxYB5DC2Ae/g

```

Allow Overrides

- Enter a **Name**.
- Choose **Enrollment Type** > **Manual**.
- Click **CA Only**.
- Paste in the CA text from step 9.a, on page 841.

e) Click **Save**.

## History for DHCP and DDNS

| Feature                                                                           | Minimum Management Center | Minimum Threat Defense | Details                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

The threat defense provides other information such as the domain name to SLAAC clients when they send Information Request (IR) packets to the threat defense. The threat defense only accepts IR packets and does not assign addresses to the clients.</p> <p>New/modified screens:</p> <ul style="list-style-type: none"> <li>• <b>Devices &gt; Device Management &gt; Interfaces &gt; Add/Edit Interfaces &gt; IPv6 &gt; DHCP</b></li> <li>• <b>Objects &gt; Object Management &gt; DHCP IPv6 Pool</b></li> </ul> <p>New/modified commands: <b>show ipv6 dhcp</b></p>                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## CHAPTER 18

# SNMP for the Firepower 1000

---

This chapter describes how to configure SNMP for the Firepower 1000.

- [About SNMP for the Firepower 1000, on page 845](#)
- [Enabling SNMP and Configuring SNMP Properties for Firepower 1000, on page 845](#)
- [Creating an SNMP Trap for Firepower 1000, on page 847](#)
- [Creating an SNMP User for Firepower 1000, on page 848](#)

## About SNMP for the Firepower 1000

The Simple Network Management Protocol (SNMP) is an application-layer protocol that provides a message format for communication between SNMP managers and agents. SNMP provides a standardized framework and a common language used for the monitoring and management of devices in a network.

The SNMP framework consists of three parts:

- An SNMP manager—The system used to control and monitor the activities of network devices using SNMP.
- An SNMP agent—The software component within the Firepower 1000 chassis that maintains the data for the Firepower chassis and reports the data, as needed, to the SNMP manager. The Firepower chassis includes the agent and a collection of MIBs. To enable the SNMP agent and create the relationship between the manager and agent, enable and configure SNMP in the management center.
- A managed information base (MIB)—The collection of managed objects on the SNMP agent.

The Firepower 1000 chassis supports SNMPv1, SNMPv2c and SNMPv3. Both SNMPv1 and SNMPv2c use a community-based form of security.

## Enabling SNMP and Configuring SNMP Properties for Firepower 1000

---

**Note** This procedure only applies to the Firepower 1000.

---

## Procedure

**Step 1** Choose **Devices > Device Management**.

**Step 2** Click **SNMP**.

**Step 3** Complete the following fields:

| Name                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Admin State</b> check box   | Whether SNMP is enabled or disabled. Enable this service only if your system includes integration with an SNMP server.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Port</b> field              | The port on which the Firepower chassis communicates with the SNMP host. You cannot change the default port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Community</b> field         | <p>The default SNMPv1 or v2 community name or SNMP v3 username and password that the Firepower chassis includes on any trap messages it sends to the SNMP host.</p> <p>Enter a valid community string for SNMPv1 and SNMPv2:</p> <ul style="list-style-type: none"> <li>• Alphanumeric string between 1 and 32 characters and special characters ! (exclamation), - (hyphen), ~ (tilde), &amp;&amp; (double ampersand), [ ] (square brackets), ^ (carat), ' (single quote), " (double quotes), and &lt; &gt; (angle brackets).</li> <li>• Do not use @ (at sign), \ (backslash), ? (question mark) or an empty space.</li> <li>• The string can also be in ASCII characters ranging 0x21 to 0x7E inclusive, excluding HTML interjection vectors, namely single quote ('), double quotes ("), and angle brackets (&lt; &gt;).</li> </ul> <p>Enter a valid username and password for SNMPv3:</p> <ul style="list-style-type: none"> <li>• Username can be alphanumeric string and can include @ (at sign), \ (backslash), . (period), _ (underscore), and - (hyphen).</li> <li>• The password restrictions are same as the community string restrictions.</li> </ul> <p>Note that if the <b>Community</b> field is already set, the text to the right of the empty field reads <b>Set: Yes</b>. If the <b>Community</b> field is not yet populated with a value, the text to the right of the empty field reads <b>Set: No</b>.</p> |
| <b>System Admin Name</b> field | <p>The contact person responsible for the SNMP implementation.</p> <p>Enter a string of up to 255 characters, such as an email address or a name and telephone number.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Location</b> field          | <p>The location of the host on which the SNMP agent (server) runs.</p> <p>Enter an alphanumeric string up to 510 characters.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**Step 4** Click **Save**.

#### What to do next

Create SNMP traps and users.

## Creating an SNMP Trap for Firepower 1000

**Note** This procedure only applies to the Firepower 1000.

#### Procedure

- Step 1** Choose **Devices** > **Device Management**.
- Step 2** Click **SNMP**.
- Step 3** In the **SNMP Traps Configuration** area, click **Add**.
- Step 4** In the **SNMP Trap Configuration** dialog box, complete the following fields:

| Name                   | Description                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Host Name</b> field | The hostname or IP address of the SNMP host to which the Firepower chassis should send the trap.                                                                                                                                                                                                                                                                                            |
| <b>Community</b> field | The SNMP v1 or v2 community name or the SNMP v3 username the Firepower chassis includes when it sends the trap to the SNMP host. This must be the same as the community or username that is configured for the SNMP service.<br><br>Enter an alphanumeric string between 1 and 32 characters. Do not use @ (at sign), \ (backslash), " (double quote), ? (question mark) or an empty space. |
| <b>Port</b> field      | The port on which the Firepower chassis communicates with the SNMP host for the trap.<br><br>Enter an integer between 1 and 65535.                                                                                                                                                                                                                                                          |
| <b>Version</b> field   | The SNMP version and model used for the trap. This can be one of the following: <ul style="list-style-type: none"> <li>• V1</li> <li>• V2</li> <li>• V3</li> </ul>                                                                                                                                                                                                                          |

| Name            | Description                                                                                                                                                                                                                                                                                                                       |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type field      | If you select <b>V2</b> or <b>V3</b> for the version, the type of trap to send. This can be one of the following: <ul style="list-style-type: none"> <li>• <b>Traps</b></li> <li>• <b>Informs</b></li> </ul>                                                                                                                      |
| Privilege field | If you select <b>V3</b> for the version, the privilege associated with the trap. This can be one of the following: <ul style="list-style-type: none"> <li>• <b>Auth</b>—Authentication but no encryption</li> <li>• <b>Noauth</b>—No authentication or encryption</li> <li>• <b>Priv</b>—Authentication and encryption</li> </ul> |

**Step 5** Click **OK** to close the **SNMP Trap Configuration** dialog box.

**Step 6** Click **Save**.

## Creating an SNMP User for Firepower 1000

**Note** This procedure only applies to the Firepower 1000.

### Procedure

**Step 1** Choose **Devices > Device Management**.

**Step 2** Click **SNMP**.

**Step 3** In the **SNMP Users Configuration** area, click **Add**.

**Step 4** In the **SNMP User Configuration** dialog box, complete the following fields:

| Name                      | Description                                                                                                                                                                                           |
|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username field            | The username assigned to the SNMP user.<br><br>Enter up to 32 letters or numbers. The name must begin with a letter and you can also specify _ (underscore), . (period), @ (at sign), and - (hyphen). |
| Auth Algorithm Type field | The authorization type: <b>SHA</b> .                                                                                                                                                                  |

| Name                          | Description                                                                                                                                                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Use AES-128 checkbox          | If checked, this user uses AES-128 encryption.<br><b>Note</b> SNMPv3 does not support DES. If you leave the AES-128 box unchecked, no privacy encryption will be done and any configured privacy password will have no effect. |
| Authentication Password field | The password for the user.                                                                                                                                                                                                     |
| Confirm field                 | The password again for confirmation purposes.                                                                                                                                                                                  |
| Encryption Password field     | The privacy password for the user.                                                                                                                                                                                             |
| Confirm field                 | The privacy password again for confirmation purposes.                                                                                                                                                                          |

**Step 5** Click **OK** to close the **SNMP User Configuration** dialog box.

**Step 6** Click **Save**.

---

## CHAPTER 19

# Quality of Service

The following topics describe how to use the Quality of Service (QoS) feature to police network traffic using threat defense devices:

- [Introduction to QoS, on page 851](#)
- [About QoS Policies, on page 851](#)
- [Requirements and Prerequisites for QoS, on page 852](#)
- [Rate Limiting with QoS Policies, on page 852](#)
- [History for QoS, on page 861](#)

## Introduction to QoS

Quality of Service, or QoS, rate limits (polices) network traffic that is allowed or trusted by access control. The system does not rate limit traffic that was fastpathed.

Though QoS is supported only on the routed interfaces of threat defense devices, it is not supported on site-to-site VPN and VTI interfaces.

### Logging Rate-Limited Connections

There are no logging configurations for QoS. A connection can be rate limited without being logged, and you cannot log a connection simply because it was rate limited. To view QoS information in connection events, you must independently log the ends of the appropriate connections to the management center database. See *Other Connections You Can Log* in the [Cisco Secure Firewall Management Center Administration Guide](#) for more information.

Connection events for rate-limited connections contain information on how much traffic was dropped, and which QoS configurations limited the traffic. You can view this information in event views (workflows), dashboards, and reports.

## About QoS Policies

QoS policies deployed to managed devices govern rate limiting. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

The system matches traffic to QoS rules in the order you specify. The system rate limits traffic according to the first rule where all rule conditions match the traffic. Traffic that does not match any of the rules is not rate limited.

---

**Note** The total number of rules including QoS rules on the device cannot exceed 255. When this threshold is reached, a deployment warning message is displayed. You need to reduce the number of rules for a successful deployment.

---

You must constrain QoS rules by source or destination (routed) interfaces. The system enforces rate limiting *independently* on *each* of those interfaces; you cannot specify an aggregate rate limit for a set of interfaces.

QoS rules can also rate limit traffic by other network characteristics, as well as contextual information such as application, URL, user identity, and custom Security Group Tags (SGTs).

You can rate limit download and upload traffic independently. The system determines download and upload directions based on the connection initiator.

---

**Note** QoS is not subordinate to a main access control configuration; you configure QoS independently. However, the access control and QoS policies deployed to the same device share identity configurations; see [Associating Other Policies with Access Control](#), on page 1643.

---

## Requirements and Prerequisites for QoS

Network Admin

## Rate Limiting with QoS Policies

To perform policy-based rate limiting, configure and deploy QoS policies to managed devices. Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

Only one person should edit a policy at a time, using a single browser window. If multiple users save the same policy, the last saved changes are retained. For your convenience, the system displays information on who (if anyone) is currently editing each policy. To protect the privacy of your session, a warning appears after 30 minutes of inactivity on the policy editor. After 60 minutes, the system discards your changes.

## Procedure

---

- Step 1** Choose **Devices > QoS**.
- Step 2** Click **New Policy** to create a new QoS policy and, optionally, assign target devices; see [Creating a QoS Policy, on page 853](#).
- You can also **Copy** () or **Edit** () an existing policy.
- Step 3** Configure QoS rules; see [Configuring QoS Rules, on page 854](#) and [QoS Rule Conditions, on page 856](#).
- The Rules in the QoS policy editor lists each rule in evaluation order, and displays a summary of the rule conditions and rate limiting configurations. A right-click menu provides rule management options, including moving, enabling, and disabling.
- Helpful in larger deployments, you can **Filter by Device** to display only the rules that affect a specific device or group of devices. You can also search for and within rules; the system matches text you enter in the **Search Rules** field to rule names and condition values, including objects and object groups.
- Note** Properly creating and ordering rules is a complex task, but one that is essential to building an effective deployment. If you do not plan carefully, rules can preempt other rules, require additional licenses, or contain invalid configurations. Icons represent comments, warnings, and errors. If issues exist, click **Show Warnings** to display a list. For more information, see [Best Practices for Access Control Rules, on page 1620](#).
- Step 4** Click **Policy Assignments** to identify the managed devices targeted by the policy; see [Setting Target Devices for a QoS Policy, on page 854](#).
- If you identified target devices during policy creation, verify your choices.
- Step 5** Save the QoS policy.
- Step 6** Because this feature must allow some packets to pass, you must configure your system to examine those packets. See [Best Practices for Handling Packets That Pass Before Traffic Identification, on page 2602](#) and [Specify a Policy to Handle Packets That Pass Before Traffic Identification, on page 2602](#).
- Step 7** Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).
- 

## Creating a QoS Policy

A new QoS policy with no rules performs no rate limiting.

### Procedure

---

- Step 1** Choose **Devices > QoS**.
- Step 2** Click **New Policy**.
- Step 3** Enter a **Name** and, optionally, a **Description**.
- Step 4** (Optional) Choose the **Available Devices** where you want to deploy the policy, then click **Add to Policy**, or drag and drop to the **Selected Devices**. To narrow the devices that appear, type a search string in the **Search** field.

You must assign devices before you deploy the policy.

**Step 5** Click **Save**.

---

#### What to do next

- Configure and deploy the QoS policy; see [Rate Limiting with QoS Policies, on page 852](#).

## Setting Target Devices for a QoS Policy

Each QoS policy can target multiple devices; each device can have one deployed QoS policy at a time.

#### Procedure

---

**Step 1** In the QoS policy editor, click **Policy Assignments**.

**Step 2** Build your target list:

- Add—Choose one or more **Available Devices**, then click **Add to Policy** or drag and drop into the list of **Selected Devices**.
- Delete—Click **Delete** (  ) next to a single device, or choose multiple devices, right-click, then choose **Delete Selected**.
- Search—Enter a search string in the search field. Click **Clear** (  ) to clear the search.

**Step 3** Click **OK** to save policy assignments.

**Step 4** Click **Save** to save the policy.

---

#### What to do next

- Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

## Configuring QoS Rules

When you create or edit a rule, use the upper portion of the rule editor to configure general rule properties. Use the lower portion of the rule editor to configure rule conditions and comments.

#### Procedure

---

**Step 1** On Rules of the QoS policy editor:

- Add Rule—Click **Add Rule**.
- Edit Rule—Click **Edit** (  ).

**Step 2** Enter a **Name**.

**Step 3** Configure rule components:

- **Enabled**—Specify whether the rule is **Enabled**.
- **Apply QoS On**—Choose the interfaces you want to rate limit, either **Interfaces in Destination Interface Objects** or **Interfaces in Source Interface Objects**. Your choice must correspond with a populated interface constraint (not **any**).
- **Traffic Limit Per Interface**—Enter a **Download Limit** and an **Upload Limit** in Mbits/sec. The default value of **Unlimited** prevent matching traffic from being rate limited in that direction.
- **Conditions**—Click the corresponding condition you want to add. You must configure a source or destination interface condition, corresponding to your choice for **Apply QoS On**.
- **Comments**—Click **Comments**. To add a comment click **New Comment**, enter a comment, and click **OK**. You can edit or delete this comment until you save the rule.

For detailed information on rule components, see [QoS Rule Components, on page 855](#).

**Step 4** Save the rule.

**Step 5** In the policy editor, set the rule position. Click and drag or use the right-click menu to cut and paste.

Rules are numbered starting at 1. The system matches traffic to rules in top-down order by ascending rule number. The first rule that traffic matches is the rule that handles that traffic. Proper rule order reduces the resources required to process network traffic and prevents rule preemption.

**Step 6** Click **Save** to save the policy.

---

### What to do next

- Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

### Related Topics

[Best Practices for Access Control Rules, on page 1620](#)

## QoS Rule Components

### State (Enabled/Disabled)

By default, rules are enabled. If you disable a rule, the system does not use it and stops generating warnings and errors for that rule.

### Interfaces (Apply QoS On)

You cannot save a QoS rule that rate limits all traffic. For each QoS rule, you must apply QoS on either:

- **Interfaces in Source Interface Objects**—Rate limits traffic through the rule's source interfaces. If you choose this option, you must add at least one source interface constraint (cannot be **any**).
- **Interfaces in Destination Interface Objects**—Rate limits traffic through the rule's destination interfaces. If you choose this option, you must add at least one destination interface constraint (cannot be **any**).

### Traffic Limit Per Interface

A QoS rule enforces rate limiting *independently* on *each* of the interfaces you specify with the Apply QoS On option. You cannot specify an aggregate rate limit for a set of interfaces.

You can rate limit traffic by Mbits per second. The default value of **Unlimited** prevents matching traffic from being rate limited.

You can rate limit download and upload traffic independently. The system determines download and upload directions based on the connection initiator.

If you specify a limit greater than the maximum throughput of an interface, the system does not rate limit matching traffic. Maximum throughput may be affected by an interface's hardware configuration, which you specify in each device's properties (**Devices > Device Management**).

### Conditions

Conditions specify the specific traffic the rule handles. You can configure each rule with multiple conditions. Traffic must match all conditions to match the rule. Each condition type has its own tab in the rule editor. For more information, see [QoS Rule Conditions, on page 856](#).

### Comments

Each time you save changes to a rule you can add comments. For example, you might summarize the overall configuration for the benefit of other users, or note when you change a rule and the reason for the change.

In the policy editor, the system displays how many comments a rule has. In the rule editor, use the Comments tab to view existing comments and add new ones.

## QoS Rule Conditions

Conditions specify the specific traffic the rule handles. You can configure each rule with multiple conditions. Traffic must match all conditions to match the rule. Each condition type has its own tab in the rule editor. You can rate limit traffic using:

See one of the following sections for more information.

[Network Rule Conditions, on page 857](#)

[User Rule Conditions, on page 857](#)

[Application Rule Conditions, on page 857](#)

[Port Rule Conditions, on page 858](#)

[URL Rule Conditions, on page 860](#)

[Custom SGT Rule Conditions, on page 860](#)

## Interface Rule Conditions

Interface rule conditions control traffic by its source and destination interfaces.

Depending on the rule type and the devices in your deployment, you can use predefined *interface objects* called *security zones* or *interface groups* to build interface conditions. Interface objects segment your network to help you manage and classify traffic flow by grouping interfaces across multiple devices; see [Interface, on page 1296](#).

---

**Tip** Constraining rules by interface is one of the best ways to improve system performance. If a rule excludes all of a device's interfaces, that rule does not affect that device's performance.

---

Just as all interfaces in an interface object must be of the same type (all inline, passive, switched, routed, or ASA FirePOWER), all interface objects used in an interface condition must be of the same type. Because devices deployed passively do not transmit traffic, in passive deployments you cannot constrain rules by destination interface.

## Network Rule Conditions

Network rule conditions control traffic by its source and destination IP address, using inner headers. Tunnel rules, which use outer headers, have tunnel endpoint conditions instead of network conditions.

You can use predefined objects to build network conditions, or manually specify individual IP addresses or address blocks.

---

**Note** You *cannot* use FDQN network objects in identity rules.

---

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

## User Rule Conditions

User rule conditions match traffic based the user who initiates the connection, or the group to which the user belongs. For example, you could configure a Block rule to prohibit anyone in the Finance group from accessing a network resource.

For access control rules only, you must first associate an identity policy with the access control policy as discussed in [Associating Other Policies with Access Control, on page 1643](#).

In addition to configuring users and groups for configured realms, you can set policies for the following Special Identities users:

- Failed Authentication: User that failed authentication with the captive portal.
- Guest: Users configured as guest users in the captive portal.
- No Authentication Required: Users that match an identity **No Authentication Required** rule action.
- Unknown: Users that cannot be identified; for example, users that are not downloaded by a configured realm.

## Application Rule Conditions

When the system analyzes IP traffic, it can identify and classify the commonly used applications on your network. This discovery-based *application awareness* is the basis for *application control*—the ability to control application traffic.

System-provided *application filters* help you perform application control by organizing applications according to basic characteristics: type, risk, business relevance, category, and tags. You can create reuseable user-defined filters based on combinations of the system-provided filters, or on custom combinations of applications.

At least one detector must be enabled for each application rule condition in the policy. If no detector is enabled for an application, the system automatically enables all system-provided detectors for the application; if none exist, the system enables the most recently modified user-defined detector for the application. For more information about application detectors, see [Application Detector Fundamentals, on page 2510](#).

You can use both application filters and individually specified applications to ensure complete coverage. However, understand the following note before you order your access control rules.

### Benefits of Application Filters

Application filters help you quickly configure application control. For example, you can easily use system-provided filters to create an access control rule that identifies and blocks all high risk, low business relevance applications. If a user attempts to use one of those applications, the system blocks the session.

Using application filters simplifies policy creation and administration. It assures you that the system controls application traffic as expected. Because Cisco frequently updates and adds application detectors via system and vulnerability database (VDB) updates, you can ensure that the system uses up-to-date detectors to monitor application traffic. You can also create your own detectors and assign characteristics to the applications they detect, automatically adding them to existing filters.

### Application Characteristics

The system characterizes each application that it detects using the criteria described in the following table. Use these characteristics as application filters.

**Table 51: Application Characteristics**

| Characteristic     | Description                                                                                                                                                                                 | Example                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Type               | Application protocols represent communications between hosts.<br>Clients represent software running on a host.<br>Web applications represent the content or requested URL for HTTP traffic. | HTTP and SSH are application protocols.<br>Web browsers and email clients are clients.<br>MPEG video and Facebook are web applications. |
| Risk               | The likelihood that the application is being used for purposes that might be against your organization's security policy.                                                                   | Peer-to-peer applications tend to have a very high risk.                                                                                |
| Business Relevance | The likelihood that the application is being used within the context of your organization's business operations, as opposed to recreationally.                                              | Gaming applications tend to have a very low business relevance.                                                                         |
| Category           | A general classification for the application that describes its most essential function. Each application belongs to at least one category.                                                 | Facebook is in the social networking category.                                                                                          |
| Tag                | Additional information about the application. Applications can have any number of tags, including none.                                                                                     | Video streaming web applications often are tagged high bandwidth and displays ads.                                                      |

[Best Practices for Configuring Application Control](#), on page 1617

## Port Rule Conditions

Port conditions allow you to control traffic by its source and destination ports.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

### Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic.

Application filtering is also recommended for applications, like threat defense, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

### Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as source port conditions in a single access control rule.

## Port, Protocol, and ICMP Code Rule Conditions

Port conditions match traffic based on the source and destination ports. Depending on the rule type, “port” can represent any of the following:

- TCP and UDP—You can control TCP and UDP traffic based on the port. The system represents this configuration using the protocol number in parentheses, plus an optional associated port or port range. For example: TCP(6)/22.
- ICMP—You can control ICMP and ICMPv6 (IPv6-ICMP) traffic based on its internet layer protocol plus an optional type and code. For example: ICMP(1):3:3.
- Protocol—You can control traffic using other protocols that do not use ports.

Leave matching criteria empty whenever possible, especially those for security zones, network objects, and port objects. When you specify multiple criteria, the system must match against every combination of the contents of the criteria you specify.

### Best Practices for Port-Based Rules

Specifying ports is the traditional way to target applications. However, applications can be configured to use unique ports to bypass access control blocks. Thus, whenever possible, use application filtering criteria rather than port criteria to target traffic. Note that application filtering is not available in prefilter rules.

Application filtering is also recommended for applications, like FTP, that open separate channels dynamically for control vs. data flow. Using port-based access control rules can prevent these kinds of applications from performing correctly, and could result in blocking desirable connections.

### Using Source and Destination Port Constraints

If you add both source and destination port constraints, you can only add ports that share a single transport protocol (TCP or UDP). For example, if you add DNS over TCP as a source port, you can add Yahoo Messenger Voice Chat (TCP) as a destination port but not Yahoo Messenger Voice Chat (UDP).

If you add only source ports or only destination ports, you can add ports that use different transport protocols. For example, you can add both DNS over TCP and DNS over UDP as destination port conditions in a single access control rule.

### Matching Non-TCP Traffic with Port Conditions

You can match non-port-based protocols. By default, if you do not specify a port condition, you are matching IP traffic. Although you can configure port conditions to match non-TCP traffic, there are some restrictions:

- Access control rules—For Classic devices, you can match GRE-encapsulated traffic with an access control rule by using the GRE (47) protocol as a destination port condition. To a GRE-constrained rule, you can add only network-based conditions: zone, IP address, port, and VLAN tag. Also, the system uses outer headers to match **all** traffic in access control policies with GRE-constrained rules. For threat defense devices, use tunnel rules in the prefilter policy to control GRE-encapsulated traffic.
- Decryption rules—These rules support TCP port conditions only.
- ICMP echo—A destination ICMP port with the type set to 0 or a destination ICMPv6 port with the type set to 129 only matches unsolicited echo replies. ICMP echo replies sent in response to ICMP echo requests are ignored. For a rule to match on any ICMP echo, use ICMP type 8 or ICMPv6 type 128.

## URL Rule Conditions

Use URL conditions to control the websites that users on your network can access.

For complete information, see [URL Filtering, on page 1741](#).

## Custom SGT Rule Conditions

If you do not configure ISE/ISE-PIC as an identity source, you can control traffic using Security Group Tags (SGTs) that were **not** assigned by ISE. SGTs specify the privileges of traffic sources within a trusted network.

*Custom* SGT rule conditions use manually created SGT objects to filter traffic, rather than ISE SGTs obtained from the system's connection to an ISE server. These manually created SGT objects correspond to the SGT attributes on the traffic you want to control. Controlling traffic using custom SGTs is not considered user control.

## ISE SGT vs Custom SGT Rule Conditions

Some rules allow you to control traffic based on assigned SGT. Depending on the rule type and your identity source configuration, you can use either ISE-assigned SGTs or custom SGTs to match traffic with assigned SGT attributes.

---

**Note** If you use ISE SGTs to match traffic, even if a packet does not have an assigned SGT attribute, the packet still matches an ISE SGT rule if the SGT associated with the packet's source IP address is known in ISE.

---

| Condition Type | Requires                       | SGTs Listed in Rule Editor                                                    |
|----------------|--------------------------------|-------------------------------------------------------------------------------|
| ISE SGT        | ISE identity source            | SGTs obtained by querying the ISE server, with automatically updated metadata |
| Custom SGT     | No ISE/ISE-PIC identity source | Static SGT objects you create                                                 |

## Autotransition from Custom SGTs to ISE SGTs

If you create rules that match custom SGTs, then configure ISE/ISE-PIC as an identity source, the system:

- Disables **Security Group Tag** options in the object manager. Although the system retains existing SGT objects, you cannot modify them or add new ones.
- Retains existing rules with custom SGT conditions. However, these rules do not match traffic. You also cannot add additional custom SGT criteria to existing rules, or create new rules with custom SGT conditions.

If you configure ISE, Cisco recommends that you delete or disable existing rules with custom SGT conditions. Instead, use ISE attribute conditions to match traffic with SGT attributes.

## CHAPTER 20

# Platform Settings

Platform settings for threat defense devices configure a range of unrelated features whose values you might want to share among several devices. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

**Note** In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices (7.3 and earlier, and some upgraded 7.4 devices).

# Introduction to Platform Settings

A platform settings policy is a shared set of features or parameters that define the aspects of a managed device that are likely to be similar to other managed devices in your deployment, such as time settings and external authentication.

A shared policy makes it possible to configure multiple managed devices at once, which provides consistency in your deployment and streamlines your management efforts. Any changes to a platform settings policy affects all the managed devices where you applied the policy. Even if you want different settings per device, you must create a shared policy and apply it to the desired device.

For example, your organization's security policies may require that your appliances have a "No Unauthorized Use" message when a user logs in. With platform settings, you can set the login banner once in a platform settings policy.

You can also benefit from having multiple platform settings policies on a single management center. For example, if you have different mail relay hosts that you use under different circumstances or if you want to test different access lists, you can create several platform settings policies and switch between them, rather than editing a single policy.

## Requirements and Prerequisites for Platform Settings Policies

### Supported Domains

Any

### User Roles

Admin

Access Admin

Network Admin

## Manage Platform Settings Policies

Use the **Platform Settings** page (**Devices > Platform Settings**) to manage platform settings policies. This page indicates the type of device for each policy. The **Status** column shows the device targets for the policy.

### Procedure

---

**Step 1** Choose **Devices > Platform Settings**.

**Step 2** For an existing policy, you can **Copy** () , **Edit** () , or **Delete** () the policy.

**Caution** You should not delete a policy that is the last-deployed policy on any of its target devices, even if it is out of date. Before you delete the policy completely, it is good practice to deploy a different policy to those targets.

- Step 3** To create a new policy, click **New Policy**.
- Choose a device type from the drop-down list:
    - **Threat Defense Settings** to create a shared policy for managed threat defense devices.
    - **Chassis Platform Settings** to create a shared policy for managed threat defense chassis in multi-instance mode.
  - Enter a **Name** for the new policy and optionally, a **Description**.
  - Optionally, choose the **Available Devices** or **Available Chassis** where you want to apply the policy and click **Add** (or drag and drop) to add the selected devices. You can enter a search string in the **Search** field to narrow the list of devices.
  - Click **Save**.
- The system creates the policy and opens it for editing.

- Step 4** To change the target devices for a policy, click **Edit** (✎) next to the platform settings policy that you want to edit.
- Click **Policy Assignment**.
  - To assign a device, high-availability pair, or device group to the policy, select it in the **Available Devices** or **Available Chassis** list and click **Add**. You can also drag and drop.
  - To remove a device assignment, click **Delete** (🗑) next to a device, high-availability pair, or device group in the **Selected Devices** or **Selected Chassis** list.
  - Click **OK**.

---

#### What to do next

- Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

## Chassis Platform Settings

Chassis Platform Settings apply to multiple-instance mode chassis. For details on these settings, see [Configure Chassis Platform Settings, on page 351](#).

## ARP Inspection

By default, all ARP packets are allowed between bridge group members. You can control the flow of ARP packets by enabling ARP inspection.

ARP inspection prevents malicious users from impersonating other hosts or routers (known as ARP spoofing). ARP spoofing can enable a “man-in-the-middle” attack. For example, a host sends an ARP request to the gateway router; the gateway router responds with the gateway router MAC address. The attacker, however, sends another ARP response to the host with the attacker MAC address instead of the router MAC address. The attacker can now intercept all the host traffic before forwarding it on to the router.

ARP inspection ensures that an attacker cannot send an ARP response with the attacker MAC address, so long as the correct MAC address and the associated IP address are in the static ARP table.

When you enable ARP inspection, the threat defense device compares the MAC address, IP address, and source interface in all ARP packets to static entries in the ARP table, and takes the following actions:

- If the IP address, MAC address, and source interface match an ARP entry, the packet is passed through.
- If there is a mismatch between the MAC address, the IP address, or the interface, then the threat defense device drops the packet.
- If the ARP packet does not match any entries in the static ARP table, then you can set the threat defense device to either forward the packet out all interfaces (flood), or to drop the packet.

---

**Note** The dedicated Management interface never floods packets even if this parameter is set to flood.

---

### Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **ARP Inspection**.

**Step 3** Add entries to the ARP inspection table.

- Click **Add** to create a new entry, or click **Edit** if the entry already exists.
- Select the desired options.

- **Inspect Enabled**—To perform ARP inspection on the selected interfaces and zones.
- **Flood Enabled**—Whether to flood ARP requests that do not match static ARP entries out all interfaces other than the originating interface or the dedicated management interface. This is the default behavior.

If you do not elect to flood ARP requests, then only those requests that exactly match static ARP entries are allowed.

- **Security Zones**—Add the zones that contain the interfaces on which to perform the selected actions. The zones must be switched zones. For interfaces not in a zone, you can type the interface name into the field below the Selected Security Zone list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.

- Click **OK**.

**Step 4** Add static ARP entries according to [Add a Static ARP Entry, on page 805](#).

**Step 5** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Banner

You can configure messages to show users when they connect to the device command line interface (CLI).

## Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **Banner**.

**Step 3** Configure the banner.

Following are some tips and requirements for banners.

- Only ASCII characters are allowed. You can use line returns (press Enter), but you cannot use tabs.
- You can dynamically add the hostname or domain name of the device by including the variables **\$(hostname)** or **\$(domain)**.
- Although there is no absolute length restriction on banners, Telnet or SSH sessions will close if there is not enough system memory available to process the banner messages.
- From a security perspective, it is important that your banner discourage unauthorized access. Do not use the words "welcome" or "please," as they appear to invite intruders in. The following banner sets the correct tone for unauthorized access:

```
You have logged in to a secure device.
If you are not authorized to access this device,
log out immediately or risk criminal charges.
```

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

# DNS

The Domain Name System (DNS) servers are used to resolve hostnames to IP addresses. There are two DNS server settings that apply to different types of traffic: data and special management traffic. Data traffic includes any services that use FQDNs for which a DNS lookup is necessary, such as access control rules and remote access VPN. Special management traffic includes traffic originating on the Management interface such as configuration and database updates. This procedure only applies to *data* DNS servers. For *management* DNS settings, see the CLI **configure network dns servers** and **configure network dns searchdomains** commands.

To determine the correct interface for DNS server communications, the managed device uses a routing lookup, but which routing table is used depends on the interfaces for which you enable DNS. See the interface settings below for more information.

You can optionally configure multiple DNS server groups and use them to resolve different DNS domains. For example, you could have a catch-all default group that uses public DNS servers, for use with connections to the Internet. You could then configure a separate group to use internal DNS servers for internal traffic, for example, any connection to a machine in the example.com domain. Thus, connections to an FQDN using your organization's domain name would be resolved using your internal DNS servers, whereas connections to public servers use external DNS servers. These resolutions are used by any feature that uses data DNS resolution, such as NAT and access control rules.

You can configure trusted DNS services for DNS snooping using the Trusted DNS Servers tab. DNS snooping is used to map the application domains to IPs in order to detect the application on the first packet. Apart from configuring the trusted DNS servers, you can include the already configured servers in DNS group, DHCP pool, DHCP relay and DHCP client as trusted DNS servers.

---

**Note** For an application-based PBR, you must configure trusted DNS servers. You must also ensure that the DNS traffic passes through threat defense in a clear-text format (encrypted DNS is not supported) so that domains can be resolved to detect applications.

---

### Before you begin

- Ensure you have created one or more DNS server groups. For more information, see [Creating DNS Server Group Objects, on page 1282](#).
- Ensure you have created interface objects to connect to the DNS servers.
- Ensure that the managed device has appropriate static or dynamic routes to access the DNS servers.

### Procedure

---

- Step 1** Choose **Devices > Platform Settings** and create or edit a Threat Defense policy.
- Step 2** Click **DNS**.
- Step 3** Click the **DNS Settings** tab.
- Step 4** Check **Enable DNS name resolution by device**.
- Step 5** Configure the DNS server groups.
- Do any of the following in the DNS server group list:
    - To add a group to the list, click **Add**. You cannot add another group once there are 30 filter domains configured within the existing list of server groups.
    - To edit the settings for a group, click **Edit** (✎) next to the group.
    - To remove a group, click **Delete** (🗑) next to the group. Removing a group does not delete the DNS server group object, it simply removes it from this list.
  - When adding or editing a group, configure the following settings, then click **OK**:
    - **Select DNS Group**—Select an existing DNS server group object, or click + to create a new one.
    - **Make as default**—Select this option to make this group the default group. Any DNS resolution request that does not match the filters for other groups will be resolved using the servers in this group.
    - **Filter Domains**—For non-default groups only, a comma-separated list of domain names, such as example.com,example2.com. Do not include spaces.

The group will be used for DNS resolutions for these domains only. You can enter a maximum of 30 separate domains across all groups added to this DNS platform settings policy. Each name can be a maximum of 127 characters.

Note that these filter domains are not related to the default domain name for the group. The filter list can be different from the default domain.

**Step 6** (Optional) Enter the **Expiry Entry Timer** and **Poll Timer** values in minutes.

These options apply to FQDNs that are specified in network objects only. These do not apply to FQDNs used in other features.

- **Expiry Entry Timer** specifies the minimum time-to-live (TTL) for the DNS entry, in minutes. If the expiration timer is longer than the entry's TTL, the TTL is increased to the expire entry time value. If the TTL is longer than the expiration timer, the expire entry time value is ignored: no additional time is added to the TTL in this case. Upon expiration, the entry is removed from the DNS lookup table. Removing an entry requires that the table be recompiled, so frequent removals can increase the processing load on the device. Because some DNS entries can have very short TTL (as short as three seconds), you can use this setting to virtually extend the TTL. The default is 1 minute (that is, the minimum TTL for all resolutions is 1 minute). The range is 1 to 65535 minutes.

Note that for systems running 7.0 or earlier, the expiration time is actually added to the TTL: it does not specify a minimum value.

- **Poll Timer** specifies the time limit after which the device queries the DNS server to resolve the FQDN that was defined in a network object. An FQDN is resolved periodically either when the poll timer has expired, or when the TTL of the resolved IP entry has expired, whichever occurs first.

**Step 7** Enable DNS lookups on all interfaces or on specific interfaces. These choices also affect which routing tables are used.

Note that enabling DNS lookups on an interface is not the same as specifying the source interface for lookups. The threat defense always uses a route lookup to determine the source interface. Management-only interfaces other than the dedicated Management interface cannot be used.

- No interfaces selected—Enables DNS lookups on all interfaces. The threat defense checks the data routing table only.
- Specific interfaces selected but not the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces. The threat defense checks the data routing table only.
- Specific interfaces selected plus the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on the specified interfaces and the Management interface. The threat defense checks the data routing table, and if no route is found, falls back to the management-only routing table.
- Only the **Enable DNS Lookup via diagnostic/management interface also** option—Enables DNS lookups on Management. The threat defense checks only the management-only routing table.

**Step 8** To configure the trusted DNS servers, click the **Trusted DNS Servers** tab.

**Step 9** By default, the existing DNS servers that are configured in DHCP pool, DHCP relay, DHCP client, or DNS server group are included as trusted DNS servers. If you want to exclude any of them, uncheck the appropriate check boxes.

**Step 10** To add trusted DNS servers, under **Specify DNS Servers**, click **Edit**.

**Step 11** In the **Select DNS Servers** dialog box, either choose a host object as the trusted DNS server or directly specify the IP address of the trusted DNS server:

- a) To choose existing host objects, under **Available Host Objects**, select the required host object and click **Add** to include it to **Selected DNS Servers**. For information on adding the host objects, see [Creating Network Objects, on page 1301](#).
- b) To directly provide the IP address(IPv4 or IPv6) of the trusted DNS server, enter the address in the given text field, and click **Add** to include it to **Selected DNS Servers**.
- c) Click **Save**. The added DNS servers are displayed in the **Trusted DNS Servers** page.

**Note** You can configure a maximum of 12 DNS servers per policy.

**Step 12** (Optional) To search for a DNS server that was added, using either the host name or the IP address, use the search field under **Specify DNS Servers**.

**Step 13** Click **Save**.

---

### What to do next

To use FQDN objects for access control rules, create an FQDN network object which can then be assigned to an access control rule. For instructions see, [Creating Network Objects, on page 1301](#).

## External Authentication

---

**Note** You must have administrator privileges to perform this task.

When you enable external authentication for management users, the threat defense verifies the user credentials with an LDAP or RADIUS server as specified in an external authentication object.

### Sharing External Authentication Objects

External authentication objects can be used by the management center and threat defense devices. You can share the same object between the management center and devices, or create separate objects. Note that the threat defense supports defining users on the RADIUS server, while the management center requires you to predefine the user list in the external authentication object. You can choose to use the predefined list method for the threat defense, but if you want to define users on the RADIUS server, you must create separate objects for the threat defense and the management center.

---

**Note** The timeout range is different for the threat defense and the management center, so if you share an object, be sure not to exceed the threat defense's smaller timeout range (1-30 seconds for LDAP, and 1-300 seconds for RADIUS). If you set the timeout to a higher value, the threat defense external authentication configuration will not work.

### Assigning External Authentication Objects to Devices

For the management center, enable the external authentication objects directly on **System > Users > External Authentication**; this setting only affects management center usage, and it does not need to be enabled for managed device usage. For threat defense devices, you must enable the external authentication object in the platform settings that you deploy to the devices, and you can only activate one external authentication object per policy. An LDAP object with CAC authentication enabled cannot also be used for CLI access. Be sure

that both the threat defense and the management center can reach the LDAP server, even if you are not sharing the object. The management center is essential to retrieving the user list and downloading it to the device.

### Threat Defense Supported Fields

Only a subset of fields in the external authentication object are used for threat defense SSH access. If you fill in additional fields, they are ignored. If you also use this object for the management center, those fields will be used. This procedure only covers the supported fields for the threat defense. For other fields, see *Configure External Authentication for the Management Center* in the [Cisco Secure Firewall Management Center Administration Guide](#).

### Username

Username must be Linux-valid usernames and be lower-case only, using alphanumeric characters plus period (.) or hyphen (-). Other special characters such as at sign (@) and slash (/) are not supported. You cannot add the **admin** user for external authentication. You can only add external users (as part of the External Authentication object) in the management center; you cannot add them at the CLI. Note that internal users can only be added at the CLI, not in the management center.

If you previously configured the same username for an internal user using the **configure user add** command, the threat defense first checks the password against the internal user, and if that fails, it checks the AAA server. Note that you cannot later add an internal user with the same name as an external user; only pre-existing internal users are supported. For users defined on the RADIUS server, be sure to set the privilege level to be the same as any internal users; otherwise you cannot log in using the external user password.

### Privilege Level

LDAP users always have Config privileges. RADIUS users can be defined as either Config or Basic users.

### Before you begin

- SSH access is enabled by default on the management interface. To enable SSH access on data interfaces, see [SSH Access, on page 881](#).
- Inform RADIUS users of the following behavior to set their expectations appropriately:
  - The first time an external user logs in, threat defense creates the required structures but cannot simultaneously create the user session. The user simply needs to authenticate again to start the session. The user will see a message similar to the following: "New external username identified. Please log in again to start a session."
  - If the user's Service-Type attribute is not defined or incorrectly configured in the RADIUS server, and when using the RADIUS-defined users for authentication, the user will see a message similar to the following: "Your username is not defined with a service type that is valid for this system. You are not authorized to access the system?."

In some cases, the SSH clients close the CLI window on an unsuccessful SSH connection, even before displaying the failure message. Hence, ensure that the user's Service-Type attribute is correctly defined in the RADIUS server.

- Similarly, if the user's Service-Type authorization was changed since the last login, the user will need to re-authenticate. The user will see a message similar to the following: "Your authorization privilege has changed. Please log in again to start a session."

## Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Click **External Authentication**.

**Step 3** Click the **Manage External Authentication Server** link.

You can also open the External Authentication screen by clicking **System > Users > External Authentication**.

**Step 4** Configure an LDAP Authentication Object.

- a) Click **Add External Authentication Object**.
- b) Set the **Authentication Method** to **LDAP**.
- c) Enter a **Name** and optional **Description**.
- d) Choose a **Server Type** from the drop-down list.
- e) For the **Primary Server**, enter a **Host Name/IP Address**.

**Note** If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

- f) (Optional) Change the **Port** from the default.
- g) (Optional) Enter the **Backup Sever** parameters.
- h) Enter **LDAP-Specific Parameters**.

- **Base DN**—Enter the base distinguished name for the LDAP directory you want to access. For example, to authenticate names in the Security organization at the Example company, enter `ou=security,dc=example,dc=com`. Alternatively click **Fetch DNs**, and choose the appropriate base distinguished name from the drop-down list.
- (Optional) **Base Filter**—For example, if the user objects in a directory tree have a `physicalDeliveryOfficeName` attribute and users in the New York office have an attribute value of `NewYork` for that attribute, to retrieve only users in the New York office, enter `(physicalDeliveryOfficeName=NewYork)`.
- **User Name**—Enter a distinguished name for a user who has sufficient credentials to browse the LDAP server. For example, if you are connecting to an OpenLDAP server where user objects have a `uid` attribute, and the object for the administrator in the Security division at our example company has a `uid` value of `NetworkAdmin`, you might enter `uid=NetworkAdmin,ou=security,dc=example,dc=com`.
- **Password and Confirm Password**—Enter and confirm the password for the user.
- (Optional) **Show Advanced Options**—Configure the following advanced options.
  - **Encryption**—Click **None**, **TLS**, or **SSL**.
 

**Note** If you change the encryption method after specifying a port, you reset the port to the default value for that method. For **None** or **TLS**, the port resets to the default value of 389. If you choose SSL encryption, the port resets to 636.
  - **SSL Certificate Upload Path**—For SSL or TLS encryption, you must choose a certificate by clicking **Choose File**.
  - (Not Used) **User Name Template**—Not used by the threat defense.

- **Timeout**—Enter the number of seconds before rolling over to the backup connection between 1 and 30. The default is 30.

**Note** The timeout range is different for the threat defense and the management center, so if you share an object, be sure not to exceed the threat defense's smaller timeout range (1-30 seconds). If you set the timeout to a higher value, the threat defense external authentication configuration will not work.

- (Optional) Set the **CLI Access Attribute** if you want to use a shell access attribute other than the user distinguished type. For example, on a Microsoft Active Directory Server, use the `sAMAccountName` shell access attribute to retrieve shell access users by typing `sAMAccountName` in the **CLI Access Attribute** field.
- Set the **CLI Access Filter**.

Choose one of the following methods:

- To use the same filter you specified when configuring authentication settings, choose **Same as Base Filter**.
- To retrieve administrative user entries based on attribute value, enter the attribute name, a comparison operator, and the attribute value you want to use as a filter, enclosed in parentheses. For example, if all network administrators have a `manager` attribute which has an attribute value of `shell`, you can set a base filter of `(manager=shell)`.

The names on the LDAP server must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (\_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

- Click **Save**.

### Step 5

For LDAP, if you later add or delete users on the LDAP server, you must refresh the user list and redeploy the Platform Settings.

- Choose **System > Users > External Authentication**.
- Click **Refresh** (  ) next to the LDAP server.

If the user list changed, you will see a message advising you to deploy configuration changes for your device. The Firepower Threat Defense Platform Settings will also show that it is "Out-of-Date on x targeted devices."

- Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

### Step 6

Configure a RADIUS Authentication Object.

- Define users on the RADIUS server using the Service-Type attribute.

The following are supported values for the Service-Type attribute:

- Administrator (6)—Provides Config access authorization to the CLI. These users can use all commands in the CLI.

- NAS Prompt (7) or any level other than 6—Provides Basic access authorization to the CLI. These users can use read-only commands, such as **show** commands, for monitoring and troubleshooting purposes.

The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (\_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

Alternatively, you can predefine users in the external authentication object (see Step 6.j, on page 874). To use the same RADIUS server for the threat defense and management center while using the Service-Type attribute method for the threat defense, create two external authentication objects that identify the same RADIUS server: one object includes the predefined **CLI Access Filter** users (for use with the management center), and the other object leaves the **CLI Access Filter** empty (for use with threat defenses).

- In management center, click **Add External Authentication Object**.
- Set the **Authentication Method** to **RADIUS**.
- Enter a **Name** and optional **Description**.
- For the **Primary Server**, enter a **Host Name/IP Address**.

**Note** If you are using a certificate to connect via TLS or SSL, the host name in the certificate must match the host name used in this field. In addition, IPv6 addresses are not supported for encrypted connections.

- (Optional) Change the **Port** from the default.
- Enter a **RADIUS Secret Key**.
- (Optional) Enter the **Backup Sever** parameters.
- Enter **RADIUS-Specific Parameters**.
  - **Timeout (Seconds)**—Enter the number of seconds before rolling over to the backup connection. The default is 30.
  - **Retries**—Enter the number of times the primary server connection should be tried before rolling over to the backup connection. The default is 3.
- (Optional) Instead of using RADIUS-defined users, under **CLI Access Filter**, enter a comma-separated list of usernames in the **Administrator CLI Access User List** field. For example, enter **jchrichton, aerynsun, rygel**.

You may want to use the **CLI Access Filter** method for threat defense so you can use the same external authentication object with threat defense and other platform types. Note that if you want to use RADIUS-defined users, you must leave the **CLI Access Filter** empty.

Make sure that these usernames match usernames on the RADIUS server. The names must be Linux-valid usernames:

- Maximum 32 alphanumeric characters, plus hyphen (-) and underscore (\_)
- All lowercase
- Cannot start with hyphen (-); cannot be all numbers; cannot include a period (.), at sign (@), or slash (/)

**Note** If you want to only define users on the RADIUS server, you must leave this section empty.

k) Click **Save**.

**Step 7** Return to **Devices > > Platform Settings > External Authentication**.

**Step 8** Click **Refresh** (  ) to view any newly-added objects.

For LDAP when you specify SSL or TLS encryption, you must upload a certificate for the connection; otherwise, the server will not be listed on this window.

**Step 9** Click **Slider enabled** (  ) next to the External Authentication object you want to use. You can only enable one object.

**Step 10** Click **Save**.

**Step 11** Deploy configuration changes; see [Deploy Configuration Changes, on page 218](#).

---

## Enable Virtual-Router-Aware Interface for External Authentication of Platform

Authentication, Authorization, and Accounting (AAA) for the threat defense device is managed through the management interface of the device. You can also enable virtual-router-aware data interface, data sub-interface, port-channel, or sub port-channel to manage AAA for the threat defense device. When enabled, the AAA route lookup is in the Virtual Routing and Forwarding (VRF) routing domain, and the AAA management traffic is forwarded to the data interfaces. The following server configuration are supported when using virtual-router-aware data interfaces for AAA:

- RADIUS or LDAP servers for external authentication
- FQDN, IPv4, or IPv6 server addresses

To use a virtual-router-aware interface for external authentication of a threat defense device, modify its external authentication policy by associating the authentication servers with the virtual-router-aware interface of the device.

### Before you begin

- Ensure that you have configured the required Virtual Routing and Forwarding (VRF) interface with a static route for the device. For information about configuring a VRF interface, see [Configure a Virtual Router, on page 1088](#), and for information about adding a static route, see [Add a Static Route, on page 1064](#).
- Ensure that security zones or interface groups with a single virtual-router-aware interface exists. For information about creating security zones and interface groups, see [Create Security Zone and Interface Group Objects, on page 702](#).
- Ensure that an external authentication server object is configured and enabled. For information on configuring an external authentication object, see [Configure External Authentication for the Threat Defense, on page 177](#).
- If the primary authentication server is configured with the FQDN of the server, ensure that the backup authentication server, if configured, is also with its FQDN. In addition, configure the DNS server in the

threat defense device's management interface. For information about the DNS server configuration, see [DNS](#).

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Click **External Authentication** and edit the external authentication policy.
- Step 3** In the **External Authentication** dialog box, the available security zone and interface groups are listed. To associate a virtual-router-aware interface with the external authentication servers, select the security zone or interface group having a single virtual-router-aware interface, and then do the following:
- To associate the interface object with the primary authentication server, click **Add to Primary Server**.
  - (Optional) To associate the interface object with the backup authentication server, click **Add to Backup Server**. If the **Add to Backup Server** button is inactive, it means that a backup server for external authentication is not configured in the device. Configure a backup server from **System > Users > External Authentication**. For information about configuring a backup authentication server, see [Configure External Authentication for the Threat Defense, on page 177](#).
- Step 4** Click **Ok**.
- Step 5** Save and deploy the changes.
- 

## Fragment Settings

By default, the threat defense device allows up to 24 fragments per IP packet, and up to 200 fragments awaiting reassembly. You might need to let fragments on your network if you have an application that routinely fragments packets, such as NFS over UDP. However, if you do not have an application that fragments traffic, we recommend that you do not allow fragments by setting **Chain** to 1. Fragmented packets are often used as Denial of Service (DoS) attacks.

- 
- Note** These settings establish the defaults for devices assigned this policy. You can override these settings for specific interfaces on a device by selecting **Override Default Fragment Setting** in the interface configuration. When you edit an interface, you can find the option on **Advanced > Security Configuration**. Select **Devices > Device Management**, edit a threat defense device, and select **Interfaces** to edit interface properties..
- 

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **Fragment Settings**.
- Step 3** Configure the following options. Click **Reset to Defaults** if you want to use the default settings.
- **Size (Block)**—The maximum number of packet fragments from all connections collectively that can be waiting for reassembly. The default is 200 fragments.

- **Chain (Fragment)**—The maximum number of packets into which a full IP packet can be fragmented. The default is 24 packets. Set this option to 1 to disallow fragments.
- **Timeout (Sec)**—The maximum number of seconds to wait for an entire fragmented packet to arrive. The default is 5 seconds. If all fragments are not received within this time, all fragments are discarded.

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## HTTP Access

You can enable the HTTPS server to provide a health check mechanism for a cloud load balancer, for example, for the threat defense virtual on AWS using an Application Load Balancer.

Other uses for HTTPs on the threat defense are not supported; for example, the threat defense does not have a web interface for configuration in this management mode.

This configuration only applies to data interfaces, including any you have configured as management-only. It does not apply to the dedicated Management interface. The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the management center. It has a separate IP address and static routing.

To use HTTPS, you do not need an access rule allowing the host IP address. You only need to configure HTTPS access according to this section.

You can only use HTTPS to a reachable interface; if your HTTPS host is located on the outside interface, you can only initiate a management connection directly to the outside interface.

### Before you begin

- You cannot configure both HTTPS and AnyConnect VPN module of Cisco Secure Client on the same interface for the same TCP port. For example, if you configure remote access SSL VPN on the outside interface, you cannot also open the outside interface for HTTPS connections on port 443. If you must configure both features on the same interface, use different ports. For example, open HTTPS on port 4443.
- You need network objects that define the hosts or networks you will allow to make HTTPS connections to the device. You can add objects as part of the procedure, but if you want to use object groups to identify a group of IP addresses, ensure that the groups needed in the rules already exist. Select **Objects > Object Management** to configure objects.

---

**Note** You cannot use the system-provided **any** network object group. Instead, use **any-ipv4** or **any-ipv6**.

---

## Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **HTTP Access**.

**Step 3** Check the **Enable HTTP Server** check box to enable the HTTP server.

**Step 4** (Optional) Change the HTTP port. The default is 443.

**Step 5** Identify the interfaces and IP addresses that allow HTTP connections.

Use this table to limit which interfaces will accept HTTP connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.

b) Configure the rule properties:

- **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make HTTP connections. Choose an object from the drop-down menu, or click + to add a new network object.
- **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow HTTP connections. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zones/Interfaces** list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.

c) Click **OK**.

**Step 6** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## ICMP Access

By default, you can send ICMP packets to any interface using either IPv4 or IPv6, with these exceptions:

- The threat defense does not respond to ICMP echo requests directed to a broadcast address.
- The threat defense only responds to ICMP traffic sent to the interface that traffic comes in on; you cannot send ICMP traffic through an interface to a far interface.

To protect the device from attacks, you can use ICMP rules to limit ICMP access to interfaces to particular hosts, networks, or ICMP types. ICMP rules function like access rules, where the rules are ordered, and the first rule that matches a packet defines the action.

If you configure any ICMP rule for an interface, an implicit deny ICMP rule is added to the end of the ICMP rule list, changing the default behavior. Thus, if you want to simply deny a few message types, you must include a permit any rule at the end of the ICMP rule list to allow the remaining message types.

We recommend that you always grant permission for the ICMP unreachable message type (type 3). Denying ICMP unreachable messages disables ICMP path MTU discovery, which can halt IPsec and PPTP traffic. Additionally ICMP packets in IPv6 are used in the IPv6 neighbor discovery process.

### Before you begin

Ensure that the objects needed in the rules already exist. Select **Objects > Object Management** to configure objects. You need network objects or groups that define the desired hosts or networks, and port objects that define the ICMP message types you want to control.

### Procedure

---

- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **ICMP Access**.
- Step 3** Configure ICMP rules.
- a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.
  - b) Configure the rule properties:
    - **Action**—Whether to permit (allow) or deny (drop) matching traffic.
    - **ICMP Service**—The port object that identifies the ICMP message type.
    - **Network**—The network object or group that identifies the hosts or networks whose access you are controlling.
    - **Available Zones/Interfaces**—Add the zones that contain the interfaces that you are protecting. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zones/Interfaces** list and click **Add**. These rules will be applied to a device only if the device includes the selected interfaces or zones.
  - c) Click **OK**.
- Step 4** (Optional.) Set rate limits on ICMPv4 Unreachable messages.
- **Rate Limit**—Sets the rate limit of unreachable messages, between 1 and 100 messages per second. The default is 1 message per second.
  - **Burst Size**—Sets the burst rate, between 1 and 10. The system sends this number of replies, but subsequent replies are not sent until the rate limit is reached.
- Step 5** Click **Save**.
- You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.
- 

## NetFlow

The NetFlow feature enables you to collect IP network traffic information as it enters or exits an interface. The collected traffic information is sent as collected records to a NetFlow Collector server or NetFlow Analyzer. You can analyze the data from NetFlow and determine information, such as source and destination of traffic, class of service, traffic pattern, bandwidth usage, type of traffic, traffic volume, and the causes of the congestion.

With the native NetFlow configuration support, the traffic information collection that was enabled through syslogs flow exports has to be disabled.

The NetFlow provides the option to configure the flow exporter and collectors along with flow event types that must be monitored.

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **NetFlow**.
- Step 3** Enable the **Enable Flow Export** toggle to enable NetFlow data export.
- Step 4** Configure the general NetFlow parameters that controls the frequency of events pushed to the collector.
- Active Refresh Interval**—For active connections, specify the time interval (in minutes) between flow-update events.
  - Delay Flow Create**—Specify the delay (in seconds) before sending a flow-create event. If you do not enter any value, there is no delay and the flow-create event is exported as soon as the flow is created.
  - Template Timeout Rate**—Specify the time interval (in minutes) at which the template records are sent to the collectors.
- Step 5** Click **Add Collector** to configure the collector. See [Add Collector in NetFlow, on page 880](#).
- Step 6** Click **Add Traffic Class** to configure the traffic class. See [Add Traffic Class to NetFlow, on page 881](#).
- Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## Add Collector in NetFlow

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Choose **NetFlow**.
- Step 3** Enable the **Enable Flow Export** toggle to enable NetFlow data export.
- Step 4** Click **Add Collector** to configure the collector. You can configure a maximum of five collectors.
- Step 5** From the **Host** dropdown list, choose the collector host IP address (IPv4 only) of the NetFlow event collector or server to which the NetFlow packets must be sent. Alternatively, you can click the + icon to create a new network host.
- Step 6** In the **Port** field, enter the UDP port on the collector to which the NetFlow packets must be sent.
- Step 7** From **Available Interfaces or Interface Groups**, choose the interface or interface group through which the collector must be reached. You can choose multiple interfaces or interface groups. The Interface Group object can contain only one interface for a given device. A collector can be reached only through one interface. The object can include a virtual-router-aware interface.
- You can click the + icon to create a new interface group.
- Step 8** Click **Add** to add the interfaces you chose.
- Step 9** You can also enter the interface name and click **Add** to add the interface.

**Step 10** Click **OK**.

---

## Add Traffic Class to NetFlow

### Procedure

---

- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **NetFlow**.
- Step 3** Enable the **Enable Flow Export** toggle to enable NetFlow data export.
- Step 4** Click **Add Traffic Class** to configure the traffic class.
- Step 5** In the **Name** field, enter the name of the traffic class that must match the NetFlow events.
- Step 6** In the **Type** field, choose the traffic class to filter the type of traffic you want to capture:
- **Default**—The traffic class that is matched if none of the traffic classes matches the traffic.
  - **Access List**—The specific traffic class that must match the traffic captured for the NetFlow events.
- Step 7** If you chose **Access List** as the **Type**, then you must choose the access list object from the **Access List Object** dropdown list.
- Note** You can also click the + icon to create a new extended access list object. See [Configure Extended ACL Objects, on page 1269](#).
- Step 8** In **Event Types**, check the checkboxes for the different NetFlow events that you want to capture and send to the collectors.
- Step 9** Click **OK**.
- 

## SSH Access

If you enabled management center access on a data interface, such as outside, you should enable SSH on that interface using this procedure. This section describes how to enable SSH connections to one or more *data* interfaces on the threat defense.

The threat defense uses the CiscoSSH stack, which is based on OpenSSH. CiscoSSH supports FIPS compliance and regular updates, including updates from Cisco and the open source community.

---

**Note** SSH is enabled by default on the Management interface; however, this screen does not affect Management SSH access.

---

The Management interface is separate from the other interfaces on the device. It is used to set up and register the device to the management center. SSH for data interfaces shares the internal and external user list with SSH for the Management interface. Other settings are configured separately: for data interfaces, enable SSH

and access lists using this screen; SSH traffic for data interfaces uses the regular routing configuration, and not any static routes configured at setup or at the CLI.

For the Management interface, to configure an SSH access list, see the **configure ssh-access-list** command in the [Cisco Secure Firewall Threat Defense Command Reference](#). To configure a static route, see the **configure network static-routes** command. By default, you configure the default route through the Management interface at initial setup.

To use SSH, you do not also need an access rule allowing the host IP address. You only need to configure SSH access according to this section.

You can SSH only to a reachable interface (including an interface in a user-defined virtual router); if your SSH host is located on the outside interface, you can only initiate a management connection directly to the outside interface. When you enable SSH in a user-defined virtual router, and you want VPN users to access SSH, be sure to terminate the VPN on the same virtual router. If the VPN is terminated on another virtual router, then you must configure route leaks between the virtual routers.

SSH supports the following ciphers and key exchange:

- Encryption—aes128-cbc, aes192-cbc, aes256-cbc, aes128-ctr, aes192-ctr, aes256-ctr
- Integrity—hmac-sha2-256
- Key exchange—dh-group14-sha256

---

**Note** After you make three consecutive failed attempts to log into the CLI using SSH, the device terminates the SSH connection.

---

### Before you begin

- You can configure SSH internal users at the CLI using the **configure user add** command; see [Add an Internal User at the CLI, on page 175](#). By default, there is an **admin** user for which you configured the password during initial setup. You can also configure external users on LDAP or RADIUS by configuring **External Authentication** in platform settings. See [External Authentication, on page 870](#).
- You need network objects that define the hosts or networks you will allow to make SSH connections to the device. You can add objects as part of the procedure, but if you want to use object groups to identify a group of IP addresses, ensure that the groups needed in the rules already exist. Select **Objects > Object Management** to configure objects.

---

**Note** You cannot use the system-provided **any** network object. Instead, use **any-ipv4** or **any-ipv6**.

---

### Procedure

---

- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Select **SSH Access**.
- Step 3** Identify the interfaces and IP addresses that allow SSH connections.

Use this table to limit which interfaces will accept SSH connections, and the IP addresses of the clients who are allowed to make those connections. You can use network addresses rather than individual IP addresses.

- a) Click **Add** to add a new rule, or click **Edit** to edit an existing rule.
- b) Configure the rule properties:
  - **IP Address**—The network object or group that identifies the hosts or networks you are allowing to make SSH connections. Choose an object from the drop-down menu, or click + to add a new network object.
  - **Available Zones/Interfaces**—Add the zones that contain the interfaces to which you will allow SSH connections. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zones/Interfaces** list and click **Add**. You can also add loopback interfaces and virtual-router-aware interfaces. These rules will be applied to a device only if the device includes the selected interfaces or zones.
- c) Click **OK**.

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

## SMTP Server

You must identify an SMTP server if you configure email alerts in the Syslog settings. The source email address you configure for Syslog must be a valid account on the SMTP servers.

### Before you begin

Ensure that the network objects that define the host address of the primary and secondary SMTP servers exist. Select **Objects > Object Management** to define the objects. Alternatively, you can create the objects while editing the policy.

### Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Click **SMTP Server**.

**Step 3** Select the network objects that identify the **Primary Server IP Address** and optionally, the **Secondary Server IP Address**.

**Step 4** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

---

# SNMP

Simple Network Management Protocol (SNMP) defines a standard way for network management stations running on PCs or workstations to monitor the health and status of many types of devices, including switches, routers, and security appliances. You can use the SNMP page to configure a firewall device for monitoring by SNMP management stations.

The Simple Network Management Protocol (SNMP) enables monitoring of network devices from a central location. Cisco security appliances support network monitoring using SNMP versions 1, 2c, and 3, as well as traps and SNMP read access; SNMP write access is not supported.

SNMPv3 supports read-only users and encryption with DES (deprecated), 3DES, AES256, AES192, and AES128.

---

**Note** The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for threat defenses running versions 6.6 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those threat defenses will fail.

---

---

**Note** SNMP configuration supports Routed and Diagnostic interface only.

---

---

**Note** To create an alert to an external SNMP server, access **Policies > Action > Alerts**

---

## Procedure

---

**Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.

**Step 2** Select **SNMP**.

**Step 3** Enable SNMP and configure basic options.

- **Enable SNMP Servers**—Whether to provide SNMP information to the configured SNMP hosts. You can deselect this option to disable SNMP monitoring while retaining the configuration information.
- **Read Community String, Confirm**—Enter the password used by a SNMP management station when sending requests to the threat defense device. The SNMP community string is a shared secret among the SNMP management stations and the network nodes being managed. The security device uses the password to determine if the incoming SNMP request is valid. The password is a case-sensitive alphanumeric string of up to 32 characters; spaces and special characters are not permitted.
- **System Administrator Name**—Enter the name of the device administrator or other contact person. This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.

- **Location**—Enter the location of this security device (for example, Building 42, Sector 54). This string is case-sensitive and can be up to 127 characters. Spaces are accepted, but multiple spaces are shortened to a single space.
- **Port**—Enter the UDP port on which incoming requests will be accepted. The default is 161.

**Step 4** (SNMPv3 only.) [Add SNMPv3 Users, on page 890.](#)

**Step 5** [Add SNMP Hosts, on page 893.](#)

**Step 6** [Configure SNMP Traps, on page 894.](#)

**Step 7** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## About SNMP

SNMP is an application-layer protocol that facilitates the exchange of management information between network devices and is part of the TCP/IP protocol suite. Threat Defense provides support for network monitoring using SNMP Versions 1, 2c, and 3, and support the use of all three versions simultaneously. The SNMP agent running on the threat defense interface lets you monitor the network devices through network management systems (NMSes), such as HP OpenView. Threat Defense supports SNMP read-only access through issuance of a GET request. SNMP write access is not allowed, so you cannot make changes with SNMP. In addition, the SNMP SET request is not supported.

You can configure the threat defense to send traps, which are unsolicited messages from the managed device to the management station for certain events (event notifications) to an NMS, or you can use the NMS to browse the Management Information Bases (MIBs) on the security devices. MIBs are a collection of definitions, and the threat defense maintain a database of values for each definition. Browsing a MIB means issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the NMS to determine values.

An SNMP agent notifies the designated management stations if events occur that are predefined to require a notification, for example, when a link in the network goes up or down. The notification it sends includes an SNMP OID, which identifies itself to the management stations. The agent also replies when a management station asks for information.

## SNMP Terminology

The following table lists the terms that are commonly used when working with SNMP.

*Table 52: SNMP Terminology*

| Term  | Description                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Agent | <p>The SNMP server running on the Secure Firewall Threat Defense. The SNMP agent has the following features:</p> <ul style="list-style-type: none"> <li>• Responds to requests for information and actions from the network management station.</li> <li>• Controls access to its Management Information Base, the collection of objects that the SNMP manager can view or change.</li> <li>• Does not allow SET operations.</li> </ul> |

| Term                                | Description                                                                                                                                                                                                                                                                                                                     |
|-------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Browsing                            | Monitoring the health of a device from the network management station by polling required information from the SNMP agent on the device. This activity may include issuing a series of GET-NEXT or GET-BULK requests of the MIB tree from the network management station to determine values.                                   |
| Management Information Bases (MIBs) | Standardized data structures for collecting information about packets, connections, buffers, failovers, and so on. MIBs are defined by the product, protocols, and hardware standards used by most network devices. SNMP network management stations can browse MIBs and request specific data or events be sent as they occur. |
| Network management stations (NMSs)  | The PCs or workstations set up to monitor SNMP events and manage devices.                                                                                                                                                                                                                                                       |
| Object identifier (OID)             | The system that identifies a device to its NMS and indicates to users the source of information monitored and displayed.                                                                                                                                                                                                        |
| Trap                                | Predefined events that generate a message from the SNMP agent to the NMS. Events include alarm conditions such as linkup, linkdown, coldstart, warmstart, authentication, or syslog messages.                                                                                                                                   |

## MIBs and Traps

MIBs are either standard or enterprise-specific. Standard MIBs are created by the IETF and documented in various RFCs. A trap reports significant events occurring on a network device, most often errors or failures. SNMP traps are defined in either standard or enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. SNMP traps are compiled into the ASA software.

If needed, you can also download RFCs, standard MIBs, and standard traps from the following locations:

<http://www.ietf.org/>

Browse the SNMP Object Navigator to look up Cisco MIBs, traps, and OIDs from the following location:

<https://snmp.cloudapps.cisco.com/Support/SNMP/do/BrowseOID.do?local=en>

In addition, download Cisco OIDs by FTP from the following location:

<ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz>

## Supported Tables and Objects in MIBs

The following sections list the supported tables and objects for the specified MIBs.

### Remote Access VPN Polling

*Table 53: CISCO-REMOTE-ACCESS-MONITOR-MIB*

| Counter         | OID                                            | Description                                   |
|-----------------|------------------------------------------------|-----------------------------------------------|
| Active Sessions | crasNumSessions<br>(1.3.6.1.4.1.9.9.392.1.3.1) | The number of currently active sessions.      |
| Users           | crasNumUsers<br>(1.3.6.1.4.1.9.9.392.1.3.3)    | The number of users who have active sessions. |

| Counter       | OID                                                 | Description                                     |
|---------------|-----------------------------------------------------|-------------------------------------------------|
| Peak Sessions | crasNumPeakSessions<br>(1.3.6.1.4.1.9.9.392.1.3.41) | The number of peak RA sessions since system up. |

### Site-to-Site VPN Tunnel Polling

**Table 54: CISCO-REMOTE-ACCESS-MONITOR-MIB**

| Counter                  | OID                                                           | Description                                                               |
|--------------------------|---------------------------------------------------------------|---------------------------------------------------------------------------|
| LAN to LAN Sessions      | crasL2LNumSessions<br>(1.3.6.1.4.1.9.9.392.1.3.29)            | The number of currently active LAN to LAN sessions.                       |
| Peak LAN to LAN Sessions | crasL2LPeakConcurrentSessions<br>(1.3.6.1.4.1.9.9.392.1.3.31) | The number of peak concurrent LAN to LAN sessions since the system is up. |

### Connection Polling

**Table 55: CISCO-FIREWALL-MIB**

| Counter                     | OID                                                           | Description                                                                        |
|-----------------------------|---------------------------------------------------------------|------------------------------------------------------------------------------------|
| Active Connections          | cfwConnectionActive<br>(1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.6) | The number of connections currently in use by the entire firewall.                 |
| Peak Connections            | cfwConnectionPeak<br>(1.3.6.1.4.1.9.9.147.1.2.2.2.1.3.40.7)   | The highest number of connections in use at any one time since system startup.     |
| Connections Per Second      | cfwConnectionPerSecond<br>(1.3.6.1.4.1.9.9.147.1.2.2.3)       | The current connections per second rate on the firewall.                           |
| Peak Connections Per Second | cfwConnectionPerSecondPeak<br>(1.3.6.1.4.1.9.9.147.1.2.2.4)   | The highest number of connections per second on the firewall since system startup. |

**NAT Translation Polling***Table 56: CISCO-NAT-EXT-MIB*

| Counter                  | OID                                                          | Description                                                                                                                                                                                                                                                                                                                                                         |
|--------------------------|--------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Active Translations      | cneAddrTranslationNumActive<br>(1.3.6.1.4.1.9.9.532.1.1.1.1) | The total number of address translation entries that are currently available in the NAT device. This indicates the aggregate of the translation entries created from both the static and dynamic address translation mechanisms.                                                                                                                                    |
| Peak Active Translations | cneAddrTranslationNumPeak<br>(1.3.6.1.4.1.9.9.532.1.1.1.2)   | The maximum number of address translation entries that are active at any one time since the system startup. This indicates the high watermark of address translation entries that are active at any one time since the system startup.<br><br>This object includes the translation entries created from both the static and dynamic address translation mechanisms. |

**Routing Table Entries Polling***Table 57: IP-FORWARD-MIB*

| Counter             | OID                                         | Description                                                        |
|---------------------|---------------------------------------------|--------------------------------------------------------------------|
| Active Translations | inetCidrRouteNumber<br>(1.3.6.1.2.1.4.24.6) | The total number of current inetCidrRouteTable entries that valid. |

**Interface Duplex Status Polling***Table 58: CISCO-IF-EXTENSION-MIB*

| Counter                | OID                                                         | Description                                                                |
|------------------------|-------------------------------------------------------------|----------------------------------------------------------------------------|
| Duplex Status          | cieIfDuplexCfgStatus<br>(1.3.6.1.4.1.9.9.276.1.1.2.1.20)    | This object specifies the configured duplex status on the given interface. |
| Detected Duplex Status | cieIfDuplexDetectStatus<br>(1.3.6.1.4.1.9.9.276.1.1.2.1.21) | This object specifies the detected duplex status on the given interface.   |

**Snort 3 Intrusion Event Rate Polling***Table 59: CISCO-UNIFIED-FIREWALL-MIB*

| Counter                      | OID                                                         | Description                                                                                                    |
|------------------------------|-------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| Snort 3 Intrusion Event Rate | cufwAaicIntrusionEvtRate<br>(1.3.6.1.4.1.9.9.491.1.5.3.2.1) | The rate at which intrusion events were recorded by Snort on this firewall averaged over the last 300 seconds. |

**BGP Peer-Flap Trap Notification***Table 60: BGP4-MIB*

| Counter       | OID                                                      | Description                                                                                                                 |
|---------------|----------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| BGP Peer-flap | bgpBackwardTransition<br>(1.3.6.1.4.1.9.9.491.1.5.3.2.1) | The BGPBackwardTransition Event is generated when the BGP FSM moves from a higher numbered state to a lower numbered state. |

**CPU Utilization Polling***Table 61: CISCO-PROCESS-MIB*

| Counter               | OID                                                     | Description                                           |
|-----------------------|---------------------------------------------------------|-------------------------------------------------------|
| CPU Total Utilization | cpmCPUTotal1minRev<br>(1.3.6.1.4.1.9.9.109.1.1.1.1.7.1) | Total system CPU utilization for the last one minute. |

| Counter                         | OID                                                                                                                             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------------------|---------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Individual CPU Core Utilization | Associated parameters and values of cpmCPUTotal1minRev<br>1.3.6.1.4.1.9.9.109.1.1.1.7.2 to<br>1.3.6.1.4.1.9.9.109.1.1.1.7.(n+1) | Individual CPU core utilization values for the last one minute, where 'n' represents the number of cores.<br><br>Examples: <ul style="list-style-type: none"> <li>• 36141991091.1.1.1.7(n+2)<br/>- Aggregate system CPU utilization % (This value is same as the system cpu usage from 36141991091.1.1.1.7.1 in single context mode).</li> <li>• 36141991091.1.1.1.7(n+3)<br/>- Snort average CPU utilization % (total aggregate value of all snort instances)</li> <li>• 36141991091.1.1.1.7(n+4)<br/>- System process average % (average of "Sysproc" cores)</li> </ul> |

**Note** The SNMP OIDs 1.3.6.1.2.1.25.3.3 and 1.3.6.1.2.1.25.3.4 pertaining to CPU monitoring (hrProcessorTable and hrNetworkTable) were removed on ASA FirePOWER. You can view and monitor the CPU health details of the device only through its device manager.

In ENTITY-MIB, two new vendor OIDs were added for the dual EPM 2X100G and 4X200G cards of Secure Firewall 4200 for slot 2 and slot 3—cevFPRNM4X200Gng and cevFPRNM2X100Gng.

## Add SNMPv3 Users

**Note** You create users for SNMPv3 only. These steps are not applicable for SNMPv1 or SNMPv2c.

Note that SNMPv3 only supports read-only users.

SNMP users have a specified username, an authentication password, an encryption password, and authentication and encryption algorithms to use.

**Note** When using SNMPv3 with clustering or High Availability, if you add a new cluster unit after the initial cluster formation or you replace a High Availability unit, then SNMPv3 users are not replicated to the new unit. You must remove the users, re-add them, and then redeploy your configuration to force the users to replicate to the new unit.

The authentication algorithm options are MD5 (deprecated, pre-6.5 only), SHA, SHA224, SHA256, and SHA384.

**Note** The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTDs running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those threat defenses will fail.

The encryption algorithm options are DES (deprecated, pre-6.5 only), 3DES, AES256, AES192, and AES128.

**Note** The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for threat defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those threat defenses will fail.

## Procedure

- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Click **SNMP > Users**.
- Step 3** Click **Add**.
- Step 4** Select the security level for the user from the **Security Level** drop-down list.
  - **Auth**—Authentication but No Privacy, which means that messages are authenticated.
  - **No Auth**—No Authentication and No Privacy, which means that no security is applied to messages.
  - **Priv**—Authentication and Privacy, which means that messages are authenticated and encrypted.
- Step 5** Enter the name of the SNMP user in the **Username** field. Usernames must be 32 characters or less.
- Step 6** Select the type of password, you want to use in the **Encryption Password Type** drop-down list.
  - **Clear text**—The threat defense device will still encrypt the password when deploying to the device.
  - **Encrypted**—The threat defense device will directly deploy the encrypted password.
- Step 7** In the **Auth Algorithm Type** drop-down list, select the type of authentication you want to use: SHA, SHA224, SHA256, or SHA384.

**Note** The MD5 option has been deprecated. If your deployment includes SNMP v3 users using the MD5 authentication algorithm that were created using a version previous to 6.5, you can continue to use those users for FTDs running versions 6.7 and previous. However, you cannot edit those users and retain the MD5 authentication algorithm, or create new users with the MD5 authentication algorithm. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses the MD5 authentication algorithm to those threat defenses will fail.

**Step 8** In the **Authentication Password** field, enter the password to use for authentication. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values.

**Note** The length of the password will depend on the authentication algorithm selected. For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

**Step 9** In the **Encryption Type** drop-down list, select the type of encryption you want to use: AES128, AES192, AES256, 3DES.

**Note** To use AES or 3DES encryption, you must have the appropriate license installed on the device.

**Note** The DES option has been deprecated. If your deployment includes SNMP v3 users using DES encryption that were created using a version previous to 6.5, you can continue to use those users for threat defenses running versions 6.7 and previous. However, you cannot edit those users and retain DES encryption, or create new users with DES encryption. If your management center manages any threat defenses running Versions 7.0+, deploying a platform settings policy that uses DES encryption to those threat defenses will fail.

**Step 10** Enter the password to use for encryption in the **Encryption Password** field. If you selected Encrypted as the Encrypt Password Type, the password must be formatted as xx:xx:xx..., where xx are hexadecimal values. For encrypted passwords, the length of the password depends on the encryption type selected. The password sizes are as follows (where each xx is one octal):

- AES 128 requires 16 octals
- AES 192 requires 24 octals
- AES 256 requires 32 octals
- 3DES requires 32 octals
- DES can be any size

**Note** For all passwords, the length must be 256 characters or less.

If you selected Clear Text as the Encrypt Password Type, repeat the password in the **Confirm** field.

**Step 11** Click **OK**.

**Step 12** Click **Save**.

You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Add SNMP Hosts

Use Host to add or edit entries in the SNMP Hosts table on the SNMP page. These entries represent SNMP management stations allowed to access the threat defense device.

You can add up to 8192 hosts. However, only 128 of this number can be for traps.

---

**Note** In 7.4 and later, the Management and Diagnostic interfaces are merged. If Platform Settings for syslog servers or SNMP hosts specify the Diagnostic interface by name, then you must use separate Platform Settings policies for merged and non-merged devices (7.3 and earlier, and some upgraded 7.4 FTDs).

---

### Before you begin

Ensure that the network objects that define the SNMP management stations exist. Select **Device > Object Management** to configure network objects.

---

**Note** The supported network objects include IPv6 hosts, IPv4 hosts, IPv4 range and IPv4 subnet addresses.

---

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Click **SNMP > Hosts**.
- Step 3** Click **Add**.
- Step 4** In the **IP Address** field, either enter a valid IPv6 or IPv4 host or select the network object that defines the SNMP management station's host address.
- The IP address can be an IPv6 host, IPv4 host, IPv4 range or IPv4 subnet.
- Step 5** Select the appropriate SNMP version from the **SNMP version** drop-down list.
- Step 6** (SNMPv3 only.) Select the username of the SNMP user that you configured from the **User Name** drop-down list.
- Note** You can associate up to 23 SNMP users per SNMP host.
- Step 7** (SNMPv1, 2c only.) In the **Read Community String** field, enter the community string that you have already configured, for read access to the device. Re-enter the string to confirm it.
- Note** This string is required, only if the string used with this SNMP station is different from the one already defined in the **Enable SNMP Server** section.
- Step 8** Select the type of communication between the device and the SNMP management station. You can select both types.
- **Poll**—The management station periodically requests information from the device.
  - **Trap**—The device sends trap events to the management station as they occur.
- Note** When the SNMP host IP address is either an IPv4 range or an IPv4 subnet, you can configure either **Poll** or **Trap**, not both.

- Step 9** In the **Port** field, enter a UDP port number for the SNMP host. The default value is 162. The valid range is 1 to 65535.
- Step 10** Select the interface type for communication between the device and the SNMP management station under the **Reachable By** options. You can select either the device's Management interface or an available security zone/named interface.
- **Device Management Interface**—Communication between the device and the SNMP management station occurs over the Management interface.
    - When you choose this interface for SNMPv3 polling, all configured SNMPv3 users are allowed to poll and are not restricted to the user chosen in [Step 6, on page 893](#). Here, SNMPv1 and SNMPv2c are not allowed from an SNMPv3 host.
    - When you choose this interface for SNMPv1 and SNMPv2c polling, the polling is not restricted at all to the version selected in [Step 5, on page 893](#).
  - **Security Zones or Named Interface**—Communication between the device and the SNMP management station occurs over a security zone or interface.
    - Search for zones in the **Available Zones** field.
    - Add the zones that contain the interfaces through which the device communicates with the management station to the **Selected Zone/Interface** field. For interfaces not in a zone, you can type the interface name into the field below the **Selected Zone/Interface** list and click **Add**. You can also choose a loopback interface and virtual-router-aware interfaces. The host will be configured on a device only if the device includes the selected interfaces or zones.
- Step 11** Click **OK**.
- Step 12** Click **Save**.
- You can now go to **Deploy > Deployment** and deploy the policy to assigned devices. The changes are not active until you deploy them.

## Configure SNMP Traps

Use SNMP Traps to configure SNMP traps (event notifications) for the threat defense device. Traps are different from browsing; they are unsolicited “comments” from the threat defense device to the management station for certain events, such as linkup, linkdown, and syslog event generated. An SNMP object ID (OID) for the device appears in SNMP event traps sent from the device.

Some traps are not applicable to certain hardware models. These traps will be ignored if you apply the policy to one of these models. For example, not all models have field-replaceable units, so the **Field Replaceable Unit Insert/Delete** trap will not be configured on those models.

SNMP traps are defined in either standard or enterprise-specific MIBs. Standard traps are created by the IETF and documented in various RFCs. SNMP traps are compiled into the threat defense software.

If needed, you can download RFCs, standard MIBs, and standard traps from the following location:

<http://www.ietf.org/>

Browse the complete list of Cisco MIBs, traps, and OIDs from the following location:

### SNMP Object Navigator

In addition, download Cisco OIDs by FTP from the following location:

<ftp://ftp.cisco.com/pub/mibs/oid/oid.tar.gz>

### Procedure

- 
- Step 1** Choose **Devices > Platform Settings** and create or edit the threat defense policy.
- Step 2** Click **SNMP > SNMP Traps** to configure SNMP traps (event notifications) for the threat defense device.
- Step 3** Select the appropriate Enable Traps options. You can select either or both options.
- Check **Enable All SNMP Traps** to quickly select all traps in the subsequent four sections.
  - Check **Enable All Syslog Traps** to enable transmission of trap-related syslog messages.
- Note** SNMP traps are of higher priority than other notification messages from the threat defense as they are expected to be near real-time. When you enable all SNMP or syslog traps, it is possible for the SNMP process to consume excess resources in the agent and in the network, causing the system to hang. If you notice system delays, unfinished requests, or timeouts, you can selectively enable SNMP and syslog traps. You can also limit the rate at which syslog messages are generated by severity level or message ID. For example, all syslog message IDs that begin with the digits 212 are associated with the SNMP class; see [Limit the Rate of Syslog Message Generation, on page 912](#).
- Step 4** The event-notification traps in the **Standard** section are enabled by default for an existing policy:
- **Authentication** – Unauthorized SNMP access. This authentication failure occurs for packets with an incorrect community string.
  - **Link Up** – One of the device’s communication links has become available (it has “come up”), as indicated in the notification.
  - **Link Down** – One of the device’s communication links has failed, as indicated in the notification.
  - **Cold Start** – The device is reinitializing itself such that its configuration or the protocol entity implementation may be altered.
  - **Warm Start** – The device is reinitializing itself such that its configuration and the protocol entity implementation is unaltered.
- Step 5** Select the desired event-notification traps in the **Entity MIB** section:
